Background/Aim: To understand the genetic alterations of K-ras gene in North Indian patients with pancreatic diseases, and the possible correlation between the presence of mutation, histopathological findings and other risk factors are assessed by standard questionnaire. **Methods:** A total of 65 pancreatic cancer patients, 50 chronic pancreatitis and 50 controls were inducted in the study. K-ras mutations were examined using the PCR RFLP, followed single-strand confirmation polymorphism (SSCP) and automated DNA sequencing. **Results:** K-ras mutational analysis in surgically resected tissue samples of the pancreatic carcinoma was 72.30 %(47/65) which was significantly higher than the chronic pancreatitis 6% (3/50) (P<0.01). It was also found that K-ras mutation rate was progressively increased from normal duct at the tumor free resection margin to pancreatic carcinoma. The mutation pattern of Kras codon 12 observed in pancreatic carcinoma was GGT_GGA and this was identical in chronic pancreatitis also. In this study male showed more prevalence of K-ras mutations than female. The age > 40 yrs showed statistically higher incidence of pancreatic cancer than chronic pancreatitis (P<0.05*). Smoking was found to be one of the risk factor for pancreatic cancer compared to chronic pancreatitis (p<0.05*). Other possible associated risk factors like alcohol consumption, diabetes, tea, coffee, Milk products and dietary habits were found to be statistically non-significant. **Conclusion:** This study shows evidence of K-ras gene mutation to be statistically higher in pancreatic cancer compared to chronic pancreatitis and this suggests that K-ras gene represent a critical early step in the genesis of pancreatic cancer.

J06.05
Similarity of DNA methylation profile in tissues with benign breast disorders and lymph nodes metastasis in patients with breast cancer

N. A. Skryabin[1], *I. N. Lebedev*[1], *N. V. Cherdyntseva*[2];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Institute of Oncology, Tomsk, Russian Federation.*

Despite many works examining the individual gene methylation in various malignancies, the question about the specificity of the methylation profiles of the large groups of genes in the carcinogenesis dynamics remains open. This study was aimed to assess the DNA methylation profile in tissues with benign breast disorders (BBD), breast cancer (BC) and lymph nodes metastasis (LNM). We analyzed 6 samples with BBD, 19 samples with BC, 5 samples with LNM, and 6 control histologically normal epithelium samples from women with BC using Illumina GoldenGate Cancer Panel I (Illumina, USA). Cluster analysis identified a group of samples with a high similarity of DNA methylation profile. This group included all tissues with BBD and LNM (except one) and one sample from each of the BC and control groups (p<0.001). The t-test revealed 261 CpG sites responsible for the combined clustering of these samples (FDR<0.01). All other samples with BC and morphologically normal epithelium were not clustered and showed a high heterogeneity of the DNA methylation profile. The relatively common DNA methylation profile in the samples with BBD and LNM may indicate a significant impact of epigenetic modifications into early origin of cell clones with BBD and LNM phenotypes in breast cancer. This study was performed using biological samples from the Integration Project of the Siberian Branch of Russian Academy of Medical Sciences for the breast cancer research.

J06.06
Chromosomal abnormalities in follicular thyroid carcinoma

A. V. Kanugovi, *M. Barath, P. A. Taskar;*
Padmashree Dr.D.Y.Patil University-Dept. Of Biotechnology and Bioinformatics, Navi Mumbai-400614, Maharashtra, India.

Follicular carcinomas are the second most common thyroid cancers; the mortality being decided by the degree of invasion. A left hemithyroidectomy specimen was observed and it was reported that the section showed a nodule composed of cells arranged in diffuse microfollicular pattern and macrofollicles. The cells were cuboidal with moderate cytoplasm and oval uniform vesicular nuclei. Nuclear crowding was observed and the neoplasm showed molecular focal capsular invasion. Deletion of a part of chromosome 22q was reported. Recent studies have mapped tumor suppressor loci associated with meningioma and neurofibromatosis type 2 (NF2) to 22q. The deleted region reported has been expected to consist of the region corresponding to that of the tumor suppressor genes associated with NF2 and meningiomas. In this case, t(2;3)(q13;p25) translocation and the PAX8-PPAR gamma1 fusion was also expected to be present. Rap1, a member of Ras family, has been implicated in the regulation of oncogenic pathways in thyroid and it has been found to regulate the ERK cascade and it is specifically required for the RET/PTC-induced activation of BRAF-MEK-ERK. Rap1 functions as a molecular switch which cycles between inactive GDP-bound and active GTP-bound forms. Rap1GAP, a GTPase activating protein, functions as negative regulator of Rap1 activity. It was also reported that loss of Rap1GAP function may be implicated in promotion of invasion in follicular thyroid carcinoma as the tumor was found to be minimally invasive. The study of extent of loss of Rap1GAP activity can be used to determine the degree of invasiveness of the tumor.

Rabl's Orientation Today: Implications for Diagnostic Genetics, Epigenetics and Aetiology of Chromosome Aberrations

J. P. Chaudhuri[1], *J. U. Walther*[2];
[1]*LMU - Kinderklinik, Phoenix / Munich, Germany,* [2]*LMU - Kinderklinik, Munich, Germany.*

Rabl's orientation of chromosomes - all centromeres polarized to the centrosome, while the telomeres flutter at the opposite pole - is a time-tested phenomenon. Moreover a wealth of observations in plants and animals indicate that the chromosomes are probably distributed in two groups, each representing one of the two parental genomes (Kikuchi S et al., Genes Genet Syst 82(5): 369, 2007; Chaudhuri et al., Anticancer Res. 28:3573, 2008).

Here we present our observations predominantly made on blood and bone marrow cells which match to the scheme of maternal and paternal chromosomes forming two different groups, both in interphase and metaphase. Cytologic findings about the centrioles in relation to their ploidy status and this order of chromosomes in two groups suggest a more detailed appearance of Rabl´s orientation.

The polar distribution of the centromeres of all chromosomes towards the centrsome results obviously from each chromosome of one of the two sets being tethered to one of the two centrioles in the centrosome of a diploid cell. On the basis of this phenomenon genomic karyotyping may be feasible which determines the parental origin of acquired chromosome abnormalities, contributes to understanding the origin of the aberration itself by tracing the right ontogenetic development and genealogic lineage and may facilitate studies on epigenetics (Chaudhuri et al., Cellular Oncology 27:327, 2005).

P07.02
HR-CGH and array CGH analysis of acute myeloid leukemia patients with normal or complex aberrant karyotype by G-banding.

D. Koczkodaj[1], *A. A. Filip*[1], *S. Zmorzynski*[1], *B. Pieńkowska-Grela*[2], *B. Grygalewicz*[3], *W. Tomczak*[4];
[1]*Medical University of Lublin, Department of Cancer Genetics, Lublin, Poland,* [2]*Maria Sklodowska-Curie Memorial Cencer Centre and Institute of Oncology, Warsaw, Poland,* [3]*Maria Sklodowska-Curie Memorial Cencer Centre and Institite of Oncology, Warsaw, Poland,* [4]*Department of Hematooncology and Bone Marrow Transplantation Medical University, Lublin, Poland.*

Acute myeloid leukemia (AML) is the most common type of leukemia among the elderly. Lymphocytes of approximately 55% of AML patients show various chromosomal aberrations, including structural and numerical alterations. Such changes may not only correlate with morphological and clinical data, but also serve as prognostic factors.
In our study we analyzed bone marrow samples of 40 AML patients with normal (10 patients) or complex (30 patients) karyotype by conventional cytogenetics. We then assessed the genomic changes by the means of high resolution comparative genomic hybridization (HR-CGH) and microarray CGH method. Genomic losses were found more frequently than gains. The most frequent losses affected 7q (30%), 3p (20%) and 5q (18%), and the most frequent genomic gains included 11q (30%) and 21q (20%).
In patients with initially normal karyotypes it was possible to determine single or multiple aberrations with aCGH. In this group losses were also more frequent than gains. Changes detected using array CGH were verified by the analysis performed with FISH technique in all cases.
The number of aberrations found by means of aCGH was significantly higher as compared with GTG results, which indicates that aCGH enables more sensitive karyotype examination and may be used in the search for new prognostic and predictive factors in AML.

P07.03
Balanced translocations in myelodysplastic syndromes.

D. Costa[1], *C. Muñoz*[1], *A. Carrió*[1], *D. Berneaga*[1], *C. Gómez*[1], *A. Arias*[1], *M. Belkaid*[2], *E. Campo*[1], *B. Nomdedeu*[3];
[1]*Hematopathology Section. Hospital Clínic., Barcelona. Catalonia, Spain,* [2]*Hematology Service.Hospital Clínic., Barcelona. Catalonia, Spain,* [3]*Hematology Service. Hospital Clínic., Barcelona. Catalonia, Spain.*

INTRODUCTION: Myelodysplastic syndromes (MDS) are a group of clonal haematopoietic stem cell diseases characterized by cytopenia(s), dysplasia in one or more of the major myeloid cell lines, ineffective haematopoiesis, and an increased risk of developing acute myeloid leukaemia (AML). Chromosomal abnormalities are detected in half of patients with the novo MDS, with losses and gains of genetic material being the most frequent cytogenetic findings. Balanced translocations are not frequently associated with MDS. Recurrent translocations associated with MDS are the t(3;21)(q26.2;q22.1),t(5;12)(q33;p13), t(3;12)(q26;p13),t(11;16) (q23;p13.3),t(6;9)(p23; q34).
OBJECTIVE: To identify the frequency of balanced translocations in patients diagnosed with MDS in our centre.
PATIENTS AND METHODS: Four hundred and twenty cytogenetic studies were performed on bone marrow samples from patients diagnosed with MDS.
RESULTS: Twenty seven balanced translocations were diagnosed in 23 (5,4%) patients, who were classified according to the WHO (2008) criteria: refractory anaemia (AR) (n=1), refractory cytopenia with multilineage dysplasia (n=7), AR with excess of blasts-1 (n=8), AR with excess of blasts-2 (n=5), and chronic myelomonocytic leukaemia (n=1). Seventeen of the 27 (63%) translocations were found as a part of a complex karyotype (>=3 chromosomal abnormalities). Two new translocations (2;3)(p21;q26.2) and t(13;17)(q21;p13), were found in two patients. All chromosomes were involved in the translocations, with the exception of chromosomes 8, 18, 21 and Y.
REMARKS: The infrequency of balanced translocations in MDS makes their identification and reporting imperative for the recognition of the recurrent ones. This increases the likelihood of identifying which genes are possibly involved in the pathogenesis of the neoplasia.

P07.04
BACs On Beads™ technology, an alternative to CGH array for tumor analysis

E. Rouleau[1], *D. Molina Gomes*[2], *F. Bru*[2], *S. Tozlu-Kara*[1], *A. Briaux*[1], *R. Lidereau*[1], ***F. Vialard***[3];
[1]*INSTITUT CURIE - HOPITAL RENE HUGUENIN, ST CLOUD, France,* [2]*HOPITAL DE POISSY-ST GERMAIN, POISSY, France,* [3]*Hopital de Poissy-St. Germain, Poissy, France.*

Objective : BACs On Beads™ (BoBs) (Perkin Elmer, Turku, Finland) has been recently validated by our team showing its robustness and versatility for evaluating chromosome abnormalities in pre-natal diagnostic. In BoBs technology the Bacterial Artificial Chromosomes are immobilized onto encoded beads that are used to assay gains and losses. We reported here our preliminary study on 12 breast tumor DNA from frozen tissue. Methods : We evaluate here the Karyolite, a new kit which could screen all abnormalities with 3 to 4 beads per chromosome. 3 BACs are encoded per beads to increase the specificity. 12 breast tumors DNA were extracted with phenol chloroform from frozen tissue. Karyolite BoBs was performed at Poissy hospital using a L200 Luminex and 44k Agilent's CGH array at Institut Curie-René Huguenin. Results: Out of those 12 tumors DNA, no false positive result in BoB was found according to CGH array analysis. At the opposite, and as suppose by the beads design, small chromosome abnormalities as segmental duplications or deletions were not retrieved. All large chromosome abnormalities (one to half of a chromosome arm) were identified without any ambiguity. Conclusions : For tumor analysis, BoBs technology could open very interesting outlets as it is cheaper, less time consuming (100ng of DNA), low material consumption, and rapid throughput. Position in diagnosis is still under discussion as only low number of locus are explored. However, this could be proposed as an alternative to CGH array with dedicated specific beads design to breast cancer chromosome abnormality.

P07.05
Investigation of Human Papillomavirus and Biomarkers of Disease Progression and Therapy in Cervical neoplasia

P. L. Cummins, *H. Lambkin, F. Ryan;*
D.I.T, Dublin, Ireland.

Cervical cancer represents the fifth highest female cancer mortality rate and second most common occouring malignancy worldwide. While curable in early stages, the prognosis for advanced stage disease is poor and mortality rates remain high. We aim to evaluate and compare the expression of various proteins/genes as markers of progression, from early stage neoplasia right through to invasive carcinoma. Primary investigations will involve the use of a wide range of biomarkers including diagnostic, prognostic and therapeutic markers, as well as identifying human papillomavirus status/type in correlation with abnormal expression patterns. Samples will include biopsy material from normal, low grade, high grade and invasive neoplasia.
In particular we will be investigating the epithelial growth factor receptor (EGFR), as its over expression/activation has been identified as a common feature of multiple cancer types and contributes to epithelial tumour growth. This will be evaluated through the use of specific antibodies directed against various domains of the receptor, as well as family dimerization partner human epidermal growth factor receptor 2 (HER2) and downstream effector proteins (AKT, p-AKT and mTOR); involved in up regulation of mRNA translation, cellular growth, proliferation and survival (anti-apoptosis). In addition to IHC, fluorescent insitu probes directed against the EGFR gene will allow for identification of increased gene copy number which contributes to accelerated tumour growth. Analysis of these biomarkers may yield information of use in predicting whether specific tyrosine kinase inhibitor (TKI) chemotherapies directed against EGFR, could prove to be an effective future therapy for invasive cervical cancer patients.

Indication for CDKN2A mutation analysis in familial pancreatic cancer-families without melanomas

F. Harinck[1], *I. Kluijt*[2], *N. van der Stoep*[3], *R. Oldenburg*[4], *A. Wagner*[4], *C. M. Aalfs*[5], *R. H. Sijmons*[6], *E. J. Kuipers*[1], *P. Fockens*[7], *T. A. M. van Os*[5], *M. J. Bruno*[1];
[1]*Department of Gastroenterology and Hepatology, Erasmus MC, University*

Medical, Rotterdam, Netherlands, [2]Familial Cancer Clinic, The Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Center for Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, [4]Department of Clinical Genetics, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [5]Department of Clinical Genetics, Academic Medical Center, University of, Amsterdam, Netherlands, [6]Department of Clinical Genetics, University Medical Center Groningen, Groningen, Netherlands, [7]Department of gastroenterology and Hepatology, Academic Medical Center,, Amsterdam, Netherlands.

Background: Carriers of a CDKN2A-gene mutation run a high risk of developing melanomas. In addition, they have an additional increased risk of developing pancreatic cancer (PC). Familial pancreatic cancer (FPC) patients with a personal or family history of melanomas are therefore offered CDKN2A-mutation analysis. On the other hand, CDKN2A testing is not generally recommended in the literature in FPC families without a history of melanomas.

Methods: FPC families were defined as families with clustering of PC and not meeting diagnostic criteria of specific other familial cancer syndromes. Medical details of cancer diagnoses were retrieved and reviewed. Blood samples were obtained for DNA isolation from PC-patients or first degree relatives (FDR) and analyzed for mutations in CDKN2A.

Results: Among 40 FPC families, DNA analyses were carried out in 28 families (70%), leading to identification of CDKN2A-mutations in six families (21.4%) None of the CDKN2A families fulfilled the diagnostic criteria of familial atypical multiple mole melanoma (FAMMM) syndrome and in three CDKN2A families no melanomas and/or dysplastic nevi were observed. In these latter three families two different CDKN2A-mutations were found; in two families the Dutch founder mutation p16-Leiden (c.225_243del, p.Ala76fs) and in the third family the c.19_23dup, p.Ser8fs-mutation. After disclosure of the CDKN2A-mutation in one of the families, a curable melanoma was diagnosed at subsequent dermatological surveillance in a 17-year old female family member.

Conclusion: CDKN2A-mutation analysis should be included in genetic testing in FPC families, even in the absence of reported melanomas. This strategy will enhance the recognition of individuals at risk for PC and facilitate the early detection of melanomas.

The initial experiences with detection of hTERC and MYCC genes in HPV positive cells in cervical carcinoma and cervical intraepithelial dysplasia using Vysis Cervical FISH Probe Kit

P. Kuglik[1], *V. Vranova*[1], *L. Moukova*[2], *M. Kissova*[1], *I. Slamova*[3], *H. Filkova*[3]; *[1]Faculty of Science, Institute of Experimental Biology, Brno, Czech Republic, [2]Department of Gynaecological Oncology, Masaryk Memorial Cancer Institute, Brno, Czech Republic, [3]Department of Medical Genetics, University Hospital, Brno, Czech Republic.*

It is known that this cervical cancer develops from precancerous intraepithelial neoplasia (CIN) which are characterized by series of genetic abnormalities. The progression of cervical intraepithelial dysplasia to cervical carcinoma has been associated especially with the genomic integration of oncogenic human papilloma virus (HPV) and gain of the human telomerase genes hTERC (3q26) and c-MYC (8q24).

Recently, Vysis Cervical FISH Probe Kit was designed to identified HPV infected cells and determine copy number of the hTERC a c-MYC genes via fluorescence *in situ hybridization* in cervical cytology specimens.

In our work, we have studied genetic aberrations on a series of cytological specimens obtained from patients of Department Gynaecological Oncology of Masaryk Memorial Cancer Institute Brno with cervical carcinoma or proven precarcinoma (CIN2/CIN3). The patiens were divided into two groups.

Using classical I-FISH gain of hTERC gene was found in 8 (42 %) of 19 patiens with cervical carcinoma, all woman with hTERC gain were HPV positive and 63 % of them showed positive lymphovascular invasion.

In 15 patiens we tested gain of hTERC and MYCC genes in HPV positive cells using new Vysis Cervical FISH Probe Kit and relationships between HPV infection, chromosomal alterations and diagnosis were analysed.

Our work confirmed that gain of hTERC is significantly associated with cervical carcinoma and worse prognosis. Furthermore we conclude that Vysis Cervical FISH Probe Kit can be used as effective diagnostic procedure to identity the patients carrying highly risking HPV infection and chromosomal aberrations associated with this malignancy.

Oligonucleotide microarrays uncover new aberrations in Chronic Lymphocytic Leukemia not previously identified by standard cytogenetic methods

C. D. Kashork[1], *K. A. Kolquist*[1,2], *R. Schultz*[1], *M. L. Slovak*[1,3], *V. Cawich*[1], *C. Valentin*[1], *S. Minier*[1], *N. Neill*[1], *S. Byerly*[1], *A. Morton*[1], *B. C. Ballif*[1], *L. G. Shaffer*[1]; *[1]Signature Genomics, Spokane, WA, United States, [2]Sacred Heart Medical Center, Spokane, WA, United States, [3]Current affiliation: Quest Diagnostics Nichols Institute, Chantilly, VA, United States.*

Chronic lymphocytic leukemia (CLL) is the most commonly diagnosed leukemia in the western world and is highly variable, with life expectancies ranging from months to decades. Traditional cytogenetic studies have provided genetic insight into the disease, leading to prognostic significance and treatment for individual patients. Microarray technology has made significant impact in the assessment of constitutional genetic disorders, and this same application has the capacity to enrich the understanding of hematologic malignancies. In this study we show the utility of an oligonucleotide array designed for the detection of copy gains and losses found in leukemia and lymphoma. We performed microarray assessment of 35 samples with a working diagnosis of CLL. Ten had previous chromosome analyses. The average number of abnormalities revealed by banding was 4, whereas the average number of abnormalities revealed by microarray analysis was 6.5. Additional information not seen by karyotype and fluorescence *in situ* hybridization (FISH) was uncovered in 31% of cases. Novel findings were identified, including losses and gains of susceptibility loci on 11q24, 8p21, 4p16p15 and 5q35. Our results support microarray analysis as a diagnostic tool for identifying cytogenetic abnormalities that are associated with CLL. Further use of microarrays in CLL will likely identify recurrent novel aberrations, which may prove to be new treatment targets.

P07.09

Molecular cytogenetic study of derivative chromosome 9 deletion in 336 Tunisian chronic myeloid leukemia patients

A. Bennour[1], *I. Ouahchi*[1], *Y. Ben Youssef*[2], *M. Zaier*[2], *A. Laatiri*[3], *I. Harrabi*[4], *B. Meddeb*[5], *M. Elloumi*[6], *A. Khelif*[2], *A. Saad*[1], *H. Sennana*[1]; *[1]Cytegenetics Department, CHU Farhat Hached, Sousse, Tunisia, [2]Department of Hematology, CHU Farhat Hached, Sousse, Tunisia, [3]Department of Hematology, CHU Fattouma Bourguiba, Monastir, Tunisia, [4]Department of Epidemiology and Medical Statistics, CHU Farhat Hached, Sousse, Tunisia, [5]Department of Hematology, CHU Aziza Othmana, Tunis, Tunisia, [6]Department of Hematology, CHU Hedi Chaker, Sfax, Tunisia.*

The Philadelphia chromosome (Ph), produced by the t(9;22)(q34;q11.2) is the cytogenetic hallmark of chronic myeloid leukemia (CML). Deletions on derivative chromosome 9 (der (9)) may occur with t(9; 22) and could influence the disease progression.

The aims of this study are to investigate the frequency of derivative der (9) deletion in Tunisian patients with CML, and to assess the correlation between this deletion and the cytogenetic response for patients treated with hydroxyurea (HU) or imatinib (IM). Karyotype analysis of 336 patients with CML was performed with R-banding. Fluorescence in situ hybridization was carried using home brew probes 17L7 and 248J22 for detecting respectively adjacent 5'ABL and 3'BCR deletions on der(9).

Cytogenetic study demonstrated typical t(9;22)(q34;q11) translocation in 89,6% and variant translocation in 10,4% of patients. Interphase-FISH studies showed deletion of der(9) in 59 (17,6%) of the 336 patients, 23 (39%) of them had variant rearrangements. There are 19 patients with solely 5'ABL deletion and 40 with concomitant 5'ABL and 3'BCR deletions. Cytogenetic response was evaluated during 18 months with HU or IM therapy.

Our results demonstrate that: (a) all patients with 3′BCR deletion have 5′ABL deletion, (b) 5′ABL and 3′BCR deletions arise simultaneously with Philadelphia chromosome formation, (c) deletions on der(9) chromosome were frequently encountered in older patients and in patients presenting variant rearrangements, (d) both 5'ABL and 3'BCR

deletions were associated with cytogenetic response failure in patients treated with HU , although patients treated with IM and carrying deletions on der(9) presented better cytogenetic response.

P07.10
Clonal evolution in Chronic Lymphocytic Leukaemia

C. Lopez[1], *D. Costa*[1], *C. Gomez*[1], *A. Arias*[1], *N. Villamor*[1], *D. Colomer*[1], *M. Rozman*[1], *T. Baumann*[2], *E. Montserrat*[2], *E. Campo*[1], *A. Carrio*[1];
[1]*Hematopathology Unit. Hospital Clinic de Barcelona, Barcelona, Spain,* [2]*Hematology Unit. Hospital Clinic de Barcelona, Barcelona, Spain.*

INTRODUCTION Chronic lymphocytic leukaemia is characterised by variable clinical course. The most frequent chromosomal abnormalities are trisomy 12, deletion of 13q14.3, 11q22.3 and 17p13; each of these is a relevant prognostic factor. These abnormalities may appear at diagnosis or during follow-up.
The goal of this study is to determine the frequency of clonal evolution in CLL patients. Clonal evolution (CE) is defined as newly acquired aberration during the disease course.
MATERIAL AND METHODS One hundred and twenty-five patients with CLL were analysed by conventional and/or molecular cytogenetics (FISH) at diagnosis and during follow-up. Two samples from the same patient were studied after a minimum follow-up time of 6 months after the first genetic study. The median time between diagnosis and follow-up was 38 months (range 6-116).
RESULTS 30% of the patients (21/71) showed CE using conventional cytogenetics. 57% of the patients with normal karyotype at diagnosis showed chromosomal abnormalities during follow-up. Twenty-three of 53 patients (43%) had CE by FISH; in 17 of them, FISH abnormalities were observed at diagnosis and new chromosomal aberrations were acquired during disease course.
CONCLUSION Clonal evolution is a significant event in CLL patients. The most frequent abnormality which appeared during disease course was del(13q). The median time to follow-up for CE was 10 months. Conventional and molecular cytogenetics were necessary to detect clonal evolution in CLL patients. We believe that CE could be a new prognostic factor and an indicator of change in clinical course of the disease.

P07.11
Emergence of karyotypically unrelated clone during complete remission of acute monocytic leukemia

I. Petkovic[1], *J. Konja*[2], *R. Lasan*[3], *G. Petkovic*[4], *M. Aničić*[2];
[1]*Clinical Hospital "Sestre molosrdnice", Children's Hospital Zagreb, Zagreb, Croatia,* [2]*KBC Rebro, Zagreb, Croatia,* [3]*KBC Rebro, Zagreb, Croatia,* [4]*Children's Hospital Srebrnjak, Zagreb, Croatia.*

AML is a heterogeneous group of disease. Besides morphological and cytogenetic heterogeneity, of interest are different types of remissions. One form of remission is characterized by repopulation of the marrow by normal cells, and the other by clonal cell proliferation. The data on clonal remission are limited, and some 40 cases have been reported so far. The frequency of clonal remission is variable and range from 1% to 12% of acute leukemia. Nature, mechanisms of origin and clinical significance of clonal cell proliferation at remission are not elucidated yet. We present the results of clinical and cytogenetic investigation in a girl with AML and unrelated clonal chromosome aberration during remission and literature review of published data on clonal remission in patient with acute leukemia. Our patient is 3½-old-girl referred to the hospital with hepatospenomegaly, hematomas and polymicroadenia. Cytomorphologic analysis revealed AML-M5A. Chromosome study at diagnosis showed abnormal clone with 48,XX,+21,+mar and at remission following induction therapy a normal karyotype was observed. Eleven months after diagnosis, while the patient was in first complete remission an unrelated abnormal clone with t(1;18) was observed. This report highlights the importance of cytogenetic study in patients follow up and detection of unrelated clonal rearrangement during remission of acute leukemia.

P07.12
Fluorescence In Situ Hybridization on peripheral blood for BCR/ABL fusion gene detection is a robust alternative method for evaluation of minimal residual disease in CML.

C. Jardan, *D. Jardan, R. Talmaci, D. Coriu, A. Colita;*
UMF "Carol Davila, Bucharest, Romania.

CML is the first malignancy for which a specific chromosomal abnormality was described - Philadelphia chromosome. Monitoring of minimal residual disease in CML by detection of Philadelphia chromosome is an important part of response evaluation of patients in treatment with tirozinkinase inhibitors, because it allows early detection of suboptimal response or resistance to treatment.
Materials and Methods: We analyzed 25 bone marrow specimens using interphase FISH and compared the results with those of conventional cytogenetics and with interphase FISH on peripheral-blood specimens.
Results: in comparison to conventional cytogenetics - interphasic FISH on peripheral blood did not generated any discrepancies in percent of BCR/ABL positive nuclei.
Conclusion: Fluorenscent in situ hybridisation is a molecular cytogenetics technique which allows minimal residual disease monitoring on interphase nuclei. MRD monitoring on peripheral blood has the advantage of generating results in short time (even in 24h) and is less invasive than bone marrow biopsy. In comparison with bone marrow culture it has the advantage of being a direct method which abolish artifacts introduced by the culture. On the over side - it has disadvantage of being able to identify only specific chromosomal malformations - Philadelphia chromosome in this case, all other important aberrations in disease progression being omitted. For the use of this method in MRD there is a need for large standardization studies, present clinical standard being conventional cytogenetics. In this study we analyzed FISH techniques as a rapid and uninvasive alternative method for MRD monitoring in CML patents undergoing tirozine-kinase inhibitor treatment.

P07.13
Genome-wide analysis of recurrent copy number abnormalities and copy neutral-loss of heterozygosity in colorectal cancer

V. Barresi[1], *C. Capizzi*[1], *N. Musso*[1], *G. Privitera*[2], *T. Luca*[2], *S. Castorina*[1], ***D. F. Condorelli***[1];
[1]*University of Catania, Catania, Italy,* [2]*Fondazione GB Morgagni, Catania, Italy.*

Two forms of genetic instability have been observed in colorectal cancer (CRC): chromosomal instability, that is present in 85% cases and is characterized by structural and numerical chromosomal abnormalities (aneuploidy); and microsatellite instability (MSI), characterized by a deficiency of the mismatch repair system and associated to a normal or quasi-normal karyotype. Recent advances in molecular cytogenetics techniques are likely to introduce a revolution in the field. In the present study we analysed a series of 57 CRC samples and their related normal mucosae by high resolution genomic arrays (Affymetrix SNP 6.0 arrays) and set up a series of bioinformatics tools that allow the generation of a rapid report on broad (>25% of a chromosomal arm) and small somatic copy number abnormalities (CNAs), somatic homozygous deletions, focal high level amplifications, and regions of loss of heterozygosity (LOH). MSI tumors represented 14% of our CRC series and showed a median values of somatic broad CNAs of 3 (range 1-6), while microsatellite stable (MSS) tumors showed a median value of 12 (range 0-24). Therefore all MSI tumors were below a threshold of 6 CNAs, while 18% of MSS were below this threshold, representing a group of microsatellite and chromosomal stable tumors. No correlation was observed between the number of tumor associated CNAs and the number of somatic copy neutral-LOH regions, suggesting that different mechanisms underlie such chromosomal abnormalities. Analysis of recurrent CNAs identified somatic homozygous deletions that cannot be ascribed to regions of inherent fragility.

P07.14
Genomic imbalances identified by array-CGH in endometrial cancers

F. Schneider[1,2], *E. raimond*[1,3], *E. Landais*[1,2], *J. Andrieux*[4], *P. Birembaut*[5,6], *D. Gaillard*[1,2], *O. Graesslin*[1,3], ***M. Doco-Fenzy***[1,2];
[1]*CHU-REIMS, REIMS, France,* [2]*Service de Génétique CHU-REIMS, Reims, France,* [3]*service de gynécologie, Reims, France,* [4]*Institut de Génétique*

Médicale, Hopital Jeanne de Flandre, CHRU, LILLE, France, [5]Laboratoire Pol Bouin, CHU-REIMS, REIMS, France, [6]INSERM UMR-903, Reims, France.

Background: Endometrial cancer is the third most common female malignancy in Europe. While most patients with early stage disease have a good prognosis, there are women who will recur as endometrial carcinoma is the third cause of gynecologic cancer death. But it is sometimes difficult to determine the clinical prognosis with classical histo-pathological factors. Previous studies on endometrioid adenocarcinomas using Comparative Genomic Hybridization (CGH) showed large chromosomal alterations with gain in 1q, 19p, 19q, 8q, 10q and 10p; and losses in 4q, 16q and 18q.

Material and Method: The aim of this study was to investigate chromosomal alterations by array-CGH to identify discrepancies in two different groups of tumors and hyperplasia, in relation to grade, stage and clinical data. Tissue specimens were obtained from 37 patients (31 neoplasms and 6 hyperplasia) and array-CGH analysis was performed using genomic DNAs extracted from frozen specimens.

Results: Copy number variations (CNV) were detected in 24 cases of neoplasm (77 %) but not in hyperplasia. On average, four CNV by case were observed with a 1:1 ratio between amplification and deletion. The most frequent alterations were trisomy for chromosomes 7 and 8, gains for segment 1q and losses in regions 9p, 11p,16q and 17p. We found two amplifications and two deletions for 10q and 11q regions.

Conclusion: These preliminary data need to be confirmed by further investigations in order to establish new significant prognostic factors and the specific chromosomal regions affected by copy number changes will be interesting to investigate in further genetic studies.

P07.15

Genomic instability at common fragile site *FRA14B* in cancer

***D. Zheglo**, L. Brueckner, A. Blumrich, M. Schwab, L. Savelyeva;*
DKFZ, Heidelberg, Germany.

Common fragile sites (cFS) are chromosomal regions prone to breakage under conditions partially inhibiting DNA synthesis. Approximately 90 cFSs have been cytogenetically identified, but few of these have been completely characterized. Most characterized cFSs coincide with extremely large genes and hotspots of chromosomal rearrangements in cancer. We localized an aphidicolin-inducible cFS, *FRA14B*, to an 800kb region of the 14q23 chromosome band using six-color FISH mapping with BAC probes on metaphase chromosomes of aphidicolin-treated lymphocytes. *FRA14B* overlaps the large gene encoding gephyrin (*GPHN*, 670kb), a protein involved in synapse development and molybdenum cofactor biosynthesis. To assess the possible role of *FRA14B* in generating cancer-associated rearrangements, we performed oligonucleotide array CGH on 150 cell lines and primary tumors. We detected multiple breakpoints within this cFS in 13 cancer genomes of melanoma and glioma cell lines and neuroblastoma, colon cancer and breast cancer cell lines and primary tumors. The breakpoints clustered at the first intron of *GPHN* and extra-genic regions, but not within exons. Subsequent validation of CGH results using FISH revealed at least two apparently normal copies of *GPHN* per genome in the majority of tumors and cell lines bearing rearrangements. All deletions were limited to introns or located within additional ectopic copies of *GPHN*. *GPHN* transcripts were detectable by RT-PCR in all the cell lines. In summary, activation of newly-mapped cFS, *FRA14B*, can cause the instability of *GPHN*, the role of which in cancer development remains to be investigated.

P07.16

Investigation of chromosomal aberrations in hepatocellular carcinoma patients as detected by fluorescence *in situ* hybridization

***M. S. Aly**[1,2], M. A. Alabbood[1];*
[1]Faculty of Science, Jazan University, Jazan, Saudi Arabia, [2]Faculty of Science, Beni Suef University, Beni Suef, Egypt.

Hepatocellular carcinoma (HCC) is a very common and highly malignant tumor, associated mainly with chronic viral hepatitis, cirrhosis of any cause, aflatoxin exposure and ethanol consumption. Cytogenetic analysis on HCC has been limited because of poor hepatocyte growth in vitro. Conventional cytogenetic studies have demonstrated frequent abnormalities of specific chromosomes in HCC. Molecular cytogenetic approaches have been applied only rarely in the characterization of HCC. The main aim of this study was to evaluate genetic aberrations of different chromosomes in HCC. The study included 45 patients with HCC, who have been diagnosed and treated at National Cancer Institute, Cairo University, Egypt.

Interphase cytogenetics by fluorescence in situ hybridization with the use of a panel of centromere-associated DNA probes for chromosomes 1, 4, 8, 9, 13, 17, 20 and Y were performed on paraffin-embedded HCC specimens.

The most common chromosomal aberrations detected were gain of chromosomes 8 in 12 cases (34.28%), 17 in 6 cases (17.14%). Loss of chromosome Y was detected in 6 of male cases (30%). Monosomy 4 was also detected in 5 cases (14.28%). Negative correlation could be detected only between chromosome 4 and 8. ($r = -0.381$, $P < 0.05$). Correlations between gain or loss of chromosomes and the different clinicopathologic parameters in the patients investigated, indicated negative correlation between: chromosome Y and age and chromosome 1 and cirrhosis.

Gains and losses of DNA found in this study probably involve oncogenes and tumor suppressor genes that play a role in the puzzle of hepatocarcinogenesis.

P07.17

ERBB2 (Her-2/neu) Amplification Status Determination by Copy Number Variation Analysis

***A. Garuti**[1], R. Petraroli[2], C. Zanchi[2], I. Rocco[1], G. Cirmena[1], C. Palermo[1], G. Zoppoli[1], L. Egry[2], S. Blakely[2], A. Ballestrero[1], F. Patrone[1];*
[1]Dipartimento di Medicina Interna - Università degli Studi, Genova, Italy, [2]Life Technologies Corporation, Foster City, CA, United States.

Gene copy number variations by DNA amplification are a genetic alteration that can lead to deregulation of gene expression, and eventually contribute to neoplastic transformation. Amplification of the *ERBB2* gene abnormality is known to influence breast cancer (BC) prognosis and response to therapies. Currently, Her-2/Neu protein product expression and/or gene amplification are usually detected by Immunostaining or by molecular techniques such as fluorescence in situ hybridization (FISH). Here, we determined Her-2/Neu amplification status on 45 clinical research BC samples using TaqMan® Copy Number Assays, and previously characterized with immunostaining and FISH methods. A side-by-side testing on the Applied Biosystems® 7900HT Fast Real-Time PCR System and the Applied Biosystems® 7500 Fast Dx Real-Time PCR Instrument was performed to evaluate data reproducibility between the two systems. Our results demonstrate that the results obtained with the TaqMan® Copy Number Assays were highly concordant with those previously reported by FISH, on both the Applied Biosystems® 7900HT Fast Real-Time PCR System and the Applied Biosystems® 7500 Fast Dx Real-Time PCR Instrument. Therefore, we demonstrate that the Copy Number Real Time method can be an easy, robust, and economically advantageous method for Her-2/Neu amplification status evaluation. We conclude that the Applied Biosystems® 7500 Fast Real-Time Dx Instrument is an ideal instrument for clinical laboratories that require not only technically reliable and economically feasible methods, but also routinely controlled instruments. TaqMan® Copy Number Assays and 7900HT Fast Real-Time PCR System are for research use only, and not intended for any animal or human therapeutic or diagnostic use

P07.18

The assessment of ErbB2 gene over expression in respectable gastric Cancer and its Relationship with histopathology subtype, grading and stage of disease

***M. Y. A. S. Soltani Delgosha**[1,2,3];*
[1]Reza Oncology Center, Mashhad, Islamic Republic of Iran, [2]Omid hospital, Mashhad, Islamic Republic of Iran, [3]Emam Reza Hospital, Mashhad, Islamic Republic of Iran.

Background: ErbB2 gene, also called Her2, is located in chromosome 17 (17q12-q21) and encodes a 185-kd transmembrane tyrosine kinase receptor (p185), which is a member of the epidermal growth factor receptor family. Amplification of the ErbB2 gene and overexpression of the ErbB2 protein have been observed in various solid tumors, including breast and gastric carcinomas. We aimed to evaluate the ErbB2 content in respectable gastric cancer in this country and its relationship with clinicopathologic parameters of tumors.

Methods: This study was a prospective analysis of 100 specimens

from 100 patients with respectable gastric carcinoma which were admitted in three hospitals in this country. Indirect immunostaining was used to evaluate the expression of this receptor in formalin-fixed paraffin-embedded tissue sample.
Result: ErbB2 amplification was present in 26(26%) of 100 gastric carcinoma. ErbB2 was more common in the intestinal type of gastric cancer (33%) than in the diffuse (5%) or the mixed type (0%) (p=0.001), also ErbB2 was more common in well-differentiated gastric cancer than other grade (p=0.001), but it was not associated with gender, age at diagnosis or clinical stage.
Conclusion: ErbB2 amplification is common in intestinal type and well-differentiated gastric carcinoma but there was no correlation between ErbB2 expression and tumor stage. The relatively high percentage of ErbB2 expression positive tumors will provide a useful target for immunotherapy of these cancers.

P07.19
Cytogenetic characterization of pediatric mixed phenotype acute leukemia with complex karyotype

E. Tassano, *E. Tavella, C. Micalizzi, C. Cuoco, C. Panarello, C. Morerio; Laboratorio di Citogenetica Ematoncologica, IRCCS Istituto G.Gaslini, Genova, Italy.*

Mixed phenotype acute leukemias (MPALs), defined by the 2008 WHO classification, are rare leukemias in which blasts express antigens of both lymphoid and myeloid lineages. Furthermore MPALs are partitioned according to the two cytogenetic abnormalities reported quite frequently in the affected patients, namely rearrangements leading to *BCR-ABL1* fusion and translocations involving 11q23 and *MLL* gene. Karyotype abnormalities have been documented in about 80-90% of MPAL pediatric patients, with no uniquely associated specific chromosomal aberration. Here we report on a case of childhood MPAL showing a complex karyotype, characterized by M-FISH and array-CGH. The patient was a 5-year-old girl diagnosed with MPAL (T/myeloid) based on the expression of T-lymphoid cyCD3 and myeloid MPO antigens. Cytogenetic analysis by Q-banding technique on peripheral blood and bone marrow blasts revealed a hypodiploid karyotype with structural changes involving chromosomes 1, 9, 12, 13, 16. To characterize the rearranged chromosomes, M-FISH analysis was performed. Further array-CGH using 5500 BAC clones (565 Kb median resolution) showed partial losses of 1p, 9, 13q, 16q. The gain of chromosome 12p was also evident. Overall, based on the combined results of Q-banded mitoses, M-FISH and array-CGH, it was possible to define the karyotype as: 45,XX,der(1)t(1;12)(p36.12;p13.2) t(1;12)(q12;p13.2),-9,der(12)t(1;12)(q12;p13.2)t(12;13)(q24;q14.3), der(13)t(12;13)(q24;q14.2), der(16)t(9;16)(q31.1;q21). The combination of conventional cytogenetic techniques with M-FISH and array-CGH has allowed a careful analysis of complex chromosome alterations. The analysis of a larger series of MPAL patients could help to identify diagnostic and/or prognostic markers of this rare type of leukemia.

P07.20
Genomic screening of hyperdiploid subgroup of multiple myeloma patients using oligo-based arrayCGH technique

J. Smetana[1,2], *R. Zaoralová*[1,2], *P. Kuglík*[2], *H. Grešliková*[1,2], *R. Kupská*[1], *P. Němec*[1,2], *A. Mikulášová*[1,2], *K. Beránková*[2], *R. Hájek*[1,3];
[1]*Babak Research Institute, Brno, Czech Republic,* [2]*Faculty Of Science, Masaryk University Brno, Brno, Czech Republic,* [3]*Department of Internal Medicine, Haemato-Oncology, University Hospital Brno, Brno, Czech Republic.*

Multiple myeloma (MM) is the second most common hematological malignancy. It is
characterized by malignant transformation of clonal proliferation of B-lymphocytes and their
accumulation in bone marrow There are two major genetic subclasses of MM: a hypediploid variant associated with the incidence of chromosome number changes, mainly trisomies of chromosomes 3,5,7,9,11,15,19 and 21, and a non-hyperdiploid variant associated with high incidence IgH locus translocations. and thus with poor disease prognosis.
Main aim of this study was to perform genomic screening of hyperdiploid subgroup of MM patients using oligo-arrayCGH technique focusing on finding new prognostic markers for MM diagnosis.
We analyzed 67 bone marrow samples. DNA was obtained from CD138+ cells separated by MACS or FACS techniques.
Taking together, hyperdiploidy (defined in MM as extra copy of chromosomes 5, 9, or 15 together in karyotype) was found in 48% (31/65 patients). Most common chromosomal changes involved trisomies of chromosomes 3,5,7,9,11,15,19,21 (incidence >50%). Gain(1q) was observed in 40% of H-MM cases (12/31). Most common loss was 13,6 MBp minimal deleted region (MDR) in 8pter-8p22 (25%, 8/31), -13 (23%, 7/31) and del(16q) (20%, 6/30). In one case, we observed biallelic deletion of *TRAF3* involved in MM pathology through deregulation of NF-kappaB pathway and amplification of *SALL1*, transcriptional repressor supposed to be a part HDAC complex.
Array-CGH provide us powerful tool for characterization of another genomic changes important for diagnosis and classification of the development of this hematological malignancy.
Supported by grants and projects MSM 0021622434; MSM0021622415, IGA NS10207-3/2009; 10406-3 and LC 06027.

P07.21
Case report of a rare karyotype in a patient with multiple myeloma

M. Souto[1], *P. Botelho*[1], *M. Cunha*[2], *M. Guerra*[2], *O. Osvaldo*[1], *E. Ribeiro*[1], *R. Pinto Leite*[1];
[1]*Serviço de Genética, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal,* [2]*Serviço de Hematologia, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal.*

Multiple myeloma (MM) is a malignancy disorder characterized by the proliferation of a single clone of plasma cells (PC) derived from B cells in the bone marrow. In this tumors there is a high genetic instability resulting in a wide variety of genetic and chromosomal abnormalities. Cytogenetics abnormalities are considered an important prognostic indicator and are observed in 30-50% of the cases. The most frequent are monosomy or deletions of chromosome 13, translocations involving the immunoglobulin heavy chain locus (IGH) and ploidy status.
The authors present the results of a cytogenetic study in a seventy three years old male patient with MM.
Bone marrow cell culture and GTL banding was done according to protocols in the laboratory. Cytogenetic analysis was performed following the standard cytogenetic guidelines. FISH painel (13q-, 17p-, t(4;14), t(11;14)) was applied.
The karyotype was: 47, XY, +8, t(6;19)(p21.3:p13.3), t(11;14)(q13;q32)[16] / 46, XY [3]. FISH was positive to t(11;14) (88%).
In this patient we found a characteristic anomaly in MM, confirmed by FISH, a trisomy 8 that is a rare event in lymphoid neoplasia and a translocation not described in the literature. FISH is a sensitive method to investigate cytogenetics of MM but it should be performed always with conventional cytogenetics analysis. They are important to predict treatment responses and prognosis.rte superior do formulário
The authors compare the cytogenetic findings and the patient's clinical status with those described in the literature.

P07.22
Translocation (x;20)(q13;q13.3) in a patient with myeloproliferative disorder: Case report and review of the literature

R. MEDDEB[1], *P. Frère*[2], *G. Vanstraelen*[3], *M. Jamar*[1], *C. Herens*[1], *V. Bours*[1];
[1]*Human Genetic center, CHU, University of Liège, LIEGE, Belgium,* [2]*hemato-oncologie , centre hospitalier Pelzer-la tourelle, verviers, Belgium,* [3]*Hémato-oncologie, Centre Hospitalier Peltzer-La Tourelle, verviers, Belgium.*

Rearrangements involving the X chromosome are rare in hematological malignancies. Only a few recurrent translocations involving the X and different autosomes have been associated with hematological malignancies.
In contrast, structural alterations of the long arm of chromosome 20 are non-random recurring abnormalities in patients with myelodysplastic syndromes (MDS), myeloproliferative disorder (MPD) and acute myeloid leukemia (AML). This suggests the loss of function of tumor suppressor genes at this location.
In this study, we describe an additional case of t(X;20)(q13;q13) in a myeloproliferative disorder (MPD). To the our knowledge, this is the fith case of MPD associated with this rearrangement.
The patient was an 75-year-old female presenting with a thrombocytosis at 1.600.000/mm³. The bone marrow evaluation suspected a MPD of type essential thrombocytemia. Cytogenetic studies performed on bone marrows cells demonstrated a homogeneous karyotype with a

t(X; 20) (q13.q13.3) as the sole abnormality.
In total, the translocation t(X;20) has been reported in nine previous cases : 4 MPD, 3 MDS and 2 AML patients. It is invariably found in old women (mean age of 69 years), which suggests a probable influence of epigenetic factors. We will discuss the possible implication of the inactive X in the translocation, which may exercise a position effect on 20q. The silencing of 20 q genes may be involved in the clinical presentation of myeloid disorders especially as deletions 20q represent one of the most frequent chromosomal abnormalities seen in myeloid disorders. Our case further confirms the recurrent character of the t(X;20)(q13;q13) in myeloid malignancies.

Monitoring DNA damage in Tunisian hospital Staff using cytokinesis block micronucleus method and chromosomal aberration test

S. BOURAOUI[1], *A. DRIRA*[2], *A. BRAHEM*[2], *N. MRIZEK*[2], *H. BEN KHELIFA*[1], *N. BOUALI*[1], *R. BERGUIGA*[1], *I. BEN ABDALLAH*[1], *S. BRAHEM*[1], *A. BENNOUR*[1], *H. ELGHEZAL*[1], *F. TABKA*[2], *A. SAAD*[1];
[1]*Department of Cytogenetic and Reproductive Biology, Farhat Hached University Teaching Hospital, Sousse, Tunisia,* [2]*Department of Occupational and Environmental medicine, Farhat Hached University Teaching Hospital, Sousse, Tunisia.*

Introduction: Hospital staff is exposed to many compounds which are suspected to be genotoxic and carcinogenic. Micronucleus test (MNs) and chromosomal aberrations test (CAs) are an excellent means to evaluate the genotoxicity and the risk associated with theses releases. Our study reports the finding of these genotoxicity tests for hospital staff exposed to ionizing radiation (RI), anti-cancer drugs and formaldehyde (FA) from Farhat Hached Hospital of Sousse (Tunisia).
Patients and Methods: Assessment of chromosomal damage was carried out in peripheral lymphocytes of 20 nurses handling anti-cancer drugs, in 31 exposed to FA, and in 45 exposed (RI). We used controls matched for age, gender and life style.
MNs frequency was evaluated after cytokinesis block. A total of 1000 binucleated cells were scored for each subject. Mitomycin C was used for detection of CAs.
Results: The frequency of binucleated micronucleated cells was significantly higher in all exposed groups when compared with controls ($p < 0.05$). The frequency of CAs was also significantly higher in exposed than in controls. For example, in nurses handling anti-cancer drugs, the frequency of MNs was 9.4‰± 2.88 versus 4.36‰± 1.32 in controls. In CA analysis, we detected in exposed group a significant increase (about 5.7 fold) of CAs.
Conclusion: Based in the fact that exposure to MNs and CAs are an excepted markers of exposure to genotoxic substances, our finding of higher frequency of CAs and MNs in peripheral lymphocytes of exposed workers indicates that FA, anti-cancer drugs and (RI) are a mutagenic agents in humans.

P07.24
Usefulness of complex genomic profiles for the differential diagnosis of osteosarcomas mimicking aneurysmal bone cyst.

C. Galant, P. Docquier, J. Malghem, ***H. A. Poirel****;*
Cliniques univ saint-Luc - UCL, Brussels, Belgium.

Aneurysmal bone cyst (ABC) is a rare primitive lytic bone lesion. Translocation of the *USP6* locus occurs in over 60% cases leading to its overexpression. Although classical forms are characteristics on radiological & histological levels, some cases remain difficult to distinguish from a telangectatic osteosarcoma (OS).
We report 2 cases of a lytic lesion of the proximal humeral epiphyso-metaphysis in a 16 yr-old boy (pat1) & in a 13 yr-old girl after a traumatism (pat2). On both, a first biopsy showed an aspect of ABC. The X-Ray confirmed the evolution of the lesion. A second surgical procedure consisted of curettage, phenolisation, allograft and plating. Additional curettages were performed in patient 2. However, 4 months & 5 years after the ABC discovery, respectively for pat1 and pat2, the histology was in favour of malignancy.
Complex clonal chromosomal alterations were detected from the first specimens of both cases in 4-27% cells. Clonal evolution was further observed: duplication of the initial clone in both cases associated with the acquisition of *CDKN2A*/9p21 & *TP53*/17p13 deletions (pat1) & of *CDKN2A*/9p21 deletion and increased amplifications of *MDM2*/12q15 locus on a giant chromosome (pat2). No *USP6* rearrangement was detected in both cases.
The detection of complex genomic alterations, specially tumor suppressor loci deletions or *MDM2* amplification gave strong arguments in favor of a malignancy, confirmed on the surgical specimen. Genomic data, even in a very few proportion of cells, were useful to reach finally the diagnosis of OS on limited specimens where no clear criteria were present.

P07.26
A case of Chronic Myelogenous Leukaemia Ph+ and Splenic Marginal Zone-B Cell Lymphoma with t(6;14)(p21;q32)

R. C. Narvaiza-Martínez*, A. Bengoa-Alonso, B. Hernández-Charro, M. A. Pérez-Juana-Del-Casal, A. Valiente-Martín, M. A. Ramos-Arroyo;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

Chromosomal translocation t(6;14)(p21.1;q32.3) appears mainly in Multiple Myeloma and Plasma Cell Leukaemia, but it has also been reported in Diffuse Large B-Cell Non-Hodgkin Lymphoma and Marginal Zone B-Cell Lymphoma.
We report a case of a 65-year-old patient who was diagnosed with possible Chronic Myelogenous Leukaemia, which was confirmed by cytogenetic and molecular studies: 46,XY,t(9;22)(q34;q11)[7], ratio bcr-abl/abl p210 (84%). After being treated with Gleevec®, the study of his bone marrow showed a 55.7% of mature lymphoid cells, (54.1% B-lymphocytes). Cytogenetic studies then showed two cellular lines: 46,XY,t(9;22)(q34;q11)[14]/46,XY[2], and a decrease in the ratio bcr-abl/abl p210 (5.3%). Eleven months after the first analysis, the t(9;22) could only be detected by molecular studies; however, an additional cellular line was present when lymphocytic line was stimulated: 45,X,-Y,t(6;14)(p21;q32)[13]/46,XY[21]. Fluorescence In Situ Hybridization (FISH) for RB1, TP53, ATM and centromere of chromosome 12 were normal. The patient was then diagnosed with a Chronic Myelogenous Leukaemia + Splenic Marginal Zone B-Cell Lymphoma. Cytogenetic follow-up analysis demonstrated an increase in the cellular line with t(6;14). FISH studies using a LSI IgH dual color, break apart rearrangement probe, showed that 52% of the cells had the IgH translocation with loss of the telomeric part of the probe. A decrease in the t(6;14) line was observed after treatment with splenectomy and additional bcr-abl p210 studies indicated that the patient was in major molecular response.
Our report contributes to the clinical and cytogenetic description of the rare association between Splenic Marginal Zone B-Cell Lymphoma with t(6;14) and Chronic Myelogenous Leukaemia.

P07.27
Derivative (6)t(1;6)(q21;p21): a recurrent cytogenetic abnormality in two cases of pediatric therapy-related myelodysplastic syndrome

E. Tassano, E. Tavella, C. Cuoco, C. Panarello, ***C. Morerio****;*
Laboratorio di Citogenetica Ematoncologica IRCCS Istituto G.Gaslini, Genova, Italy.

Childhood myelodysplastic syndromes (MDSs) are a rare group of clonal hematopoietic stem cell disorders occurring de novo or secondary to cytotoxic chemotherapy and/or radiotherapy for a previous malignancy. Cytogenetic aberrations have been detected in about 50% of de novo MDS and in almost all therapy-related MDS (t-MDS) patients. The most common abnormalities are complete or partial loss of chromosome 7 and trisomy 8. Unbalanced rearrangements involving the long arm of chromosome 1 and leading to its trisomy, usually as t(1;7), are also recurrent. We report two cases of pediatric t-MDS with der(6)t(1;6)(q21;p21). This unbalanced translocation has been reported in the literature associated with adult chronic myeloproliferative disorders. The first patient developed refractory cytopenia 9 years after suspension of chemo- and radiotherapy for a medulloblastoma diagnosed at the age of 7 months. The second patient, a 6-year-old boy, is slowly developing MDS features after a diagnosis of neuroblastoma 4S at age 1 month and of anaplastic lymphoma 10 months later. Cytogenetic analysis of peripheral blood and bone marrow blasts of both patients revealed der(6)t(1;6)(q21;p21). FISH for the painting of chromosomes 1 and 6 confirmed the rearrangement. Further array-CGH analysis performed on the bone marrow of the second patient, using 5500 BAC clones, showed

gain of material of chromosome 1 (q21.1->q44) and chromosome 6 (p22.1->p12.1) and loss of material of chromosome 6 (p25.3->p22.1). Array-CGH analysis is being carried out in the other patient to verify whether the imbalance is identical.

[1]*Centro Hospitalar de Tras-os-Montes e Alto Douro, Vila Real, Portugal,* [2]*CECAV, Department of Veterinary Sciences, University of Trás-os-Montes and Alto Douro, Vila Real, Portugal,* [3]*Department of Surgical Oncology, Portuguese Institute of Oncology, Porto, Portugal,* [4]*Health Faculty, Fernando Pessoa University, Porto, Portugal.*

Tumor cell lines are valuable preclinical models in oncological studies concerning human cancer, potential treatment modalities and pharmacologically studies.

Human cancer urothelial cell lines represent important tools in the study of bladder cancer, particularly in evaluating the chemoprevention of different compounds and the therapeutic effect of anticancer drugs on apoptosis and cell proliferation.

Although the karyotypic aspects of some cell lines have sometimes been taken into account, the cytogenetic studies are usually limited to classical methods. Documenting their chromosome composition adds valuable genetic data and offers a reference to evaluate genomic changes that may occur *in vitro*.

HT1376 is an invasive transitional carcinoma cell line used frequently in bladder cancer research. Established in 1977 and diagnosed as stage 2, grade 3 this cell line has a karyotype of high complexity and is not yet characterized cytogenetically.

In this work, we have attempted to cytogenetic characterize the HT1736 bladder carcinoma cell line by a combination of classical cytogenetics analysis (GTL, NOR and CBG banding) and fluorescence *in situ* hybridization (subtelomeric, painting, alpha satellite and unique sequence probes). We also evaluate the degree of DNA fragmentation of the cell line and in normal urothelial cells as a control.

Using this approach, we have identified several novel rearrangements that could reflect useful molecular markers involved with the development of bladder cancer. They can be important in improving prognostic on tumor diagnosis, and to develop new therapeutic approaches.

Investigation of *FANCA* mutations and their effects on the expression of *FANCA* in Iranian patients with Fanconi anemia

A. Saffar Moghadam*, F. Mahjoubi;*
National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.

Fanconi Anemia (FA) is an autosomal instability syndrome characterized by progressive bone marrow failure (anemia),developmental anomalies (various congenital malformations), high cancer susceptibility (acute nonlympocytic leukaemia) and cellular hypersensitivity to cross linking agents such as diepoxybutane (DEB) and mitomycin C (MMC). The patients display lots of phenotypic variations. At least 13 genes and corresponding complementation groups are underlying the disease. Eight of the FA proteins (FANCA, -B, -C, -E, -F, -G, -L and -M) and other components assemble in a nuclear complex, the FA “core complex”.In this study we aimed to screen mutations in FANCA gene in Iranian patients diagnosed with fanconi anemia. Chromosomal breakage analysis with MMC was performed to establish diagnosis of FA in 40 Iranian patients. RNA was extracted from the blood and consequently cDNA was synthesized. The cDNA of each patient amplified with 22 set PCR reaction. The size of the amplicons were between 200 and 250 bp. Each PCR product screened with SSCP (Single Strand Conformational Polymorphism) and HRM (High Resolution Temperature Melting Curve) for mutation detection. The aberrant SSCP band or HRM was sent for direct sequencing. In this presentation we will demonstrate our data regarding FANCA mutation frequency among Iranian FA patients. Furthermore, we will present some of the new mutations found in this group of FA patients

The radiation-induced aberrations of chromosomes in lymphocytes of breast cancer patients

E. A. Domina*;*
Institute of experimental pathology, oncology and radiobiology, Kiev, Ukraine.

Aim. To investigate cytogenetic effects in peripheral blood lymphocytes (PBL) of breast cancer patients exposed in vitro to γ-irradiation in the low dose range with regards to individual radiation sensitivity.

Material and Methods. The irradiation of lymphocytes isolated from healthy donors was carried out on therapeutic apparatus “Rockus” (with 60Co source) in range of 0,1-1,0 Gy. The metaphase analysis of chromosome aberrations had been carried out with group kariotyping including G2-radiation sensitivity assay.

Results. Background frequency of chromosome aberrations in PBL of breast cancer patients was 7.2±0.95/100 cells and was 6-fold higher than in the cjntrol group of healthy donors. The peculiarity of spontaneous aberrations spectrum consist in the emergence of dicentric chromosomes (0.16/100 cells) in 55% of examined patients. When the PBL culture was irradiated in the low dose range (0.1-0.5 Gy), the dose curve had an abnormal shape with the formation of the plateau (dose-independent part). The boundaries of its location depends on the individual radiation sensitivity of patients, the second plateau could be formed with increase of individual radiation sensitivity.

Conclusions. For the first time, it was shown that individual radiation sensitivity significantly affects the yield of radiation-induced chromosome aberrations in PBL of breast cancer patients and this effect was dependent on radiation dose. This dates are advisable by radiation therapy of early forms of breast cancer.

Dept. of Medical Genetics, Selcuklu Medical Faculty, Selcuk Unıversity, Konya, Turkey.

Leukemia is a malignant disease characterized with uncontrolled proliferation by loosing the ability to differentiate of hemotopoietik cells. Acute lymphoblastic leukemia (ALL) occurs with the abnormal uncontrolled and excessive proliferation of lymphoblast. ALL is responsible for approximately 80% of childhood leukemia and approximately 20% of adult leukemia. Many numerical and structural abnormalities play an important role in the risk assessment and the diagnosis of ALL. Numerical anomalies are in the form of chromosomal losses and gains. Losses and gains of some chromosomes are more common than the other chromosomes. In current study, numerical changes in chromosomes 8, 10, 11, 17, 18, X and Y were determined in 30 ALL patients by using FISH technique. Chromosomal changes were observed in all patients as monosomy X in 12 patients (40%), disomy X in all 18 male patients (100%), trisomy X in 16 patients (53%), tetrasomy X in 4 patients (13%), loss of Y in 2 patients (11%), disomy Y in 14 patients (78%), monosomy 8 in 29 patients (97%), trisomy 8 in 26 patients (87%), tetrasomy 8 in 3 patients (10%), monosomy 10 in 22 patients (73%), trisomy 10 in 9 patients (30%), monosomy 11 in 27 patients (90%), trisomy 11 in 8 patients (27%), tetrasomy 11 in 1 patient (3%), monosomy 17 in all patients (100%), trisomy 17 in 9 patients (30%) and monosomy 18 in 19 patients (63%). These analyzes of numerical abnormalities in patients with ALL provide useful data for diagnosis and prognosis.

MMP-13 (-77A>G) gene polymorphism and susceptibility to abdominal aortic aneurysm or aortoiliac occlusive disease

A. Korcz[1], *O. Zakerska*[1], *K. Pawlaczyk*[2], *M. Molińska-Glura*[2], *G. Oszkinis*[2], *R. Słomski*[1], *M. Gabriel*[2];

[1]*Polish Academy of Sciences, Institute of Human Genetics, Poznan, Poland,* [2]*Poznan University of Medical Sciences, Poznan, Poland.*

Objective: Abdominal aortic aneurysm (AAA) and aortoiliac occlusive disease (AIOD) are common vascular disorders considered to be complex diseases with both genetic and environmental risk factors involved. Involvement of various matrix metalloproteinases is very important in the pathogenesis of these diseases. Matrix metalloproteinase-13 (MMP-13) was shown to be up-regulated in AAAs and atherosclerotic lesions of aorta. A functional MMP-13 promoter polymorphism (-77A>G) was found to be associated with functional status in rheumatoid arthritis. The aim of the present study was to examine if MMP-13 (-77A>G) gene polymorphism is a susceptibility factor of AAA or AIOD in Polish patients. Results: Based on a PCR-RFLP analysis the MMP-13 genotypes (A/A; A/G/; G/G) were determined in three selected groups: 300 patients with AAA and 312 patients with AIOD who underwent surgery; 313 individuals from control group. Genotypes were compared with demographic and clinical data of subjects and analyzed in relation to risk factors. No significant differences in genotype distribution and allele frequencies of MMP-13(-77A>G)gene polymorphism in the study groups were found. Conclusion: This study found no evidence of association of MMP13 (-77A>G)gene polymorphism with AAA or AIOD in Polish patients.

P08.02

A study role of the Alu-insertion of the gene ATP-binding cassette transporter ABCA6 in lipid metabolism

I. Nikolaev, *E. Vorobieva, V. Gorbunova;*

Bashkir State Pedagogical University it. M.Akmulla, Ufa, Russian Federation.

INTRODUCTION: We studies gene, encoding ATP-binding cassette transporter ABCA6 is located on the chromosome 17 (17q24.2-3) consist of 38 exons and 39 introns. Alu-element Ya5_435 localized in the 25 intron of the gene ABCA6. ABCA6 involved in ATP-dependent transport of various molecules through biological membranes, and supports the lipid homeostasis of the body, localized on the surface of macrophages.

MATERIALS AND METHODS: We studied samples DNA of 318 individuals in the age of 18-65 years living in Republic Bashkortostan and them parameters of lipid profile. The analysis genetic polymorphism is realized by polymerase chain reaction (PCR). Assessing the impact of Alu-insertion in a gene ABCA6 on lipid metabolism was performed by ANOVA.

RESULTS: We found that the genotype ABCA6 *I /*I leads to a decrease in the level of high density lipoproteins (HDL), and allele ABCA6*D - an increase (F = 5.196; ρ = 0.023). Genotype ABCA6*D/*D leads to an increase in triglyceride (TG) levels, and allele ABCA6*I - to decrease (F = 7.242; ρ = 0.008). Thus, the Alu-insertion into ABCA6 is associated with a low level HDL and TG of the person.

Drug response in patients who underwent chemotherapy is accompanied by many adverse effects. The prediction of therapeutic effect may vary depending on individual gene variability. Many studies focus on the association between phenotype and DNA variations in genes of interest. Comprehensive approach in genotyping of numerous variants is needed to achieve improvements in personalized medicine such as selection of appropriate drug for treatment.

This work focuses on the design of a pharmacogenetically relevant panel which could be applied for the rapid genotyping of patients treated with methotrexate, thiopurines, 5-FU, irinotecan or taxanes prior to treatment as well as in studies searching for new genotype-phenotype associations. We selected 97 variable positions in 36 genes which were previously associated or may be potentially involved with altered drug response. Of these, 94 SNPs were genotyped by APEX microarray method, which is a valuable tool for fast, reliable and cost-effective typing. Variations of tandem repeats or gene deletions were genotyped by capillary electrophoresis and PCR detection, respectively. Direct sequencing served as reference method for validation of APEX chip and control of observed results. 300 DNA samples from unrelated healthy volunteers were tested to estimate genotype frequencies for a Slovak population, which may be helpful in estimation of central European frequencies. All data were checked for H-W equilibrium and genetic linkage between loci and haplotype analysis were also performed.

With a prevalence of around 2% intellectual disability (ID) is a frequent cause of severe disability. Significant excess of ID in the progeny of consanguineous matings and functional considerations suggest that autosomal recessive forms of ID (ARID) must be relatively common. To shed more light on the causes of ARID, we have set out in 2003 to perform systematic clinical studies and autozygosity mapping in large consanguineous Iranian families with non-syndromic ARID (NS-ARID). Previously we have reported 12 novel ARID loci as well as 2 causative gene defects in this cohort. By tripling the size of our cohort we were able to identify 27 additional unrelated families with NS-ARID and single-linkage intervals; 14 of these define novel loci for NS-ARID. Altogether, 13 out of 39 single linkage intervals observed in our cohort were found to cluster at 6 different loci on chromosomes 1p34, 4q27, 5p15, 9q34, 11p11-q13 and 19q13, respectively. Five of these clusters consist of two significantly overlapping linkage intervals, and on chr 1p34, three single linkage intervals coincide. We showed by Monte-Carlo simulation that the probability for this distribution to be due to chance is only 1.14*10(-5). Thus, in contrast to our previous conclusions, here we indicate that common molecular causes of NS-ARID do exist, and in the Iranian population, the most frequent ones may well account for several percent of the patients. Mutation screening by next generation sequencing in order to find the underlying gene defects at these loci is ongoing.

P08.05

Linkage analysis in 147 Iranian families with Autosomal recessive non-syndromic hearing loss

M. Babanejad[1], *N. Bazazzadegan*[1], *Z. Fattahi*[1], *N. Nikzat*[1], *K. Jalalvand*[1], *P. Nikooei*[2], *S. Arjangi*[1], *M. Taghdiri*[3], *P. Jamali*[4], *R. Smith*[5], *K. Kahrizi*[1], *H. Najmabadi*[1];

Shiraz, Islamic Republic of Iran, [4]Genetic counseling centre, Shahrood, Islamic Republic of Iran, [5]Molecular Otolaryngology Research Laboratories, Department of Otolaryngology Head and Neck Surgery, University of Iowa, Iowa City, IA, United States.

Hearing impairment is the most common sensory disorder and affects about 1 of every 1000 newborns. In developed countries at least 50% of the cases are due to genetic defects most often resulting in non-syndromic deafness (70%), of which autosomal recessive inheritance predominates (80%). Although hearing loss is very heterogenous, mutations in GJB2 gene (at DFNB1 locus) are the major cause of autosomal recessive non-syndromic hearing loss (ARNSHL) in many populations. Our previous study showed that mutations of GJB2 gene do not contribute to the major genetic load of deafness in the Iranian population.

To determine the other important loci in ARNSHL in our population, 147 deaf Iranian families with 2 or more affected members, who were negative for GJB2 gene mutations, were subjected to linkage analysis using flanking or intragenic STR markers for 34 loci.

Until now, 59 families have been linked to 18 loci: 9 families to DFNB4, 8 to DFNB3, 4 to DFNB24, 4 to DFNB21, 4 to DFNB7/11, 4 to DFNB2, 3 to DFNB28, 3 to DFNB29, 3 to DFNB37, 3 to DFNB42, 2 to DFNB16, 2 to DFNB30, 2 toDFNB31, 2 to DFNB49, 2 to DFNB59 and one family for each of 4 loci including: DFNB6, DFNB9, DFNB18, DFNB53. Mutation analysis of the corresponding genes revealed several novel mutations. In conclusion, DFNB1, DFNB4, DFNB3 and DFNB2 are the most prevalent loci in ARNSHL in Iranian population. Linkage study for remaining families and mutation screening for the rest of linked families, are underway.

P08.06

DFNB93, a novel locus for autosomal recessive moderate-to-severe hearing impairment

M. A. Tabatabaiefar[1,2,3], *F. Alasti*[3,4], *L. Shariati*[2], *E. Farrokhi*[2], *E. Fransen*[3], *M. R. Noori-Daloii*[5], *M. Hashemzadeh Chaleshtori*[2], *G. Van Camp*[3];

[1]Department of Medical Genetics, School of Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran, [2]Cellular and Molecular Research Center, School of Medicine, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran, [3]Department of Medical Genetics, University of Antwerp, 2610, Antwerp, Belgium, [4]Natinal Institute for Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran, [5]Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: Hearing impairment (HI) is the most common sensory defect in humans. Autosomal recessive non-syndromic HI (ARNSHI) is linked to over 70 chromosomal loci, with about half of the corresponding genes identified. Novel loci and their genes can increase our insight into the mechanisms of HI. While the phenotype of the majority of families is severe to profound, DFNB21 *(TECTA)* has been described to show a recognizable milder audiometric profile. Presented here is a novel locus in an Iranian family with moderate to severe ARNSHI, localizing to a new locus on chromosome 11q12.3-13.2. **Methods:** Linkage to DFNB21 (*TECTA*) as well as 14 other known loci was ruled out. Illumina 6K SNP chips (Linkage IVb panel) were used for a genome scan, followed by fine mapping by microsatellite markers. **Results:** Genome wide linkage revealed a multipoint LOD score of 3.51 on 11q12.3-13.2. The homozygous linkage interval is flanked by the markers D11S1765 (60.68 Mb) and D11S1975 (70.30 Mb) spanning a 9.62 Mb interval. The name DFNB93 was assigned to this locus by the Human Genome Organization (HUGO) Nomenclature Committee. **Conclusion:** The new DFNB93 locus partially overlaps with the DFNB63 locus. However, it does not include the responsible *LRTOMT* gene. Furthermore, DFNB63, unlike DFNB93, accounts for severe to profound HI. DFNB93 is the second ARNSHI locus with a distinctive audiometric profile. The sequencing of coding regions and exon-intron boundaries of several candidate genes including *LRTOMT*, *CFL1*, *KCNK4* and *RELA* revealed no disease causing variants.

Analysis of MDR1 (ABCB1) gene polymorphisms in Behcet's Disease

A. RÜSTEMOGLU[1], *Ü. GÜL*[2], *G. GÜMÜS AKAY*[3], *M. GÖNÜL*[2], *A. KARADAG*[4], *Ö. ATES*[1], *E. PISKIN*[2], *S. SAHIN*[1], *A. SUNGUROGLU*[4];

[1]Gaziosmanpasa University, Medical Faculty, Department of Medical Biology, TOKAT, Turkey, [2]Second Dermatology Clinic, Ankara Numune Education and Research Hospital,, ANKARA, Turkey, [3]Ankara University, Brain Studies Application and Research Center, ANKARA, Turkey, [4]Ankara University, Faculty of Medicine, Department of Medical Biology, ANKARA, Turkey.

Behcet's disease (BD) is a chronic multisystem disorder. The cause of BD remains a mystery; infectious agents, immune mechanism, and genetic factors are implicated in the etiopathogenesis of the disease, which remains to be explained.

The human MDR1 gene encodes a P-gp (P-glycoprotein) plays a key role in determining drug bioavailability, and drug response exist amongst different populations.

In this study, we were investigated genotype and haplotype distribution of MDR1 gene polymorphisms in BD patients, and genetic differences from the control group. Three MDR-1 genetic markers (C1236T, G2677T/A and C3435T) were analyzed in 97 BD patients and 107 unrelated Turkish subjects. The genotyping analysis was performed by PCR-restriction fragment length polymorphism (RFLP) methods. Statistically analysis of data was performed by using Arlequin 3.1.1 and SPSS 16.0 Softwares.

Our result showed that, genotypic and allelic frequencies each three separated SNP in MDR1 gene is not associated with BD (p>0.05). In the haplotype study, we have found two haplotypes may have be protective to BD. T-G-T haplotype were found 4.7 % in control but were not found in BD patients (p=0.002). The other haplotype C-T-T was detected 7.0 % in control and 2.2 % in BD patients (p =0.019; odds ratio, [OR], 0.28; 95% confidence interval [95% CI], 0.09-0.86). Our study was showed that MDR1 gene and their polymorphisms may be associated with BD in Turkish patients.

P08.08

Next generation sequencing from raw data to mutation report

B. Wolf[1,2], *D. Atlan*[1], *P. Kuonen*[3];

[1]Phenosystems SA, Blonay, Switzerland, [2]Ecole d'ingenieurs et d'architectes de Fribourg, Fribourg, Switzerland, [3]Ecole d'ingénieurs et d'architectes de Fribourg, Blonay, Switzerland.

Next Generation Sequencing is knocking on the door of diagnostics laboratories which are still reluctant to handle such a large amount of data. Although various software packages have been developed, both open and closed source, for the research and bio-informatics community, none of them really addresses all the specific needs of the diagnostics community, namely:

User-friendliness: use-ability by non bioinformaticians

Patient centric database system

Variant consequence prediction support

Flexibility to analyze data from various equipments

Connectivity to public and private databases

We present here the first version of Gensearch®NGS, a framework to analyze, visualize, interpret and manage NGS data in a patient centric database. The framework integrates all steps from quality control to alignment, variant detection, visualization and interpretation support (UMD Predictor, Human Splice Finder, dbSNP,□) up to reporting, both internally and publicly to the Gen2Phen Café Rouge. Gensearch®NGS is built around the concept of plug-ins, allowing use of either proprietary tools for alignment and variant calling or any major public tool (e.g. BWA, Stampy, Bowtie, VarScan). The framework hides the complexity of those tools. Also integrated is a tool to visualize the alignments in a fast, efficient and user friendly way, it integrates data from external databases, like Ensembl, as well as variants found on any other patient from the user database. The framework also integrates the possibility to use Cloud Computing through POP-C++ and POP-Java programming tools to distribute alignment tasks and, therefore to improve performances. Gensearch®NGS has been developed and validated within the FP7 NMDchip project.

P08.09

Association study between Coronary Artery Disease and rs1333049 and rs10757274 polymorphisms in 9p21 locus in Khuzestan province

a. foroughmand[1], *E. Nikkhah*[1], *M. Jadbabaee*[2], *H. Galehdari*[1];

[1]shahid chamran university, Ahvaz, Islamic Republic of Iran, [2]. Department of cardiology, Jondishapoor University of medical sciences, Ahvaz, Ahvaz, Islamic

Republic of Iran.

Introduction: Coronary Artery Disease (CAD) is a Multifactorial and Heterogenic disease. In CAD atherosclerosis plaques have been formed in internal wall of coronary artery. That reducing coronary blood flow may lead to Myocardial Infarction. Many genes and loci, such as the 9p21 locus are believed to be involved in the etiology of CAD. Two polymorphisms of 9p21 locus, rs1333049 and rs10757274 have shown remarkable association with CAD in several studies.

Methods: We collected blood samples from 170 CAD patients and 100 healthy persons as control from Hospitals in Ahvaz**.** Association of rs13333049(C/G) and rs10757274 (A/G) polymorphisms with CAD was evaluated using Tetra ARMS PCR technique.

Results: In rs1333049 polymorphism frequencies of CC, CG and GG genotypes in patients were respectively 18.2%, 65.3% and 16.5% and in control cases were 25%, 67% and 8% respectively. GG Genotype in rs1333049 polymorphism was found in CAD patients more than control cases (OR: 0.354, 95%CI= 0.138-0.912, P=0.032).

In rs10757274 polymorphism frequencies of AA, AG and GG genotypes in patients were respectively 8.2%, 58.3% and 33.5% and in control cases were 35%, 63% and 2% respectively. GG Genotype in rs10757274 polymorphism was found in CAD patients more than control cases (OR: 0.014, 95% CI: 0.003 -0.065, P value: 0.0001).

Conclusion: The rs1333049 polymorphism shows a weak association with CAD but rs10757274 Polymorphism has significantly associated with CAD. These variants may help in identification of patients with increased risk for coronary artery disease.

P08.10

CFHR5 mutation screening in sporadic patients with macroscopic hematuria or unknown etiology nephropathy

H. Stefanou[1], *K. Voskarides*[1], *Y. Athanasiou*[2], *A. Pierides*[3], *C. Deltas*[1];
[1]*University of Cyprus, Nicosia, Cyprus,* [2]*Nicosia General Hospital, Nicosia, Cyprus,* [3]*Hippocrateon Hospital, Nicosia, Cyprus.*

Our team contributed to the molecular investigation of a new autosomal dominant renal disease seeming to be endemic in Cyprus, which is characterized by microscopic and synpharyngitic macroscopic hematuria, renal failure (especially in males) and C3 glomerulonephritis. Affected individuals were found to have an internal duplication of exons 2-3, of the complement factor H-related protein 5 (*CFHR5*) gene. Results from 105 Cypriot patients carrying this mutation show that 41% of male patients over 50-yo develop end stage of renal disease.

No other mutations have been reported in *CFHR5* gene in relation to C3 glomerulonephritis or other glomerulonephritis cases. We screened 20 sporadic cases with macroscopic hematuria or unknown cause nephropathy, for mutations in the CFHR5 gene. We used SURVEYOR endonuclease digestion, which identifies and cleaves at mismatched base-pairs in heteroduplexes. The exons and flanking intronic regions of *CFHR5* were amplified with appropriate primers. If cleavage was evident at the digested PCR product (agarose electrophoresis), DNA re-sequencing was performed.

Four variants were identified (5UTR+249TC, P46S, IVS1+17TA, IVS5+33TG), but their frequencies found through 200 chromosomes of the general population, did not differ from the patients cohort. P46S and IVS5+33T>G (novel SNP) were also genotyped in additional 38 unknown glomerulonephritis and 39 unknown nephropathy patients but again the SNPs frequencies were comparable with the ones of the general population, therefore they cannot be associated with a pathogenic effect. It is probable that some patients carry large rearrangements or gross indels that cannot be easily identified with the method we used.

P08.11**

Human *cis*-regulatory SNPs (*cis*-SNPs) altering transcription factors binding and gene expression

V. Adoue[1], *T. Kwan*[1], *B. Ge*[1], *M. Ouimet*[2], *V. Gagne*[2], *K. Gunderson*[3], *D. Sinnett*[2], *T. Pastinen*[1];
[1]*McGill University, Montreal, QC, Canada,* [2]*Hôpital Ste-Justine, Université de Montréal, Montreal, QC, Canada,* [3]*Illumina Inc, San Diego, QC, United States.*

Up to 30% of RefSeq transcripts are regulated by *cis*-SNPs leading to phenotypic differences. These variants can be identified by mapping differences in allelic expression (AE) on Illumina1M/2.5M BeadChips. Mapped *cis*-rSNPs explain >50% of population variance in AE.

Our systematic approach to isolate causal *cis*-rSNPs includes integrative analysis of AE-mapping data in CEU and YRI LCLs with the intersection of common SNPs (1000 Genomes) and functional non-coding elements (wgENCODE) catalogs, along with ChIP-seq assays and assessing promoters and enhancers at high coverage.

Fine-mapped *cis*-rSNPs are enriched in regulatory elements and show predominant localization to 5' transcription start site. Reporter gene assays validated 62% of promoter *cis*-rSNPs. Integrative genomic approaches can successfully isolate causal *cis*-rSNPs beyond promoters: *rs909685* is strongly associated with differential AE of *SYNGR1*, shows association by RNA-seq. in LCLs, is located in active chromatin (DNaseI HS), and shows an allelic H3K4me1 signal in our ChIP-seq. analysis. The allelic enhancer activity at this site was verified by reporter gene assays, underscoring the capacity of population genomic approaches in revealing function and variation of non-coding sequence elements. Multiple other sites show converging functional data suggesting specific mechanisms for common *cis*-rSNP action. However, despite numerous functional genomic datasets, only a subset of mapped *cis*-rSNPs yield straightforward hypotheses, suggesting the need for further tools for assessing non-coding DNA. Additional information can be derived from our comparisons of *cis*-rSNPs observed in LCLs with those from other cell lineages and will guide how to more comprehensively enumerate causal *cis*-rSNPs in the human genome.

Genome Wide Association Study of Left Ventricular Phenotypes - ASCOT-HACVD genetic study

P. Surendran[1,2], *C. Vangjeli*[2], *N. McCarthy*[2], *S. Thom*[3], *P. Sever*[3], *E. O'Brien*[2], *N. Poulter*[3], *A. Barron*[3], *J. Mayet*[3], *A. Hughes*[3], *A. Stanton*[2], *D. Shields*[1];
[1]*School of Medicine and Medical Science, University College Dublin, Dublin, Ireland,* [2]*Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin, Ireland,* [3]*International Centre for Circulatory Health, National Heart and Lung Institute, Imperial College London, St. Mary's Campus, Paddington, London, United Kingdom.*

Background: Alterations in left ventricular (LV) structure and function provide independent prediction of myocardial infarction and stroke. These echocardiographic traits are moderately heritable (~20-40%). The aim of this study was to identify genetic variants associated with these LV prognostic markers across the whole human genome.

Methods: 885 hypertensive participants in the Hypertension Associated CardioVascular Disease (HACVD) sub-study of the Anglo-Scandinavian Cardiac Outcomes Trial underwent echocardiography 1.5 and 3.5 years post randomization to BP and lipid lowering therapies. The average value of four measures of LV structure and function were studied; LV hypertrophy (LVM/height$^{2.7}$, LVMi), diastolic dysfunction (e'), systolic function (ejection fraction) and LV filling pressure (E/e'). 318,000 Single Nucleotide Polymorphisms (SNPs) were directly genotyped (Illumina HumanCNV 370 Duo BeadChip), and approximately 3.5 million loci were imputed using IMPUTE from Hapmap rel#24 reference. Poorly imputed SNPs were excluded from further analysis. GWAS was performed using linear regression analysis under an additive model, adjusted for cardiovascular risk factors, and for principal components representing major genetic variation within the study population.

Results and Discussion: None of the directly genotyped SNPs showed significant associations with any of the LV phenotypes. By contrast a number of regions containing imputed SNPs with low minor allele frequencies (<2%) were significantly associated with LVMi. Permutation testing indicated that these SNPs were significant after correction for multiple testing of both genotypes and phenotypes. It is difficult to distinguish whether these associations reflect unmeasured genetic stratification in the population or direct causation by chromosomal regions. Hence replication studies are underway.

P08.13

Multivariate association analysis of arterial calcification in the Nelson Study.

J. van Setten[1], *I. Isgum*[1], *R. J. van Klaveren*[2], *P. A. de Jong*[1], *M. A. Viergever*[1], *C. Wijmenga*[3], *W. P. Mali*[1], *P. I. W. de Bakker*[1,4,5];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Erasmus MS, Rotterdam, Netherlands,* [3]*University Medical Center Groningen, Groningen, Netherlands,* [4]*Broad Institute of MIT and Harvard, Cambridge, MA, United*

States, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.
Atherosclerosis is a major cause of death in the industrialized world. Although the relation between calcium deposits and atherosclerotic plaques is well known, little is known about the genetic basis of calcification. We studied common genetic variation in the NELSON study for a role in aorta and coronary artery calcification.
The Nelson study is a prospective cohort for early detection screening of lung cancer. We analyzed genome-wide SNP genotype data collected in 3082 participants with multiple chest CT scans. We developed a novel image-processing algorithm to quantify levels of calcification in the aorta and the coronary arteries.
We compared three methods in order to find genetic loci associated with coronary artery calcification and aorta calcification (R^2=0.13): a polygenic model, cross-trait meta-analysis, and multivariate regression. Although no single SNPs reach genome-wide significance (p<5E-08), polygenic analysis shows that coronary artery and aorta calcification share a substantial genetic background. The explained variance increases when more SNPs are included, reaching approximately 13% for both traits when SNPs with P-values of up to 0.05 are included in the model.
These results demonstrate that large-scale genome-wide meta-analyses of calcification may reveal important genes involved in forming calcium deposits.

P08.14
Genetic polymorphisms in CYP17 and AR genes and the risk of premature coronary artery disease

*K. Agiannitopoulos[1], A. Kyparissi[1], A. Mpakalgianni[1], M. Georgoutsou[1], A. Manginas[2], S. Papamenzelopoulos[2], **K. Lamnissou**[1];*
[1]Dept of Genetics & Biotechnology, Faculty of Biology, University of Athens, Athens, Greece, [2]1st Cardiology Dept, Onassis Cardiac Surgery Center, Athens, Greece.
Background: Gender differences and sex hormones are known to influence the risk of developing Coronary Artery Disease (CAD). Several genes are involved in the synthesis or function of sex hormones. Two of them which play a crusial role during the human sex steroidogenesis or function are the cytochrome P450c17α gene (CYP17) and the androgen receptor gene (AR). The aim of this study was to investigate the effect of two single nucleotide polymorphisms (SNPs) of these genes in developing premature CAD.
Methods: A total of 370 Greek cohorts were investigated for the genetic variations T/C of the promoter of the CYP17 and G/A of the AR. The patient group consisted of 230 CAD patients as documented by coronary angiography, aged less than 58 years, while 150 healthy individuals served as controls. All cohorts were genotyped by the PCR-RFLP method.
Results: Statistical analysis indicated no significant differences in genotype or in allele frequencies between the patient and the control group, for both the studied polymorphisms.
Conclusion: The genetic variations T/C CYP17 and G/A AR, could not be a useful genetic markers for premature CAD in our Caucasian population.

P08.15
A Genome wide linkage analysis on large Coronary Artery Disease family suggests linkage to chromosome 19

***K. Inanloo**[1], S. Davaran[1], A. Zand Parsa[1], J. Fan[2], E. Elahi[1];*
[1]Tehran University, Tehran, Islamic Republic of Iran, [2]Illumina Inc, San Diego, CA, United States.
Coronary artery disease (CAD) is the most common type of heart disease and the leading cause of death worldwide in both men and women. A positive family history is a recognized cardiovascular risk factor. We identified a family with multiple siblings affected with early onset CAD and some CAD risk factors, suggesting a strong genetic component. A genome-wide linkage analysis was performed on this family using Illumina 370K Gene Chips. Linkage with a lod score of 1.8 to chromosome 19q13.11-q13.33 was observed. The interval spans 14Mbp and contains 446 annotated genes. *ApoE* was a promising candidate gene within the locus, but mutation screening of coding region of *ApoE* did not revealed a disease causing mutation. While attempting to minimize the region by studying other families, a few other promising candidate genes are being screened.

P08.16
TIMP2 polymorphism, left ventricular function and prognosis after myocardial infarction with ST elevation.

***J. Lipkova**[1], M. Pavkova Goldbergova[1], J. Parenica[2], M. Poloczek[2], J. Spinar[2], P. Kala[2], A. Vasku[1];*
[1]Department of pathological physiology, Faculty of medicine, Masaryk university, Brno, Czech Republic, [2](2) Internal Cardiology Department, Faculty Hospital Brno, Brno, Czech Republic.
Objective: Genetic variations of tissue inhibitors of matrix metalloproteinases (TIMP) are known to be involved in the process of development and progress of acute myocardial infarction. TIMPs play important role in process of plaque formation, destabilization and rupture within the myocard by regulation of extracellular matrix proteins degradation. In this study, we investigated the possible role of polymorphism in TIMP2 in acute myocardial infarction with ST elevations.
Methods: 556 patients with STEMI and 141 stable patients >50 years without MI in anamnesis and without LV systolic dysfunction were enrolled into the study. Levels of B-type natriuretic peptide (BNP) and N-terminal pro B-type natriuretic peptide (NT-proBNP) were measured at the time of hospital admission before primacy PCI and 24h, 3months and 12 months after MI onset. The TIMP2 intron polymorphism rs8176329 located at 17 chromosome was detected by RT-genotyping.
Results: No significant differences in genotype distribution and/or allele frequencies were observed when comparing STEMI patients and stable patients. Within the STEMI patient group lower prevalence of AA variant have been observed in subjects with acute heart failure (AHF) in time of hospitalization (p=0.048). We have found the association among GG genotype and higher BNP levels (p=0.03), higher NT-proBNP levels respectively
(p=0.008).
Conclusion: Taken together, our results provide evidence that GG variant correlate with higher levels of BNP and NT-proBNP, which strongly correspond to association of GG genotype with acute heart failure.

P08.17
Inference of cross-level interaction between genes and contextual factors in a matched case-control metabolic syndrome study: a Bayesian approach

***S. Wang**[1], W. Chen[1], L. Chuang[2], P. Hsiao[1], P. Liu[3], C. Hsiao[1];*
[1]Institute of Epidemiology, College of Public Health, National Taiwan University, Taipei, Taiwan, [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [3]Clinical Informatics and Medical Statistics Research Center, Chang Gung University, Taipei, Taiwan.
Background: Genes, environment, and the interaction between them are each known to play an important role in the risk for developing metabolic syndrome. Environmental influences can be measured at the individual level, such as by personal characteristics and lifestyle choices, or at the group-level (called contextual variables), such as by community factors and degree of local area development. To examine the interaction between genes and contextual factors, traditional approaches usually adopt asymptotic tests to assess whether the interaction exists. Such tests are limited as they cannot evaluate or quantify the strength of difference in genetic effects across different clusters or categories of the contextual variable. **Methods:** In this study, we utilize a Bayesian hierarchical mixed-effects model to investigate whether the genetic effect is modified by residential environment in a matched case-control metabolic syndrome study. The group-level contextual covariate, availability of exercise facilities, contains four categories, from low to high. Based on posterior samples from Markov chain Monte Carlo methods, the interaction between this group-level environmental condition and the individual-level genetic effect is evaluated by differences in allelic effects under various contextual categories. **Results:** The Bayesian analysis indicates that the effect of rs1801282 on metabolic syndrome development is modified by the contextual environmental factor such that, even with the same genotype, living in a residential area with low availability of exercise facility may result in higher risk. **Conclusions:** In summary, the Bayesian hierarchical mixed-effects model considered here provides a quantitative assessment for the cross-level interaction between genes and contextual variables.

P08.18

Time trends in the incidence of cystic fibrosis over a 40-year period

V. Scotet[1], *I. Duguépéroux*[1,2], *M. Audrézet*[1,2], *G. Rault*[3], *M. Roussey*[4], *P. Saliou*[1,2], *C. Férec*[1,2];

[1]*Inserm U613, Brest, France,* [2]*CHRU Morvan, Laboratoire de génétique moléculaire, Brest, France,* [3]*CRCM, Roscoff, France,* [4]*CRCM, Rennes, France.*

Cystic fibrosis (CF) is a recessive disorder whose incidence has, for a long time, been estimated to 1/2500 live births in Caucasians. Newborn screening (NBS) programs allows now a better appreciation of the disease incidence that appears lower than in the past. Here we reported time trends in CF incidence over a long period (40 years: 1970-2009) in an area where CF is frequent (Brittany, France) and where NBS is implemented since a long time (1989).

The study enrolled the CF patients born in Brittany since 1970. The cases born before the set up of NBS were registered through active enquiries and combination of data sources. Time trends in incidence rates were examined using Poisson regression and expressed by the average percent change (APC).

Over the 40-year period, 569 CF children born in Brittany were registered. The average number of cases born each year varied from 17.7 in the 1970's (decade 1970-79) to 11.8 nowadays (decade 2000-09). This corresponded to a decline in incidence rate of 29.0% (from 1/2260 to 1/3183, p=0.0039). Poisson regression also showed that the incidence rate decreased over the whole period (annual APC: -1.2%, 95% CI: [-1.8; -0.5], p=0.0012), and especially since the availability of prenatal diagnosis in the 1980's (annual APC: -2.0%, 95% CI: [-3.7; -0.3], p=0.0216).

This study highlights how the incidence of CF evolved in an area where CF is frequent and where carrier screening is not underway. It reports a clear decline in incidence that results from a complex mixture of factors.

P08.19

The alpha2 isoform of the catalytic subunit of AMP variants have a key role to susceptibility to type 2 diabetes

F. Davoodi Salestani[1], *P. Keshavarz Kiasaraei*[1], *R. Habibi*[2], *M. Ghasemi*[3];

[1]*Azad University of Guilan-Rasht, Rasht, Islamic Republic of Iran,* [2]*Guilan University of Medical Science, Rasht, Islamic Republic of Iran,* [3]*Oloom Tahghighat University, Tehran, Islamic Republic of Iran.*

AMP-activated protein is a key regulator of cellular metabolism, and its activity is induced by both metformin and thiazolidinedione anti-diabetic medications. It has therefore been proposed both as a putative agent in the pathophysiology of type 2 diabetes (T2D) and as a valid target for therapeutic intervention. The gene encoding the alpha2 isoform of the catalytic subunit of AMPK (PRKAA2) is located at one of the Japanese T2D loci mapped previously. PRKAA2 is, therefore a good candidate gene for insulin resistance and T2D. We therefore set out to test for the association of common variants and common haplotype in the PRKAA2 gene with type 2 diabetes and related phenotypes. We undertook an extensive case-control association study using a total of 911 unrelated Japanese T2D patients and 876 control subjects at 6 single nucleotide polymorphism in the PRKAA2 gene. We observed association of nominal significance with two intronic SNP in the PRKAA2 (rs932447; OR=0.62; 95%CI=0.40-0.96; P=0.033, AND rs1418442; OR=0.62, 95% CI=0.40=0.96; P=0.030, both under a dominant model). However, we were unable to observe the association between the PRKAA2 haplotype and T2D. Our result indicate that the PRKAA2 gene variant have an important impact on T2D susceptibility in Japanese.

P08.20

Lack of association of the KCNJ11 E23K variant with risk of type 2 diabetes in a Iranian population

P. Keshavarz[1], *M. Ghasemi*[2], *R. Habibi*[1], *M. Hedayeti emami*[1], *E. Kazemnejad*[1];

[1]*Guilan University of Medical Science, Rasht, Islamic Republic of Iran,* [2]*Oloom Tahghighat University, Tehran, Islamic Republic of Iran.*

The beta-cell ATP-sensitive potassium (KATP) channel consists of subunit of the inwardly rectifying potassium channel Kir6.2 and subunit of the sulfonylurea receptor 1 (SUR1).The gene KCNJ11 (Kir6.2) has a key role in glucose-stimulated insulin secretion and thus has always been considered as excellent susceptibility candidate for type 2 diabetes(T2D). An association between a common polymorphism in KCNJ11gene (E23K) and T2D has been reported in several but not all populations. We investigated whether E23K polymorphism in the KCNJ11gene is associated with T2D in the Iranian population. In this study, We performed a case-control association with 398 T2D patients and 420 Iranian control subjects using TaqMan assay. The case and control subjects had similar frequencies of the allele K (35.9 vs. 35.7%, P>0.05), then there was no significant difference between case and control subjects according to allele K frequency (OR =1.01, (95% CI) 0.825-1.236, P=0.928).Also, by genotype frequency comparison, no difference were observed between frequency of various genotypes regarding to diverse genotype models(ressecive , dominant and codominant model) of KCNJ11 E23K variant in our population. In conclusion, the presented study demonstrated the absence of the key role of KCNJ11 E23K variant in the occurrence of type 2 diabetes in a Iranian Population. Tis finding may conclusive due to limitation of sample size. A subsequent study with a larger sample size is recommended.

P08.21

The lipid-associated GALNT2 gene variant rs4846914 confers a highly elevated risk for type 2 diabetes

N. Polgar[1], *P. Kisfali*[1], *A. Maasz*[2], *E. Baricza*[1], *B. Duga*[1], *M. Mohas*[3], *I. Wittmann*[3], *B. Melegh*[1];

[1]*Department of Medical Genetics, University of Pécs, Pécs, Hungary,* [2]*Department of Medical Genetics, University of Pecs, Pécs, Hungary,* [3]*2nd Department of Internal Medicine and Nephrology Center, University of Pécs, Pécs, Hungary.*

The UDP-N-acetyl-alpha-D-galactosamine:polypeptide N-acetylgalactosaminyltransferase 2 (GALNT2) has been recently implicated in the modulation of antgiopoietin-like protein - 3 (ANGPTL3) activity via O-glycosylation. GALNT2 is therefore indirectly contributing to plasma triglyceride level modifications as ANGPTL3 is an inhibitor of lipoprotein lipase, the enzyme responsible for triglyceride hydrolysis. Besides, recent genome-wide association studies identified GALNT2 variant rs4846914 in association with blood lipid level alterations. As the GWAS studies do not provide functional information, we studied and we supposed the possible association of this variant in type 2 diabetes mellitus (T2DM) and metabolic syndrome (MS) patients.

A total of 308 type 2 diabetic patients, 394 metabolic syndrome patients and 246 healthy controls were genotyped by PCR-RFLP method.

We detected a significantly higher ratio of GG homozygotes among both T2DM and MS patients than in controls. In addition, in multiple regression analysis adjusted for body mass index, triglyceride and total cholesterol levels as well as age and sex, the GG genotype is associated with the development of type 2 diabetes, with an unusually high odds ratio of 5.218 (CI [95%] 2.811-9.683; p<0.001), while carriers of the G allele demonstrate a lower risk of T2DM (OR 1.659; [CI95%] 1.027-2.678, p=0.038).

The data presented here revealed a differentiated risk nature of the lipid profile modifying GALNT2 natural gene variant rs4846914, as the variant did not show an association with metabolic syndrome in our cohort, but appears to confer a exceptionally risk for type 2 diabetes, which strong association that has not been reported in the literature available.

P08.22

Comparative genetics of gestational diabetes mellitus in humans and dogs.

M. L. Arendt[1], *T. Fall*[2], *A. Ratnakumar*[1], *L. J. Kennedy*[3], *A. D. Short*[3], *B. Catchpole*[4], *W. E. R. Ollier*[3], *Å. Hedhammar*[2], *G. Andersson*[2], *K. Lindblad-Toh*[1,5], *O. Kämpe*[1];

[1]*Science for Life Laboratory, Uppsala University, Uppsala, Sweden,* [2]*Swedish University of Agricultural Sciences, Uppsala, Sweden,* [3]*University of Manchester, Manchester, United Kingdom,* [4]*Royal Veterinary College, London, United Kingdom,* [5]*Broad Institute, Cambridge, MA, United States.*

Gestational diabetes mellitus affects approximately 2-10% of human pregnancies and has a major impact on both maternal and foetal health. Family history of diabetes and ethnic background are two of the known risk factors for development of disease, which suggest a genetic background for the condition.

In dogs, the pregnant or the non-pregnant dioestral bitch develops peripheral insulin resistance, which can progress to diabetes mellitus. The dioestral phase of the canine sex hormone cycle mimics pregnancy

with regard to hormone levels and length. Elevated levels of growth hormone (GH) have been detected in diabetic dogs reflecting the placental GH secretion in human pregnancies. The dog has hence proven to be a good naturally occurring model of gestational diabetes. Epidemiologic studies show that certain dog breeds have a higher prevalence of diabetes suggesting a genetic predisposition as in humans.
We have performed genome-wide association studies in three high risk dog breeds: the Swedish Elkhound, the Norwegian Elkhound and the Border Collie, using the ~170k Illumina SNP array. Four preliminary loci have been identified, although more dogs are currently being genotyped. Candidate loci will be resequenced to identify candidate mutation and the functional consequences will be evaluated in dogs and humans. Candidate genes will also be examined in humans. We anticipate that our findings will progress the understanding of diabetes development in humans and dogs.

P08.23
A genome-wide association study in Doberman Pinschers identifies a new locus for dilated cardiomyopathy (DCM)

*T. Mausberg[1], G. Wess[2], J. Simak[2], L. Keller[2], M. Drögemüller[1], C. Drögemüller[1], M. T. Webster[3], H. Stephenson[4], J. Dukes-McEwan[4], **T. Leeb**[1];*
[1]University of Bern, Bern, Switzerland, [2]University of Munich, Munich, Germany, [3]University of Uppsala, Uppsala, Sweden, [4]University of Liverpool, Liverpool, United Kingdom.

Dilated cardiomyopathy (DCM) is a heterogeneous group of heart diseases with a strong genetic background. Currently, many human DCM cases exist, where no causative mutation can be identified. DCM also occurs with high prevalence in several large dog breeds. In the Doberman Pinscher a specific DCM form characterized by arrhythmias and/or echocardiographic changes has been intensively studied by veterinary cardiologists. We performed a genome-wide association study in Doberman Pinschers in the frame of the EU-LUPA project. Using 71 DCM cases and 70 controls collected in Germany we identified a genome-wide significant association to DCM on dog chromosome 5. We validated the association in an independent cohort collected in the United Kingdom. The raw p-value of the best associated SNP in the combined cohorts is 7.04×10^{-10}. There is no known DCM candidate gene under the association signal. Therefore, DCM in Doberman Pinschers offers the chance of identifying a novel DCM gene that might also be relevant for human health.

P08.24***
Relation between DNA methylation and gene expression

K. R. van Eijk[1,2], *S. de Jong[1,2], T. Langeveld[1], E. Strengman[1], E. Janson[1], J. H. Veldink[3], L. H. van den Berg[3], R. S. Kahn[2], C. G. F. de Kovel[1], S. Horvath[4], M. P. M. Boks[2,5], R. A. Ophoff[1,2,4];*
[1]Department of Medical Genetics, UMC Utrecht, Utrecht, Netherlands, [2]Department of Psychiatry, Rudolf Magnus Institute of Neuroscience, UMC Utrecht, Utrecht, Netherlands, [3]Department of Neurology, Rudolf Magnus Institute of Neuroscience, UMC Utrecht, Utrecht, Netherlands, [4]Center for Neurobehavioral Genetics, Neuropsychiatric Institute, University of California, Los Angeles, CA, United States, [5]Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands.

Epigenetic mechanisms are important for regulating the cellular machinery including gene expression. DNA methylation is one form of epigenetic control that is most commonly studied. However, little is known about the complex relation between DNA methylation and gene expression. This study is an effort to decipher how DNA methylation affects gene expression.
For this study we used (Illumina) array-based genome-wide DNA methylation and gene expression data obtained in whole blood of 150 healthy controls. After quality control and removal of batch effects we performed regression analysis with DNA methylation as a predictor of gene expression levels. Age and gender were used as covariates. We tested association of every methylation probe with every gene expression probe, resulting in over 400 million tests. Significance thresholds were adjusted for *cis* (region of 500 kb of both sides of a gene) and *trans* (genome-wide). Available genome-wide SNP data was used to investigate the genetic control of DNA methylation and gene expression at these loci.
We observed both positively and negatively associations between gene expression probes and DNA methylation probes. For *cis* 3,615 combinations of 386,993 possible combinations were significant, of which 1,932 negatively and 1,683 positively (53.4% vs 46.6%). Explained variance from the DNA methylation levels ranged from 1 to 52 percent. Overall the results show that DNA methylation levels and gene expression levels are both positive as well as negatively correlated. Data on CpG properties, genetic regulation and *trans* association provide further insight into the complex processes of gene expression and DNA methylation.

P08.25
Identifying genetic determinants of congenital heart defects in Down syndrome

M. Sailani[1,2], *P. Makrythanasis[1], S. Deutsch[1], E. Migliavacca[1], A. Sharp[1], J. Delabar[3], L. Perez-Jurado[4], C. Serra-Juhe[4], G. Merla[5], S. Vicari[6], E. Kanavakis[7], R. Rabionet[8], X. Estivill[8], S. Antonarakis[1,2];*
[1]University of Geneva, Geneva, Switzerland, [2]NCCR Frontiers in Genetics, Geneva, Switzerland, [3]University of Paris, Paris, France, [4]Universitat Pompeu Fabra, Barcelona, Spain, [5]IRCCS, San Giovanni Rotondo, Italy, [6]Children's Hospital Bambino Gesù, Rome, Italy, [7]Medical University of Athens, Athens, Greece, [8]Centre for Genomic Regulation, Barcelona, Spain.

Congenital heart defect (CHD) occurs in ~40%, and AVSD (Atrio-Ventricular Septal Defect) is observed in 16% of Down syndrome (DS) cases. Here, we test the hypothesis that genomic variation in concert with the trisomy 21 determines the risk for CHD. This case-control GWAS includes 156 DS without CHD and 192 DS with CHD (AVSD=72, ASD=53, VSD=67). Trisomic and disomic SNPs were called separately. Trisomic single-locus association reveals 4 SNPs as CHD risk alleles (Bonferroni adjusted p-values < 0.05). One of these SNPs was also identified as a risk factor for AVSD+VSD combined (p=0.008), while a 5th SNP was identified as risk factor for ASD (p= 0.002) and AVSD+ASD combined (p=0.05). No significant signal was identified from the non-chr21 GWAS. We then performed a 2-locus genomewide analysis. A significant interaction signal was observed between loci on chr5 and chr6 (p=0.002). Since DS is likely to be a disorder of gene expression, we focused on 2-locus interactions using only eQTLs. Interestingly, 2-locus model analysis on chr21 eQTLs reveals an interaction between eQTLs for PDE9A and WDR9 genes and eQTLs for C21orf56 and C21orf57 genes.
Furthermore, the 2-locus analysis of non-chr21 eQTLs identifies an interaction between eQTLs for CLCNKA on chr1 and USMG5 on chr10 (p=0.01). A search for chr21 risk CNVs for AVSD using tiling 135K chr21 array did not show any significant risk variation. We propose that the CHD risk of DS is determined by not only trisomy 21 but also the genome-wide interaction of specific alleles.

P08.26
A novel locus for autosomal recessive dystonia with mental retardation maps to chromosome 6

E. Jaberi[1], *M. Rohani[2], M. Rezvani[2], E. Elahi[1];*
[1]School of Biology, University College of Science, University of Tehran, Tehran, Islamic Republic of Iran, [2]Department of Neurology, Tehran University of Medical Sciences, University of Tehran, Iran, Tehran, Islamic Republic of Iran.

Introduction: Dystonia is a clinical syndrome with sustained muscle contraction, twisting, and abnormal postures. Some cases are familial, but most are sporadic and of uncertain cause. Presently, ten genes and seven additional loci have been reported to be associated with monogenic primary dystonias. We aimed to identify the genetic cause of dystonia in an affected Iranian family.
Materials & methods: Whole genome homozygosity mapping was performed in a consanguineous Iranian family with three dystonia affected children using high density single nucleotide polymorphism chips**.** Affected individuals were DYT1 negative and exhibited childhood-onset, segmental dystonia and mental retardation.
***Results*:** Haplotype analysis showed that all the affected individuals shared a common haplotype expanding 13cM on chromosome 6. Parametric linkage analyses resulted in a lod score of 1.6. More than 200 annotated genes exist within the linked region. Screening of four candidate genes has not revealed a disease causing mutation.
Conclusions: These findings indicate that a novel dystonia gene exists on chromosome 6. Mutation screening of other candidate genes within the linked region is being performed.

P08.27

Genetic of EBA

***H. Sadeghi**, R. Ludwig, A. Recke, S. Mueller, S. Ibrahim;*
UK-SH, Lubeck, Germany.

Epidermolysis bullosa acquisita (EBA) is an autoimmune blistering disease, characterized by antibodies to type VII collagen (COL7). At the moment little is known about the genetic susceptibility for EBA. To find key genetic factors (MHC and non-MHC EBA susceptibility genes) that control inflammation at the effector phase of EBA, we used a multi-step approach. First, different and 16 genetically well characterized inbred strains were tested for their susceptibility for EBA in the passive model. This allowed the identification of 8 associated loci indicating EBA severity to be regulated by loci on chromosomes 1, 6, 8, 9, 11, 12, 15 and 16. To confirm these, we used mice from an advanced 4-way intercross breeding of 4 different strains with different major histocompatibility complex (MHC) haplotype (MRL, NZM, BXD2, and Cast). For example on chromosome 8 and 9 that have already been tested, we could confirm the genes on chr 9. We demonstrated that low statistical significant of full Genome-Wide Association Study with characterized inbred mouse strains together with outbred family of mice allows for individual gene discovery for classic genetic linkage analysis.

P08.28

Whole genome linkage analysis in a large consanguineous Turkish family with idiopathic generalized epilepsy

***F. N. Tuncer**[1], E. Yucesan[1], O. Ozdemir[1], I. Karacan[1], S. A. Ugur Iseri[1], N. Bebek[2], B. Baykan[2], U. Ozbek[1];*
[1]Istanbul University, Institute for Experimental Medicine, Genetics Department, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Neurology Department, Istanbul, Turkey.

Epilepsy is a complex neurological disorder that affects 1% of the world's population. Among different forms of epilepsies, idiopathic generalized epilepsies (IGE) are characterized by bilateral and synchronous generalized seizures in the absence of detectable brain lesions or metabolic abnormalities. Thus, the primary etiology for this disorder is believed to be genetic.

The proposed study includes a large highly inbred consanguineous family with multiple IGE affected individuals. The ultimate aim is identifying a new epilepsy gene to help in delineating the molecular mechanisms of this disease. Physical, neurological and EEG examinations were performed on the subjects recruited with information on family history. These examinations revealed 5 affected individuals, a mother with three children and their cousin, who exhibit varying types of seizures. Along with these individuals, 4 unaffected individuals from this family were genotyped using Illumina Infinium HumanLinkage-12 Genotyping BeadChip (6090 SNPs). The genotype data were delineated using easyLinkage software platform, where Mendelian genotyping errors were determined using PedCheck, two and multipoint lod scores were calculated under the assumption of autosomal recessive inheritance via SuperLink and SimWalk, respectively, and haplotypes were constructed through GeneHunter. Analyses revealed a promising locus on chromosome 2p12, which was further analyzed through fine-mapping with additional microsatellites spanning a region of 75.36Mb-78.52Mb. However, microsattellite alleles were heterozygous in the 3 affected sibs rejecting linkage under autosomal recessive inheritance.

Future objectives include acquisition of extensive clinical data and dense SNP genotyping of the family members in an attempt to unravel small regions that may have been overlooked.

P08.29

The eNOS 4a/5b polymorphism increases the risk for end-stage renal disease in Romanian diabetic patients

***D. Cimponeriu**[1], P. Apostol[1], I. Radu[1], M. Stavarachi[1], M. Toma[1], A. Craciun[2], C. Serafinceanu[2], N. M. Panduru[3], D. A. Ion[3];*
[1]University of Bucharest, Department of Genetics, Bucharest, Romania, [2]N. C. Paulescu Institute, Bucharest, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background: Diabetic patients have a high risk of developing end-stage renal disease (ESRD). Some polymorphisms seem to increase the risk for renal failure in different populations.

Objectives: The aims of this case-control study were to estimate the possible impact of eNOS 4a/5b, MTHFR C677T, MTR A2756G, ACE-ID, ATR1 A1166C, HSPG2 BamH1 and TGFb C/T polymorphisms on the ESRD development in diabetic and nondiabetic patients.

Materials and methods: Clinical information and blood samples were collected from 1350 unrelated Caucasians represented by dDM1 (type1 diabetes mellitus dialysed patients, n=225), DM1 (type1 diabetes mellitus patients without renal disease, n=180), dDM2 (type 2 diabetes mellitus dialysed patients, n=225), DM2 (type 2 diabetes mellitus patients without renal disease, n=180) and HC (healthy controls, n= 540). Genomic DNA was extracted from blood samples with Wizard Genomic DNA purification Kit (Promega). Genotyping was performed by PCR and RFLP techniques.

Results: The frequencies for these genotypes are in Hardy-Weinberg equilibrium. Our results are not in agreement with several earlier studies which have indicated a strong association between investigated polymorphisms and ESRD in some Caucasian populations. Only eNOS 4a/5b increases the risk for renal failure in DM1 and DM2 patients (OR=2.2).

Conclusion: Our study, performed in Romanian population, shows that eNOS 4a/5b polymorphism is associated with ESRD development in diabetic subjects.

Aknowledgements: This work was supported by CNCSIS - UEFISCDI, project number PNII - IDEI 2150/2008 and by the Sectoral Operational Programme Human Resources Development, financed from the European Social Fund and Romanian Government under the contract number POSDRU/89/1.5/S/64109.

P08.30

EX-HOM: EXome HOMozygosity in small consanguineous pedigrees

*T. Pippucci[1], M. Benelli[2], A. Magi[2], P. Martelli[3], P. Magini[1], F. Torricelli[2], R. Casadio[3], **M. Seri**[1], G. Romeo[1];*
[1]Medical Genetics Unit, Department of Gynaecological, Obstetric and Paediatric Sciences, University of Bologna, Bologna, Italy, [2]Diagnostic Genetic Unit, Careggi Hospital, AOUC, University of Florence, Bologna, Italy, [3]Laboratory of Biocomputing, CIRB/Department of Biology, University of Bologna, Bologna, Italy.

Objective: We provide the proof of principle that exome sequencing of only two affected siblings born to first cousin parents is capable of directly identifying a single candidate gene for an autosomal recessive disorder. This strategy, which we call EX-HOM (EXome-HOMozygosity), combines in a single step the capacity of exome sequencing to identify all the coding variants present in a genome with the property of homozygosity mapping to limit the search for candidate genes to specific chromosomal regions.

Methods: We sequenced the exomes of two siblings born to first cousin parents affected with dysmyelinating leukodystrophy and spastic paraparesis caused by a mutation in *FA2H* . We extracted homozygosity information directly from exome sequencing data, without performing previous SNP genotyping, and selected the candidate variants contained in the homozygous regions shared by the two affected siblings.

Results: We identified five regions of shared homozygosity, accounting for 94.2 Mb, and containing three candidate variants. Among these, the known *FA2H* mutation remained the only prominent one.

Conclusion: In small consanguineous pedigrees, the EX-HOM approach is a direct way to identify the candidate genetic defect, bypassing obstacles such as genetic heterogeneity and the need for large pedigrees.

P08.31

Determining R202Q allele frequency in FMF patients

***S. Yigit**[1], T. Tasliyurt[2], S. Uzun Kaya[2], N. Bozkurt[1], B. Kisacik[2], O. Ates[1];*
[1]Department of Medical Biology, Gaziosmanpasa University, Tokat, Turkey, [2]Department of Internal Medicine, Gaziosmanpasa University, Tokat, Turkey.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of serositis, abdominal pain, arthritis and pleuritis. FMF frequenty affects populations around the eastern Mediterranean origin, especially Sephardic Jews, Armenians, Turks, Arabs and Greeks. Disease is caused by mutations in MEFV gene, which encodes a protein named Pyrin/Marenostrin. In the Infever Database, more than 180 gene alterations polymorphisms/mutations located in the MEFV gene.

In the present study, we used 100 FMF patients and 104 healthy controls. We detected R202Q mutation (605 G>A) at exon 2 of the MEFV gene in Turkish FMF patients and healthy controls.
We tested the existence of the mutation by PvuII restriction enzyme digestion after PCR amplification of the exon-2. In patients group, we detected homozygous R202Q mutation (AA allele) in 9 people, and heterozygous R202Q mutations in 49 subjects. However, in control group, we detected homozygous R202Q mutations in 3 subjects and R202Q heterozygous mutations in 27 subjects.
The present study demonstrats that R202Q allele could be a risk factor for FMF. Currently, we are testing a higher number of subjects in both patient and control groups.

P08.32
The effect of missing data on type I error rate of family-based association tests in the presence of linkage and no association

T. S. Hiekkalinna[1,2], *M. Perola*[1,2], *J. D. Terwilliger*[2,3];
[1]National Institute for Health and Welfare, Finland, Helsinki, Finland, [2]Institute for Molecular Medicine Finland FIMM, Helsinki, Finland, [3]Department of Genetics and Development, Columbia University, New York, NY, United States.

One common element in family-based association studies is incomplete data, meaning missing phenotype and/or genotype information, especially on late onset diseases. There are several family-based association analysis methods which claim that missing data is not an issue and proper type I error rates are holding.
In this study, we examined the type I error rates of several commonly used family-based association tests in genetic epidemiology as to their performance under increasing proportion of missing data on parents and/or founders using mixtures of singletons and families. We assumed complete linkage, but no association between disease and marker loci under a variety of inheritance models.
The results of our study showed enormous type I error rate with some popular methods when proportion of missing data was increasing. This can lead to false conclusions of positive association and therefore wasting of resources in follow up studies. Results from a simulation-based study will be presented.

P08.33
Lack of association between single nucleotide Polymorphism and BCL11A HBS1L-MYB situations with increased levels of fetal hemoglobin

F. Hashemi gorji, M. Hamid, A. Arab, A. Amirian, S. Zeinali, ***M. Karimipoor****;
Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*

Variable levels of fetal hemoglobin may persist into adulthood, although they have no clinical consequences in otherwise healthy people. High HbF levels have a major impact on the hemoglobin disorder such as Beta- Thalassemia Major. Increased HbF production ameliorates the severity of both diseases. The level of HbF in adults is inherited as a quantitative trait, and is largely genetically controlled with a heritability of 89%. HBS1L-MYB intergenic regions on chromosome 6q23, BCL11A on chromosome 2p16 and γ-globin genes on chromosome 11, account for up to 50% of the variation in HbF levels in patients with sickle cell anemia or Beta- Thalassemia Major thalassemia and in healthy adults. Common single nucleotide polymorphisms (SNPs) at the BCL11A and HBS1L-MYB loci have been implicated previously in HbF level variation. In this study, three common SNPs were genotyped for rs4895441, rs11886868 and rs28384513 using PCR-RFLP method among 50 major β-thalassemia patients with high levels of HbF. Digestion carried out by RsaI, MboII and BstxI respectively. Mutant allelic frequencies were in healthy patient. P-value was higher than 0.05 at three SNPs. There was no association between the studied polymorphisms and the variation in HbF levels in patients. Other variations may have a role in enhancing the fetal hemoglobin in our population. Different populations have different variants modifying the severity of a sickle cell anemia and Beta- Thalassemia Major in the word.

P08.34
Study of polymorphic variant of gene alleles of apolipoprotein C-3 (APOC-3) in individuals with different levels of high density lipoprotein

R. Kajumova*, L. Kayumova, E. Vorobjeva, V. Gorbunova;
Bashkir State Pedagogical University name of M.Akmulla, Ufa, Russian Federation.*

Genetic factors, along with environmental play an important role in the determination of the lipid metabolism in humans. APOC-3 gene (11q23.1-q23.2) encodes a protein apolipoprotein C-3, which is one of the main regulators of lipid metabolism in the human body and, in particular, regulates intravascular triglyceride splitting. We studied polymorphic gene variant C3238G APOC-3 and analyzed associations of the polymorphic variant with a level of high density lipoprotein (HDL) of human serum.
Material for the study included DNA samples from 339 individuals. Determining the level of HDL cholesterol by standard enzymatic methods. Analysis of polymorphic variant APOC-3 (C3238G) was performed by PCR-RFLP.
Results: The group of persons with low levels of HDL cholesterol in the blood serum revealed increase of genotype APOC-3 *G/*G (83,33% vs. 74% in the group of individuals with indicators of HDL in normal, P = 0.0005). When comparing those with high levels of HDL (79.1%) and those with rates of HDL do not normally found statistically significant differences.
Conclusions: The found that the polymorphic variant C3238G gene APOC-3 is associated with the level of high density lipoprotein (HDL), and genotype APOC-3 *G/*G is a marker of low levels of HDL.

P08.35
Detecting gene effect by simultaneously testing many minuscular gene-gene or gene-environment interactions

M. T. LO[1,2], *W. C. LEE*[1,2];
[1]Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan, [2]Research Center for Genes, Environment and Human Health, National Taiwan University, Taipei, Taiwan.

We proposed a new approach for detecting the gene effect by simultaneously testing many small gene-gene (GG) or gene-environment interactions. The presence of GG interactions indicated that the gene is susceptible to the outcome, in spite of the state of the marginal effect. The interaction effects between two genes were determined by an interaction term in a logistic regression model. Test statistic is summation of Wald chi-square values of GG interaction tests in the regression models. If each Wald test for interaction is independent, under null hypothesis, the test statistic followed a chi-square distribution with m (number of GG interaction tests) degrees of freedom. If Wald tests are not independent, significance for test statistic is evaluated by permutation. For this approach, power evaluation in four scenarios according to asymptotic power functions determined by sample size and number of genes interacting with the gene of interest. Requirement for binary variables and being unfavorable for rare gene are major limitations of this approach.

P08.36
A genome-wide genetic map based on the ERF study data

N. M. Belonogova[1], *T. I. Axenovich*[1], *C. M. van Duijn*[2];
[1]Institute of Cytology & Genetics SD RAS, Novosibirsk, Russian Federation, [2]Erasmus MC, Rotterdam, Netherlands.

In multipoint linkage studies, the Lod-score values can depend much on the genetic map in use. It is desirable for a genetic map to reflect the true frequencies of recombination events in studied population, at both overall scale and local level.
In this study, a genome-wide genetic map was built using CRIMAP software on a sample of 2834 members of a large pedigree from a young isolate in the Netherlands genotyped for 5549 SNP markers of Illumina 6k linkage panel as a part of the ERF study. The large pedigree was split into 391 smaller subpedigrees with no overlapping in meioses. The total sample included 1928 meioses with mean of 716.2 and 1287.8 informative meioses per SNP marker on autosomes and X chromosome, respectively.
The total genetic length of sex-averaged, male and female ERF genetic map were 3288.5, 2325.1 and 4094.6 cM, respectively, which

is ~12.8% shorter than the sum of corresponding intervals of Rutgers map v.2, the finest genetic map available to date for Caucasians. At the local level, 73 between-marker intervals showed the strongest differences in genetic length between two maps (the Rutgers estimate fell out of 99.99% CI of the respective ERF map interval). Unexpectedly, 46 (63%) of these intervals were longer for ERF map despite its shorter total genetic length. As all these differences can reflect the true features of local and global recombination rates in ERF population, the information obtained can be used to refine genetic maps for linkage analysis of ERF data.

P08.37
Dealing with stratification and cryptic relatedness in GWAS: a case study in a canine population.

M. Kierczak[1], *K. Tengvall*[2], *K. Lindblad-Toh*[2,3], *Ö. Carlborg*[1];
[1]*Comp. Genetics Group, Department of Animal Breeding and Genetics, Swedish University of Agricultural Sciences, Uppsala, Sweden,* [2]*Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden,* [3]*Broad Institute of MIT and Harvard, Cambridge, MA, United States.*

Canine models are constantly gaining importance in biomedical studies and have been successfully used to increase our understanding of diseases in human. However, canine populations often show significant degree of stratification and cryptic relatedness. Several methods have been proposed to account for genetic structure: genomic control, structured association, PCA-based and mixed models.

The majority of the methods have been designed to be used primarily for the analysis of human populations and to account for only some aspects of genetic structure. Therefore, genome-wide association studies in canine populations often call for more specific solutions. Here, we present a workflow that we successfully applied to analyze a structured canine population with cryptic relatedness present.

We analyzed 184 German shepherds (91 cases and 93 controls) using Illumina 170K canine SNP array. First, we used autosomal IBS matrix, MDS and K-means clustering to determine population structure. We confirmed that apart from population stratification, there is some degree of cryptic relatedness between the individuals. Next, we tested 4 different methods of dealing with genetic structure: 1) structured association (SA), 2) PCA-based approach (PCA) 3), mixed model (MM) and 4) a combination between mixed model and structured association (MM-SA). We obtained the following values of the λ inflation factor (λ>1 indicates that the association test statistics is inflated due to genetic structure): λ_{NO_GC}=1.93, λ_{SA}=1.15, λ_{PCA}=1.07, λ_{MM}=1.00 and $\lambda_{MM\text{-}SA}$=1.02.

We found the MM and MM-SA approaches to be most suitable to account for both the population stratification and cryptic relatedness.

P08.38
Comparison of two strategies for genotype calling

M. Valentini[1], *I. Zara*[1], *M. Muggiri*[1], *M. Moro*[1], *C. Podda*[1], *L. Leoni*[1], *C. Jones*[1], *S. Sanna*[2];
[1]*CRS4 (Center for Advanced Studies, Research and Development in Sardinia), Pula, Italy,* [2]*Istituto di Ricerca Genetica e Biomedica (ex INN), Consiglio Nazionale delle Ricerche (CNR), Monserrato, Italy.*

Sample size needed to perform Genome-wide Association scans is drastically increasing. Recent studies have shown that batch effects are not negligible when clustering algorithms are used to perform genotype calling (GC); thus calling becomes a challenging step in large data sets. To reduce the run time while minimizing batch effects we evaluated two different strategies to call genotypes on a distributed computing environment, using a cohort of > 6,000 individuals genotyped with the Affymetrix 6.0 array, and the Birdseed-v2 calling algorithm included on the Affymetrix Power Tools (APT) package. First, we divided the probesets in batches of 50,000 probes with 5,000 overlapping and ran jobs in parallel. Since the same normalization matrix was used by all jobs, the results are expected to be equivalent to those obtained in a unique run. GC was completed on 15 days, using 18 CPU with 16Gb RAM, but required large amount of disk space. To further reduce the run time, we ran the APT on 7 clusters of 1,000 individuals with 100 overlapping, balancing the ratio of cases and controls to mimic the proportion observed in the entire dataset, and maximizing plates representation within each group. GC was completed in 2 days, using only 6 CPU and significantly less disk space. Discordance rate was 0.1% between genotypes of overlapping individuals among clusters, and on average, 0.45% of genotypes differed from those called with the first strategy. Thus the second approach can be a valid alternative for conducting GC in large data sets.

P08.39
Rules for resolving Mendelian inconsistencies in nuclear pedigrees typed for two-allele markers

S. Khan;
Department of Statistics, Islamia College University Peshawar, Peshawar, Pakistan.

Gene-mapping studies regularly rely on examination for Mendelian transmission of marker alleles in a pedigree, as a way of screening for genotyping errors and mutations. For analysis of family data sets, it is usually necessary to resolve or remove the genotyping errors prior to analysis. At the Center of Inherited Disease Research (CIDR), to deal with their large-scale data flow, they formalized their data cleaning approach in a set of rules based on PedCheck output. We examine via carefully designed simulations that how well CIDR's data cleaning rules work in practice. We found that genotype errors in siblings are detected more often than in parents for less polymorphic SNPs and vice versa for more polymorphic SNPs. Through computer simulation, we conclude that some of the CIDR's rules work poorly in some situations and we suggest a set of modified data cleaning rules that may work better than CIDR's rules.

P08.40
New glaucoma related locus on chromosome 20p13

I. Zorkoltseva[1], *N. Belonogova*[1], *L. van Koowijk*[2], *A. Kirichenko*[1], *T. Axenovich*[1], *C. van Duijn*[2];
[1]*Institute of Cytology and Genetics, Novosibirsk, Russian Federation,* [2]*Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands.*

Morphologic characteristics of the optic disc are associated with primary open angle glaucoma and can be considered as its endophenotypes. To identify new genes related to glaucoma we analyzed the endophenotypes in large pedigree from Dutch isolated population. We performed genome-wide linkage and association analyses of combined quantitative traits obtained by principal component analysis of seven parameters of the optic disc (disc area, rim area, superotemporal and inferotemporal rim areas, rim-to-disc area ratio, cup-to-disc ratio and cup shape measure) measured in 1,979 participants. Two independent principal components and two factors were generated. The first principal component, PC1, explained about 52% of the total variance and had the high loadings of four rim related traits and cup-to-disc ratio. In the factor score FAC1 obtained by rotation of PC1, the number of initial parameters with high loading was minimized to three rim related traits. We found the strongest linkage signal (LOD = 4.46) for FAC1 on chromosome region 20p13. This signal has been confirmed by suggestive linkage peak for PC1 (LOD = 2.28) and association of rs58532 in the linked region with PC1 (the lowest *p*-value = 8.2×10^{-6}, FDR *q*-value = 0.027). The associated region points to a cluster of genes encoding several members of signal-regulatory-protein (SIRP) family, the regulatory membrane proteins. The closest gene, *SIRPA*, is likely to be involved in IGF-1-mediated AKT-activation, which has an anti-apoptotic effect. The new locus suggests a link between growth regulation and rim related parameters that are endophenotypes for glaucoma.

P08.41
Haplogrep as a tool for mitochondrial DNA analysis

M. Álvarez-Cubero[1], ***B. Sánchez Martín-Moreno***[1], *L. Martínez-González*[2], *M. Saiz*[1], *J. Álvarez*[1,2], *J. Lorente*[1,2];
[1]*Legal Medicine and Toxicology Department, Faculty of Medicine, University of Granada, Granada, Spain,* [2]*GENYO (Pfizer - University of Granada & Andalusian Government Centre for Genomics & Oncology), Granada, Spain.*

In the last decades, the analysis of variations in mitochondrial DNA in human populations has provided a lot of information about things like molecular anthropology, genealogy and some genetic diseases. Thanks to web programs like HaploGrep, based on the data of Phylothree.org and updated at the same time that Phylothree.org database, we could manage a big amount of information about sequences of DNAmt. These kind of programs makes it easier and quicker the processing of all the data and obtaining a classification of a hundred of samples into different

haplogroups. HaploGrep also informs us about the probability of each sample in the assigned haplogroup, the probability of the followed haplogroups with a high value and the most representatives' mutations of each single haplogroup. The obtained results are represented in a graphic way like tables and phylogenetic threes. In this study we could observe different applications of this web program. One is to see the genetic influence in the population flow of an ancient population (North African) in the actual South Spanish population. Another is the analysis of the crossbreeding in South American populations as a result of Spanish and Mayan admixture. The last one consists in the use of this program analyzing the similarities and differences between patients and controls in diseases like cancer. Whereas in crossbreeding and population studies the utility of this program has been proved, we are testing how useful it could be in the analysis of cancer although some clinical significative differences have been marked.

Hearing is a complex trait but, until now, few genes are known to contribute to its variability and little is known about genetic factors involved in age-related hearing loss (ARHL). To discover genes and pathways underlying auditory function and ARHL we planned an integrated strategy characterized by three approaches. A) a GWAS meta-analyzing quantitative traits data from 6 isolated populations . Results led to the identification of eight suggestive significant loci ($p<10^{-7}$) with a series of genes expressed within the inner ear. Additional biological candidates ($p<10^{-6}$) were identified. Some of these new loci map to already known hereditary hearing loss loci whose genes still need to be identified. Data have also been used to construct a highly significant "in silico" pathway for hearing function characterized by a network of 49 genes, 34 of which are certainly expressed in the ear. B) a similar GWAS on qualitative traits from the same populations leading to the identification of some loci on the following chromosomes 2,13,19,17,16,20 involving in some cases genes related with hearing development and hearing function but also genes whose function is still unknown. A replica phase is now in progress on a series of case/controls coming from different European countries. C) whole exome sequencing of cases selected from large pedigrees showing segregation of ARHL and coming from the same isolated populations. Preliminary results provide new insights into the molecular basis of hearing function and ARHL and may suggest new targets for hearing impairment treatment and prevention.

P08.43

Genetic Analysis of Autosomal Dominant and Recessive Hereditary Spastic Paraplegia

B. Özeş[1], *Ç. Atay*[1], *H. N. Ceylan*[2], *Y. Parman*[2], *E. Battaloğlu*[1];
[1]*Bogazici University, Istanbul, Turkey,* [2]*Istanbul University, Istanbul, Turkey.*

Hereditary spastic paraplegias (HSPs) describe a heterogeneous group of neurodegenerative disorders with progressive spasticity in the lower limbs. HSPs can be inherited in autosomal dominant, recessive, or X-linked forms. To date, 41 spastic paraplegia loci and 17 genes have been identified with diverse functions such as axonal transport, regulation of the cytoskeleton, and mitochondrial function.
In the first part of the study, the most commonly mutated autosomal dominant genes, SPG4 (Spastin), SPG3A (Atlastin), SPG31 (REEP1), ve SPG7 (NIPA1) were screened in 42 families. Using the SSCP method and subsequent DNA sequencing one patient and his father were found to have an insertion mutation (c.310_311insA) leading to a truncated Spastin protein. Another patient revealed a heterozygous c.1741C>T change (p.Arg581X) leading to a premature stop codon in the same gene. Still one other patient was heterozygous for a missense mutation, c.941A>G (p.H258R) in *Atlastin.* All identified mutations were previously reported.
In the second part of the study, linkage to autosomal recessive loci for which the genes have been identified (SPG5, SPG7, SPG11, SPG15, SPG20 and SPG21 loci) was investigated in 15 families. Parents were consanguineous in 11 families with at least two affected siblings. Linkage was found to SPG11 in four families, to SPG15 in two families, and to SPG21 in one family. Sequencing of the relevant genes is currently being performed to identify the causative mutation in these families. In two of the families, linkage to all tested loci was excluded that should be further investigated for other known AR-HSP loci.

P08.44

The HIF1A Pro582Ser polymorphism in Russian weightlifters

R. Gabbasov[1], *A. Danilova*[1], *A. Hakimullina*[2], *I. Ahmetov*[1];
[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.*

Power performance is determined by high anaerobic potential (high reserves of ATP, creatine phosphate, and glycogen; high concentration and activities of glycolysis and phosphagenic system enzymes; predominance of fast-twitch muscle fibers in skeletal muscles, etc.). *HIF-1* gene, expressed in all mammalian tissues, attends in organism's response to hypoxia via controlling glucose metabolism and genes involved in different cellular functions. HIF1A, the regulatory subunit of *HIF-1* gene's dimeric product, contains a missense polymorphism Pro582Ser (C/T at bp 85; rs11549465). The rare T allele (proline to serine change) by increasing HIF-1A protein's activity and stability may improve glucose metabolism. The study aimed to determine the influence of the *HIF1A* Pro582Ser polymorphism on power performance. One hundred and eight professional weightlifters of regional and national standard were recruited for the study. Controls were 434 healthy unrelated volunteers, citizens of Kazan, without any competitive sport experience. Genotyping was performed on DNA samples obtained from buccal epithelium cells by DNA extraction kit. Genotyping for the *HIF1A* Pro582Ser variants (rs11549465) was performed by PCR and restriction enzyme digestion. The number of carriers of the rare Ser allele (Pro/Ser or Ser/Ser) was significantly higher in weightlifters than in controls (28.7% vs. 13.4; P=0.0001). Thus, *HIF1A* gene Pro582Ser polymorphism is associated with elite power athlete status, which suggests an important role for HIF-1a in skeletal muscle adaptation to power training.

Identification Of The Gene Responsible For The 4H Syndrome.

E. CHOUERY[1], *V. Delague*[2], *N. Jalkh*[1], *D. Rodriguez*[3], *B. Chabrol*[4], *O. Boespflug-Tanguy*[5], *A. Mégarbané*[1];
[1]*Saint-Joseph University, Beirut, Lebanon,* [2]*INSERM UMR_S 910, « Génétique Médicale et Génomique Fonctionnelle » Faculté de Médecine de la Timone,, Marseille, France,* [3]*Service de neuro-pédiatrie, Hôpital Trousseau, Paris, France,* [4]*Service de neurologie pédiatrique, CHU La-Timone, Marseille, France,* [5]*5 Service de Neurologie Pédiatrique et des Maladies Métaboliques, Hôpital Robert Debré, Paris, France.*

Dentoleukoencephalopathies with autosomal recessive inheritance are very rare. In 2003, we reported, for the first time, a large inbred Syrian pedigree with oligodontia associated with a degenerative neurologic condition characterized by progressive ataxia, pyramidal syndrome, central white matter abnormalities and cortical atrophy (AJMG, 2003,118A(1):76-81).
A SNP genomewide linkage analysis, in this family, led to the identification of a candidate linkage region at chromosome 10q22, with a maximum multipoint lod score value of 5.66 (NPL score = 7.65). The candidate genomic interval contained 95 known genes including the Prosaposin gene (*PSAP)* responsible for metachromatic leukodystrophy, which was excluded. Sixteen additional candidate genes were screened by fluorescent sequencing and excluded.
Sequencing of the seventeenth candidate gene revealed an intronic variation which segregates perfectly in the family and affects the

splicing of the corresponding transcript.
Screening of this gene was performed in 5 supplementary families affected with the 4H syndrome (Leukodystrophy Hypomyelinating with Hypodontia and Hypogonadotropic Hypogonadism), a condition similar to the one we described in the Syrian family, but with additional hypogonadotropic hypogonadism. Several different missense and nonsense point mutations were detected in the gene, therefore demonstrating the implication of this gene in both the 4H syndrome and the syndrome described by us in the Syrian family.
Functional analyses are underway in order to understand the physiopathology of these syndromes. Results will be published soon.

P08.46
Fast Linkage calculation of Affymetrix SNP 6.0 genotype data using a new program SNP6-LINK

H. Eiberg, *L. Hansen;*
ICMM; University of Copenhagen, Copenhagen, Denmark.

Ott 1976 (Am J Hum Genet 28, 528-529) introduced the program LIPED for linkage analysis of large family pedigrees with or without loops and the program is ideal for two-point linkage analyses. We have previously constructed a helper program, LIPED.COM, that automatically make an input file to LIPED, allowing LOD score calculations for more than 800 markers and the results to be present in a usable form. This program has been tested by mapping more than 800 markers using families from the Copenhagen Family Bank (Eiberg et al. Clin Genet 1989; 36:415-418).
The development of SNP microarray chip technology (Affymetrix chip) for testing >10^6 SNP alleles has made new demands for the linkage analysis. We have therefore modified our linkage helper programs to analyze genotype output files for > 10^6 loci. The materials can be analyzed fast and the results shown graphically. This program, SNP6-LINK, demands a simple FORTRAN programming for each new project and several families can be analyzed in one process and the program can use Illumina genotype output files. Several parameters can be adjusted before calculations as heterozygote mating for recessive traits, which reduce the output graphical presentation to fewer but informative positive or negative LOD scores. Also bed files for uploading of LOD scores to UCSC Genome Browser can be produced. The LOD score calculations for more than a million SNP's in nuclear families takes less than half an hour, and can be run using low RAM PC with Windows Excell and a FORTRAN 99 compiler.

P08.47
A candidate gene study for Major Depressive Disorder in STAR*D and GAIN cohorts identifies potential statistical interaction between several candidate genes.

M. Lekman[1], *H. Källberg*[2], *D. Charney*[3], *H. Manji*[4], *J. Rush*[5], *F. McMahon*[6], *S. Paddock*[7], *I. Kockum*[1];
[1]*Dept. of Clinical Neuroscience, Stockholm, Sweden,* [2]*Institute of Environmental Medicine, Stockholm, Sweden,* [3]*Dept. of Psychiatry, Mount Sinai School of Medicine, New York, NY, United States,* [4]*Dept. of Health & Human Services (DHHS), Bethesda, Bethesda, MD, United States,* [5]*) Dept. of Psychiatry, University of Texas South-western Medical Center, Dallas, TX, United States,* [6]*Genetic Basis of Mood & Anxiety disorders, NIMH, NIH, Dept. of Health & Human Services (DHHS), Bethesda, MD, United States,* [7]*Dept. of Neuroscience, Stockholm, Sweden.*

Major depressive disorder (MDD) is a severe lifelong psychiatric illness with a heterogeneous background likely caused by interaction of a multiple set of genetic and environmental influences. Despite decades of genetic studies no genetic risk factor has been successfully validated for MDD.
Most genetic studies have so far relied on single SNP association analyses. However, it is likely that in the susceptibility of multifactorial diseases risk factors interact to increase disease susceptibility. In the present study we have analyzed interactions of SNPs in the GAIN MDD-study located in candidate genes selected from the STAR*D-cohort.
Forty-seven markers that were found to be nominally associated in the GAIN MDD-study were included in the study. Each marker was then tested for interaction with 2866 genotyped or imputed markers in the same set of genes. The interaction model assumed a dominant effect from one marker. Interaction was then defined as deviation from additivity and measured using the attributable proportion. Odds ratios (OR's) were used as risk estimates. Departure from additivity indicated that two factors were jointly involved in disease susceptibility. We identified a total of 16 interactions. The strongest p-values were in the order of 10(-14) and represented interactions between markers in GRIK4-NR3C2, ARHGAP10-GRIA2 and HTR2C-FKBP5 genes.
A subsequent pFDR-test confirmed that the interaction effects were robustly reported. However, using OR's may have inflated the risk estimates. Therefore, these results are currently validated using a permutation-analysis.

A detailed view on Model-Based Multifactor Dimensionality Reduction with quantitative traits for detecting gene-gene interactions: different ways of adjusting for lower-order effects

J. M. Mahachie John[1,2], *T. Cattaert*[1,2], *F. Van Lishout*[1,2], *K. Van Steen*[1,2];
[1]*Systems and Modeling Unit, Montefiore Institute, University of Liege, Liege, Belgium,* [2]*Bioinformatics and Modeling, GIGA-R, University of Liege, Liege, Belgium.*

Understanding the effects of genes on the development of complex diseases and traits in humans is a major aim of genetic epidemiology. In particular, if there exist significant main effects unaccounted for during epistasis screening, false positives arise and therefore epistasis results reported might not be genuine. In this study, we use simulation to assess the effect of implementing different corrective measures for lower-order effects in an MB-MDR context of two-locus detection, on both power and family-wise error rate.
The implemented MB-MDR strategy reduces the multi-locus genotype dimension to one with three possible outcomes, while pooling multi-locus genotypes into three groups of risk (High, Low and No Evidence) based on the liberal p-value threshold 0.1. Adjusting for main effects is performed in two categories: main effects screening prior to and during MB-MDR run.
Data are simulated according to two quantitative trait models (M27 and M170) of Evans et al. 2006 that incorporate varying degrees of epistasis, and include a range of allele frequencies p: 0.1, 0.25, 0.5, at the predetermined functional SNPs. We consider 500 simulation replicates, involving 2000 unrelated individuals. MB-MDR screening is performed on 100 SNPs which are assumed to be in Hardy-Weinberg Equilibrium. No linkage disequilibrium exists between the SNPs.
In conclusion, preliminary results showed that indeed uncorrected for main effects results have false positives amounting to as high as 100%. Also, additive modeling, the mainly used first strategy in the context of main effects GWAS may not be sufficient for epistasis screening.

P08.49
Imputation-free Meta-Analysis with YAMAS (Yet Another Meta-Analysis Software)

C. Meesters[1,2], *M. Leber*[2], *C. Herold*[1], *M. Mattheisen*[2,3], *D. Drichel*[1], ***T. Becker***[1];
[1]*German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany,* [2]*Institute for Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany,* [3]*Institute of Human Genetics, Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany.*

The success of GWAS is motivation enough to exchange and combine available data resources to expediently discover genetic risk factors for human traits. The primary tool is meta-analysis (MA) of imputed data.
A main purpose of imputation prior to MA is to avoid loss of SNPs. With YAMAS we present a software that avoids such loss without the need to impute. By using reference data from the HAPMAP and 1000 genomes projects users are enabled to analyze all SNPs that are present in at least one study. For each SNP that is missing in one study, the marker from the study with largest r^2, according to the reference data, with the missing marker is chosen as a "proxy SNP". Furthermore, based on reference haplotype frequencies, "proxy alleles" of a SNP and its proxy-SNP are identified. For each SNP, MA of that SNP is done by combining the association results of the SNP or, if not available the proxy-SNP, across studies.
We present results from a power simulation study and compare the performance of MA with imputation and imputation-free MA. Imputation-free MA in general is not quite as powerful as MA with imputation, since the marker panel is still smaller. However, in most scenarios, the power loss is only very moderate.
In summary, MA with the YAMAS proxy-algorithm is a quick and easy

alternative, yielding ad hoc results and thereby giving an incentive to follow-up analysis. Keeping in mind that collaborative MA efforts are frequently long-lasting, the time advantage becomes apparent.

MicroRNAs 340* AND 624* are upregulated in platelets in patients with coronary artery disease

B. M. Sondermeijer[1], *A. Bakker*[1], *A. Halliani*[1], *S. Maiwald*[1], *S. Sivalapalaratnam*[1], *T. A. Mulders*[1,2], *M. W. J. de Ronde*[1], *A. J. Tijsen*[1], *A. A. Marquart*[1], *P. A. Moerland*[1], *M. D. Trip*[1], *J. C. M. Meijers*[1], *E. E. Creemers*[1], *S. Pinto*[1];

[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*University of Maastricht, Maastricht, Netherlands.*

Rationale Coronary artery disease (CAD) is a cause of mortality, underscoring the need for innovative diagnostic strategies. Platelets play a role not only in acute thrombotic disease, but also in the process of atherosclerotic plaque formation. This is exemplified by the beneficial use of anti-platelet therapy. MiRNAs are emerging as attractive biomarkers since they exhibit tissue- and cell-specific expression. We aim to identify novel biomarkers for diagnostic strategies. We hypothesized that platelet derived miRNA expression patterns differ between patients with CAD and controls.

Methods & Results We isolated RNA from platelets of 12 male patients with premature CAD and 12 age- and sex-matched healthy controls and performed miRNA array expression profiling (Illumina beadchips). We validated our findings in two independent cohorts by qPCR. Microarray profiling identified 214 of the 893 mature human miRNAs to be differentially expressed ($p< 0.05$). When corrected for background noise and corrected for multiple testing, miR340*, miR451, miR454*, miR545:9.1, miR615-5p, and miR624* and miR1280* were identified with an expression level that was at least 1.5-fold different in patients as compared to controls. The array and validation demonstrated that miR340* and miR624* had significantly higher expression levels in patients as compared to controls ($P< 0.05$).

Conclusion Two platelet derived microRNAs are significantly upregulated in patients with CAD as compared to healthy controls

Clinical Relevance Platelet MiR340* and miR624* are upregulated in CAD, therefore they may be a potential biomarker in CAD.

Investigation of five loci (DFNB6, DFNB25, DFNB39, DFNB42, DFNB91) in 100 Iranian families with Autosomal recessive non-syndromic hearing loss by linkage analysis

E. Sohrabi[1], *N. Bazazzadegan*[1], *S. Arzhangi*[1], *H. Azimi*[2], *M. Kasiri*[3], *R. Smith*[4], *K. Kahrizi*[1], *H. Najmabadi*[1];

Hearing loss in humans is the most genetically heterogeneous trait known. This impairment affects more than 270 million people worldwide. Genetic causes of hearing loss are estimated to account for 68% of cases in newborns and 55% of cases by the age of four. Autosomal recessive non-syndromic hearing loss (ARNSHL) is the most common type of inherited hearing impairment. Due to the wealthy gene pool, Iran is a valuable source to identify the genes involved in different conditions.

To date, several genes have been studied in deaf Iranian population. Here we are studying 5 genes (*TMIE*, *GRXCR1*, *HGF*, *ILDR1*, and *SERPINB6*) for mutations that result in ARNSHL. Mutations in these genes have been identified in Iranian, Indian, Pakistani and Turkish families.

The objective of this study was to determine the prevalence of mutations in these genes in the Iranian population. A total of 100 families with ARNSHL are being investigated by screening for homozygosity to these five loci (DFNB6, DFNB25, DFNB39, DFNB42, and DFNB91). After homozygosity mapping is completed, sequencing analysis will be done to detect the gene mutation. To date, analysis of 100 families for DFNB6 locus has been completed and an Azeri family has been linked to *TMIE* gene. Further analysis and mutation detection is underway.

Key words: Non-syndromic hearing loss, DFNB, Iran.

P08.52
Fast approximate test for genome-wide association studies based on population data

G. R. Svishcheva, *T. I. Axenovich, Y. S. Aulchenko;*

Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Genome-wide association (GWA) analysis is a powerful tool for identifying loci affecting complex traits. While standard association tests assume independence across samples, several approaches account for non-independence expected in presence of genetic substructure. The mixed models are among the most powerful methods allowing to account for relationship structure of the sample. However, application of mixed models to GWA scans is computationally demanding, and as a rule the computational time shows quadratic dependency on the number of subjects, requiring application of high performance computing when thousands of subjects and/or multiple traits are studied. Previously, two approximate methods, FASTA/mmScore (Chen and Abecasis, 2007; Aulchenko et al., 2010) and GRAMMAR (Aulchenko et al., 2007), have been proposed. mmScore gives unbiased estimates of model parameters, but computational time is quadratic on number of subjects, while GRAMMAR shows linear dependency, though results in biased effect estimates and conservative test statistics.

Here we propose new approximate method, which leads to unbiased effect estimates, has proper distribution of the test statistics, and is as fast as GRAMMAR. Our method is based on transformation of a vector of dependent phenotype residuals into a vector of independent ones by application of the matrix approximation allowing reduction of an effect of a covariance matrix to an effect of scalar factor. We derived an analytical formula for this scalar factor, making possible to apply simple linear regression method to estimate the effects and test statistics. This scalar factor is an analytical correction to GRAMMAR approach, which eliminates its conservatism and bias.

Osteoarthritis (OA), also referred to as degenerative disease of the synovial joints, is caused by cartilage degradation going together with osteophyte formation and subchondral sclerosis causing pain and disability. To date, no cure is available and treatment is limited to pain relief.

OA is considered a complex disease in which both genetic and environmental factors contribute to its development. The estimated heritability differs per joint site and is estimated between 40 to 65%. It has been proposed, however, that this genetic component is highly polygenic with multiple risk alleles conferring small effects. Nevertheless, few consistent OA susceptibility genes emerged to date. Deep phenotyping may help to stratify OA into genetically and environmentally homogeneous subsets, thereby enhancing power and allowing identification of variants with larger impact on specific disease aspects.

Here, we set out to identify OA susceptibility loci conferring risk to generalized OA in the GARP study by genome wide association (GWAS). In the GARP study we have collected sibling pairs with symptomatic OA at multiple joint locations. We have identified 20 putative OA susceptibility loci with p-values $\leq 1*10^{-5}$ that are now being replicated both *in silico* (3 OA cohorts) and by *de novo* genotyping (1 OA cohort). In addition to the identification of loci conferring risk to OA, data obtained in the GWAS will be used for the identification

of pathways or groups of genes involved in the development of OA. Together, our results can contribute to a better understanding of OA pathology as well as its treatment.

P08.54
The Gln/Arg of human Paraoxonase polymorphisms (PON1 Leu55Met and Gln192Arg; PON2 Ser311Cys) is not related to acute myocardial infarction in the Tunisian population.

***S. Mehri**, S. Mahjoub, M. Hammami;*
Laboratory of Biochemistry, UR "Human Nutrition and Metabolic Disorders" Faculty of Medicine, Monastir, Tunisia.

Introduction: Paraoxonases (PONs) are closely related antioxidant enzymes encoded by clustered genes on chromosome 7q. Two particular polymorphisms, namely PON1-192 and PON2-311, in the genes encoding the antioxidant enzymes paraoxonase-1 (PON1) and paraoxonase-2 (PON2) have been associated with an increased risk of acute myocardial infarction (AMI). However, previous findings have been contradictory. We evaluated three PON polymorphisms (PON1 Leu55Met and Gln192Arg; PON2 Ser311Cys) in Tunisian patients with AMI.
Methods: 168 AMI patients compared to 169 healthy volunteers.
Results: PONs allele and genotype frequencies did not differ between patients and controls.
The PON polymorphisms (PON1 Leu55Met and Gln192Arg; PON2 Ser311Cys) were not significantly associated with AMI (p=1.11, p=0.09, p=1.46 respectively). No significant differences in age, sex, BMI, waist circumference, total Cholesterol, HDL-C and LDL-C were detected among the three-genotype subgroups of PON1 Leu55Met, PON1 Gln192Arg and PON2 Ser311Cys in the AMI patients.
Conclusions: The PON1 Leu55Met, PON1 Gln192Arg and PON2 Ser311Cys polymorphisms are not related to acute myocardial infarction in Tunisian population

Genome-wide association study of the PolyCystic Ovary Syndrome: distribution of promising gene variants associated with testosterone in the LURIC cohort

***U. Lam**[1], E. Wehr[1], N. Schweighofer[1], O. Trummer[1], B. Genser[2], B. Boehm[3], B. Winkelmann[4], W. März[5,6], T. Pieber[1], B. Obermayer-Pietsch[1];*
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Metabolism, Graz, Austria, [2]BG Statistical Consulting, Graz, Austria, [3]University of Ulm, Department of Internal Medicine, Division of Endocrinology and Diabetes, Ulm, Germany, [4]Department of Cardiology, Heart Center Ludwigshafen, Ludwigshafen, Germany, [5]University of Heidelberg, Department of Public Health, Social and Preventive Medicine, Mannheim, Germany, [6]Synlab Center of Laboratory Diagnostics, Heidelberg, Germany.

PolyCystic ovary syndrome (PCOS) causes hormonal imbalances affecting fertility, and metabolic diseases like obesity, type 2 diabetes, cardiovascular problems and quality of life. A genetic background of the PCOS is supported by affected families. Aim of the study is the detection of new genetic pathways for potential diagnostic and therapeutic targets in PCOS.
PCOS phenotype definition was based on hormonal and metabolic variables in women in comparison to men. Our Genome-Wide Association Study (GWAS) focuses on genetic alterations of a special PCOS phenotype, regarding high testosterone levels in female and male LUdwigshafen RIsk and Cardiovascular (LURIC) patients.
In total, 908.398 single nucleotide polymorphisms (SNPs) were generated as GWAS raw data. Those SNPs have been analyzed following multiple steps and have been annotated with different criteria for autosomal and X chromosome-linked genes, separately, using WGAViewer Software. The significant associations between SNPs at 17 loci in LURIC female and 9 loci in the whole cohort with high levels of testosterone were identified.
With the replication results of these candidate SNPs in our 669 carefully phenotyped PCOS and 410 control subjects, we expect to identify genetic variants contributing to diagnosis and new therapeutic aspects for PCOS prevention and treatment.

P08.56
Impact of polygenic profile to the performance of endurance and strength/power athletes

***V. Ginevičienė**[1], A. Jakaitienė[1], L. Tubelis[2], V. Kučinskas[1];*
[1]Department of Human and Medical Genetics, Vilnius, Lithuania, [2]Lithuanian Olympic sports centre, Vilnius, Lithuania.

We investigated five genetic polymorphisms that are candidates explaining individual variations in human physical performance phenotypic traits (*ACE* I/D (rs1799752); *ACTN3* C/T (rs1815739); *PPARGC1A* G/A (rs8192678); *PPARA* G/C (rs4253778); *PPARG* C/G (rs1801282)) in professional Lithuanian athletes (n=193) and in the general population of Lithuania (nonathletic controls, n=250). According to Williams and Folland (*J Physiol* 586:113-121, 2008) we calculated (1) the 'total genotype score' (TGS, the combination of five polymorphisms with the maximum value of '100' for the theoretically optimal polygenic score) in the athlete groups and in the Lithuanian population; and (2) the probability for the occurrence of Lithuanian individuals with the 'perfect' polygenic physical performance phenotype (power-oriented, endurance-oriented) profile. The TGS was calculated for the "power" and "endurance" groups of the Lithuanian athletes. We found the mean TGS significantly higher for the elite power-oriented athletes (44.4±11.3) compared to controls (33.6±13.2) ($p<0.05$) indicating more favorable polygenic profile for power-oriented athletes. No significant differences were found comparing the athletes in the endurance group (65.7±13.9) and controls (66.4±13.2). The obtained probability of a Lithuanian individual possessing a theoretically optimal endurance-oriented polygenic profile for up to five candidate genetic polymorphisms, equals to 1% (or 1 among 99 Lithuanian individuals); the optimal power-oriented polygenic profile accordingly 0.0007% (or 1 among 132650 Lithuanian individuals). The optimal combination of genotypes may occur more frequently in a very large population. Although, if there was a larger number of polymorphisms included in the analysis, the probability of possessing the optimal polygenic profile would diminish.

P08.57
Association of COMT and MTHFR polymorphisms with cognition in schizophrenia

*D. Kontis[1], C. Sofocleous[2,3], E. Theoxari[1], S. Kleisas[1], E. Kanavakis[4], **H. Fryssira**[5];*
[1]1st Psychiatric Department, Psychiatric Hospital of Attica,, Athens, Greece, [2]Department of Medical Genetics, School of Medicine, Athens University. "Aghia Sophia" Children's Hospital,, Athens, Greece, [3]Research Institute for the Study of Genetic and Malignant Disorders in Childhood, "Aghia Sophia" Children's Hospital, Athens , Greece., Athens, Greece, [4]Department of Medical Genetics, School of Medicine, Athens University. "Aghia Sophia" Children's Hospital, Athens, Greece, [5]Department of Medical Genetics, School of Medicine, Athens University. "Aghia Sophia" Children's Hospial, Athens, Greece.

Objectives: The investigation of the effect of COMT (Val108/158Met) and MTHFR (C677T) polymorphisms on cognitive function in schizophrenia.
Material and Methods: 92 patients with chronic schizophrenia and 61 controls were assessed on cognitive functioning using the Wechsler Adult Intelligence Scale-(WAIS-III) and the Cambridge Neuropsychological Test Automated Battery (CANTAB). The CANTAB tests measured: speed of movement (MOT), pattern and spatial recognition memory (PRM, SRM respectively), spatial working memory (SWM), planning (SOC) and cognitive flexibility (IEDSS). RFLP analysis was performed to allow characterization of COMT and MTHFR polymorphisms.
Results: Participants were divided into four groups according to their genetic polymorphisms [VALC (Val-Val & CC), VALT (Val-Val & CT or TT), METC (Val-Met or Met-Met CC), METT (Val-Met or Met-Met & CT or TT)]. Positive correlations of COMT and MTHFR polymorphisms to cognition were recorded in both the group of patients with schizophrenia and the control group. Patients with VALT polymorphisms presented higher full scale and performance IQ than patients with VALC [$F(1, 42)=5.803$; $p=0.020$ and $F(1,42)=4.339$; $p=0.043$, respectively]. In all patients there was also a significant main effect of COMT in SOC, with those carrying VALC having a worse performance compared to the ones with METC [Kruskal-Wallis ($df=2$)$=6.828$, $p=0.033$]. Finally, in respect to PRM, SRM and SWM controls carrying VALT performed

better than those with VALC.
Conclusion: The above findings support the association of COMT and MTHFR genes with the cognitive performance in schizophrenia and are consistent with a possible epistatic nature of the polymorphisms studied.

P08.58
molecular analysis of Prader-Willi and Angelman syndromes: A study of twenty Tunisian patients

R. Meddeb[1], *M. Trabelsi*[1], *M. Chaabouni*[1], *Y. Laaribi*[1], *F. Maazoul*[1], *I. Ouertani*[1], *L. Ben Jemaa*[1], *N. Khouja*[2], *F. Fdhila*[3], *H. Bouhamed Chaabouni*[1], *R. Mrad*[1];
[1]*Department of Congenital and Hereditary Disease Hospital Charles Nicolle, Tunis, Tunisia,* [2]*Department of Pediatric Neurology Institution of Neurology, Tunis, Tunisia,* [3]*Hospital of Pediatrics, Tunis, Tunisia.*

Prader-Willi syndrome (PWS) and Angelman syndrome (AS) are neurobehavioral disorders that result from the loss of expression of imprinted genes in the paternal and maternal chromosome 15, respectively.
The aim of this work is to achieve a molecular study for 20 patients (7 AS; 13 PWS) in order to determine the exact molecular mechanism involved.
A positive methylation-specific PCR (MS-PCR) enabled the reliable diagnosis of 13 PWS and 7 AS patients. For all these cases, we applied FISH technique. Thereafter, we have developed a linkage analysis method by testing 8 polymorphic genetic markers within the PWS/AS critical region 15q11q13.
FISH study allows us to classify our 20 subjects in two groups: 6 of 13 PWS (46%) patients had microdeletion of paternal 15q11-q13 and 6 of 7 AS patients (85%) had microdeletions of maternal 15q11-q13. The genotype and linkage analyses of the 8 non deletional probands and their family disclosed that Angelman patient had inherited two paternal alleles of chromosome 15 and 5 of 7 non deletional PWS (38%) subjects had a maternal uniparental disomy of chromosome 15 (UPD 15). Among these PWS patients, 4 cases had a maternal heterodisomy and one had a maternal isodiomy. Moreover, and despite the abnormal methylation patterns of the 15q11-q13 region, the 2 remaining PWS cases presented none of the alterations shown by the above groups.
A combination of these methods is important for the identification of genetic alterations involved in our PWS or AS patients and the assessment of the risk of recurrence.

P08.59
Investigation of candidate loci for primary open angle glaucoma in a Brazilian family through SNP array.

B. A. C. Santos, ***M. B. Melo****, C. A. Braghini, R. Secolin, F. R. Torres, V. P. Costa, J. P. C. Vasconcellos;*
State University of Campinas, Campinas, Brazil.

Glaucoma is one of the major causes of irreversible blindness worldwide, characterized by progressive loss of optic nerve ganglion cells, associated with correspondent visual field damage. Among several forms of glaucoma, the most prevalent is the primary open angle glaucoma (POAG). The increase of intraocular pressure is the most important risk factor for the development of POAG. There are at least 14 loci (*GLC1A* - *GLC1N*) associated with POAG identified from genetic mapping studies, most of them involving families that follow a Mendelian inheritance pattern but only three genes were identified. The first described gene was myocilin (*MYOC* - *GLC1A*), followed by optineurin (*OPTN* or Optic Neuropathy Induced Protein - *GLC1E*) and WD Repeat-Containing Protein 36 (*WDR36* - *GLC1G)* genes. The purpose of this study was to evaluate regions in the genome associated with glaucoma through linkage study in one POAG informative family, through single nucleotide polymorphism (SNP) microarray. Comprehensive ophthalmic evaluation was performed and genomic DNA obtained from one Brazilian family (19 individuals) with POAG. Genome-wide linkage analysis was conducted using the Affymetrix 10K SNP array and analyzed by JINGLEFIX and MERLIN softwares. The SNP array generated 8.962 valid SNPs. Three chromosomal regions (1p, 5q and 14q) with lod scores equal to 1.9, 2.1 and 1.8, respectively were observed. Although the results do not show values of lod scores more than 3.00, these three regions are of great interest because they will be refined with microsatellites markers to identify potential susceptibility genes for POAG.
Supported by FAPESP.

BAFF and FCGRIIIA polymorphisms are predictive factors of response to rituximab in Rheumatoid Arthritis (RA)

A. RUYSSEN-WITRAND[1], *S. ROUANET*[2], *B. Combe*[3], *M. Dougados*[4], *G. VIVIER*[5], *X. LE LOET*[6], *J. SIBILIA*[7], *J. TEBIB*[8], *X. MARIETTE*[9], *A. CONSTANTIN*[1];
[1]*PURPAN Teaching Hospital, TOULOUSE, France,* [2]*Roche, PARIS, France,* [3]*Lapeyronie Hospital, MONTPELLIER, France,* [4]*COCHIN HOSPITAL, PARIS, France,* [5]*DOCS, PARIS, France,* [6]*ROUEN HOSPITAL, ROUEN, France,* [7]*HAUTEPIERRE HOSPITAL, STRASBOURG, France,* [8]*LYON-SUD HOSPITAL, LYON, France,* [9]*KREMLIN BICETRE HOSPITAL, KREMLIN BICETRE, France.*

The presence of RF or ACPA was previously reported as predictive factors of response to rituximab (RTX) in RA. SMART is a randomized open trial assessing 2 strategies of re-treatment in patients (pts) responding to RTX after failure or intolerance to anti-TNF therapy. The objective of this ancillary study was to identify genetic markers predictive of response to a first course of RTX. The potential association between single-nucleotide polymorphisms (SNP) in 10 candidate genes involved in B cell pathways and response to RTX was investigated. Baseline clinical and biologic factors were collected. Univariate and multivariate analyses were performed to identify predictive factors of good or moderate EULAR response in comparison with non response at week 24. Among the 115 pts (age = 56±11 years, 80% of women, 14±9 years of disease duration, baseline DAS28 = 5.7±0.9, 70%RF+, 82% ACPA+), 93 (81%) were responders. One non-synonymous coding SNP (rs396991) of FCGRIIIA (1q23) and one SNP (rs9514828) in the 5' regulatory region (-871 C/T) of BAFF (13q32-q34) were associated with response to RTX. For FCGRIIIA, G allele carriers had higher response rate (91% of responders versus 70%, OR=4.6 [95%CI: 1.5-13.6], p=0.006) in comparison to non carriers. For BAFF, C allele carriers had higher response rate (85% of responders versus 64%, OR=3.2 [1.1-9.1], p=0.03) in comparison to non carriers. These results were confirmed in multivariate analysis. In RA pts failing to anti-TNF, two polymorphisms of FCGRIIIA and BAFF appear as additional factors associated with higher response rate after a first course of RTX.

PredictABEL: an R package for the assessment of risk prediction models

S. Kundu*, Y. Aulchenko, C. van Duijn, C. Janssens;*
Erasmus Medical Center, Rotterdam, Netherlands.

The rapid identification of genetic markers for multifactorial diseases from genome-wide association studies is fuelling interest in investigating the predictive ability and health care utility of genetic risk models. Various measures are available for the assessment of risk prediction models, each addressing a different aspect of performance and utility. Even though the assessment of risk prediction models is relatively standard, there is no single statistical package that would allow for the computation and production of all these measures and plots. Therefore, we developed PredictABEL, an R package that contains functions to obtain all descriptive tables, measures and plots that are used in genetic risk prediction studies. The package contains functions for the various measures that are used in empirical studies, including univariate and multivariate odds ratios (OR) of the predictors, the c-statistic (or area under the receiver operating characteristic (ROC) curve (AUC)), Hosmer-Lemeshow goodness of fit test, reclassification table, net reclassification improvement (NRI) and integrated discrimination improvement (IDI). Also included are functions to create plots, such as risk distributions, ROC curves, calibration plot, discrimination box plot and predictiveness curves. In addition to functions to assess the performance of risk models, the package includes functions to obtain weighted and unweighted risk scores as well as predicted risks using logistic regression analysis. These logistic regression functions are specifically written for models that include genetic variables, but they can also be applied to models that are based on non-genetic risk factors only. PredictABEL is freely available at the CRAN website (http://cran.r-project.org/).

P08.62
Identification of novel mutations in CRB1 and CERKL genes by genomewide homozygosity mapping in Turkish families with autosomal recessive retinitis pigmentosa

D. Yücel[1], *R. K. Özgül*[2];
[1]*Hacettepe University, Department of Pediatrics, Metabolism Unit, Ankara, Turkey,* [2]*Hacettepe University, Institute of Child Health, Department of Pediatrics, Metabolism Unit, Ankara, Turkey.*

Retinitis pigmentosa (RP), the most common form of inherited retinal dystrophies, shows extremely high clinical and genetic heterogeneity. To date, more than 35 genes have been associated with this disease in all modes of inheritance. Although the number of RP causative genes is continuously expanding, more than 40% of the cases remain undefined. All available mutation detection techniques of all known RP genes remain labor intensive, time consuming, and expensive. To overcome these challenges and to generate a high volume, cost-effective, and efficient screening tool, microarray which is high-throughput molecular screening techniques has been prefered.

Whole genome genotyping was performed by Affymetrix 250K SNP array in two consanguineous Turkish families in which two children have RP. Homozygosity mapping have shown linkage to chromosome 1 and chromosome 2 in these families respectively. RP causing CRB1 and CERKL genes located in these chromosomal region was selected as a first candidate gene for mutation screening. The mutation screening in these genes revealed the presence of two novel mutations: 701dupACAGG(fs)□.710X in CRB1 gene, IVS1+5G>C in CERKL gene.

Mutation frequency survey of different populations for CERKL and CRB1 mutations showed that they account for 1% of all arRP associated gene mutations. Genomewide genotyping approach is a useful in selection of candidate genes among many disease causing RP genes. This study was supported by Scientific Research Fund of Hacettepe University (BAP Project No: 0801601003).

[1]*University of Pittsburgh, Pittsburgh, PA, United States,* [2]*University of Washington, Seattle, WA, United States,* [3]*Johns Hopkins University, Baltimore, MD, United States,* [4]*West Virginia University, Morgantown, WV, United States.*

Background/Objective: Due to limited health care access and elevated oral disease, the Center for Oral Health Research in Appalachia (COHRA) began evaluating risk factors for dental caries in families who were also included as part of the NIH Gene, Environment Association Studies Consortium (GENEVA) genome-wide association study (GWAS) of dentalcaries. Dental caries is heritable (29%~40%) even after adjustments for shared environment. Saliva flow may impact caries risk and be under control by multiple genes. We integrate GWAS of saliva flow with existing protein databases to identify corresponding gene networks in the COHRA-GENEVA population.

Methods: Caries status, demographics, and unstimulated saliva flow rates (ml/min) were obtained from COHRA-GENEVA subjects (n = 1506; 647 males and 859 females). Subjects self-reported as Caucasian, and were 5-75 years old. Heritability of saliva flow was estimated at 49%. GWAS was conducted of unstimulated saliva flow (mean=0.581(ml/min), sd=0.418). Illumina 610-Quad platform genotypes were generated by the Center for Inherited Disease Research. Genotype quality control was conducted by the GENEVA Coordinating Center and U. Pittsburgh using standardized protocols. Single-SNP GWAS results were integrated into dmGWAS software to identify genetic modules based on joint consideration of SNP results and existing 63,995 gene pairs from the Protein Interaction Network Analysis (PINA) database.

Results: Single SNP GWAS results suggest regions of chromosomes 2, 8, 9, 10, 13 and 22 may be associated with a saliva flow rate. We are currently applying pathway-integration approaches to GWAS data to prioritize gene webs influencing saliva flow.

Next-generation sequencing of known and putative susceptibility genes for schizophrenia and autism spectrum disorders to detect rare high-penetrant risk variants

D. W. Morris, *S. Furlong, E. Kenny, P. Cormican, C. Fahey, R. Anney, G. Donohoe, A. Corvin, L. Gallagher, M. Gill;*
Trinity College Dublin, Dublin, Ireland.

Schizophrenia (SZ) and autism spectrum disorders (ASD) are complex neurodevelopmental disorders that share certain phenotypes including cognitive deficits and some behavioural characteristics. Such similarities suggest that these disorders may share an underlying pathology and thus may share some genetic risk variants. This study involves next-generation sequencing of the exonic regions of 215 potential susceptibility genes in an Irish sample of 150 cases of ASD, 300 cases of SZ and 300 controls, in order to identify single nucleotide polymorphisms, indels and structural variants contributing to one or both disorders. A multiplex target enrichment method is used whereby DNA samples are multiplexed together using DNA indexes/barcodes and enriched for the exonic regions of these genes using the Agilent SureSelect target enrichment method. This is followed by 80bp paired-end sequencing in a single lane of an Illumina GAII. Gene selection comprised of five categories: 1) Interactors of NRXN1, 2) Interactors of DISC1, 3) Genes within the Glutamate Receptor Complexes; NMDA, mGluR5 and AMPA, 4) Cell adhesion molecules and 5) Functional and Positional Candidates. Analysis of the pilot set of samples indicates that the approach undertaken is successful with an even spread of sequence information for 24 indexed samples per lane, >8X coverage for 84% of target regions and overall SNP concordance with previous GWAS data (Affymetrix 6.0) of 99.3%. In addition to description of this novel sequencing method, data will be presented on the rare variant analysis in the SZ and ASD samples.

P08.65
Frequency of serotonin transporter promoter gene polymorphism in opioid addiction

N. Ghasemi[1], *M. Shaikhha*[2], *T. Nazari*[3];
[1]*Research and Clinical Centre for Infertility,Yazd Shahid Sadoughi Medical Sciences University, Yazd, Islamic Republic of Iran,* [2]*Research and Clinical Centre for Infertility, Yazd Shahid Sadoughi Medical Sciences University, Yazd, Islamic Republic of Iran,* [3]*Yazd Shahid Sadoughi Medical Sciences University, Yazd, Islamic Republic of Iran.*

Background: Association studies of polymorphism in the promoter region (5′-HTTP) of the gene encoding the serotonin transporter protein in addiction have shown conflicting results. The most frequently observed alleles of the 5′-HTTLPR polymorphism are the short and long variants, which the short variant is associated with lower transcriptional activity than long variant. Aim of the present study was to evaluate the possible association between 5-HTT genotype and the availability to experiment illegal drugs among adolescents.

Methods: Thirty one opium dependent males, aged 20-50 years, entered the study, after informed consent. They referred to the rehabilitation centre to give up addiction. Thirty one normal volunteer were chosen for control, which were matched in age, sex and socioeconomic situation with cases. A whole blood sample (5 ml) from each participant was collected and stored for subsequent detection of DNA using phenol-chloroform method. DNA isolated from whole blood was PCR-amplified. The PCR products were resolved in 2.5% agarose gel containing 50 mg/ml ethidium bromide in TAE buffer (40 mM Tris-acetate, 1mMEDTA pH 8.0).

Results: Short allele frequency in cases and controls were 0.532 and 0.387 respectively. Long allele frequency in cases and controls were 0.468 and 0.613 respectively. Despite of OR=1.8 this study indicate no significant association between frequency of s allele and addiction to opioid.

Conclusions: Although previous findings indicated association of short allele with addiction, this study did not confirm these results. Several possibilities exist for these discrepant results, including small sample size, potential population stratification, and categorical phenotypes.

TDT analysis used for searching new molecular markers involved in SMA disease

M. Stavarachi[1], *P. Apostol*[1], *M. Toma*[1], *N. Butoianu*[2], *C. Burloiu*[2], *D. Craiu*[2], *N. M. Panduru*[3], *D. Cimponeriu*[1];
[1]*University of Bucharest, Department of Genetics, Bucharest, Romania,* [2]*"Al. Obregia" Clinical Psychiatry Hospital, Bucharest, Romania,* [3]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.*

Clinical heterogeneity of spinal muscular atrophy (SMA) disease suggests the involvement of some unidentified genetic factors, in addition to those already known. Taking into account the role of vitamin D in neuronal and muscular cells physiopathology, we think that vitamin D receptor (*VDR*) gene might be a candidate gene for SMA heterogeneity. The aim of our study was to asses, through a transmission disequilibrium test (TDT), the relationship between four vitamin D receptor markers and this ruthless disease.

We included in our study 30 SMA subjects (clinically and molecular diagnosed) and their both parents. These nuclear families were genotyped for *VDR* gene *FokI*, *BsmI*, *ApaI* and *TaqI* polymorphisms, by PCR-RFLP technique. TDT analysis realized with FBAT software showed that the "*t*" allele of *TaqI* polymorphism is transmitted from parents to affected offspring more often than statistically expected (p=0.04). For the other alleles, no statistically significant results were noticed. Also, we didn't identify the preferential transmission of any estimated four-locus haplotype. This is the first report about using TDT analysis in investigation of SMA disease. Even we analyzed a small number of nuclear families, we think that our preliminary results sustain the hypothesis of *VDR* gene involvement in this pathology, but extended research is needed to be performed in order to assess our results.

This work was supported by CNCSIS - UEFISCDI, project number PNII - IDEI 2152/2008.

SNP array analysis in 4 patients in an attempt to identify the mitochondrial pyruvate carrier

M. Brivet[1], *A. Boutron*[1], *G. Touati*[2], *L. Burglen*[3], ***C. Redin***[4], *P. De Lonlay*[2], *J. Mandel*[4];
[1]*Laboratoire de Biochimie , AP-HP Hôpital de Bicêtre, Le Kremlin Bicêtre, France,* [2]*Centre de Référence Maladies Métaboliques, AP-HP Hôpital Necker-Enfants Malades, Paris, France,* [3]*Génétique, AP-HP Hôpital Trousseau, Paris, France,* [4]*IGBMC, Illkirch Graffenstaden, France.*

Transport of pyruvate into mitochondria is fundamental to glucose oxidation and ATP production. However, the mammalian transporter has
not yet been identified.

We previously reported a patient with encephalopathy associated to persistant hyperlactatemia and normal lactate/pyruvate ratios, in whom pyruvate dehydrogenase deficiency was ruled out by enzymatic assays and mutation screening. A defect of pyruvate transport across the mitochondrial membrane was considered as an alternative hypothesis.

Parallel methods in disrupted and digitonin-permeabilized fibroblasts were designed to measure the oxidation of [14C] pyruvate : digitonin allows pyruvate to bypass the plasma membrane and directly reach the mitochondrial membrane. We established that [14C]-pyruvate oxidation was normal in disrupted fibroblasts and severely impaired in permeabilized fibroblasts whose mitochondrial membrane was intact. Two other patients were further identified. All 3 families are of Algerian descent and consanguineous.

In an attempt to identify the disease-causing gene, homozygosity mapping using the DNA of the first two families (3 affected members) was performed on a GeneChip 250K SNP array from Affymetrix. Several common regions covering more than 35 contiguous homozygous SNPs were uncovered but neither corresponded to genes of the mitochondrial transporter family. DNA from the proband from the recently identified third family is being similarly analysed, and should restrict the number of candidate regions, assuming genetic homogeneity. This will also allow us to test, through haplotype analysis, the hypothesis of a founder effect, and search for the mutated gene.

P08.68
TRIB1 genes polymorphism in type 2 diabetes mellitus and metabolic syndrome patients

P. Kisfali[1], *G. Szabó*[1], *E. Baricza*[1], *B. Duga*[1], *K. Hetyésy*[2], *B. Melegh*[1];
[1]*Department of Medical Genetics, University of Pécs, Pécs, Hungary,* [2]*Central Laboratory, Aladar Petz County Hospital, Győr, Hungary.*

Type 2 diabetes mellitus (T2DM) and metabolic syndrome (MS) have polygenic background. Characterized by gene-gene and gene-environment interactions with onset in adulthood, usually at age 40 to 60 but occasionally in adolescence if a person is obese. The penetrance is variable, possibly 10 to 40%

The human tribbles-1 (*TRIB1*) gene is located at chromosome 8q24. Hepatic-specific overexpression of TRIB1 reduces levels of plasma TG and cholesterol by limiting VLDL production. The rs17321515 was shown to be associated with severe HTG and HLP types 2B, 3, 4 and 5. In Asian Malay population, this polymorphism located on the *TRIB1* locus showed an association with elevated total- and LDL-cholesterol and with increased risk of CHD and CVD and also, in a Japanese cohort this variant was significantly associated with triglyceride levels and LDL-cholesterol concentrations. A total of 426 T2DM, 489 MS patients and 253 controls were genotyped by PCR-RFLP. We observed relationships between triglycerides and any genotypes in T2DM and MS patients. Triglyceride levels where higher in minor homozygotes than in two other genotype groups (T2DM: AA:2.12±0.28; AG:1.79±0.12; GG:1.99±0.21; MS: AA:2.49±0.18; AG:2.10±0.09; GG:2.15±0.16 and $p<0.05$). The total serum cholesterol and HDL-cholesterol level did not differ between groups of different genotypes. Multiple logistic regression analysis revealed that this genotype protect for the development of T2DM (OR=0.495; 95% CI:0.292-0.827; p=0.007). The analyzed TRIB1 (rs17321515) SNP is associated with elevated triglyceride levels in AA homozygotes in T2DM and metabolic syndrome groups and protect for development of T2DM.

P08.69
Associations of STAT3, JAK2 and CCR6 polymorphisms with ulcerative colitis and Crohn's disease.

I. Janicsek[1], *N. Polgar*[1], *V. Csongei*[2], *M. Szabo*[3], *V. Zambo*[1], *B. Melegh*[1];
[1]*University of Pécs, Department of Medical Genetics, Pécs, Hungary,* [2]*University of Pécs, Department of Immunology and Biotechnology, Pécs, Hungary,* [3]*Robert Koch Hospital, Edelény, Hungary.*

Recent genome-wide association studies have identified many genetic factors in association with the development of inflammatory bowel diseases ulcderative colitis (UC) and Crohn's disease (CD).In this study we investigated the possible association of the natural variants of the following genes: signal transducer and activator of transcription 3 (STAT3-rs744166), janus kinase 2 (JAK2-rs10758669) and chemokine (C-C motif) receptor 6 (CCR-rs2301436) in patients with UC or CD. DNA of 309 CD, 307 UC, and 496 control patients were genotyped by PCR/RFLP method. Although no significant differences were detected between the patient groups and the controls regarding the STAT3 T risk allele frequencies, we found a significantly higher frequency of rs744166 TT homozygotes in UC patients than in controls, while no such association could be observed in patients with CD. For the JAK2 polymorphism rs10758669, we found an elevated overall frequency of the C risk allele in CD patients but not in UC patients, while the frequecies of CC homozygotes did not differ significantly in the UC and CD groups compared to controls. As for the CCR6 rs2301436 variant, we detected a statistically elevated ratio of risk AA homozygotes in UC patients, but not in the CD group when compared to controls. Regression analysis revealed a risk nature of STAT3 rs744166 TT genotype for ulcerative colitis (OR 1.498, 95% CI 1.121-2.000; p=0.006, adjusted 0.009). On the other hand, in our cohort we could not detect such associations of JAK2 variant rs10758669 or CCR6 variant rs2301436 with UC or CD.

Evidence of DLL1 as a susceptibility locus in Indian Visceral leishmaniasis

S. Mehrotra[1], *A. Mishra*[1], *M. Fakiola*[2], *S. E. Jamieson*[3], *D. Selvi Rani*[4], *S. Sundar*[1], *J. M. Blackwell*[3];
[1]*Institute of Medical Sciences, Banaras Hindu University, Varanasi, India,* [2]*Cambridge Institute for Medical Research and Department of Medicine, University of Cambridge School of Clinical Medicine, Cambridge, United*

Kingdom, [3]Telethon Institute for Child Health Research, Centre for Child Health Research, The University of Western Australia, Subiaco, Western Australia, Australia, [4]Centre for Cellular and Molecular Biology, Hyderabad, India.

Previous genome wide linkage studies in Sudanese and Brazilian populations identified chromosome 6q27 as a strong candidate region containing a gene(s) regulating susceptibility to visceral leishmaniasis (VL). The region contains genes involved in the host immune response, amongst which the most compelling candidate susceptibility gene for VL is *DLL1* (Delta Like Protein 1), a member of the notch signalling pathway that directs naïve T helper differentiation towards Th1, Th2 or regulatory T cell lineages.

This population-based study investigated the role of the 6q27 genes (*PHF10*, *C6orf70, DLL1*, *FAM120B*, *PSMB1*, *TBP*) in Indian VL by genotyping (Sequenom) twenty-one single nucleotide polymorphisms in 941 VL cases and 992 ethnically-matched controls. Logistic regression analyses using additive and genotypic models show significant associations with variants at *DLL1* (rs1884190) and *FAM120B* (rs9366198, rs9460106, rs2103816). FAM120B_rs9460106 (intronic) was the most associated SNP (OR=1.22; 95%CI=1.07-1.39; *P*=0.0027), but the associated variants all fall within a strong linkage disequilibrium block. Quantitative gene expression was analysed in 19 paired pre- (Day 0), and post- (Day 30) treatment splenic aspirate samples from VL patients receiving antileishmanial drug therapy. *DLL1* was significantly (*P*<0.0001) higher expression in Day 0 samples compared to Day 30.

These genetic and functional studies in an endemic Indian population provide strong evidence for *DLL1* acting as a susceptibility locus in India.

Tru9I polymorphism in vitamin D receptor gene and bone mineral density association in different menopausal situation: Tehran lipid and glucose study

*F. Hosseinpanah, **S. Poormohammadvali-Behnami**, M. S. Daneshpour, N. Ahmadi, F. Azizi;*

Research Institute for Endocrine Science, Tehran, Islamic Republic of Iran.

Introduction: The vitamin D endocrine systems play a central role in control of bone and calcium homeostasis. Thus, alterations in the vitamin D pathway lead to disturbances in mineral metabolism. Several genetic variations have been identified in the VDR. The aim of this study was is to test whether there is an association between G/A polymorphism (Tru9I) in intron 8 and bone mineral density (BMD) and menopausal statues.

Material and methods: In this study 137 healthy free-living post menopausal women and underwent BMD randomly selected. Serum 25(OH) D, calcium, phosphorus and bone mass were measured (81 premenopausal; 56 postmenopausal). Hardy-Weinberg equilibrium analysis was used. To examine the selected polymorphism RFLP-PCR were used with Tru9I.

Result: The result showed that T allele frequency was 0.82. After adjustments for age, in premenopausal subjects mean BMD for femoral neck T carriers were higher than t carriers ($p < 0.05$) but the opposite results in postmenopausal women have been seen.

Conclusion: Our findings suggest that the VDR Tru9I polymorphism may be associated with BMD and age as a covariable play a significant role. These results highlight the importance of the genetic factors in the bone mineral density of woman in different hormonal stage.

P08.72

LD-based SNP genotype calling from next-generation sequencing data

***A. Menelaou**, J. Marchini;*

University of Oxford, Oxford, United Kingdom.

The 1000 Genomes project (1KGP) aims to construct a detailed catalogue of human polymorphism using next-generation sequencing technologies which consist of short reads of DNA mapped to a reference genome. These reads can be used for the detection of structural variation, indels and SNPs. However, it is costly to sequence many individuals at high depth. An alternative approach is to sequence many samples at low coverage and then combine the information across samples to detect and genotype variant sites.

Our method assumes that a scaffold of haplotypes at known SNPs is available, e.g. , from the HapMap project. At each potentially variant site we use a Gibbs sampling phasing scheme to update each individuals haplotypes at that site and known SNPs in small flanking window. Rather than using an HMM in the phasing updates we use a simple, fast and novel method based on approximating a new haplotype as a draw from an appropriately chosen multivariate normal distribution. Since the haplotypes at the known sites are static many of the calculations involved can be efficiently implemented so that the method is fast and scales well. The evidence for variation at the site and estimates of individual genotypes can be obtained by summarizing the MCMC samples.

We have applied our method to a set of CEU individuals from Pilot 1 of the 1KGP and we compare our SNP and genotype calls with other existing methods. The number of SNP calls made and the genotype accuracy is comparable with other methods.

P08.73

Screening of 10 SNPs of LINGO1 gene in patients with essential tremor in Latvian population

***I. Radovica**[1], I. Inashkina[1], E. Vitols[2], L. Smeltere[3], E. Jankevics[1];*

[1]Latvian Biomedical Research and Study Centre, Riga, Latvia, [2]Paul Stradins University, Riga, Latvia, [3]Paul Stradins University Clinical Hospital, Riga, Latvia.

Essential tremor (ET) is one of the most common neurological disease, with a prevalence (age ≥ 40 years) estimated to be 4.0 % and prevalence in the oldest exceeding 20.0 %. An autosomal dominantly inherited form of ET is genetically linked to two loci on chromosomes 3q13 (ETM1) and 2p24.1 (ETM2) in families from different parts of the world. Numerous of candidate genes, including hypothetical, - HS1-BP3, HCLS1, DRD3, LINGO1, LINGO2, C2orf43, LOC 100129278, FLJ 21820, LOC 645949 - have been suggested during last years, but none of them was maintained up to now.

A marker within the LINGO1 gene, rs9652490, showing significant genome-wide association with ET, was recently reported in an Icelandic and North American populations. To replicate this association in an independent population from Latvia, we sequenced regions of LINGO1 gene involving 10 markers (rs2137110, rs8030859, rs34476171, rs9652490, rs7177008, rs13313467, rs8028808, rs11856808, rs72744599 and one novel SNP) in 141 unrelated Latvian ET patients (sporadic n = 64 and familial n = 77) and 130 normal controls, matched by age and gender.

We observed significant association with A/G genotype of the marker rs96532490 in familial ET compared to controls (P = 0.0426, OR = 1.92, 95 % CI: 1.06 - 3.46). No other significant association was found. Our results suggest that the LINGO1 variants analyzed are not a major risk factor for developing ET in Latvian population, which propose the existence of other unknown genetic risk factors responsible for ET phenotype.

P08.74

Selection of endophenotypes in association mapping

***Y. Chiu**, H. Kao;*

National Health Research Institues, Zhunan, Taiwan.

Most common diseases such as hypertension, diabetes, asthma, schizophrenia, heart diseases, etc. have a complex etiology involving both genetic and environmental factors. This complexity challenges investigators in finding the relationships between phenotypes and genotypes. One option to dissolve the complexity is to select an “endophenotype” to signify quantitative measures that are more proximate to the biological etiology of a clinical disorder than its signs and symptoms and thus less genetically complex than the disorder’s underlying mechanism. Since the endophenotype is influenced by fewer genetic and environmental risk factors than the disorder, its use would result in greater statistical power to detect the effects of individual genes. In practice, it is common for investigators to measure numerous phenotypes on affected individuals, to achieve a substantial possibility of success in gene mapping, a systematic statistical method on the selection of endophenotypes would be helpful on identification of disease genes. In this study, we applied a developed statistical approach to select valid endophenotypes in linkage or association mapping. This approach allows investigators to assess the significance of an endophenotype on a pathway as incorporating a proper endophenotype into gene mapping can enhance the efficiency of disease locus estimate. This approach is applicable to all kinds of study designs in association mapping and linkage mapping.

Screening for *MYOXVA* gene mutations of DFNB3 locus in Autosomal recessive non-syndromic, *GJB2* negative Iranian Deaf population

Z. Fattahi[1], *M. Babanejad*[1], *E. Shearer*[2], *N. Bazazzadegan*[1], *N. Almadani*[3], *N. Nikzat*[1], *S. Arjangi*[1], *K. Jalalvand*[1], *R. Abtahi*[4], *B. Azadeh*[5], *K. Kahrizi*[1], *R. Smith*[2], *H. Najmabadi*[1];

[1]*Genetics Research Centre, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Molecular Otolaryngology Research Laboratories, Department of Otolaryngology Head and Neck Surgery, University of Iowa, Iowa City, IA, United States,* [3]*Royan Institute, Reproductive Biomedicine & Stem Cell, Tehran, Islamic Republic of Iran,* [4]*Saveh Welfare Organization, Saveh, Islamic Republic of Iran,* [5]*Isfahan Welfare Organization, Isfahan, Islamic Republic of Iran.*

Myo15A gene is located in DFNB3 locus on chromosome 17p11.2, and encodes Myosin XVA, which is an unconventional myosin and is critical for the formation of stereocilia in hair cells of the inner ear. Recessive mutations in this gene can lead to profound Autosomal recessive non-syndromic hearing loss (ARNSHL) in humans and *shaker2* (*sh2*) phenotype in mice.

Here, we performed a family study on 140 Iranian families in order to determine mutations causing ARNSHL. The families, who were negative for *GJB2* gene mutations, were subjected to linkage analysis. Eight of them were linked to DFNB3 locus using intragenic or flanking STR markers. This data suggests that the frequency of *Myo15A* mutation is about 5% in the Iranian deaf population. Sequencing of *Myo15A* in these families led to the identification of five unreported mutations - 3 missense mutations, 1 nonsense mutation and 1 deletion which results in frame shift mutation followed by premature stop codon.

J08.02

G-2548A polymorphism of the human leptin gene (LEP) promoter region associated with the level of serum lipoprotein

L. Kayumova*, E. Yakshembitova, E. Vorobjeva, V. Gorbunova;*

Bashkir State Pedagogical University name of M.Akmulla, Ufa, Russian Federation.

Leptin - a peptide hormone that is secreted by fat cells and is involved in the regulation of energy metabolism and body weight. It reduces appetite, increases energy expenditure, changes the metabolism of fats and glucose, as well as neuroendocrine function or direct influence, or activation of specific structures in the central nervous system.

Gene LEP, encodes the protein leptin is localized on 7q31.3.

We have studied the polymorphic variant G-2548A promoter region of the gene LEP.

Material for the study included DNA samples from 350 individuals. Determining the level of low density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol by standard enzymatic methods. Analysis of polymorphic loci LEP G-2548A was performed by PCR-RFLP.

Results: The group of persons with indicators of LDL in the normal range was a statistically significant increase of homozygous genotype LEP *G/*G (27.34% against 15.38% in the group of persons with high levels of LDL, P= 0.0192).

Also in the group of persons with higher than normal rates of HDL showed a significant increase of genotype LEP *G/*G (37.5% vs. 24.03%, P=0.0407) and allele LEP *G (60.94% against, 49.65%) against a group of individuals with indicators of HDL cholesterol within normal limits.

Conclusions: The findings suggest that the allelic variant G-2548A contributes to the determination of lipid metabolism. In particular, the residents of the Republic of Bashkortostan, a favorable genetic marker serum levels of LDL and HDL may be LEP *G allele and genotype of LEP *G/*G.

Association of the G72/G30 genes with psychiatric disorders

I. Akhmerova[1], *A. Zainullina*[2], *R. Valinurov*[1], *E. Khusnutdinova*[2];

[1]*Republican Mental Health Clinic â„–1, Ministry of Health of the Republic of Bashkortostan, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation.*

Earlier studies have shown the significant role of G72 and G30 genes in the pathogenesis of many psychiatric disorders. The present study is aimed at the analysis of the association of the rs3918342, rs2391191 and rs978714 of G72 gene and rs1341402 of G30 gene with schizophrenia and affective disorders. DNA samples of 144 schizophrenia patients and 129 affective mood disorders patients from Bashkortostan (Russia) have been used as the material for this study. The control group comprised 165 volunteers of the same age and ethnic background not registered in any mental health or drug abuse clinics and denying psychiatrically burdened family history. Case-control comparisons were based on association analysis, linkage disequilibrium and haplotype frequency estimations. The C allele (rs3918342) associated with an increased risk of schizophrenia (OR=1,49) and affective disorders (OR=1,46). Maximum likelihood analysis of haplotype distribution demonstrated the presence of linkage disequilibrium between the two loci rs2391191 and rs1341402. The case group with schizophrenia showed bigger CG haplotype frequency compared to that in the controls, however, the difference has not reached the statistical significance (P=0,081).

J08.04

VEGF gene polymorphism association with diabetic foot ulcer

M. M. Amoli[1], *M. Mehrab-Mohseni*[1], *J. Tavakkoly Bazzaz*[2], *S. Hasani-Ranjbar*[1], *N. Roohipour*[1], *P. Amiri*[1], *F. A. Sayahpour*[1];

[1]*EMRC, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medicine, Tehran university of Medical Sciences,, Tehran, Islamic Republic of Iran.*

Objective: Functional polymorphisms within vascular endothelial growth factor (VEGF) gene have shown association with various conditions including diabetic neuropathy and retinopathy. In this study we have performed a candidate gene association study in order to examine VEGF gene polymorphism association with diabetic foot ulcer (DFU).

Methods: The study group comprised of type 2 diabetes patients with (N=247) and without (N=241) DFU. Healthy control subjects (N=98) were also recruited from the same area. The ARMS-PCR technique was applied for genotyping of VEGF gene SNPs at positions -7*C/T and -2578*C/A.

Results: The frequency of genotype AA was significantly decreased in patients with DFU compared with diabetic subjects without DFU (AA vs CA+CC, p=0.003, OR= 0.44, CI = 0.24-0.80.). Also there was a significant decrease in frequency of A allele in patients with DFU compared to the controls (p=0.02, OR= 0.68, CI = 0.48-0.96).

Conclusion: It seems that lower frequency of A allele in patients with DFU is conferring a protective effect which might be as a result of increased angiogenesis in patients carrying this allele.

AGTR1 c.*86A>C and AGT c.620C>T polymorphism genotypes and the aerobic capacity of elite Lithuanian athletes

A. Pranculis[1], *V. Ginevičiene*[1,2], *V. Kučinskas*[1];
[1]*Departament of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Lithuanian Olympic Sports Centre, Vilnius, Lithuania.*

Angiotensinogen (AGT) and angiotensin II type 1 receptor genes (AGTR1) are important for the angiotensin- renin system which is crucial for the function of the cardiovascular system and affects ones physical capacity. We analyzed AGTR1 c.*86A>C polymorphism which is located in the 3â€~UTR and has major impact on gene transcription and mRNA stability. The angiotensinogen gene (AGT) regulates the expression of AGT (angiotensin II precursor) in the liver. The missense AGT c.620C>T polymorphism might have serious impact on the production of angiotensin and subsequently an athletes physical capacity.

The statistical analysis of the polymorphisms and their association with physical capacityâ€™s phenotypical index VO2max in a group of 149 elite Lithuanian athletes showed their significant association. The athletes were stratified into three groups (speed/power, endurance and mixed sports groups) according to the sport propagated. 240 unrelated subjects from the general Lithuanian population were used as a control group.

Statistical analysis revealed no significant VO2max differences between athletes with different AGT c.620C>T polymorphism genotypes. AGT C/C genotype was significantly more frequent in the endurance group compared to the speed/power group. The AGTR1 A/A genotype athletes have statistically significantly higher VO2max index than the C/C genotype athletes. C allele of the AGTR1 A/C polymorphism was significantly more frequent in the speed/power group compared to other sports groups and the control group. We conclude that while both AGTR1 and AGT polymorphism genotypes indicate tendancy towards a certain sport type, but only AGTR1 A/C polimorphism genotypes could be used for VO2max index value size prediction.

Existence of association between P86L polymorphism in *CALHM1* gene and risk of developing late-onset Alzheimer's disease in the Iranian population

m. jafari aqdam[1], *h. khorram khorshid*[1], *k. kamali*[2], *m. ohadi*[1];
[1]*university of social welfare and rehabilitation, tehran, Islamic Republic of Iran,* [2]*Reproductive Biotechnology Research Centre, Avicenna Research Institute, ACECR, tehran, Islamic Republic of Iran.*

Introduction: Alzheimer's disease (AD) is a genetically heterogeneous neurodegenerative disease and Late-Onset type (LOAD) is the most common form of dementia affecting people over 65 years old. AD is a complex disease with multifactorial etiology. This disease is characterized by hippocampal atrophy and cerebral Aβ peptide deposition. *CALHM1* gene is located on 10q24.33 and encodes a multipass transmembrane glycoprotein that controls cytosolic $Ca2^+$ concentrations and Aβ levels. *CALHM1* P86L polymorphism (rs2986017) is significantly associated with LOAD in independent case controls in a number of studies. This polymorphism increases Aβ levels by interfering with CALHM1 mediated $Ca2^+$ permeability.

Aims: This study was performed to determine whether this polymorphism contributes to the risk for LOAD in Iranian population.

Methods and Materials: One hundred and forty one AD patients and 141 healthy controls were recruited in this study. After extraction of genomic DNA, the genotype and allele frequencies were determined in case and control subjects using PCR/RFLP method.

Results: The statistical analysis showed a significant difference in the heterozygote genotype frequency in case and control groups and polymorphic allele had a protective role between two groups. Also after stratifying the subjects by their *APOE-ε4* status, no significant association was observed.

Discussion: Our study suggests that P86L polymorphism could be a risk and protective factor for late-onset Alzheimer's disease (LOAD) in Iranian population. However, to confirm these results, further study with a bigger sample size may be required.

Keywords: Alzheimer's disease, Polymorphism, Association study, Population, *CALHM1* gene.

Association of LOC387715 gene polymorphism with both forms of advanced age-related macular degeneration in Turkish patients

M. Yılmaz[1], *D. Yücel*[2], *R. K. Özgül*[3];
[1]*Hacettepe University Department of Genetics, Ankara, Turkey,* [2]*Hacettepe University Department of Pediatrics, Metabolism Unit, Ankara, Turkey,* [3]*Hacettepe University, Institute of Child Health,Department of Pediatrics, Metabolism Unit, Ankara, Turkey.*

Age-related macular degeneration (AMD) is a clinically heterogeneous disorder and the leading cause of irreversible central vision loss in the elderly population. Although AMD etiology remains elusive, many environmental and genetic risk factors have been shown for AMD. A69S polymorphism (rs10490924:G>T) in *LOC387715* gene on chromosome 10q26, is known to increase the risk of developing AMD. The purpose of this study is to investigate whether the one of the major risk allel in the *LOC387715*, were associated with advanced AMD in Turkish patients.

A total of 182 individuals, including 95 individuals with unrelated late AMD patients and 87 age-matched healthy individuals as a control group were genotyped by direct sequence analysis. Single SNP for A69S genotyping results were analyzed for deviations from H-W equilibrium and no significant deviations were detected ($p<0.05$; controls, p=0.92 ; cases, p=0.23). Odds ratios and 95% confidence intervals were calculated by logistic regression method. Findings showed that homozygote individuals with TT genotype have an increased risk (OR=4, 1.52-10.52%) for AMD when compared with GG genotype in Turkish population. This study suggest that the LOC*387715* polymorphism has significantly associated for both types of end-stage AMD in Turkish populations.

*Ban*I/D13S141/D13S175 represents a novel informative haplotype at the *GJB2* gene region in Iranian population

H. Rezaei, ***S. Vallian****;*
University of Isfahan, Isfahan, Islamic Republic of Iran.

Non-syndromic sensorineural hearing loss (NSHL) represents the most cause of hearing loss in Iranian patients. In view of the large numbers of mutations identified in *GJB2*, mutations analysis of the gene has been time-consuming and cost-effective. Alternatively, molecular markers which are highly linked to the *GJB2* gene have proven to be useful in carrier detection and prenatal diagnosis of NSHL families. These markers usually show a population dependent based haplotype frequency. However, to date, no information on the genotyping and frequency of the markers is present for the Iranian population. In the present study, genotyping and the haplotype frequency of three markers including *Ban*I, D13S141 and D13S175, at the *GJB2* region were investigated. The haplotype frequency was estimated using PHASE program. The input data contained two alleles (+ and -) for *Ban*I, four alleles for D13S141 and seven alleles for D13S175. Among the 42 possible haplotypes estimated, four haplotypes showed relatively high frequency (≥5%). Therefore, a combination of *Ban*I/D13S141/D13S175 could be suggested as an informative haplotype for possible carrier detection and prenatal diagnosis of NSHL in Iranian population.

ACTN3 R577X polymorphism in Russian power athletes

A. A. Danilova[1], *A. M. Druzhevskaya*[2], *R. T. Gabbasov*[1], *A. V. Borisova*[1], *I. I. Ahmetov*[1];
[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.*

The alpha-actinin-3 (ACTN3) gene encodes a Z-disc structural protein which is found only in fast glycolytic muscle fibers. A common nonsense polymorphism in codon 577 of the ACTN3 gene (R577X) results in alpha-actinin-3 deficiency in XX homozygotes. Previous reports have shown a lower proportion of the ACTN3 XX genotype

in power-oriented athletes compared to the general population. In the present study we tested whether XX genotype was under-represented in Russian power-oriented athletes. The study involved 142 Russian weightlifters of regional or national competitive standard. ACTN3 genotype and allele frequencies were compared to 974 controls. The frequency of the ACTN3 X allele (30.3% vs. 38.3%; P = 0.011) was significantly different between weightlifters and controls. Although the frequency of the ACTN3 XX genotype (8.5% vs. 13.9%; P = 0.11) was not significantly lower in the whole group of weightlifters in comparison with controls, it was significantly lower (0%; P = 0.039) in highly elite athletes (n = 27), supporting the hypothesis that the presence of α-actinin-3 has a beneficial effect on the function of skeletal muscle in generating forceful contractions at high velocity. In conclusion, ACTN3 R577X polymorphism was associated with elite power athlete status in Russians.

P09.002
TOMM40 polymorphisms are associated with cardiovascular phenotypes

R. Salakhov[1,2], *V. V. Kashtalap*[2], *O. A. Makeeva*[1,2], *O. L. Barbarash*[2];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Institute of Complex Problems of Cardiovascular Diseases, Kemerovo, Russian Federation.*

TOMM40 gene which encodes the channel-forming subunit of a translocase of the mitochondrial outer membrane had been recently proved to be involved in Alzheimer's disease. In several GWA studies of lipid profile multiple signals had been detected with TOMM40 SNPs, although their independent role in cardiovascular pathology is still under discussion, mainly because of the strong linkage disequilibrium between TOMM40 and APOE.

In our study we genotyped several TOMM40 variants in a cohort with acute coronary syndrome (ACS, n=176) and healthy subjects (n=184). Association with a number of cardiovascular phenotypes was analyzed. In healthy women rs157580 was associated with the level of total cholesterol, very low-density lipoproteins cholesterol, low-density lipoprotein cholesterol, and triglycerides. In ACS group rs2075650 was associated with blood pressure parameters and low-density lipoproteins cholesterol. TOMM40 rs741780 was associated with coronary artery stenosis more than 50% (p=0.048), and rs1160985 with extracoronary stenosis (p=0.038). The progression of heart failure in 1 year follow up was associated with rs157580 (p=0.006).

These results demonstrate that TOMM40 may be involved in cardiovascular diseases.

Genome-wide association study of acute stroke in Russia

E. Bondarenko[1], *I. Shetova*[2], *N. Shamalov*[2], *P. Slominsky*[1], *S. Limborska*[1], *V. Skvortsova*[2];
[1]*Institute of Molecular Genetics, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Scientific research institute of cerebrovascular pathology and stroke, Russian State Medical University, Moscow, Russian Federation.*

A number of previous genome wide association studies (GWAS) recently identified some genome variants to be associated with stroke in local populations. The aim of our study was to assess the individual risk of stroke development in Slavonic population.

We performed a case-control association study in 694 stroke patients from Moscow Slavonic population and 715 controls from the same population. Standard examinations including CT, MRI, duplex, Echo-CG, CTA, MRA were performed to identify the stroke cases. The stroke subtypes were diagnosed according to the TOAST criteria. Whole genome associative study was performed using DNA microarrays HumanCyto12 v. 2 ("Illumina", USA), allowing typed more than 300, 000 SNP and CNV regions also.

The resulting raw data were processed using software packages Genome Studio, PLINK, Helix Tree and eventually found several SNPs associated with the development of acute stroke. The most statistically significant association with the rs4578424 DNA marker, located on gene TUB locus on chromosome 15. This gene encodes a protein that participates in the system of signal transduction through G proteins, and may be associated with violation of lipid metabolism.

Our data suggest the association of rs4578424 on chromosome 15 with total stroke risk formation.

P09.004
Protective effect of the polymorphic variant at the IL2 gene in Polish patients with Addison's disease

M. Fichna[1,2], *M. Zurawek*[1], *P. Fichna*[3], *D. Januszkiewicz*[1,4], *M. Gryczynska*[2], *J. Nowak*[1];
[1]*Institute of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*Department of Endocrinology and Metabolism, Poznan University of Medical Sciences, Poznan, Poland,* [3]*Department of Paediatric Diabetes and Obesity, Poznan University of Medical Sciences, Poznan, Poland,* [4]*Department of Paediatric Oncology, Haematology and Transplantology, Poznan University of Medical Sciences, Poznan, Poland.*

Autoimmune Addison's disease (AAD) is a rare enocrinopathy with several susceptibility loci. Polymorphic variants of the *IL2* and *IL2RA* genes have recently been described to confer risk for several autoimmune disorders. *IL2* encodes interleukin-2, involved in maintaining peripheral T-cell immune tolerance, whereas *IL2RA* encodes specific alpha subunit of its receptor. This study was aimed to investigate the associations of selected *IL2* (rs6534349 A/G, rs2069762 T/G, rs3136534 A/C) and *IL2RA* (rs11594656 T/A, rs2104286 A/G, rs7093069 C/T) single nucleotide polymorphisms (SNPs) with AAD in a Polish cohort. The analysis comprised 124 AAD patients and 436 healthy controls. Genotyping was performed by PCR-RFLP or PCR-SSCP.

The *IL2* rs3136534 C allele appeared significantly decreased in AAD compared to the control group (29.4% *vs.* 39.1%, p=0.005), yielding an OR of 0.65 (95%CI 0.48-0.88). The difference in distribution of its genotypes also revealed statistical significance (p=0.009). By contrast, the allele and genotype frequencies of five other SNPs did not present significant differences between patients and controls (p>0.05). Linkage disequilibrium measures revealed moderate linkage between investigated SNPs (D' 0.66-0.94, r^2≤0.25 for IL2, and D' 0.13-0.84, r^2≤0.33 for IL2RA). Three locus A-T-C *IL2* haplotype, including minor rs3136534 allele, was found significantly less frequently among affected subjects *vs.* controls (26.6% vs. 38.3%, p=0.0007). The analysis of inferred *IL2RA* haplotypes did not add any further information.

In conclusion, this study indicates plausible protective effect of the minor allele at rs3136534 in AAD. No association of AAD with other investigated *IL2* and *IL2RA* SNPs was found. Supported by grant N402359738.

The genome-wide analysis of the ageing: the women only study.

R. Tamm[1,2], *K. Fischer*[2], *E. Mihailov*[1,3], *M. Alver*[1], *T. Esko*[1,2], *A. Metspalu*[1,2,3];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [3]*Estonian Biocentre, Tartu, Estonia.*

Background: As ageing is complex phenotype influenced by a variety of genes and molecular pathways, environment and stochastic factors, different approaches are needed to determine the underlying cause of these phenomena. The Estonian Biobank provides a very good opportunity to study frequency changes of the SNPs in different age groups. Whole genome SNP analysis using Illumina arrays (for example HumanCNV370-Duo and HumanOmniExpress) and a data-driven model in identifying genetic variants is more promising than scrutinizing the candidate genes. Concentrating only on females minimizes confounding effects resulting from differences between sexes.

Methods: The aim of the study was to examine allele frequency dependent discrepancies by conducting a genome-wide association study with >1.8 million HapMap2 Imputed and Quality Controlled SNP markers on 1500 Estonian women from different age groups (<40, 40-60, 60-80 and >83). To test the age dependence, the allele frequencies in all 4 age groups were compared using the Cochran-Armitage test for trend. Genome-wide significance was concluded for p-values less than 10^{-8}.

Results and Conclusions: Results suggest association between allele frequency differences in several loci, including 2p21, 2p16.3, 5q12 and 7q36.2 of different age groups as studied. These findings indicate to the loci, which include the alleles, which are increased and/or decreased in the oldest.

P09.006
Genetic dissection of Age-Related Macular Degeneration: evaluation of the impact of novel and known variations in the Italian polulation

*F. Ricci[1], **T. Lepre**[2], C. De Felici[1], F. Taglia[2], F. Missiroli[1], R. Cascella[2], S. Zampatti[2], C. Eandi[3], A. Cusumano[1], G. Novelli[2,4], E. Giardina[2];*
[1]Department of Ophthalmology, University of Rome "Tor Vergata", Rome, Italy, [2]Department of Biopathology, Centre of Excellence for Genomic Risk Assessment in Multifactorial and Complex Diseases, School of Medicine, University of Rome, Rome, Italy, [3]Department of Clinical Physiopathology, Eye Clinic, University of Torino, Torino, Italy, [4]Division of Cardiovascular Medicine, Department of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR 72205, AR, United States.

Age-related macular degeneration is a common ocular disease affecting more than one million of Italian people. Here we show the results of a large, multicentric case-control study aimed to discover new genetic variants associated with the disease and to confirm the effect of the known susceptibility polymorphisms in the Italian population. A number of 1157 Italian subjects were recruited and classified in three different categories: the first one includes patients with diagnosis of AMD (n=367), the second is composed by subjects clinically evaluated, without any sign of disease (n=330) and the last one includes subjects not clinically evaluated (general population, n=920). All subjects were genotyped for nine variants: del443ins54 and rs10490924 in *ARMS2* gene, rs1061170 and rs1410996 in *CFH* gene, rs9332739, rs547154, rs4151667 and rs2230199 in genes coding for complement proteins and rs2227306 in *IL8* gene. Our data disclose a new risk variant (rs2227306) located within *IL8* gene (p=0.007), confirm the major role of *ARMS2* (del443ins54, p=4.99*10^{-16}) and *CFH* (rs1061170, p=1.60*10^{-23}) on the susceptibility to AMD and rule out a major involvement of the other variations.

P09.007
Mutational analysis in paediatric patients with X-linked and autosomal recessive forms of ocular albinism

***K. Trebušak Podkrajšek**[1], B. Stirn Kranjc[2], T. Hovnik[1], J. Kovač[1], T. Battelino[1];*
[1]University Children´s Hospital, Ljubljana, Slovenia, [2]Eye Hospital, Ljubljana, Slovenia.

Ocular albinism (OA) is a group of inherited disorders with reduced pigmentation of the eyes and associated decreased visual acuity, nystagmus, strabismus and photophobia. X-linked OA is caused by mutations of the *GPR143* gene, encoding a pigment cell specific receptor. Autosomal recessive ocular albinisms (AROA) represent clinically mild variants of the occulocutaneous forms of albinisms (OCA), where apart from ocular characteristics, hypopigmentation of the skin and hair is usually present. AROA may result from mutations in any of the genes responsible for OCA, namely *TYR*, *OCA2* and rarely *TYRP1* or *MATP*. Ocular albinism is difficult to differentiate clinically from other forms of albinism in young patients, especially in those with light complexion. Therefore, genetic analysis presents a possibility for an early definitive diagnosis.

Direct sequencing of the coding regions of the *GPR143, TYR* and *OCA2* genes were performed in 17 patients with clinical signs of ocular albinism aged 2 to 17 years. Four patients had X-linked OA due to mutations in *GPR143* gene (29%). Two detected mutations were novel (p.Gly296Arg, c.360+5G>A). Five patients had AROA due to mutations on both alleles of the *TYR* gene (29%). One patient had *TYR* mutation on only one allele and therefore this is not completely explaining the clinical characteristics. Three detected *TYR* mutations were novel (p.Tyr451Cys, p.Ala355Val, p.Asp197Asn). Surprisingly, none of the patient had AROA due to mutations in *OCA2* gene. Two patients had *OCA2* mutations in only one allele. In five patients no pathological mutations were detected (29%).

P09.008
GST M1 and GST T1 polymorphisms and their possible relation to alcohol dependence

***P. Levy**[1], C. Marinho[1], S. Pombo[2], S. Ladeiro[1], J. Ferreira[1], J. Neves Cardoso[2], M. Bicho[1];*
[1]Genetics Laboratory, Centre of Metabolism and Endocrinology, Medical School of Lisbon, Lisbon, Portugal, [2]Psychiatric Unit of Santa Maria General Hospital, Lisbon, Portugal.

Alcoholism is a heterogeneous disorder with a multiple genetic background. Glutathione-S-transferases (GST) are polymorphic enzymes that belong to phase II metabolism and are responsible for detoxification of a large number of electrophiles compounds by conjugation with glutathione. The aim of this study is to investigate the clinical significance of GSTM1/T1 polymorphisms in alcohol dependence and their importance in relation to Lesch's typology. Genotype distributions of GSTM1/T1 deletion polymorphisms were examined in a sample of 96 patients with known history of alcohol dependence and 324 healthy individuals. GSTM1 non null genotype frequency was significantly higher in patient group compared to controls (64.6% *vs* 47.2%) and may be considered a risk factor related to alcohol consumption (OR=2.038; 95%CI [1.272-3.267], p=0.004). No significantly results were obtained in relation to the GSTT1 polymorphism. The conjugation of GSTM1/T1 non-null genotypes in the same individual does not increase the risk for alcoholism. Although, the GSTM1 non null genotype appears to be a susceptibility factor to alcoholism, only patients classified as Type III and IV according to Lesch's Typology show higher risk for alcohol dependence. This study is the first report about the GSTM1 polymorphism as a risk factor for alcoholism. Our results pointed to significantly differences in ethanol-preferring phenotype, as a human psychopathological state, and GST M1 polymorphism as a susceptibility gene for alcohol consumption, which probably indicated that this enzyme may increase tolerance to some alcohol metabolites involved in different biochemical pathways potentially linked to the risk for some additive behaviours.

P09.009
A sequence variation in the promoter of the placental alkaline phosphatase gene (ALPP) is associated with allele-specific expression in human term placenta.

***L. BELLAZI**[1], S. Germond[1], C. Dupont[1], I. Brun-Heath[1], A. Taillandier[2], P. De Mazancourt[1], M. N. Dieudonné[1], E. Mornet[1,2];*
[1]Unité de pathologie cellulaire et génétique UPRES-EA2493, Université de Versailles Saint Quentin, Poissy, France, [2]Laboratoire SESEP, Centre hospitalier de Versailles, Le Chesnay, France.

Placental alkaline phosphatase (PLAP), encoded by the ALPP gene, is produced by the fetal side of the placenta. This enzyme displays strong genetic variability with three common alleles giving rise to six common electrophoretic phenotypes, and a number of rare variants. Some of these variants were reported to be associated with pathology of pregnancy. We show here that the two most common ALPP allelic variants, *PI*^{1} and *PI*^{2}, differ in mRNA expression level. The differential expression was independent of the parental origin and probably results from linkage disequilibrium with sequence variation rs2014683G>A in the ALPP gene promoter that was shown to have allele-specific binding patterns to placental nuclear proteins. Allele-specific expression in human term placenta may account for association of some variants with pathology.

Polyalanine repeat expansions in NIPA1 are associated with amyotrophic lateral sclerosis

*H. M. Blauw[1], **W. van Rheenen**[1], P. W. J. van Vught[1], M. Koppers[1], F. P. Diekstra[1], E. J. N. Groen[1], M. A. van Es[1], E. A. J. Willemse[1], E. Strengman[2], A. C. Ludolph[3], S. Waibel[3], C. Schulte[4,5], W. Robberecht[6,7,8], P. van Damme[6,7,8], J. H. Veldink[1], L. H. van den Berg[1];*
[1]Department of Neurology, Rudolph Magnus Institute of Neuroscience, University Medical Center Utrecht, Utrecht, Netherlands, [2]Complex Genetics Section, Division of Biomedical Genetics, Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Neurology, University of Ulm, Ulm, Germany, [4]Department for Neurodegenerative Diseases, Hertie Institute for Clinical Brain Research, Tübingen, Germany, [5]German Center for Neurodegenerative Diseases, Tübingen, Germany, [6]Department of Neurology, University Hospital Leuven, Leuven, Belgium, [7]Laboratory of Neurobiology, University of Leuven, Leuven, Belgium, [8]Vesalius Research Center, Flanders Institute for Biotechnology (VIB), Leuven, Belgium.

Introduction: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease, which cause is still unknown. Genetic risk factors are thought to play a major role in its pathogenesis. Recent research has described deletions in NIPA1 increasing susceptibility for

ALS. Mutations in this gene are known to cause hereditary spastic paraparesis. In this study we investage whether missense mutations in NIPA1 and expansions its polyalanine repeat might play a role in ALS as well.

Methods: DNA samples were collected from 2293 ALS patients and 2777 healthy controls, of three different populations (Dutch, Belgian, German). All exons of NIPA1 were sequenced and fragment analysis was performed to determine the polyalanine repeat length. Alleles were grouped according to their length, with short alleles consisting of 13 alanines respectively.

Results: Sequencing reveiled 7 missense mutations in patients and 6 in controls (p = 0.59). In all populations the long repeat occured more frequently in patients, 2.82% compared to 1.80% in controls (OR = 1.63, p = 0.0007). Patients with these long alleles had a worse median survival (HR 1.58, p = 0.0001) and an earlier disease onset (HR 1.39, p = 0.005).

Conclusion: We found that missense mutations in NIPA1 do not play a major role in ALS. Instead, we found that short polyalanine expansions in NIPA1 are associated with ALS. In addition, these expansions are associated with an earlier disease onset and worse prognosis. These results further underscore the role of NIPA1 in ALS pathogenesis.

CHRNA4 rare variants constitute a predisposing factor for sporadic ALS: results of a replication study in an Italian cohort of 682 patients

*M. Zollino[1], **S. Lattante**[1], G. Marangi[1], A. Conte[2], M. Luigetti[2], A. Del Grande[2], A. Chiò[3], M. Corbo[4], G. Mora[5], J. Mandrioli[6], F. Giannini[7], E. Capoluongo[8], A. Bizzarro[2], G. Neri[1], M. Sabatelli[2];*

[1]Institute of Medical Genetics, Università Cattolica del Sacro Cuore, Roma, Italy, [2]Neurological Institute, Università Cattolica del Sacro Cuore, Roma, Italy, [3]Department of Neuroscience, University of Turin, Torino, Italy, [4]NEuroMuscolar Omnicentre (NEMO), Milano, Italy, [5]ALS Center, Salvatore Maugeri Foundation, Milano, Italy, [6]Dipartimento di Neuroscienze, S.Agostino-Estense Hospital and University of Modena, Modena, Italy, [7]Department of Neuroscience, Neurology Section, University of Siena, Siena, Italy, [8]Laboratory of Clinical Molecular Diagnostic, Institute of Biochemistry, and Clinical Biochemistry, Università Cattolica del Sacro Cuore, Roma, Italy.

Amyotrophic Lateral Sclerosis is a fatal neurodegenerative disorder, sporadic (sALS) in 95% of cases. Currently, multiple genetic and environmental factors are considered to contribute to disease liability. We previously observed that rare missense variants within the cytosolic loop of α3,α4,β4 subunits of neuronal nicotinic acetylcholine receptors (nAChRs) were over-represented in a group of 245 sALS patients compared with 450 controls.

Tested functionally in vitro, the observed variants were found to disrupt the receptor properties, leading to the hypothesis that they are a predisposing factor for sALS.

We made a replication study in new independent cohorts of 682 Italian sALS patients and 1300 age- and ethnically-matched controls, respectively. Sequencing analysis of *CHRNA4* gene, encoding for α4 subunit of nAChRs, revealed six heterozygous missense variants and a three-nucleotide insertion in 13 patients (1.9%). Four of the missense variants were detected in six controls, four were present in both groups (but were more numerous in patients), six were detected exclusively in controls. The three-nucleotide insertion has never been detected in controls. Using SIFT and PolyPhen, almost all variants found both in patients and controls or only in controls were predicted to be benign, while 50% of variants found exclusively in patients were predicted to be damaging. Combining present data with those reported previously, a total of 5 variants were detected only in patients but neither in 3500 chromosomes nor in dbSNP nor in 1000Genomes-Project data.

These data confirm our previous results, suggesting a possible role for *CHRNA4* variants as predisposing factor for sALS.

Overlap exists for patients with Amyotrophic Lateral Sclerosis (ALS) and patients with frontotemporal lobar degeneration (FTLD), both clinically and pathologically as well as genetically. About 5-10% of ALS patients are diagnosed with FTLD, while FTLD patients can develop motor neuron symptoms. Furthermore, TDP-43 inclusions have been found in the majority of ALS patients and in cases of FTLD (FTLD-TDP). Previously, linkage studies in families with both ALS and FTLD have identified a locus on chromosome 9p13-21. We hypothesized that ALS and FTLD may be part of a spectrum of neurodegenerative disease and we sought to identify a common genetic basis for this neurodegenerative disease. We obtained genome-wide SNP genotype data from previously published studies on ALS and FTLD-TDP and performed genome-wide imputation based on the HapMap3r2 reference. After quality control, genome-wide data for ~1.2M SNPs were available for nearly 4,400 ALS patients and over 13,000 controls and for 440 (pathology-proven) FTLD-TDP cases and 1,400 independent unaffected controls. Joint analysis of ALS and FTLD identified SNPs in locus chromosome 9p21.1 and SNP rs12608932 in gene *UNC13A* as shared genetic variants contributing to susceptibility to both neurodegenerative disorders. Using a conservative rank-products analysis, weighing ALS and FTLD sample sizes equally, the associations were found to be consistent. By analyzing a subset of FTLD patients without motor neuron disease signs, we found that individuals with ALS symptoms did not solely drive the signal for both loci. Our study narrows the previously identified shared genetic locus on chromosome 9 and, additionally, implicates *UNC13A* as a shared risk locus further corroborating the role of *UNC13A* in neurodegeneration.

UNC13A modifies susceptibility and survival in amyotrophic lateral sclerosis

*F. P. Diekstra[1], P. W. J. van Vught[1], W. van Rheenen[1], M. A. van Es[1], W. Robberecht[2,3], P. M. Andersen[4], L. H. van den Berg[1], **J. H. Veldink**[1];*

[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Neurology, University Hospital Leuven, University of Leuven, Leuven, Belgium, [3]Laboratory for Neurobiology, Vesalius Research Centre, Flanders Institute for Biotechnology (VIB), Leuven, Belgium, [4]Department of Clinical Neuroscience, Umeå University Hospital, Umeå, Sweden.

A large genome-wide screen in amyotrophic lateral sclerosis (ALS) showed that the common variant rs12608932 in gene UNC13A was associated with disease susceptibility. UNC13A regulates the release of neurotransmitters (including glutamate) by neuronal synaptic vesicles. Two attempts to replicate association with ALS susceptibility in small samples have not been successful. As a discovery cohort, we used genotype data from individuals of Dutch, Belgian or Swedish descent (1767 cases, 1817 controls) who had participated in a previously published genome-wide study of ALS and for whom survival data were available. An independent replication cohort of 450 ALS patients and 524 unaffected controls was recruited from a population-based study of ALS in The Netherlands. Using capillary sequencing we determined rs12608932 genotypes in the replication cohort. We

present an independent replication of association with rs12608932 (odds ratio 1.91, P = 0.01 for a recessive genetic model). Additionally, we show association of the minor allele of rs12608932 with shorter survival of ALS patients (genome-wide cohort: hazard ratio 1.22, P = 0.01; replication cohort: hazard ratio 1.62, P = 0.005 using a recessive model). ANOVA analyses showed that our data was best fitted with a recessive model. In our study we found a higher minor allele frequency in ALS cases compared to previous studies, while the minor allele frequency in controls was comparable. Our study shows the importance of patient selection methods in replicating genetic variants that affect both susceptibility and survival, as these characteristics can vary greatly between population-based and referral-based cohorts.

Functional failure of neuromuscular junctions in transgenic *drosophila melanogaster* with human *APP* overexpression

G. Kislik, *S. Sarantseva;*
Petersburg Institute of Nuclear Physics Russian Academy of Sciences, Gatchina, Russian Federation.

Although abnormal processing of amyloid-β precursor protein (APP) has been implicated in the pathogenic cascade leading to Alzheimer's disease (AD), the normal function of this protein and its role in synaptic dysfunction in AD is poorly understood. At the same time, deficits in synaptic plasticity and cognitive functions were detected in APP knockout or APP knockdown animal models. Moreover, independent evidences indicated that abnormal metabolism of APP (mutant APP or APP overexpression) might contribute to synaptic dysfunction independently from Aβ. We show previously that overexpression of full length human APP but not its truncated forms are sufficient for abnormal expression of synaptic proteins in the *Drosophila melanogaster* brain. To clarify APP function, we expressed wild-type APP and its mutant form *APP-Swedish* in larval motoneurons. We showed that APPs overexpression caused a dramatic functional disruption in the neuromuscular junction (NMJ). The NMJs exhibited abnormal endo/exocytosis that was determined by incorporation of the styryl dye FM2-64. Analysis of mitochondria distribution showed that motor neurons overexpressing *APP (APP-Swedish)* had a significant reduction of functional mitochondria in the presynaptic terminal. We propose that APP regulates synaptic structure and functions and its overexpression leads to synaptic pathology independently from neurotoxic effect of Aβ.

Alzheimer's Disease: Causes, New risk Factors

J. Gharesouran[1], *M. Mohaddes Ardebili*[1], *M. Rezazadeh*[1,2], *T. Yeghaneh*[1];
[1]*Department of Medical Genetics, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Student Research Committee, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.*

We still don't fully understand what causes Alzheimer's disease. What is clear is that Alzheimer's develops as a result of a complex cascade of biological processes that take place over many years inside the brain. But the majority of Alzheimer's cases are late-onset, usually developing after age 65, and this form of the disease shows no obvious inheritance pattern. However, in some families, clusters of cases are seen. The deposition of amyloid in the form of plaques is thought by many scientists to trigger the cascade of events leading to Alzheimer's pathology. Amyloid now is believed to be a critical target for eventual treatment. The best evidence that amyloid causes the disease comes from the genetic studies in which mutations of APP, PS1, PS2 and APOE e4 (the genes so far identified as causing some cases of Alzheimer's) all facilitate amyloid accumulation. Some current research is focused on the association between these two forms of ApoE and Alzheimer's disease. A growing body of research is also helping to identify various candidate genes. Several other genes also appear to influence the development of Alzheimer's disease: inflammatory pathways genes (TNF-α, CCR2, CCR5), calcium homeostasis modulator 1 (CALHM1), neuronal sortilinrelated receptor gene (SORL1). We examined a total of 160 samples prepared from patients diagnosed as being affected by Alzheimer's disease and 163 healthy controls from west northern Iran (Eastern Azerbaijan) for variants of these genes and genotype frequencies were statistically analyzed.

Alzheimer's disease (AD) is the most common form of dementia; it is genetically complex and shows heritability up to 79%. Extended runs of homozygosity (ROHs) have been shown to occur at a high frequency in the human genome and may account for some of the unexplained genetic heritability of AD. Previous studies of ROHs in AD have failed to identify an overall excess burden of ROHs in sporadic late-onset AD cases, but one study did identify a ROH on chromosome 8 which was significantly overrepresented in cases when compared to controls. Using data generated from an AD genome-wide association study (GWAS) we describe here a statistical comparison of ROHs greater than 1Mb in a UK and Ireland series genotyped on the Illumina 610-quad array.

There were 1,955 AD cases, 955 elderly screened controls and 529,205 autosomal markers which were suitable for use in this study. ROHs analyses were performed using PLINK 1.07.

A total of 63,204 ROHs were identified. Burden analysis revealed no significant difference in the number of ROHs per person between cases and controls for ROHs greater than 1 Mb or when the data was stratified by size.

No region was significantly associated with disease after correction for multiple testing. The chromosome 8 region found to be associated with AD in a previous study did not show any association in this dataset.

In summary, ROHs are common in our outbred population, however statistically these ROHs are not a risk factor for late-onset AD in our dataset.

P09.017
Genetics of anal furunculosis in the German Shepherd Dog: Genome-wide association, replication, fine-mapping and comparative genomics.

J. P. Massey[1], *A. D. Short*[1], *X. Ke*[1], *W. Newman*[2], *C. A. Anderson*[3], *W. E. R. Ollier*[1], *L. J. Kennedy*[1];
[1]*Centre for Integrated Genomic Medical Research (CIGMR), The University of Manchester, Manchester, United Kingdom,* [2]*Department of Medical Genetics, The University of Manchester, Manchester, United Kingdom,* [3]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom.*

Anal furunculosis (AF) is characterised by ulceration and fistulation of perianal tissue and particularly affects German Shepherd Dogs (GSD). It has drawn parallels with perianal Crohn's disease in humans. An immune-mediated aetiopathology has been suggested due to a strong MHC association and clinical response to ciclosporin. A Genome-wide association study (22,362 SNPs) was performed on 21 affected and 25 unaffected GSDs. Areas of potential interest were followed-up by genotyping 91 SNPs in a further 54 cases and 110 controls. Three loci were significantly associated after multiple testing had been taken into account. A good candidate gene region on chromosome 34 was discovered, in which there were five protective SNP associations (p = 0.018 - 0.029, OR = 0.391 - 0.466). Additionally, we have identified a region of extended homozygosity (selective sweep) on chromosome 3 associated with this disease. Targeted sequencing of these regions is currently underway. As this canine disease is of comparative interest to human medicine, an analysis was carried out using Crohn's disease patients: 456 with perianal disease and 1197 without perianal complications. We selected 34 regions containing 42 SNPs showing

some association with AF from the follow-up study which could be syntenically mapped to the human genome. When investigating 1Mb regions around these SNPs in the perianal Crohn's disease cohort, there were 25 SNP associations having a raw p value < 0.05, including one upstream of the canine candidate gene (p = 0.023). This suggests a possible common genetic component to both these canine and human conditions.

A long non-coding RNA accounts for Angelman syndrome-like neurodevelopmental disorder

S. Villatoro[1], *M. Banez-Coronel*[1], *L. Armengol*[2], *M. Viñas*[3], *E. Gabau*[3], *M. D. Coll*[4], *M. Guitart*[3], *X. Estivill*[1];
[1]*Center for Genomic Regulation (CRG), Barcelona, Catalonia, Spain,* [2]*qGenomics SL, Barcelona, Catalonia, Spain,* [3]*Corporacio Sanitaria Parc Tauli, Sabadell, Catalonia, Spain,* [4]*Universitat Autonoma de Barcelona, Bellaterra, Catalonia, Spain.*

Angelman syndrome (AS) is a neurodevelopmental disorder characterized by severe mental retardation and autistic-like features. AS is due to lack of UBE3A gene expression, but in 15% of the cases the molecular cause still remains unknown. Long non-coding RNAs (lncRNA) constitute a large portion of the human transcriptome, which regulates gene expression by different mechanisms, including splicing, translational repression and epigenetic regulation. The spatial and temporal expression of lncRNA appears to be extremely important for the development and function of the central nervous system. Our study is focused on an AS-like patient with an unusual combination of a deletion that involves lncRNA AK097590 inherited from one parent, and a rare SNP within AK097590 inherited from the other parent. Besides, this SNP leads to a change in the predicted secondary structure of AK097590 that may affect its normal function. We have performed AK097590 knock down experiments in differentiated human neuroblastoma cells. qPCR assays have demonstrated that a decrease of AK097590 levels is sufficient to modify the expression of UBE3A, PRKCG and PPP2R1A. Interestingly, these genes have a role in synaptic plasticity and long-term depression, which are reduced in AS murine models. Our results suggest that changes in the expression levels of AK097590 may contribute to the clinical features associated to AS, offering a novel molecular basis for the cases non associated with mutations in UBE3A. A better understanding of the regulatory mechanism of AK097590 lncRNA and its target genes may help in the development of therapeutic strategies for these neurodevelopmental disorders.

TNFalpha gene polymorphisms in Romanian HLA-B27-positive patients with ankylosing spondylitis

O. Popa[1], *M. Bojinca*[1], *V. Bojinca*[1], *M. Dutescu*[2], *M. Milicescu*[1], *R. Caisan*[2], *M. Meirosu*[3], *R. Sfrent-Cornateanu*[1], *C. Bara*[1], *L. Popa*[4];
[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania,* [2]*National Hematology Institute Prof. Dr. C.T. Nicolau, Bucharest, Romania,* [3]*ICA Research and Development, Bucharest, Romania,* [4]*Grigore Antipa National Museum of Natural History, Bucharest, Romania.*

Background: Ankylosing spondylitis (AS), the prototypic seronegative spondyloarthritis is a chronic inflammatory condition of the spine and sacroiliac joints. HLA-B27 is a genetic marker for AS. Moreover, elucidating the role of tumor necrosis factor alpha (TNFalpha) in AS has important diagnostic and therapeutic significance, given the good results obtained with anti-TNF therapy in these patients.
Objectives: The aim of this study was to investigate three TNFalpha gene single nucleotide polymorphisms (SNPs) in HLA-B27-positive ankylosing spondylitis patients from Romania.
Methods: 112 Romanian unrelated AS patients (97M/15F) and 76 (40M/36F) ethnically match healthy controls were genotyped for TNF-alpha -308G/A, -238G/A and -857C/T polymorphisms using TaqMan SNP Genotyping Assays C-7514879-10, C-2215707-10 and C- 11918223-10 (Applied Biosystems, USA). All subjects were HLA-B27 positives. Association tests for each polymorphism and for the estimated haplotypes were performed with the software package PLINK v 1.07.
Results: The minor allele TNF-857T was more frequent in AS patients (24%) than in controls (19%), but not statistically significant (p=0.2). None of the three SNPs were individually associated with susceptibility to AS in HLA-B27-positive patients.
Two haplotypes showed a negative association with the disease: 308G238A (p=0.04) and 857T238A (p=0.005).
Conclusion: These data indicate that haplotypic variations in the TNFalpha gene influence disease susceptibility in HLA-B27 positive individuals in our population. The protective effect of these haplotypes could be related to differences in TNFalpha production or could reflect the association of different HLA-B27 haplotypes with ankylosing spondylitis.

P09.020

Replication study of genome-wide discovered loci associated with anti-tumour necrosis factor treatment outcome in patients with rheumatoid arthritis. Results from the DREAM registry.

M. Umicevic Mirkov[1], *H. Scheffer*[1], *T. R. D. J. Radstake*[2], *A. Lee*[3], *P. M. Houtman*[4], *H. L. M. Brus*[5], *C. M. de Gendt*[6], *M. A. F. J. van de Laar*[7], *P. K. Gregersen*[3], *P. L. C. M. van Riel*[2], *B. Franke*[1], *M. J. H. Coenen*[1];
[1]*Department of Human Genetics Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Department of Rheumatology Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*The Feinstein Institute for Medical Research, Manhasset, NY, United States,* [4]*Department of Rheumatology Medical Centre Leeuwarden, Leeuwarden, Netherlands,* [5]*Department of Rheumatology Twee Steden Hospital, Tilburg, Netherlands,* [6]*Department of Rheumatology Rijnstate Hospital, Arnhem, Netherlands,* [7]*Department of Rheumatology University Twente & Medisch Spectrum Twente, Enschede, Netherlands.*

Agents blocking tumour necrosis factor (anti-TNF) are widely used for the treatment of rheumatoid arthritis (RA). Unfortunately, ~30% of the patients do not respond to this treatment. Although there is some indication that genetic variants may influence the response to anti-TNF none of these variants can reliably predict treatment outcome. We aimed to replicate findings from three published genome-wide studies. RA patients treated with anti-TNF from the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry were included. Single Nucleotide Polymorphisms (SNPs) located within 50 kb of SNPs previously found associated with anti-TNF outcome were extracted from genome-wide data (Illumina HumanHap550-Duo/Human660W-Quad BeadChips). Single-SNP and gene-based association analysis were performed in PLINK using the percentage disease activity score (DAS28) change at 3 (n=503) and 6 months (n=386) as outcome.
16 of the 24 SNPs included were located near or within the genes *GBP6, LASS6, AKO93144, PON1, MOBKL2B, C9orf72, TEC, PDZD2, EYA4, BC118985* and *PTPRC.* The other SNPs were located in gene-desserts on chromosome 1p22.3, 1q24.1, 4p15.1,11p14.2, 12p12.3 and 20p11.21. Only the single SNP analysis at six months revealed significant findings. Three SNPs, located in *GBP6* (p=0.016), which is regulated by inflammatory cytokines, locus 20p11.21 (p=0.006) and PDZD2 playing a role in insulin secretion related to disease severity in early RA patients (p=0.045), were associated with treatment outcome. All associations lost significance after multiple-testing correction.
Three previously reported loci show suggestive association with anti-TNF response in the Dutch population. Larger datasets are required to determine whether these genetic variants are indeed associated with anti-TNF outcome.

P09.021

Association study between telomere length and Age-Related Hearing Impairment in 3527 Caucasian individuals and 663 Japanese individuals.

S. Bonneux[1], *N. Suzuki*[2], *E. Fransen*[1,3], *S. Usami*[2], *G. Van Camp*[1];
[1]*Department of Medical Genetics, University of Antwerp, Antwerp, Belgium,* [2]*Department of Otorhinolaryngology, Shinshu University School of Medicine, Matsumoto, Japan,* [3]*StatUa Center for Statistics, University of Antwerp, Antwerp, Belgium.*

It has been proposed that individuals with shorter telomere length are more susceptible to age-related disorders. In somatic cells, telomere length declines with age contributing to loss of cells with age when telomeres reach a critical minimal length. Average telomere length was shown to be a heritable trait (Slagboom et al., 1994).
Age-Related Hearing Impairment (ARHI) is the most common sensory disorder and the most important cause of hearing loss in the elderly, with a negative impact on the quality of life. It is a complex disease influenced by genetic as well as environmental factors. Here we test

whether a shorter average telomere length leads to increase of ARHI susceptibility. In 3527 European and 663 Japanese individuals, we determined the telomere length in white blood cells using a monochrome multiplex quantitative PCR protocol (described by Cawthon, 2009). We performed association testing between the telomere length and the 3 Principal Components of the ARHI phenotype (Huyghe et al., 2008). In addition, we tested this association adjusting for environmental factors that were previously implicated in telomere shortening. The most important of these factors include smoking and BMI.

Slagboom et al. (1994), Am J Hum Genet. 55:876-882.
Cawthon (2009), Nucleic Acids Rev. 37:e21.

P09.022

Association analysis of *Dysbindin* polymorphisms P1635 and P1655 with Schizophrenia

F. Alizadeh[1], *M. Ghadiri*[2], *M. S. Yekani Nejad*[3], *N. Jalilian*[1], *M. R. Noori-Daloii*[1];
[1]*Departmetn of Medical Genetics,School of Medicine,Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Iran Psychiatric Hospital, Tehran, Islamic Republic of Iran,* [3]*Tehran Univ. of Medical Sciences,Department of Biostatics, Tehran, Islamic Republic of Iran.*

Schizophrenia is a severe psychiatric disorder that has a lifetime prevalence of ~1% in most of the population studied. Similar to many common complex disorders, schizophrenia is a multifactorial disorder that is characterized by the contribution of multiple susceptibility genes that could act in conjunction with epigenetic processes and environmental factors. There is quite impressive evidence supporting the association between genetic variants in dysbindin and schizophrenia in populations. In the present study, we investigated the association between polymorphisms P1635 and P1655 in dysbindin gene with schizophrenia. Subjects were 115 unrelated patients with schizophrenia and 117 unrelated healthy volunteers. Genome-DNA was extracted from blood sample by using the standard salting out method. Genotyping was done with the PCR-RFLP method. The allele and genotype association were analyzed with χ^2 test. As the result, no significant difference was observed between patients and controls in allelic frequencies or genotypic distributions of the P1635 SNP (p=0.809), but we could find a significant difference between case and controls for the P1655 SNP (p=0.009). **).** Also we could find a significant association in A-C haplotype in patient with SCZ (p=0.004, OR= 1.7) and a protective effect in A-G haplotype (p= 0.003, OR=0.57). The present study may provide further support for an association between P1655 SNP and schizophrenia in Iranian populations. Studies with more markers and subjects for various populations will be necessary to understand the genetic contribution of Dysbindin gene for the development of schizophrenia.

P09.023

Association analysis of polymorphisms in selected genes in Slovenian children with asthma

P. Perin[1,2], *U. Potočnik*[1,2];
[1]*Faculty of chemistry and chemical engineering, University of Maribor, Maribor, Slovenia,* [2]*Medical faculty, University of Maribor, Maribor, Slovenia.*

Many candidate genes initially associated with asthma or asthma phenotypes were not confirmed as asthma genes in the follow up independent studies in different populations. In the most association studies candidate genes were compared between controls and all asthma patients in one group. The aim of our study was the association analysis of selected genes in Slovenian asthmatic children. We analyzed candidate genes in all asthmatics and separately in the group of atopic asthmatics and the group of non-atopic asthmatics. In addition, we have analyzed the correlation among selected polymorphisms, clinical parameters and response to therapy with glucocorticoids. Using bioinformatics tools nine single nucleotide polymorphisms (SNPs) in nine different candidate genes were selected. We have genotyped 304 children with asthma and 195 healthy controls. We have performed genotyping by polymerase chain reaction (PCR) and by the restriction fragment length polymorphism (RFLP) analysis. We have found significant association of genes CCR5, IL13 and RANTES and asthma. Our study was the first that associated IL12B and IL13 gene with a nitrogen in the exhaled air of asthmatic patients. In addition we were the first ones who associated IL13 and ORMDL3 with response to asthma therapy with glucocorticoids in the group of atopic asthmatics. Our results contribute to our understanding of the asthma pathogenesis. Identification of polymorphisms associated with asthma phenotypes and response to therapy may lead custom tailored and better management of asthma patients.

Assessing the reproducibility of eight asthma candidate gene associations in the Spanish population

M. Pino-Yanes[1,2], *T. Carrillo*[3], *A. Sanchez-Palacios*[4], *J. Villar*[5,2,6], *R. Gonzalez*[7], *I. Sanchez-Machin*[7], *J. Figueroa*[4], *J. Cumplido*[3], *M. Torres-Galvan*[8], *A. Corrales*[1,2], *O. Acosta Fernandez*[9], *J. Garcia-Robaina*[7], ***C. Flores***[1,2];
[1]*Research Unit, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain,* [2]*CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain,* [3]*Allergy Unit, Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria, Spain,* [4]*Allergy Unit, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain,* [5]*Multidisciplinary Organ Dysfunction Evaluation Research Network (MODERN), Research Unit, Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria, Spain,* [6]*Keenan Research Center, St. Michael´s Hospital, Toronto, ON, Canada,* [7]*Allergy Unit, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain,* [8]*Research Unit, Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria, Spain,* [9]*Neumology Unit, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain.*

Before the advent of genome-wide association studies (GWAS), a massive number of independent candidate genes studies suggested that SNPs from *ADAM33, ADRB2, CD14, MS4A2* (alias *FCER1B*), *IL13, IL4, IL4R,* and *LTA-TNF* genes were among the most replicated associations with asthma. To date, except for the *IL13-IL4* region, none of these genes was found in close proximity of GWAS hits in asthma or related traits. Among studies with Spanish samples, most have comprised direct associations of 1-2 SNPs/gene and limited case numbers. To test the credibility of associations of these eight candidate genes with asthma, we systematically evaluated previously associated SNPs as well as tagging SNPs (average r^2=0.96) in a large study sample of 606 asthmatic cases from the Genetics Of Asthma (GOA) study and 1259 population-based controls. After population stratification adjustments based on 83 additional SNPs, we found nominal significant associations with asthma for 14 SNPs in 4 genes (*IL4R*, *ADAM33, MS4A2,* and *LTA-TNF;* 0.004≤p-value≤0.047), including some of the previously associated SNPs (*MS4A2*: Gly237Glu; *IL4R*: Gln551Arg, Cys406Arg and Ser478Pro; *LTA-TNF*: -857C/T and -753G/A). Despite no associations would remain significant after adjusting for the multiple comparisons performed, these findings suggest that *IL4R*, *ADAM33, MS4A2,* and *LTA-TNF* genes should be more exhaustively analyzed for putative causal variants.

This work was supported by FUNCIS 23/07, and EMER07/001 and PI081383 from Spanish Ministry Fund for Health (Instituto de Salud Carlos III, Spain).

The association between 17q12-21 SNPs and asthma in the Volga-Ural region of Russia.

A. S. Karunas[1], *B. B. Yunusbayev*[1], *Y. Y. Fedorova*[1], *N. N. Ramazanova*[2], *S. Z. Zagidullin*[2], *E. I. Etkina*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation.*

Asthma is one of the most common multifactor diseases, in which many cells and cellular elements play a role. The first GWAS for asthma discovered a significant association between 17q12-21 SNPs and childhood asthma in Europeans. Consistently, its results have been successfully replicated in independent populations of European and Asian ancestries. The aim of our investigation was to identify asthma susceptibility genes in the Volga-Ural region of Russia. The study included 358 unrelated patients with physician-diagnosed asthma and 369 disease-free control subjects of different ethnic origin (Russians, Tatars and Bashkirs). The genotyping was carried out using the Illumina Human610 quad array at the CNG (France) as a part of GABRIEL (A Multidisciplinary Study to Identify the Genetic and Environmental Causes of Asthma in the European Community). Statistical tests for association were carried out using PLINK 1.06 software package. In order to control for population stratification, we performed Eigenstrat analysis for cases and controls, removing outliers. After QC filters,

550915 SNPs genotyped in 330 cases and 348 controls were used for testing the association of SNPs to asthma. Some markers on chromosome 17q12-21 within the ORMDL3/GSDMB locus showed the most statistically significant association in this study ($p \leq 5x10^{-7}$). The maximum association was at the SNP rs7216389 within 1 intron of the GSDMB gene ($p=1.013x10^{-7}$). In summary, we have found the association asthma in the Volga-Ural region of Russia with SNPs at the previously reported ORMDL3/GSDMB locus on 17q12-21. Supported by a contract from the EC (018996).

Genotyping of *ATG16L1* rs2241879 and IL23R rs1004819 polymorphisms among Polish patients with Crohn's disease and localization of symptoms in gastrointestinal tract

L. Jakubowska-Burek[1], *J. Hoppe-Golebiewska*[2], *S. Hryhorowicz*[3], *M. Kaczmarek-Rys*[2], *M. Kucharski*[1], *K. Linke*[1], *R. Slomski*[4], *A. Dobrowolska-Zachwieja*[1];

[1]*Department of Gastroenterology, Human Nutrition and Internal Diseases, Poznan, Poland,* [2]*Institute of Human Genetics Polish Academy of Science, Poznan, Poland,* [3]*The NanoBioMedical Centre, Adam Mickiewicz University in Poznan, Poznan, Poland,* [4]*Institute of Human Genetics Polish Academy of Science, Department of Biochemistry and Biotechnology University of Natural Sciences in Poznan, Poznan, Poland.*

Introduction: Crohn's disease (CD), next to ulcerative colitis (UC), belongs to Inflammatory Bowel Diseases (IBD). Genes *ATG16L1* and *IL23R* may predispose for the development of the disease.

Aim: of the research was the analysis of polymorphisms: *ATG16L1* rs2241879 and IL23R rs1004819 among Polish CD patients. We also wanted to find out if any of these two polymorphisms is related to localization of GIT symptoms.

Materials and methods: 96 Polish patients with CD and 96 individuals from population group were qualified for research. Method used for genotyping was pyrosequencing. Statistical analysis was performed.

Results: Analysis of ATGrs2241879 revealed that the most frequent was GA genotype (55,7% among CD patients, 48,7% in population group), next AA (27,1% and 31,2%, respectively) and GG (17,1% and 20,1%). Analysis of IL23Rrs 1004819 revealed that TC genotyope was the most frequent among CD patients - 51,1% (35,4% in population group), while in population group the most frequent was CC genotype (48,7%, and 44,7% among CD patients). TT genotype was observed in 4,3% of CD patients and 15,9% of population group. Alleles analysis didn't reveal any statisticaly significant differences in frequency of genotypes and alleles. Statistical analysis revealed that the most frequent genotype in ATGrs2241879 among patients with intestinal manifestation of the disease was GA, while in IL23R rs1004819 it was TT genotype($p=0.005$).

Conclusions: Although we did not find any statistically significant differences in genotypes frequency among CD patients and population group, we observed some tendencies related to intestinal localization of symptoms and specific genotypes.

No increased risk for atherosclerosis in migraine patients from the ERF study

C. M. Weller[1], *A. H. Stam*[2], *A. J. W. Janssens*[3], *B. de Vries*[4], *Y. S. Aulchenko*[5], *B. A. Oostra*[5], *R. R. Frants*[1], *A. M. J. M. van den Maagdenberg*[1,6], *M. D. Ferrari*[6], *C. M. van Duijn*[5], *G. M. Terwindt*[6];

[1]*Department of Human Genetics, Leiden University Medical Centre, Leiden, Netherlands,* [2]*Department of Neurology, Leiden University Medical Centre, Leiden, Leiden, Netherlands,* [3]*Department of Epidemiology, Erasmus University Medical Centre, Rotterdam, Netherlands,* [4]*Department of Human Genetics, Leiden University Medical Centre, Leiden, Leiden, Netherlands,* [5]*Genetic Epidemiology Unit, Departments of Epidemiology and Clinical Genetics, Erasmus University Medical Centre, Rotterdam, Netherlands,* [6]*Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands.*

Background and Aim: Migraine, in particular migraine with aura, is associated with an increased risk of ischemic stroke and coronary heart disease. It is unknown whether this is mediated by an unfavorable cardiovascular risk profile and associated atherosclerosis. Therefore, we investigated functional, structural, and genetic markers of atherosclerosis and cardiovascular disease in migraine patients.

Methods: Subjects were participants of the Erasmus Rucphen Family (ERF) genetic isolate study, in which confounding is reduced because of the relatively homogenous genetic and environmental background of subjects. Atherosclerosis was assessed in 360 migraineurs (209 had migraine without aura and 151 had migraine with aura) and 617 subjects without migraine or severe headache. Atherosclerosis was quantified by Intima Media Thickness (IMT), Pulse Wave Velocity (PWV) and Ankle-Brachial Index (ABI). A large number of putative cardiovascular risk parameters and the Framingham risk scores for coronary heart disease (CHD-score) and stroke (stroke-score) were evaluated and gene-based p-values were calculated for two genes implicated in cardiovascular disease (*MTHFR* and *ACE*).

Results: No difference was found in carotid IMT, mean PWV, or ABI between migraine patients and controls. Migraine patients had no increased odds of having an elevated CHD-score or elevated stroke-score (>10%). No association with *MTHFR* or *ACE* was found.

Conclusions: Migraineurs do not have increased risk for central or peripheral atherosclerosis. Our data suggest that traditional cardiovascular risk factors and atherosclerosis are an unlikely explanation for the previously observed association between migraine and cardiovascular disease.

P09.028

Common genetic variants in *ITGA2*, *IL1B*, *ALOX5AP*, *OR13G1*, *MMP9* genes that participate in oxidative stress and influence atherosclerosis phenotype formation

I. Pepalytė[1], *K. Grigalionienė*[1], *Ž. Petrulionienė*[2,3], *L. Bagdonaitė*[4], *Z. A. Kučinskienė*[4], *V. Kučinskas*[1];

[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Clinic Of Cardiovascular Diseases, Faculty Of Medicine, Vilnius University, Vilnius, Lithuania,* [3]*Centre Of Cardiology And Angiology, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania,* [4]*Department of Physiology, Biochemistry and Laboratory Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

Atherosclerosis is complex multifactorial disorder where both genetic and environmental factors play an essential role in the etiopathogenesis of the disease. Formation and further progression of atherosclerosis is based on the intricate biological pathways. Our previous study (Linkoping-Vilnius coronary disease risk assessment study) showed the higher mortality from coronary heart disease (CHD) of Lithuanian men in comparison with Swedish men. Subsequent observations revealed that Lithuanian men had some differences in atherosclerosis phenotype, which may be influenced by complementary factors. It appears that one of these factors could be the oxidative stress. Thus the goal of this study was to evaluate the mainstream biological pathways inducing and maintaining the atherosclerotic process by analyzing genetic biomarkers particularly in inflammatory, metabolic pathways where the main focus is laid on oxidation process. After bioinformatic analysis (Medline data mining) there were 150 SNPs in 89 genes selected for the construction of microarray based on the APEX technology (Asper Biotech, Estonia). Genotyping was carried out in 23 families and the TDT, S-TDT as well as combined analysis were performed. The following SNPs associated with atherosclerosis phenotype were identified: rs1126643, rs1143627, rs9551963, rs1151640, rs3918242 in the candidate genes *ITGA2*, *IL1B*, *ALOX5AP*, *OR13G1*, *MMP9* respectively. These genes belong to different biological pathways: trombocyte adhesion and vessel damage (*ITGA2*, *MMP9*), inflammation response (*IL1B*), cholesterol and lypoxygenase metabolic pathway (*ALOX5AP*) and nutrition (*OR13G1*). Generalized biochemical, bioinformatical and candidate genes' association results seem to support hypothesis that oxidation process may be of key importance in atherosclerosis formation.

P09.029

A comparative analysis of SNPs of ADRB1 gene in children with a bronchial asthma and in healthy children

E. A. Isupova, *M. B. Zdanova, A. N. Voitovich, G. N. Novik, V. I. Larionova; Saint-Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.*

Background: The majority of undesirable effects associated with regular use of β2-agonists in patients with the atopic bronchial asthma (BA) are connected with their action on β1-adrenoretseptor. In modern pharmacogenetics, studies on SNPs of human β1-adrenoretseptor gene (ADRB1) become topical.

Study groups: The study group included 272 children with BA (47 girls

and 225 boys) aged from 4 to 17 years old. The control group included 134 healthy children (64 girls and 70 boys) aged from 6 to 17 years old.
Methods: The genetic polymorphism of ADRB1 gene was identified by PCR-RFLP standard method.
Results: The distributions of genotypes and alleles of the SNPs in the ADRB1 gene were not significantly different between studied groups. However, we have found a significant difference between patients with various variants of BA. The patients with mild asthma had a combination of genotypes S49G/G389G [4,5% vs 0,0%] and G49G/R389R [4,5% vs 1,9%] more frequently compared to those suffered from severe asthma in whom S49S/G389G [6,7% vs 3,0%] and S49G/R389R [20,0% vs 9,1%] prevailed (p<0,05).
Conclusion: These results suggest that polymorphisms of the ADRB1 gene might play a role in severity of asthma manifestation, and that ADRB1 polymorphisms is not associated with BA in Russian population.

Canine Atopic Dermatitis (CAD) is a genetically predisposed inflammatory and pruritic allergic skin disease with characteristic clinical features. It is most commonly associated with IgE antibodies directed towards environmental allergens, often house dust mites. Onset of clinical signs is usually between 6 months and 3 years of age. Initial signs can be seasonal or non-seasonal depending on allergens involved. In a similar pattern as in human atopic dermatitis typically face, ears, paws, extremities, ventrum and flex-zones are affected. The diagnosis is based on clinical signs and exclusion of differential diagnoses, such as flea allergy dermatitis, cutaneous adverse food reactions, scabies or other pruritic ectoparasites, pruritic bacterial folliculitis and *Malassezia* dermatitis. A positive allergen-specific IgE test (serology or intradermal test) aids in defining offending allergens. Some breeds have markedly higher prevalence of CAD compared to others. German shepherds have an exceptionally high susceptibility to many immune-related diseases, including CAD.
We have performed a genome-wide association study of 91 German shepherd CAD cases and 93 controls using the Illumina ~170 K canine SNP array. In addition, IgA levels were measured in serum from the same German shepherd dogs.. In concordance with other studies, the German shepherds showed lower IgA levels compared to other breeds. Further, the IgA levels were significantly lower in German shepherd CAD cases compared to controls (p=0.000008). Thus, IgA levels were included as a covariate in genome-wide association analysis using GenABEL. Four regions with clear association are currently being investigated further in both canine and human cases and controls.

Association analysis of cytokine gene polymorphisms and atopic dermatitis in Volga-Ural region of Russia.

G. F. Gimalova[1], *A. S. Karunas*[1], *Y. Y. Fedorova*[1], *E. R. Gumennaya*[2], *S. V. Levashova*[3], *A. R. Biktasheva*[3], *E. I. Etkina*[3], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Dermatovenerologic dispensary of Bashkortostan Republic, Ufa, Russian Federation,* [3]*Bashkir Medical State University, Ufa, Russian Federation.*

Atopic dermatitis (AD) is a chronic inflammatory skin disease associated with cutaneous hyperreactivity to environmental triggers and is often the first step in the atopic march. Cytokines play crucial role in all stages of allergy and inflammation development and maintaining. Significant associations between single nucleotide polymorphisms (SNPs) in cytokines and cytokines receptors with AD have been replicated in more than one study. In this study we have screened SNPs in the IL4 (-590C>T), IL4RA (Ile50Val), IL13 (Arg130Gln) and CCL11 (−384A>G) genes in AD patients and control individuals. The AD group consisted of 214 AD patients with different ethnic origins (88 Russians, 44 Tatars and 82 individuals of mixed origins). The control group included 200 non-atopic individuals (55 Russians, 49 Tatars and 84 individuals of mixed origins). Genomic DNA was isolated by phenol-chloroform extraction. The genotyping of SNPs was performed by PCR-RFLP.
Significant differences between AD patients and control individuals of Tatar ethnic origin were found in the allelic frequencies for the Ile50Val polymorphism of the IL4R gene. The frequency of the allele Val in AD patients was significantly higher than in control group - 0.466 versus 0.327, respectively ($\chi 2=3.78$, p=0.05). The estimated odds ratio for the allele Val at this SNP was 1,8 (CI95% 0,99-3,26), for the allele Ile - 0.56 (95%CI 0.31-1.0). The analysis of -590C>T polymorphism of the IL4 gene, Arg130Gln polymorphism of the IL13 gene and −384A>G polymorphism of the CCL11 gene has detected that there are no significant differences between AD patients and healthy donors.

P09.032***
Association of the ciliary gene *AHI1* with autism

H. Y. Kroes, *S. Kevelam, R. van 't Slot, C. G. De Kovel, M. Poot;*
Dept. of Medical Genetics, Utrecht, Netherlands.

Joubert syndrome (JBTS) is an autosomaal recessive disorder characterized by hypoplasia of the cerebellar vermis, the characteristic neuroradiologic 'molar tooth sign,' and neurologic symptoms, including dysregulation of breathing and developmental delay. JBTS also includes variable features such as retinal dystrophy and renal anomalies. Up to 27% of JBTS patients show features of autism. Thus far, 10 genes for JBTS have been identified. The ciliary gene *AHI1* has been found mutated in 7 to 16% of cases with JBTS. On the other hand, of the 39 genes associated with autism, 29 (74%) encode ciliary genes. This association of ciliary genes with autism is highly significant ($P < 0.001$; two sided Fischer exact test). Therefore, we tested the hypothesis that ciliary genes may be involved in autism, by performing a candidate-gene association study with a cohort of 84 patients with autism vs. 145 healthy controls for the 10 known JBTS genes (*AHI1, NPHP1, CEP290, ARL13B, RPGRIP1L, MKS3, CC2D2A, OFD1, TMEM216,* and *INPP5E*). For *AHI1* we found nominal association with odds ratio's from 3.077 to 9.174 and p values for association < 0.0001 for SNPs rs12179084, rs2327587 and rs7766656. Our data suggest that dysfunction of primary cilia may constitute an important neuropathological pathway in autism.

P09.033
aCGH analysis of two families showing both autism and epilepsy

R. Combi[1], *S. Redaelli*[2], *V. Sansoni*[1], *C. M. Cornaggia*[3], *L. Dalprà*[2];
[1]*Dept of Biotechnology and Biosciences, University of Milano-Bicocca, Milano, Italy,* [2]*Dept of Neurosciences and Biomedical Technologies, University of Milano-Bicocca, Monza, Italy,* [3]*Clinical Psychiatry, University of Milano-Bicocca, Monza, Italy.*

Autism is a genetic disorder, with an estimated heritability greater than 90%. Over the past years, the convergence of genomic technologies has led to the identification of several susceptibility loci by means of linkage studies. Autism is associated with epilepsy in early childhood and epilepsy occurs in 10-30% of autism patients.
We analysed two families showing both autism and epilepsy. The first one is the family of a woman, showing a severe and progressive epileptic disorder, who is married with an healthy man and has six children: two girls are healthy, a girl and two boys are affected by autism, while a boy showed partial seizures only twice. The three children with autism show a moderate mental retardation and an EEG with no epileptic alterations. The second family is composed by an epileptic woman married with a healthy man and their child affected by autism.The genetic basis of autism and epilepsy were studied in these families. In particular, we performed an array-CGH analysis to search for pathological CNVs which are common to all affected members of the two families.
The study detected a single common region on chromosome 15q11.2, which has already been reported to be either deleted or duplicated in about 1% of epileptic patients. Moreover, the same region was associated with ASDs (autism spectrum disorders). We found a loss of 15q11.2 in all individuals belonging to the first family, while a gain of the region in the two affected members of the second family.

P09.034

Prevalence of fragile X syndrome in non-syndromic autistic children in western saudi arabia

M. M. Alwasiyah[1], *C. Trujillo*[2];
[1]*Aziziah Maternity & Children Hospital, Jeddah, Saudi Arabia,* [2]*Dr Erfan & Bagedo Hospital, Jeddah, Saudi Arabia.*

Prevalence of Fragile X Syndrome (FXS) in the general population is around 1 in 1000 males and 1 in 2500 females. It is widely reported in the literature that FXS in the autistic populati5%, and that 30% of the FXS cases have full Autism. Among the remaining patients with FXS, of those who do not meet the criteria for an autism spectrum disorder (ASD) diagnosis, the majority have one or more autistic features, such as hand flapping, poor eye contact and tactile defensiveness. Also it is reported that FXS is the most common single gene cause of autism, responsible for 2% to 6% of all cases of autism.

We studied 41 patients with non-syndromic Autism in Western Saudi Arabia, we determined the trinucleotide repeat number (TRN) of CGG in 5' end for the untranslated region of the gene FMR1 using PCR technique as described by Chong et al, (AJMG 51:522-526, 1994).

After performing gel electrophoresis for the PCR products using 2% agarose gel, the results analysis demonstrated that all samples have a CGG trinucleotide repeat number less than 50 repeats.

In conclusion even though our sample number is small, with the percentage reported FMR1 gene mutation seems to not play a major role in the etiology of Autism in Western Saudi Arabia. There is a much lower prevalence of FXS. We may attribute this to a larger role of recessive causes, especially if considering parental consanguinity, though there may be other reasons as well.

P09.035

Characterisation of putative autism susceptibility genes: Translating genome wide analysis to causation

G. Kenny, *R. Anney;*
Trinity College Dublin, Dublin 8, Ireland.

Introduction

Genomewide Association studies (GWAS) have been used to identify genetic markers which have strong statistical association with a disease. Establishing a functional consequence of association is required to determine a causal link between marker and disease. In a recent GWA of autism we identified a strong association within the gene MACROD2 (1). Very little is known about the function of MACROD2. This project is structured to examine the biological role of MACROD2, with the hypothesis that disruption of MACROD2 will impact on the structure and/or function of the neuron.

Results

MACROD2 is expressed almost ubiquitously across human tissues, including brain, kidney, placenta, skeletal muscle, testis and thyroid gland. Promoter mapping constructs were examined in SHSY5Y neuroblastoma cell lines. We observed differential expression of the various promoter lengths. From this preliminary data it would appear that the promoter region of MACROD2 lies ~500bp upstream from exon 1.

Discussion

GWA offer potential insight into the biology of disease. The biological characterisation of observed candidate genes must follow GWA to best take advantage of these data.

This preliminary work is part of a wider comprehensive study of MACROD2 which will include both in silico and in vitro techniques.

The authors acknowledge grant support from the HRB.

Large-scale genetic pathway analysis of copy number variants highlights important rare genetic causes and gene networks for autism spectrum disorders

D. Hadley[1], *J. Glessner*[1], *K. Wang*[2], *F. Mentch*[1], *D. Abrams*[1], *C. Kim*[1], *E. Frackelton*[1], *C. Hou*[1], *R. Chiavacci*[1], *J. Connolly*[1], *G. Lyon*[1], *H. Hakonarson*[1];
[1]*The Children's Hospital of Philadelphia, Philadelphia, PA, United States,* [2]*University of Southern California, Los Angeles, CA, United States.*

The ability to quantify individual's genomic risk for disease can facilitate the development of new interventions and improve medical practice. Many rare Copy Number Variants (CNVs) that harbor small genomic deletions and insertions have been described in the autism spectrum disorders (ASD). To identify these likely functional elements, we combined three previously published large cohorts of autistic patients with a large number of controls to analyze over 25K unrelated individuals. After stringent quality control measures, we compared 3K cases to over 19K ethnically matched controls in a two-stage genome-wide association design. In all, we uncovered 275 statistically significant distinct copy number variable regions. The 60 genes nearest these robust CNVRs are most enriched in gene networks impacting neurological disease, behavior and developmental disorder. A more focused analysis of a subset of 87 CNVRs that are predicted to disrupt 26 genes highlights GABA receptor signaling, and methionine/glutathione trans-sulfuration as the most significant canonical pathways disrupted in ASD. Furthermore, we used available family members to characterize CNVRs into inherited vs de-novo and used ethnicity information to characterize their effects in different ethnic populations. Taken together, the CNVRs we have identified impact multiple novel genes and signaling pathways, including genes involved in GABA receptor signaling, that may be important for new personalized therapeutic development.

P09.037

Identification of four mutations affecting normal splicing during the resequencing of X-chromosome synaptic genes in individuals with autism or schizophrenia

A. Piton[1,2], *L. Jouan*[3], *J. Gauthier*[3], *G. A. Rouleau*[3];
[1]*IGBMC, Strasbourg, France,* [2]*CEntre d'Excellence en Neuromique de l'Université de Montréal, Centre de Recherche du Chum, Hôpital Notre-Dame, Montréal, QC, Canada,* [3]*Entre d'Excellence en Neuromique de l'Université de Montréal, Centre de Recherche du Chum, Hôpital Notre-Dame, Montréal, QC, Canada.*

Autism (AUT) and schizophrenia (SCZ) are two common neurodevelopmental disorders, which result from the combination of genetic and environmental factors. To explore the hypothesis that rare highly penetrant mutations in different genes specific to single families are involved in these diseases, we have resequenced X-linked synaptic genes in a cohort of 285 AUT and SCZ individuals and identified truncating mutations in IL1RAPL1 and MAOB genes (Piton A, Mol. Psy., 2010). We wanted to evaluate if, besides these two mutations, some of the rare variants could have such a drastic effect at the protein level by affecting the mRNA splicing. We used an in silico approach (using Human Splicing Finder, Nnsplice, SpliceView, ESEfinder, Rescue ESE) to detect which of the rare variants could create/disrupt an acceptor site, a donor site or an exonic splicing enhancer (ESE). Fourteen variants with the best prediction scores were tested in vitro using a minigene system in the vector SPL3B. We showed that four of these variants (28%), in GABRQ, GABRA3, HDAC6 and NXF5 genes, affect the normal splicing and are predicted to lead to truncated proteins. Our results illustrate the importance of analyzing the effect of mutations at the mRNA level and have led to the identification of new genes associated with AUT. Interestingly, although it has been considered since a long time that impairments in GABA pathways play a role in AUT etiology, it is the first time that truncating mutations in GABA receptors genes are identified in patients.

P09.038

Gene ontology enrichment analysis in two independent family-based samples of over 2100 families highlights biologically plausible processes for autism spectrum disorders

R. J. L. Anney[1], *E. A. Heron*[1], *R. Segurado*[1], *M. Gill*[1], *L. Gallagher*[1], *A. G. P. Consortium*[2];
[1]*Trinity College Dublin, Dublin, Ireland,* [2]*Autism Genome Project, Consortium, United Kingdom.*

There is growing evidence to support the role of rare structural and sequence variation in the aetiology of autism spectrum disorders (ASDs). However, genome-wide association studies (GWAS) of ASDs have yielded only modest evidence to support common variation in the aetiology of disorder. GWAS rely upon statistically robust genome-wide-significant associations to identify genes and loci of risk. There are considerable modest association signals that do not meet stringent genome-wide-significance thresholds. These signals may conceal underlying patterns that are important to understanding the aetiology

of disease. We have developed a robust method, pedSNP-ratio-test (pedSRT) to examine association enrichment in biologically-linked gene-sets for family-based association studies. Using a two-stage approach we explore association enrichment in GWA data from more than 2100 families from the Autism Genome Project. Based on estimates from study-sensitive simulation we identify excess of observed and replicated association enrichment. We highlight enrichment for sets of genes involved in diverse biological processes including pyruvate metabolism, transcription factor activation and cell-signalling. Many of the genes and processes that show enrichment have previously been examined in autistic disorders and offer biologically plausibility to these findings. Moreover, our data supports the hypothesis, that in part, common variation is important in the aetiology of ASDs. This work is presented on behalf of the Autism Genome Project Consortium.

AKAPs integrate genome-wide association findings for autism spectrum disorders into signalling networks regulating steroidogenesis, neurite outgrowth and synaptic function

G. Poelmans[1], *B. Franke*[2], *D. L. Pauls*[3], *J. K. Buitelaar*[1];
[1]*Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Departments of Human Genetics and Psychiatry, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Psychiatric and Neurodevelopmental Genetics Unit, Center for Human Genetic Research, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States.*

Background: Autism spectrum disorders (ASD) are highly heritable. In recent years, several genome-wide association studies (GWAS) of ASD were published.

Methods: We have carried out a bioinformatics analysis using Ingenuity and a systematic literature analysis of 200 genes from five published GWAS that yielded association with ASD through single nucleotide polymorphisms at $P < 0.0001$, and we used the results from a sixth published GWAS to validate our findings. We also searched for overlap between the identified candidate genes and genes located in copy number variations (CNVs) in people with ASD and we identified microRNAs that downregulate gene expression of ASD candidate genes and are deregulated in ASD.

Results: A total of 120 of the 200 ASD candidate genes encode proteins that fit into three signalling networks regulating steroidogenesis, neurite outgrowth and synaptic function, and we were able to place 50 other ASD candidate genes in the identified networks. The proteins encoded by 11 ASD-linked AKAP (A-kinase anchor protein) genes functionally integrate signalling cascades within and between these networks. Lastly, we found that 70 of the 200 ASD candidate genes were found in CNVs in people with ASD and 100 of these genes were downregulated by ASD-implicated microRNAs.

Conclusions

We have identified three signalling networks for ASD that contribute to our understanding of the molecular basis of the disorder and that are functionally integrated by the AKAPs, 'druggable' proteins that need to be further investigated as possible targets for psychopharmacological treatments of ASD.

The dog provides us with a spontaneous mutational model for disease. By exploiting the unique genetic signatures underpinning domestication and breed formation we can use genome-wide association to identify disease genes, which may also have roles in human disease. Autoinflammatory diseases have no known pathogenic or autoimmune cause and are characterised by recurrent episodes of fever and inflammation. Several genes have been implicated in human disease, however the majority of cases remain unexplained. The Shar-Pei breed suffers a similar autoinflammatory disease and has coincidently undergone selection for a distinctive wrinkled skin. Using genome-wide SNP analyses, the strongest signal of a breed-specific selective sweep co-localized with the fever susceptibility locus on chromosome 13. Re-sequencing identified two partially overlapping duplications, which were unique to Shar-Pei and located upstream of Hyaluronic Acid Synthase 2 (HAS2). HAS2 encodes the rate-limiting enzyme synthesizing hyaluronan (HA), a major component of the skin. HAS2 is up-regulated and HA accumulates in the skin of Shar-Pei. A high copy number of the 16.1kb duplication was associated with increased HAS2 expression and disease ($p < 0.0001$). Fragmented HA can act as a trigger of the innate immune system and stimulate sterile fever and inflammation. The strong selection for the skin phenotype appears to enrich for a pleiotropic mutation predisposing these dogs to disease. HAS2 was not previously associated with autoinflammation and preliminary results indicate that this glycosaminoglycan may be involved in human periodic fevers. Further inroads into the significance of this pathway for disease will be discussed.

Genetic and epigenetic alterations in patients with Balkan endemic nephropathy

R. G. Staneva[1], *I. I. Dimova*[1], *P. Dimitrov*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University, Sofia, Bulgaria,* [2]*National Center of Public Health Protection, Sofia, Bulgaria.*

BACKGROUND: Balkan endemic nephropathy (BEN) represents a chronic progressive interstitial nephritis in striking correlation with uroepithelial tumors of the upper urinary tract. The disease has endemic distribution in the Danube river regions in several Balkan countries. The so far conducted investigations of environmental factors as an ethological factor proved to be futile. The family and genetic studies were inconclusive.

Epigenetic changes encompass an array of molecular modifications to both DNA and chromatin. Epigenetic tests can elucidate the intricate pathogenetic mechanisms of BEN and can prove to be the bridge between environmental factors and genetic background in BEN development.

MATERIALS AND METHODS: We've collected blood and tumor samples. We've adopted genome-wide strategy (methylated DNA immunoprecipitation (MeDIP) and whole-genome array analysis. We will perform pool analysis to identify significant methylation status differences by comparing four cohorts: (1) affected by BEN individuals with at least one affected parent; (2) healthy individuals from endemic regions with at least one affected parent; (3) healthy controls form endemic regions with no BEN family history; (4) healthy controls from non-endemic regions.

RESULTS: Our previous experiments showed that in BEN patients the 3q25 band was most frequently involved in chromosomal aberrations. In superficial (pTa) BEN tumor the genome instability was extremely high. Comparative Genomic Hybridization (CGH) showed genetic gains at 1q, 3q, 7p, 7q, 15q, and 19q in BEN tumors analysed.

CONCLUSIONS: The data gleaned from own experiments have disclosed a strong impact of genetic factors to the development of BEN and BEN-associated urothelial tumors.

P09.042
Modifying effect of the *FTO* genetic variant on longitudinal association between adolescent emotional problems and adult body mass index

D. Gaysina[1,2], *R. Hardy*[2];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*MRC Unit for Lifelong Health and Ageing, London, United Kingdom.*

Adolescent emotional problems have a long-tern effect on BMI change and obesity. Variations of *FTO* gene contribute to common forms of human obesity, and to BMI change across the life course. No study has investigated the joint effect of the *FTO* risk variant and emotional problems on BMI change across the life course. We aimed to investigate whether the effect of emotional problems on BMI change through adulthood is modified by the polymorphism of *FTO* gene.

We used data from a British 1946 birth cohort. We analyzed *FTO* rs9939609 (1238 men and 1233 women), which was previously associated with BMI in this cohort, in those with adolescent emotional problems and in those without. We tested for the interaction effect between *FTO* and affective status on BMI at ages 20, 26, 36, 43 and 53 years and on BMI change over a period of 33 years using multilevel models.

We showed that emotional problems were associated with lower BMI at age 20 (p=0.009), 26 (p=0.02) and 36 (p=0.005) years in *FTO* A allele carriers, but not in TT homozygotes. A significant interaction between *FTO* and affective status in relation to BMI was observed at age 20 (p=0.055) and 36 (p=0.008). Among A allele carriers, but not among TT homozygotes, those with adolescent emotional problems had faster rates of BMI increase across adulthood.

The relationship between emotional problems and BMI varies by *FTO* genotype. This finding has implications for predicting which people with emotional problems are at higher risk of weight gain.

P09.043
Genetic variation of glutamate-cysteine ligase modifier subunit and susceptibility to nonallergic bronchial asthma: an evidence for gene-smoking interaction

Y. Kupriyanova, *A. Polonikov, V. Ivanov, M. Solodilova, O. Vasiljeva, N. Kononykhina, V. Antsupov, I. Bulgakova, O. Bushueva, A. Bogomazov, A. Dedkov;*
Kursk State Medical University, Kursk, Russian Federation.

It is recognized that the risk of bronchial asthma (BA) is conveyed by a complex interaction of genetic and environmental factors. The focus of this study was to investigate whether genetic variation of antioxidant defense enzymes (ADE) genes plays a role in the development of BA depending on the exposure to tobacco smoking. A total 429 DNA samples (214 asthmatics and 215 controls) from adult Russian population (Central Russia) were genotyped for polymorphisms of ADE genes: catalase (-262C>T, *CAT*), superoxide dismutase (Ala16Val, *SOD2*) and glutamate cysteine ligase (-588C>T, *GCLM*) genes through PCR-RFLP assays. It has been found that a genotype -588CT was associated with increased risk of nonallergic asthma (odds ratio 2.03 95% CI 1.05-3.90). No associations with BA were found for either the *CAT* or *SOD2* polymorphisms. Association analysis stratified by smoking status has revealed that a genotype -588CT of the *GCLM* gene was significantly associated with increased risk of nonallergic BA only in smokers (odds ratio 3.60 95%CI 1.42-9.10 p=0.01). The finding provides an additional evidence for the trigger role of tobacco smoking in the penetration of susceptibility to asthma determined by genes encoding antioxidant defense enzymes. The study was supported by the Federal Targeted Programme “Scientific and Scientific-Pedagogical Personnel of the Innovative Russia in 2009-2013”.

P09.044
Novel variants of beta-subunits of sodium channel genes in Brugada Syndrome

E. Komurcu-Bayrak[1,2], *K. Endels*[1], *W. Lissens*[1], *S. Seneca*[1], *F. Bayrak*[3], *A. Sarkozy*[3], *P. Brugada*[3], *M. Bonduelle*[1], *S. J. Van Dooren*[1];
[1]*Centre for Medical Genetics, UZ Brussel & Vrije Universiteit Brussel, Brussels, Belgium,* [2]*Department of Genetics, Institute for Experimental Medical Research, Istanbul University, Istanbul, Turkey,* [3]*Heart Rhythm Management Center, UZ Brussel & Vrije Universiteit Brussel, Brussels, Belgium.*

Brugada syndrome (BrS) is a genetic disorder characterized by lethal ventricular fibrillation and right precordial ST segment elevation on ECG. Loss-of-function mutations in SCN5A cause 15-20% of BrS cases. We aimed to investigate whether mutations in the four beta-subunits of sodium channel genes (SCN1B to SCN4B) are associated with abnormal cardiac excitation in BrS.

Direct Sanger sequencing was performed in 16 clinically diagnosed BrS patients, 11 asymptomatic individuals with positive family history for BrS or sudden cardiac death (SCD) and one asymptomatic individual with a positive ajmaline test, none of whom had SCN5A mutations.

Genetic analysis revealed a novel intronic variant and 3 SNPs in SCN1B, two intronic SNPs and one 3’UTR SNP in SCN2B, a novel silent exonic variant and four 5’UTR, one silent exonic and two intronic SNPs in SCN3B, and a novel 5’UTR variant and 2 exonic silent SNPs in SCN4B.

In silico splicing analysis using Alamut (Interactive Biosoftware) predicted that the novel intronic variant in SCN1B and the exonic variant in SCN3B have no impact on splicing. The novel variant in the minimal promoter of SCN4B was detected in an asymptomatic young individual with a family history of SCD and a father clinically diagnosed as BrS. Detection of the variant within the family and control population is ongoing.

In conclusion, these novel variants and polymorphisms in the beta-subunits of sodium channel genes may have a direct or modifier effect on developing BrS, but these results need to be validated by further large scale and functional studies.

P09.045
Testing BST-2/Tetherin gene as candidate host factor involved on HIV-1 susceptibility and progression rate to AIDS

M. Laplana[1], *T. Puig*[2], *A. Caruz*[3], *J. Fibla*[1];
[1]*IRBLleida, University of Lleida, Lleida, Spain,* [2]*IRBLleida, Hospital Universitari Arnau de Vilanova, Lleida, Spain,* [3]*Unidad de Inmunogenética, Universidad de Jaén, Jaén, Spain.*

BST-2/Tetherin/CD317/HM1.24 inhibits HIV-1 release from infected cells by retaining virions on cell surface. HIV-1 Vpu protein counteracts *BST-2/Tetherin* action by sequestering and promoting its degradation. We have tested *BST-2/Tetherin* variants rs3217318 (promoter 20bp-indel) and rs10415893 (3’UTR tagSNP) for association with HIV-1 infection and disease progression. Genotypes were obtained for a cohort of 353 subjects exposed to HIV-1 infection by injection drug use; 185 infected (HIV+) and 171 non-infected (ENI). In addition a cohort of 188 healthy subjects were used as controls. Disease progression of the 185 HIV+ subjects was recorded from the first HIV-1 positive test to December 1999. A first drop on CD4 cell-count <200/!L was considered as outcome for progression. From HIV+ subjects, 75 were progressors and 110 non-progressors. No differences were observed in genotype and allele distribution between HIV+, ENI and controls; nor for rs3217318 neither for rs10415893 (Table-1). However, rs10415893 allele distribution in non-progressors showed statistically significant differences when compared with progressors (P=0.045) and controls (P=0.008). In addition, prevalence of rs10415893-GG homozygotes was higher in non-progressors when compared with both, progressors (P=0.036; OR=0.47; 95%CI:0.2-1) and controls (P=0.005; OR=0.45; 95%CI:0.25-0.79). Finally, mean time to progression for rs10415893-GG was higher than for rs10415893-(GA+AA) subjects (150 *vs.* 120 months; Log-Rank test P=0.031; unadjusted Hazard-Ratio=0.6; 95%CI:0.36-0.96, P=0.033). Our results do not support a role of BST-2/Tetherin in HIV-1 susceptibility but suggest its involvement in progression.

Table 1.- Genotype and allele distribution of *BST-2/Tetherin* polymorphic variants in cohorts

			Prevalence in cohorts (n,%)

Is CADPS2 involved in autism and intellectual disability?

G. Tortora[1], *C. Graziano*[1], *S. Miccoli*[1], *E. Bacchelli*[2], *F. Minopoli*[1], *A. Battaglia*[3], *L. Mazzone*[4], *G. Romeo*[1], *E. Maestrini*[2], *E. Bonora*[1];
[1]*U.O. Genetica Medica, Policlinico S.Orsola-Malpighi, Università di Bologna, Bologna, Italy,* [2]*Dipartimento di Biologia Evoluzionistica Sperimentale, Università di Bologna, Bologna, Italy,* [3]*Stella Maris Istituto Scientifico per la Neuropsichiatria dell'Infanzia e dell'Adolescenza, Calambrone (Pisa), Italy,* [4]*U.O. Neuropsichiatria Infantile, Dipartimento di Pediatria, Università di Catania, Catania, Italy.*

We describe a family where brother and sister show mild intellectual disability, behavior abnormalities and epilepsy, with normal brain imaging and no major dysmorphic features. Karyotype is normal, as well FMR1 analysis in the male patient. Their mother, who died of cancer at 48 years of age, and a maternal aunt are both reported to have behavioral abnormalities, mild intellectual disability, but no seizures. Two maternal uncles are healthy.

In both patients, array-CGH analysis revealed a 250 kb deletion of chromosome 7q31.32 encompassing one single gene, CADPS2. The father does not carry the deletion, indicating likely maternal inheritance. The deletion was excluded in one of the maternal uncles.

CADPS2 is a calcium binding protein that regulates the exocytosis of synaptic and dense-core vesicles in neurons and neuroendocrine cells. CADPS2 is a candidate gene for autistic disorders, since it maps in the autism susceptibility region AUTS1 on chromosome 7q31.32, which alsocorresponds to a candidate region for mood disorders. Knock-out mice show an autistic-like phenotype and some ASD (Autism Spectrum Disorders) patients show a possible defect in CADPS2 splicing. We performed, therefore, a mutation screening in 46 individuals with ASD and in 34 patients with intellectual disability who did not carry any genomic rearrangement as far as array-CGH analysis could detect. Two novel variants were identified in two unrelated ASD individuals, in exon 6 and exon 13 respectively. None of these changes was detected in 140 healthy individuals and functional analysis of these variants is currently ongoing. Detailed results will be presented.

P09.047
Screening of TCF2 and PAX2 genes for mutations associated with congenital anomalies of the kidney and urinary tract in Bulgarian patients

V. Penchev[1], *O. Beltcheva*[1], *A. Boueva*[2], *P. Miteva*[2], *R. Kaneva*[1], *V. Mitev*[1];
[1]*Molecular Medicine Center, Dept. of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria,* [2]*Department of Paediatrics, Medical University – Sofia, Sofia, Bulgaria.*

Congenital anomalies of the kidney and urinary tract (CAKUT) affect 1 in 500 children worldwide and are a leading cause of childhood end-stage renal disease. The two most common CAKUT diagnoses are the renal dysplasia and hypoplasia. The genetic background of these anomalies is still largely unknown. Several genes involved in urinary tract development have been implicated - HNF1b, PAX2, SIX2, etc. The molecular defects identified so far do not account for all the cases and cannot explain the great variability of phenotypes observed, which warrants further investigations.

In the present study we focused on two genes most commonly affected in CAKUT - TCF2 (HNF1b) and PAX2, which code for transcription factors with essential role for renal development. Defects in TCF2, most commonly large deletions, are shown to cause renal cysts, kidney dysplasia and sometimes renal agenesis, often in combination with diabetes mellitus. Point mutations in PAX2 cause renal hypoplasia and eye pathologies.

We report here on the introduction of TCF2 and PAX2 mutation screening for CAKUT patients in Bulgaria. Altogether 15 families were involved in the present study. Each of the affected individuals was tested for the presence of deletions or point mutations by means of MLPA analysis and sequencing of the coding sequences of TCF2 and PAX2. The identification of mutations in each of the affected families will facilitate the genetic counseling. Further screening for mutations in genes essential for genitourinary system development will be performed in those cases where no defects were found in TCF2 and PAX2.

P09.048
Lack of the association between T1128C variant in the neuropeptide Y gene and cannabis users

F. Tusgul[1], ***S. Oguzkan Balci***[1], *M. Nacak*[2], *A. Baransel Isir*[3], *S. Kul*[4], *S. Pehlivan*[1];
[1]*University of Gaziantep Faculty of Medicine, Department of Medical Biology, GAZIANTEP, Turkey,* [2]*University of Gaziantep Faculty of Medicine, Department of Pharmacology, GAZIANTEP, Turkey,* [3]*3University of Gaziantep, Faculty of Medicine, Department of Forensic Medicine, GAZIANTEP, Turkey,* [4]*University of Gaziantep, Faculty of Medicine, Department of Biostatistics, GAZIANTEP, Turkey.*

Objectives of the Study: Substance addiction is complex and multifactorial disease that develops based on environmental and genetic factors. Cannabis that is the most frequently used substance. Several studies suggest that a possible involvement of neuropeptide Y (NPY) system in the physiological effects of abused substances including alcohol and cocaine. The aim of this study was to examine whether T1128C functional variant of the NPY gene are associated with cannabis dependence.

Methods: In our study, 139 cannabis users and 100 healthy controls were tested for T1128C variant of NPY gene. Genotyping were performed by PCR-RFLP and the allele frequency of healthy people in Turkey was compared with the other country by two proportions z test.

Results: The genotype distribution of T1128C of NPY gene was not significantly different from that expected according to Hardy-Weinberg equilibrium in any group. There was no significant difference in the genotype distribution and allele frequency of T1128C variant between cannabis users and controls ($p>0.05$).

When the 1128C rare allele frequency of healthy people is compared with other country; it has been determined that it is coherent with America, China, Germany, Brazil, Sweden, Netherlands and Finland ($p>0.05$). On the contrary, the results obtained were different than the Japan ($p=0.022$).

Conclusion: This study is the first to search NPY gene in cannabinoid users. NPY gene T1128C variant did not reveal any relationship with the cannabis addiction. It may, therefore, be useful for considering to study NPY receptor genes for elucidating the genomic basis of addiction.

P09.049
Association study of CARD-8 (p.C10X) and NLRP3 (p.Q705K) variants with Rheumatoid Arthritis in French population

M. Ben Hamad[1], *F. Cornelis*[2], *S. Marzouk*[3], *Z. Bahloul*[3], *F. Fakhfakh*[1], *E. Petit-Teixeira*[2], *A. Maalej*[1];
[1]*Laboratory of Human Molecular Genetics, sfax, Tunisia,* [2]*GenHotel-EA3886, Evry-Paris VII Universities, AP-HP and CHSF Hospitals, Evry Genopole, France,* [3]*Department of Internal Medicine, University Hospital Hedi Chaker, sfax, Tunisia.*

Objective: NALP3, ASC, and TUCAN are components of the NALP3 inflammasome, a crucial molecular platform that regulates activation of caspase-1 and processing of interleukin (IL)-1 beta and IL-18. We undertook this study to investigate the association of caspase activating and recruitment domain 8 (CARD-8) and NLR family, pyrin domain containing 3 (NLRP3) polymorphisms with rheumatoid arthritis (RA) in French population.

Methods: CARD8 (c.30T>A, rs2043211) and NLRP3 (c.2113C>A, rs35829419) single nucleotide polymorphisms (SNPs) were genotyped in 100 French RA trio families, with the 4 grandparents of French Caucasian origin, using TaqMan 5' allelic discrimination assay on an ABI 7500 real time PCR machine (assay: C__11708080_1_ and C__25648615_10; respectively). The genetic analyses for association and linkage were performed using the comparison of allelic frequencies (AFBAC), the genotype relative risk (GRR), and the transmission disequilibrium test (TDT).

Results: Our results did not show any significant association either with CARD-8 [p = 0.894, odds ratio (OR) 1 (95% CI 0.41-2.43)] or NLRP3 [p = 0.879, odds ratio (OR) 0.87 (95% CI 0.3-2.48)] genes and RA. Moreover, stratifying patients according to the presence of rheumatoid factor (RF), anti-cyclic peptides antibodies (ACPA) and erosion did not reveal any significant association neither with CARD-8 nor with NLRP3 (p>0.05).

Conclusion: Variations in the innate immunity genes CARD-8 (p.C10X) and NLRP3 (p.Q705K) have no effect on RA susceptibility in the French population.

P09.050
Impact of selected SNPs from recent GWAS on plasma lipid concentrations in a high cardiovascular risk Mediterranean population. Interaction with environmental factors

D. Corella[1], *R. Estruch*[2], *O. Coltell*[3], *M. Guillen*[1], *P. Carrasco*[1], *C. Ortega-Azorin*[1], *M. I. Covas*[4], *J. V. Sorli*[1], *J. M. Ordovas*[5];
[1]*University of Valencia and CIBEROBN, Valencia, Spain,* [2]*Hospital Clinic, Barcelona, Spain,* [3]*University Jaume I, Castellon, Spain,* [4]*IMIM, Barcelona, Spain,* [5]*USDA-Tufts University, Boston, MA, United States.*

A recent meta-analysis of genome-wide association studies (GWAS) has revealed new statistically significant association between dozens of SNPs and plasma lipid concentrations including thousands of individuals from diverse populations. However, despite the great interest of these newly discovered significant associations, one of the potential limitations may be the low impact of these SNPs on a single population in terms of clinical relevance and not only in statistical significance. Therefore our aim was to analyze the clinical relevance (measured in terms of consistency and magnitude) of the association between some of these GWAS-SNPs reported as significantly associated with lipid traits (total cholesterol, LDL-C, HDL-C or/and triglycerides) in a high cardiovascular risk Mediterranean population. We randomly selected 20 SNPs from the recent meta-analysis (Nature, 2010) and genotyped these SNPs in 1050 high cardiovascular risk subjects (aged 67+/-7 years) participating in the PREDIMED-Valencia Study. We analyzed their associations with lipid traits as well as some gene-environment interactions. All the randomly selected SNPs (rs629301, rs1689800, rs2642442, rs514230, rs7570971, rs645040, rs13107325, rs1800562, rs3177928, rs605066, rs2072183, rs4731702, rs9987289, rs2293889, rs7941030, rs7134375, rs8017377, rs2412710, rs11649653 and rs2925979) were in Hardy-Weinberg equilibrium. The replication rate in terms of statistical significance (P<0.05) of the association of each SNP with the main trait, was low. However, we were able to detect some consistent associations (rs629301 in *SORT*1 and LDL-C; rs2642442 in *MOSC1* and total cholesterol, etc). In addition we found various statistically significant interactions with tobacco, alcohol and adherence to the Mediterranean diet that may contribute to explain the heterogeneity.

P09.051
PPARGC1B is a Genetic Determinant of the Cardiovascular Risk Factor, Thromboxane A_2 - an Anglo-Scandinavian Cardiac Outcomes Trial (ASCOT) Sub-study

N. S. McCarthy[1], *C. Vangjeli*[1], *P. Surendran*[2], *A. Treumann*[1], *C. Rooney*[2], *E. Ho*[1], *P. Sever*[3], *S. Thom*[3], *A. Hughes*[3], *P. Munroe*[4], *M. Caulfield*[4], *D. Shields*[2], *E. O'Brien*[2], *D. Fitzgerald*[2], *A. Stanton*[1];
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [2]*University College Dublin, Dublin, Ireland,* [3]*Imperial College London, London, United Kingdom,* [4]*Queen Mary University of London, London, United Kingdom.*

Introduction: Thromboxane A_2 (TxA_2), activates platelets and causes vasoconstriction. Raised urinary excretion of 11-dehydro-thromboxane B_2 (TxM), an index of TxA2 formation, is an independent predictor of atherothrombotic events. The heritability of this trait is not known. This is the first study to investigate the genetic determinants of thromboxane levels.

Materials and Methods: 544 participants in the Hypertension Associated Cardiovascular Disease Sub-study of ASCOT gave urine samples at two separate time-points. TxM was measured using liquid chromatography/ tandem mass spectrometry, expressed as pg/mg creatinine to correct for urine concentration. All subjects were genotyped on the CVD50K chip, a cardiovascular-specific chip with >50,000 SNPs. Usual quality control measures were applied. Linear regression analysis was performed, assuming an additive genetic model, adjusting for the covariates; age, sex, smoking habit, diabetes, systolic blood pressure, BMI, HDL, LDL, aspirin and anti-hypertensive regimen.

Results & Discussion: TxM levels were significantly lower in patients taking aspirin versus aspirin naïve patients (median [interquartile range] 324 [211,404] *vs* 716 [460,913] pg/mg, p<0.0001). 22 SNPs in the PPARGC1B gene were significantly associated with higher TxM (beta-values range; 123-223 pg/mg, p-values range; 0.001-0.009 after permutation to correct for multiple testing). PPARGC1B encodes peroxisome proliferator-activated receptor gamma co-activator 1β, a transcriptional co-activator previously reported to be associated with type 2 diabetes and obesity. These findings provide novel insight into the molecular biology of TxA2 biosynthesis, and its role in the causation of heart attacks and strokes.

In-depth assessment of cardiovascular parameters in three canine breeds as a preliminary step to unravel genetic determinants of physiological blood pressure variation.

V. Gouni[1], *V. Chetboul*[2,3], *E. Trehiou-Sechi*[2], *C. Misbach*[2], *A. Petit*[2], *M. Canonne-Guibert*[2], *J. Mary*[4], *R. Tissier*[3], *J. L. Pouchelon*[2,3], ***L. Tiret***[4];
[1]*Unité de Cardiologie d'Alfort, Ecole nationale vétérinaire d'Alfort, Maisons-Alfort, France,* [2]*Unité de cardiologie d'Alfort, Ecole nationale vétérinaire d'Alfort, Maisons-Alfort, France,* [3]*UMR INSERM ENVA U955, Maisons-Alfort, France,* [4]*UMR955 INRA-ENVA de Génétique Fonctionnelle et Médicale, Ecole nationale vétérinaire d'Alfort, Maisons-Alfort, France.*

Chronic values of arterial blood pressure (ABP) outside normal ranges represent a risk factor associated with cardiovascular disorders, a main cause of death in Europe. Deciphering and reversing complex morbidity mechanisms will require identifying the genetic polymorphisms that eventually contribute to systemic arterial hypertension. The genetic basis of arterial stiffness in humans, for example, has been extensively investigated through genome-wide association studies (GWAS), and this has helped identify groups of relevant genes unrelated to previously suspected mechanisms.

In parallel, comparative pathophysiology between humans and animal models has been proved relevant. In particular, the dog is unique to map loci underlying complex traits. To improve the current knowledge on the functional network underlying variations in ABP, we decided to focus on the molecular basis of physiological variations of this variable in healthy dogs. Eighty-nine dogs (age: 3.4±1.2 years, range: 1.4-5.7) were prospectively recruited. Three breeds were represented (Labrador, n=30; Doberman, n=31; Belgian Shepherd, n=28). Dogs were considered healthy on the basis of a complete clinical, biochemical and echocardiographic and Doppler examination. Using high-definition oscillometry, we showed that systolic, diastolic and mean ABP in Dobermans was significantly higher than in Belgian Shepherds and Labradors (P<0.0001). ABP was also significantly higher in Belgian Shepherds than in Labradors (P<0.0001). DNA from these dogs was

extracted and GWAS analyses to map blood pressure loci will be conducted as part of the European LUPA project (www.eurolupa.org). In addition, heart rate and shortening fraction were similar between breeds, providing clues to further select specific candidate genes.

P09.053
The Human Caveolin 1 Gene Upstream Purine Complex and Neurodegenerative disorders - A Common Signature

***A. Heidari**, M. Ohadi, M. Behmanesh;*
University of Social Welfare and rehabilitation Sciences, Tehran, Islamic Republic of Iran.

The caveolin 1 gene (*CAV1*) is over-expressed in experimental animal models of multiple sclerosis (MS). Increased expression of this gene has also been reported in the Alzheimer's disease (AD) brain. Loss of this gene, on the other hand, has recently been reported to be associated with neruodegeneration. We have recently reported a polymorphic purine complex at the 1.5kb upstream sequence of the gene with GGAA and GAAA motifs. In this study we compared the homozygote haplotype compartment across the region in groups of late-onset AD (n=240), MS (n=246), and control (n=610) subjects. Nineteen haplotypes were found to be homozygous in the patients, and not in the control pool ($p<0.000001$). The homozygote haplotypes ranged from 86-bp to 142-bp in the patients, whereas this range was between 106-bp to 122-bp in the controls. Six overlapping homozygote haplotypes were observed between AD and MS patients, strengthening the role of this region as a common etiological factor in the pathophysiology of neurodegenerative disorders, possibly through inflammatory mechanisms. The *CAV1* purine complex GGAA and GAAA motifs contain binding sites for numerous inflammatory transcription factors including the Ets, STAT, and IRF family members. Further work on the functionality of this region will shed light on the downstream events to the linked haplotypes.

P09.054
Variants of the CD36 gene and metabolic syndrome in Iranians

***A. Zadeh-Vakili**;*
Research Institute for endocrine sciences, Shaheed Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: The CD36 gene encodes for a membrane receptor that facilitates fatty-acid uptake and utilization. Genetic variants of CD36 gene have been associated with the metabolic syndrome (MetS). We aimed to evaluate the association between the rs10499859 and rs13246513 polymorphisms and MetS components.

Methods: For this case-control study, 140 MetS and 187 normal subjects were randomly selected from Tehran lipid and Glucose Study participants. Biochemical and anthropometrical variables were measured. Genotyping was performed by PCR-RFLP.

Results: Participants' mean age was 69 years and 56.3% were male. Case and control groups were not different in allele and genotype frequencies for these SNPs. However, the presence of T allele in rs13246513 C>T was significantly associated with increased levels of HDL-C (p 0.016) using a dominant model; this association was no longer statistically significant after adjustment for sex and age (p 0.751). The association of rs10499859 with diastolic blood pressure was significant (p 0.021), but disappeared after adjustment for sex and age, using recessive model (p 0.133). Association between this SNP and BMI was significant after adjustment for MetS under the dominant model (p 0.009, β^2=0.68). With regard to other MetS parameters, no significant difference was observed between genotype groups.

Conclusion: We found no difference in allele frequencies of rs10499859 and rs13246513 polymorphisms between case and control groups, indicating possibly no association between these polymorphisms and MetS. However, based on our results, these polymorphisms do affect HDL-C level and BMI, although the effect may be slight and restricted specifically to an environment-genotype.

P09.055
Copy number analysis of functional candidate genes on celiac disease linkage regions

***N. Fernandez-Jimenez**, A. Castellanos-Rubio, L. Plaza-Izurieta, I. Irastorza, G. Gutierrez, L. Castaño, J. C. Vitoria, J. R. Bilbao;*
Hospital de Cruces, Cruces-Barakaldo, Spain.

INTRODUCTION: Celiac disease (CD) is a complex, immune-mediated intolerance to dietary gluten that develops in genetically susceptible individuals. Different strategies including candidate gene association, linkage and GWAS have been employed to identify common susceptibility variation. CNV affects approximately 12% of the genome and gene dosage variation within a CNV could influence expression and disease susceptibility, but systematic studies in CD are lacking.

METHODS: The chromosomal location of significantly altered genes from a previous expression microarray experiment (9 active CD patients *vs.* 9 patients on gluten free diet) was crossed with the CD linkage regions described in the literature. Genes located within copy number variable regions present in >5% of individuals (Database of Genomic Variants, projects.tcag.ca/variation/) were selected for CNV analysis by gene-specific real-time PCR in 450 CD patients and 443 non-CD controls and assigned a predicted copy number for each sample using the maximum likelyhood approach.

RESULTS AND COMMENTS: Our candidate gene identification strategy allowed us to select 6 genes for CNV analysis: *DAZAP1*, *MBOAT7*, *PEX26*, *PRELID1*, *SYNPO* and *ZSCAN18*. To date, our results indicate that *PEX26* copy number does not vary in our population. Preliminary data suggest that ≥3 copy diplotype of *PRELID1* (overexpressed in active CD mucosa) is overrepresented in the patient group, indicating a possible association of *PRELID1* high copy number with CD risk. We are currently analyzing the rest of our candidate genes.

P09.056
Enrichment of rare coding variants in genes comprising the 39 loci associated to celiac disease

***I. Ricaño-Ponce**[1], A. Szperl[1], A. Kanterakis[1], M. J. Bonder[1], P. Deelen[1], F. van Dijk[1], J. Hanming[2], S. Ying[2], J. Xin[2], Z. Hancheng[2], L. Jiankang[2], F. Huiling[2], Y. Hu[2], M. Swertz[1], C. Wijmenga[1];*
[1]University Medical Center Groningen, Groningen, Netherlands, [2]BGI-Shenzhen, Shenzhen, China.

Celiac disease (CD) is a complex disease triggered by dietary gluten, resulting in an inflammatory response in the small intestine. It is known that human leukocyte antigen (HLA) DQ2/DQ8explains approximately 30% of CD heritability. Genome wide association studies (GWAS) identified 39 non-HLA CD loci explaining an additional 5% of the missing heritability. These 39 non-HLA loci comprise113 genes that could potentially also contain rare variants contributing to CD. GWAS arrays preclude the identification of these rare variants. In this study, high-throughput exome sequencing was used to investigate significant enrichment of novel and rare coding variants in CD cases versus controls.

Genomic DNA of15 unrelated individuals with CD was enriched for the ~30Mb of coding DNA with NimbleGen 2.1M Human Exome Arrays and sequenced using Illumina technology. Sequence variants (SV) with a quality score above 20 were annotated with our custom pipeline. On average, 91% of the exome was covered at least ten-fold and on average18.468genetic variants were identified per individual. To find rare and novel variants in the regions of interest our analysis was restricted to the 113 genes from the 39 CD loci. After removing common SV (>5%) based on HapMap and the 1000 Genome project and all SV present within non-coding regions, we are left with 20 potential variants. To perform statistical analysis in a case-control design we are currently analyzing some 100exomes from Dutch controls with the same prioritization steps.

P09.057

Upregulation of KIR3DL1 gene expression in intestinal mucosa in active celiac disease

*N. Fernandez-Jimenez, I. Santin, I. Irastorza, **L. Plaza-Izurieta**, A. Castellanos-Rubio, J. C. Vitoria, J. R. Bilbao;*
Hospital de Cruces, Cruces-Barakaldo, Spain.

INTRODUCTION: Celiac disease (CD) is a complex, immune-mediated intolerance to gluten that develops in genetically susceptible individuals and involves both innate and adaptive immune responses. Killer cell immunoglobulin-like receptors (KIRs) modulate NK and T-cell function through HLA class I interaction and have been implicated in CD.

METHODS: Qualitative expression of 14 KIR genes and 2 KIR pseudogenes was determined by SSP-PCR in biopsy pairs from 22 CD patients (taken at diagnosis and after two years on gluten free diet-GFD). Quantitative expression analysis of *KIR2DL4*, *KIR3DL1*, *KIR3DL3* and *KLRC2* (a marker of an NK-reprogrammed T-cell subpopulation augmented in CD) was performed in 35 additional CD biopsy pairs and 14 non-CD control biopsies by gene specific RT-PCR. Qualitative expression differences between groups were analyzed in 2x2 contingency tables, while expression levels were compared by paired (diagnosis/GFD) and unpaired (CD/controls) T-tests.

RESULTS: No particular KIR expression profile was observed for the different CD stages. *KIR3DL1* was more frequently expressed in active CD compared to GFD (p=0.0312) and non-CD controls (p=0.0008) with slightly increased levels in active disease (p=0.0505). *KLRC2* was overexpressed in active (p=0.0037) and GFD (p=0.0469) patients compared to non-CD controls and coexpressed with *KIR3DL1* (r^2=0.2917; p=0.001574).

DISCUSSION: Results suggest an alternative activating role for *KIR3DL1* in CD mucosa, as seen in other autoimmune diseases such as type 1 diabetes. *KIR3DL1* expression in CD could be explained in part by the increase in NK-like T cell subpopulations, but other mechanisms need to be involved.

P09.058

Contrasting the genetic background of type 1 diabetes and celiac disease autoimmunity

J. Romanos[1]*, G. Trynka*[1]*, M. Rewers*[2]*, E. Liu*[2]*, C. Wijmenga*[1]*;*
[1]*Genetics Department, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands,* [2]*Barbara Davis Center for Childhood Diabetes, University of Colorado, School of Medicine, Aurora, CO, United States.*

Type 1 diabetes (T1D) and celiac disease (CD) cluster in families and co-occur in the same patients. The same genetic regions and even the same SNPs have been associated with both diseases. Our aim was to test the genetic differences between individuals developing both diseases and those having only T1D or only CD.

Analysis1: We genotyped 32 established CD and/or T1D associated SNPs in 1115 non-Hispanic white American (NHWA) T1D patients and 260 NHWA T1D patients with also CD-autoimmunity (CDA&T1D) defined as persistent tissue-transglutaminase positivity on 2 consecutive visits. CD private risk variants in the *LPP* and *CD80* loci are associated with developing CDA&T1D when compared to T1D. Interestingly, IL18RAP*A - which is a risk allele for CD and a protective allele for T1D - was more frequently observed in the CDA&T1D group (Table).

Analysis2: Genotypes of 29 SNPs were available for 803 Dutch CD patients biopsy confirmed and showed the same allele frequencies in NHWA and Dutch controls. We compared the NHWA CDA&T1D to the Dutch CD patients. CDA&T1D individuals carried more frequently the T1D *PTPN22* risk variant and less the CD *ETS1* and *IL12A* risk variants when compared to CD individuals (Table).

This pilot study shows that to develop both diseases, individuals accumulate private T1D and CD risk variants. To improve our study, we are currently increasing sample sizes and numbers of SNPs.

Searching for causative variants in a large family with celiac disease

A. Szperl*, I. Ricaño-Ponce, P. Deelen, A. Kanterakis, F. van Dijk, M. Swertz, C. C. van Diemen, C. Wijmenga;*
University Medical Center and Groningen University, Groningen, Netherlands.

Celiac disease (CD), caused by an immune response to gluten, is a common food intolerance. CD is strongly associated to human leukocyte antigen (HLA) DQ2/DQ8. A genome-wide association study identified 39 loci which together with HLA explain 35% of CD heritability. To identify additional CD genes we performed whole-genome linkage in a four-generation Dutch family with 17 CD patients. We identified linkage to a 6Mb region on 9p21-13 (dominant model) and to a 14Mb region on 6q25 (identity by descent sharing). We hypothesize that these regions contain high risk mutations, playing a causal role in disease development in this family.

To identify potentially damaging mutations we sequenced the exomes of two affected family members, separated by four meiotic steps. Genomic DNA was enriched for coding regions using an Agilent SureSelect target kit and sequenced on a Genome Analyzer II (Illumina). On average 70% of the exomes were covered at least ten-fold and we observed ~15,000 sequence variants per individual. To reduce the number of variants we a) discarded common variants (MAF>5%) based on HapMap and the 1000Genomes Project, b) removed all non-coding variants, c) analyzed PolyPhen prediction and/or d) select on gene function. This left us with four variants (one on 9p21-13 and three on 6q25), that were validated by Sanger sequencing. The two variants that also segregated in the family are currently genotyped in a

large case-control cohort to test the association to celiac disease. Both variants map to genes involved in the transport of molecules.

P09.060
Association of the IL33 gene region with childhood allergic asthma

F. Belpinati[1], *G. Malerba*[1], *E. Trabetti*[1], *L. Xumerle*[1], *R. Galavotti*[1], *L. Pescollderungg*[2], *A. L. Boner*[1], *P. F. Pignatti*[1];
[1]*Department of Life and Reproduction Sciences, University of Verona, Verona, Italy,* [2]*Institute of Pediatrics, Hospital of Bolzano, Bolzano, Italy.*

Two recent indipendent large-scale GWAS of asthma reported the association of several markers comprising some on chromosome 9. In this region, flanking IL33 gene, we have previously found linkage of marker D9S286 with elevated IgE and SPT in Italian asthmatic families.

Here we report a family transmission study with allergic asthma in 137 trios from North-Eastern Italy ascertained through an allergic asthmatic child. Association analyses was conducted by the transmission disequilibrium test (TDT).

The phenotypes clinical asthma, total serum IgE levels, bronchial hyper-responsiveness to methacoline (BHR+), skin prick test positivity to common aeroallergens (SPT+), to house dust mites (SPT-HDM), and to graminae (SPT-GMN) were investigated.

The SNPs rs1342326 and rs928413 analysed, were in Hardy-Weinberg equilibrium and in LD with each other (D'=0.95; R^2=0.59). The observed minor allele frequency was 23% (minor allele:G, major allele:T) and 31% (minor allele:G, major allele:A) for rs1342326 and rs928413.

TDT analysis showed a preferential transmission of the rs928413-G allele to individual with SPT (T:65, NT:43, p=0.034) and in particular with SPT-GMN (T:54, NT:33, p=0.024). No other association was found.

Haplotype analyses showed that rs1342326-rs928413/T-G was preferentially transmitted to children affected by asthma (p=0.018), BHR+ (p=0.006), IgE (p=0.022), or SPT (p=0.015) and in particular by SPT-GMN (p=0.006).

These results extend the association of 9p24 with allergic asthma traits indicating the possible role of IL33 as an "alarmin" signal to immune system.

P09.061
Twelve common genetic variants explain a substantial part of the variation in BMI of obese children

L. van den Berg*, M. L. Wetzel, P. Henneman, E. Bakker, K. Willems van Dijk, H. A. Delemarre- van de Waal;*
LUMC, Leiden, Netherlands.

Results of twin and family studies suggest that up to 80% of the variation in body mass index (BMI) in children can be explained by genetic factors. A recent study (*Diabetes* 59:2980-2988) investigated 12 single nucleotide polymorphisms (SNPs) that are robustly associated with adult BMI in a large pediatric population. Direction-consistent associations with BMI were found for all of these variants in children. However, the risk factors explained a disappointing 1% of the population variation in BMI when taken together. We hypothesized that these 12 SNPs also explain variation in BMI in obese children. We studied 64 patients from our pediatric obesity clinic to test this hypothesis (39% boys; mean age=13.2; age range: 6 to 19; all children of North-West European descent). BMI-standard deviation scores (BMI-SDS) were used as a measure of body fat percentage of the children. BMI-SDS indicates how many standard deviations the child is away from the mean of a reference population of the same age and sex. Mean BMI-SDS of the study group was +2.8 (range: +1.9 to +3.8).The SNPs were genotyped using pre-designed TaqMan assays. We calculated a genetic predisposition score for each subject, i.e. the number of BMI-increasing alleles (theoretical range: 0 to 24). The genetic predisposition score significantly predicted BMI-SDS in this group of obese children (*p*=.02). The score explained 8.4% of the variation in BMI-SDS in the group. The largest effect size was found for the fat mass and obesity associated gene (*FTO*, beta=+0.2). Future plans include increasing the sample size.

P09.062
CHRNA4 exon 5 variant affects nicotinic receptor sensitivity and is associated with schizophrenia-related quantitative traits and drug treatment-response

G. Winterer*;*
Cologne Center for Genomics, Cologne, Germany.

Background: Association of CHRNA4 exon5 SNP rs1044396 with cognitive performance, associated brain function and nicotine addiction has been reported. At present, it is unclear whether rs1044396 is functional. Since patients with schizophrenia are mostly strong smokers showing cognitive deficits and abnormal brain function, CHRNA4 also might be a potential candidate gene. Methods: cDNAs (incl. rs1044396) carrying two complementary haplotypes (hap1, hap2) were injected into Xenopus Oocytes. The alpha4beta2 receptor channel was studied with voltage clamp applying acetylcholine (Ach) concentrations in increasing order. Case-control and quantitative trait association study (N = 1.253 schizophrenia cases and N = 2.880). Pharmacogenetic study in two independent sample (total: N = 220 schizophrenia patients) testing for association with treatment-response. Population-based association study of cognitive performance and brain function (functional neuroimaging) during a choice reaction task in N = 1.794 smoking and never-smoking healthy subjects. Structural magnetic resonance imaging (MRI) in N = 122 healthy subjects testing for association with cortical thickness. Results: 6% stronger current amplitudes in alpha4beta2 receptor channels in response to low Ach doses depending on haplotype. The opposite effect was seen with higher Ach doses. Schizophrenia, clinical symptoms and clinical response to drug treatment were significantly associated with genotype. Significant genotype association with verbal memory interacting with age and sex as well as brain function, task-related reaction time and cortical thickness of the medial prefrontal lobe. Discussion: Experimental evidence is provided that rs1044396 affects nicotinic alpha4beta2 receptor sensitivity. The association findings imply a role in schizophrenia pathophysiology and drug-treatment response.

P09.063
FN1 and *TIMP2* polymorphisms are associated with nonsyndromic cleft lip with or without cleft palate

T. Nikopensius[1,2], *L. Ambrozaitytė*[3], *T. Jagomägi*[4], *M. Saag*[4], *A. Matulevičienė*[3], *V. Kučinskas*[3], *A. Metspalu*[1,2,5];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Estonian Biocentre, Tartu, Estonia,* [3]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [4]*Department of Stomatology, Faculty of Medicine, University of Tartu, Tartu, Estonia,* [5]*Estonian Genome Center, University of Tartu, Tartu, Estonia.*

Nonsyndromic cleft lip with or without cleft palate (NSCL/P) is a common human birth defect with complex genetic etiology. The aim of this study was to investigate the contribution of 12 candidate genes (*FGF1*, *FGF2*, *FGFR1*, *FN1*, *MMP2*, *MMP3*, *MMP9*, *MMP25*, *TIMP2*, *TIMP3*, *WNT3*, and *WNT9B*) in predisposition to orofacial clefting. 209 tagSNPs were studied in 192 NSCL/P patients and 424 controls from Estonian and Lithuanian population. The genetic relatedness of Estonians and Lithuanians, sharing the same geographic origin, has been recently confirmed using the principal component analysis. In case-control comparisons, the minor allele of *FN1* SNP rs4968282 was associated with reduced risk of NSCL/P (OR=0.653; 95% CI 0.511-0.836; $P=6.73\times10^{-4}$), whereas the minor allele of *TIMP2* rs7502916 was associated with increased risk of NSCL/P (OR=1.465; 95% CI 1.150-1.867; P=0.0019). The minor allele of *MMP9* SNP rs6073991 was associated with reduced risk of NSCL/P (OR=0.648; 95% CI 0.480-0.874; P=0.0043). Multiple yin-yang haplotypes in *FN1* and *TIMP2* were associated with NSCL/P. The strongest associations were found for *TIMP2* haplotype CAA ($P=8.06\times10^{-4}$) and *FN1* haplotype GAA ($P=9.08\times10^{-4}$). Fibronectin is involved in cell adhesion and migration processes during embryogenesis, and the present study is the first to demonstrate an association between common SNPs and haplotypes in *FN1* and NSCL/P. Our findings provide evidence that variation in *FN1* and *TIMP2* may contribute susceptibility to NSCL/P in North-Eastern European populations.

P09.064
Genetic evidence supporting a role for MMP and TIMP genes in Cleft Lip/Palate

A. Letra[1], *R. Silva*[1], *J. M. Granjeiro*[2], *A. R. Vieira*[1];
[1]*University of Pittsburgh School of Dental Medicine, PIttsburgh, PA, United States,* [2]*Fluminense Federal University, Niteroi, Brazil.*

The complex etiology of cleft lip/palate (CL/P) is acknowledged by the number of genes and signaling pathways implicated during craniofacial development. Matrix metalloproteinases (MMPs) and their inhibitors TIMPs are responsible for degradation of the extracellular matrix and tissue remodeling during including embryonic development and may be implicated in CL/P. We have previously shown that a polymorphism in MMP3 is associated to CL/P. We genotyped 45 polymorphisms spanning selected MMP and TIMP genes in 907 unrelated Caucasian individuals. Statistical analyses were performed using PLINK software. Genotype and allele frequencies of polymorphisms were compared between cases and controls under Bonferroni correction (α=0.0016). Odds-ratios and 95% confidence intervals were also calculated. MMP3 rs522616 showed statistically significant association with all clefts (P=0.000006), cleft lip with cleft palate (P=0.0003) and with cleft palate (P=0.0002). TIMP2 rs8179096 showed association with all clefts (P=0.0007) and with cleft palate (P=0.001). Logistic regression analyses reinforced the individual associations. In silico analyses for both MMP3 and TIMP2 variants revealed several transcription factor binding sites relevant for craniofacial development. We also report for the first time the expression pattern of MMPs not yet described during murine palatogenesis. In summary, we provide additional evidence that MMP3 and also TIMP2 contribute to CL/P. Additional studies are under way to elucidate the involvement of these genes in the etiology of CL/P.

P09.065
Independent rare and common variants underly association signals for coeliac disease

G. Trynka[1], *K. A. Hunt*[2], *V. Plagnol*[3,4], **. Coeliac Disease Genetics Consortium*[1,2], *R. H. Ruerr*[5], *S. Onengut-Gumuscu*[6], *S. S. Rich*[6], *P. Deloukas*[7], *D. A. Van Heel*[2], *C. Wijmenga*[1];
[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*Blizard Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom,* [3]*Genetics Institute, University College London, London, United Kingdom,* [4]*JDRF/Wellcome Trust Diabetes and Inflammation Laboratory, University of Cambridge, Cambridge, United Kingdom,* [5]*University of Pittsburgh School of Medicine, Pittsburgh, PA, United States,* [6]*Center for Public Health Genomics, University of Virginia, Charlottesville, VA, United States,* [7]*Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom.*

Coeliac disease is an autoimmune disease with 1% prevalence in the general population and a complex genetic background. Our recent genome wide association scan (GWAS) on 15,283 case-control samples established association to 27 loci, including well known coeliac risk factor in the HLA region. Currently we genotyped 24,269 case-control samples (UK, Netherlands, Italy, Spain, Poland, India) on the Immunochip; a custom Illumina iSelect platform (196,548 variants) designed with aim of using all 1000Genomes-pilot markers to fine-map 189 risk loci reported at genome wide significance for over ten immune mediated diseases.

In the meta-analysis across all populations we observed associations (p<5x10e-8) at 14 additional loci, making a total of 41 coeliac disease risk loci. Moreover, we noted an excess of intermediate range p-values at the remaining 148 autoimmune loci, confirming the large genetic overlap between immune-mediated diseases. Finally, to get better insight into the genetic architecture underlying associations for previously established coeliac disease loci, we performed a stepwise conditional logistic regression on all 26 GWAS regions (20-50x more variants per locus on Immunochip compared to GWAS chips). Nearly half of the loci (12 of 26) showed evidence for multiple independent signals, due to both common (e.g. 3 signals at IL12A) and rare genetic variants (MAF< 0.05, e.g. at PTPN2).

Identification of multiple independent SNPs at coeliac disease associated loci helps to better define the risk of each individual locus, understand the causal mechanism behind the associated variants and provides insights into the likely genetic architecture of other common complex diseases.

P09.066
Incidence of TACI mutation in common variable immunodeficiency

S. Safaei[1,2], *m. houshmand*[1], *z. pourpak*[3], *m. moin*[3];
[1]*Special Medical Center. Genetic Laboratory, Tehran, Islamic Republic of Iran,* [2]*Immunology, Asthma & Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran,* [3]*Immunology, Asthma & Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Background: Common variable immunodeficiency disorders (CVID) are heterogeneous immunodeficiency syndromes. Heterozygoute mutations in TACI gene have previously been shown to cause recessive CVID. The aim of this study was to determine the incidence of TACI defect in CVID patients.

Method: 18 unrelated CVID patients were entered the study. PCR amplification was performed using unpublished primers, to amplify TACI.

Table1. Primers used in this study

Result:

Table2. Patient's data and the result of TACI mutation screening

Patient number/ sex	Age(year)	TACI mutation	Affected TACI domain	IgA levels (mg/dl) (adults:71-308)	IgG levels (mg/dl) (adults:658-1837)	IgM levels (mg/dl) (adults:40-263)
1/male	48	R122W (reported)	Extra-cellular domain	7	755	15
2/male	28	38insA Frameshift(new)	Extra-cellular domain	238	216	233
3/male	17	38insA frameshift(new)	Extra-cellular domain	16	743	48

Conclusion: In previous studies, the proportion of CVID patients carrying at least one TACI mutation was estimated at 10 to 20%. In the present study, we identified 3 patients with at least one TACI allele mutated out of a small cohort of 18 antibody deficiency patients, yielding a more precise estimate of 16.6%. None of these mutations were present in 20 healthy subjects. This study suggests that additional genetic and environmental factors might have effective role in causing CVID. Analysis of a larger sample of patients will be needed to determine if the novel mutation associated with a particular phenotype or predisposition to the common features of CVID.

P09.067***
Increased genomic copy number of ß-defensins on 8p23.1 and its influence on psoriasis

U. D. Hüffmeier[1], *S. Uebe*[1], *M. Apel*[1], *P. Badorf*[1], *R. Pala*[2], *H. Traupe*[3], *R. Mössner*[4], *J. Armour*[2], *H. Burkhardt*[5], *A. Reis*[1];
[1]*Human Genetics, University of Erlangen, Erlangen, Germany,* [2]*Institute of Genetics, University of Nottingham, Nottingham, United Kingdom,* [3]*Department of Dermatology, University of Münster, Münster, Germany,* [4]*Department of Dermatology, University of Göttingen, Göttingen, Germany,* [5]*Division of Rheumatology, Department of Internal Medicine II, Johann Wolfgang Goethe University, Frankfurt/ Main, Germany.*

Previously, we reported association of an increased genomic copy number of a ß-defensin cluster on 8p23.1 with psoriasis (Hollox et al. Nat Genet 2008). In the meantime, our findings have neither been replicated nor rejected by independent studies, probably due to technical difficulties of differentiating copy number states of more than four copies.

In order to check the relevance of the association finding for psoriasis, we performed extensive methodological comparisons and an independent replication study. We observed satisfying correlation coefficients between three methods used: R^2 = 0.92 for MLPA and classical PRT (n=159), R^2 = 0.93 for classical and new PRT (n=68)). Furthermore, copy numbers obtained by a high resolution SNP array

(Affymetrix 6.0) were compared with PRT copy numbers in 600 individuals. No correlation was observed indicating that the array technique is not a suitable method to detect smaller copy number differences at loci with highly variable copy numbers.
We then re-evaluated findings in the German case control cohort as published in Hollox et al. (Nat Genet 2008) and confirmed the association with a p = 1.22E-05 (Mann-Whitney-test for unrounded copy number data). For the replication study we genotyped 1315 psoriasis patients and 593 control individuals. Statistical analyses of unrounded copy number data replicated the association with higher copy number in psoriasis (p = 3.46E-03). A combination of previous and replication datasets (obtained with purified DNAs only) resulted in a p-value of 9.94E-07. Overall, our study confirms association of psoriasis with increased copy number of ß-defensin cluster on 8p23.1.

P09.068
Copy number variation analysis by high resolution SNP array in cleft lip and palate

***M. Simioni**, T. K. Araujo, T. P. Vieira, C. V. Maurer-Morelli, Í. Lopes-Cendes, V. L. Gil-da-Silva-Lopes;*
Department of Medical Genetics, University of Campinas (UNICAMP), Campinas, Brazil.

High resolution SNP array technology has provided insights into a type of genomic variation known as copy number variation (CNV). CNVs have been detected in phenotypically normal individuals as well as associated with diseases and human malformations. Over the years it has been shown that the etiology of cleft lip and/or palate (CL/P) may be related to sequence mutations in specific genes, but also to copy number abnormalities such as deletions or duplications. The purpose of this study was to determine the role of CNVs in a group of CL/P patients (syndromic and nonsyndromic) composed by 23 proband-parents trio. To screen the CNVs, we used the Genome-Wide Human SNP Array 6.0 (Affymetrix). The analysis was performed using the Affymetrix Genotyping Console software and 20 in-house control samples was the reference set. By focusing on large events (>100 kbp), we observed an excess of 325 CNVs in patients (CNV average number per patient was 14). Of these, 126 were de novo CNVs. Duplications were more frequent than deletions. Approximately 150 CNVs involved known genes, including OMIM referenced genes. Among more interesting findings there are CNVs in regions known to be associated to CL/P phenotype such as a deletion (560kb) within the 1p36.33 microdeletion syndrome region, a deletion (300kb) within the 22q11.2 deletion syndrome critical region and a patient with syndromic cleft palate with 8p23.1 duplication (3.8Mb) and 15q25-q26 duplication (17Mb). Further experiments, by a second method to validate these CNVs found are currently being performed. **Financial support: FAPESP, CNPq.**

P09.069
Effects of ACE polymorphisms on severity of coronary artery diseases may be related with hyperlipidemia

***A. I. Guney**[1], D. Ergec[2], D. Kirac[3], H. S. Ozturhan[4], M. Caner[5], K. Ulucan[1], G. Koc[1], M. Agirbasli[4];*
[1]Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [2]Yeni Yuzyil University, Faculty of Art and Science, Department of Molecular Biology and Genetics, Istanbul, Turkey, [3]Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, [4]Marmara University, Faculty of Medicine, Department of Cardiology, Istanbul, Turkey, [5]Maltepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey.

Introduction: Coronary artery disease (CAD) is a multifactorial disease which is influenced by genetic predisposition and environmental factors. Major risk factors of CAD are hypertension, diabetes mellitus, hyperlipidemia, smoking, family history and obesity. Mutations in ACE gene can also cause CAD. Thus, the aim of this study was to investigate the effects of major risk factors and ACE gene polymorphisms on CAD.
Methods: 205 consecutive patients with angiographically proven early onset CAD and also 140 control subjects with no significant coronary obstruction angiographically were recruited to the study. DNA was extracted from peripheral blood and ACE gene polymorphisms were investigated with PCR.
Results: The DD polymorphism was found statistically higher in patients than controls. Also ID polymorphism was found statistically high in patients, who have hyperlipidemia and smoking habits.
Conclusion: Many studies showed that the ID and DD polymorphism is strongly associated with the increased plasma or serum ACE levels. Thus the ID and DD polymorphism favors high ACE expression and activity, hence may predispose individuals to CAD and its complications. Although it has been suggested that hyperlipidemia is an independent risk factor for CAD, our findings showed a relationship between ID genotype and hyperlipidemia therefore the severity of CAD may be associated with hyperlipidemia. Also according to our results we consider that the combination of ID polymorphism with smoking habit may increase the development of CAD.

P09.070
Polymorphism +45T/G in ADIPOQ gene is not associated with ischemic heart disease in Central-European population

***P. Bienert**[1], J. A. Bienertova Vasku[1], F. Zlamal[1], J. Meluzin[2], V. Kincl[2], A. Vasku[1];*
[1]Department of Pathological Physiology, Masaryk University, Brno, Czech Republic, [2]1st Department of Internal Medicine-Cardioangiology, St. Ann Faculty Hospital, Masaryk University and International, Clinical Research Center, Brno, Czech Republic., Brno, Czech Republic.

Adiponectin harbours strong cardioprotective properties and the +45 T/G polymorphism in ADIPOQ locus has been reported to play an important role in diabetes development. The aim of the study was to investigate possible relationships between the SNP and coronary artery disease (CAD) in a large cohort of Central-European subjects with suspected CAD who underwent coronarography.
The 852 patients with suspected CAD referred for angiography were enrolled in the study, out of whom the 669 subjects presented with more than 50% reduction of coronary artery diameter and were classified as CADs (group 1) and 183 subjects were classified as the non-CADs (group 2). The healthy control subjects (n = 395) of the same age and gender distribution were recruited to establish normal population frequencies (group 3).
There were no significant differences in genotype distributions (p = 0.10) or in allele frequencies (p = 0.88) of +45T/G between the CADs and non-CADs (group 1 vs. group 2). However, there were significant differences in genotype distributions between subjects with coronarography (group 1+2) and without coronarography (group 3) (pg = 0.02, pa = 0.42). In multinomial regression modelling across the CADs, the +45 T/G polymorphism showed no association with ejection fraction (p = 0.87), number of affected vessels (p = 0.35) or number of stenotic lesions (p = 0.54)
Based on our observations, the +45T/G in ADIPOQ gene doesn't seem to be a major genetic determinant of CAD in the Central-European population, which contradicts findings on other CAD populations with different ethnicity.

P09.071
A genetic variant associated with the Cripto plasma levels in the Cilento isolated populations

***D. Ruggiero**, S. Nappo, R. Sorice, T. Nutile, G. Liguori, M. Ciullo;*
IGB-CNR, Naples, Italy.

Cripto, the founder member of the EGF-CFC genes, has a key role for the Vertebrate embryo development, contributing to the formation of the embryonic mesoderm. Very little is known about the variability of plasma levels of Cripto in humans: only one study described higher levels of Cripto in patients with colon and breast carcinomas. Nevertheless the genetic contribution underlying this variability remains still unknown.
We measured the Cripto plasma levels in three isolated villages from Cilento area in South Italy (N=2026). The estimated heritability was very high (0.90). To identify genetic variants influencing the levels of Cripto, we performed both linkage and genome-wide association analyses. Through the linkage analysis a strong signal on chromosome 3p21.33 was detected (LOD=6.11). This locus exactly corresponds to the location of the Cripto gene. This result was supported by the genome-wide association analysis: in fact, several SNPs in this region were strongly associated with Cripto. The most associated SNP, located 1.5 kb upstream the Cripto gene has a p-value=6.9e-74; the C allele is associated with higher levels of Cripto (CC= 673.8±29.0 pg/ml; CT= 310.5±6.9 pg/ml; TT= 46.7±4.4 pg/ml). A linkage analysis conditional on the most associated SNP resulted in a complete loss

of the peak on the chromosome 3, showing that this SNP is able to explain the entire signal.
Further studies are required to identify the causal variant for Cripto variability.

Oxidative damage of mtDNA in patients with Crohn's disease

D. Balakova[1], *M. Baldovic*[1], *G. Minarik*[1,2], *I. Cierna*[3], *M. Batovsky*[4], *T. Hlavaty*[4], *L. Kadasi*[1,5], *P. Celec*[1,2];
[1]*Department of Molecular Biology, Comenius University, Bratislava, Slovakia,* [2]*Institute of Molecular Biomedicine, Comenius University, Bratislava, Slovakia,* [3]*Children's Hospital, Comenius University, Bratislava, Slovakia,* [4]*Faculty Hospital, Bratislava, Slovakia,* [5]*Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.*

Crohn's disease (CD) is a nonspecific chronic inflammation of the gastrointestinal tract with an onset in the second to fourth decade of life. It is together with ulcerative colitis (UC) one of the two main inflammatory bowel diseases (IBD). The highest incidence of CD is in North America and Northern Europe. The etiology and molecular pathogenesis of CD is unknown but causes include genetic and environmental factors leading to defects in immunity and oxidative stress. Mitochondria produce large amounts of free radicals and have a low antioxidative status, therefore, mitochondrial DNA (mtDNA) is at high risk of oxidative damage. Furthermore, mitochondria play a crucial role in the autoimmune response, apoptosis and autophagy, all of which are implicated in the pathogenesis of CD. The aim of the study is to compare the common 4977bp deletion and fragmentation of mtDNA in CD patients and controls. We hypothesize that the frequency of the mtDNA deletion and fragmentation depends on patient's genotype. Two polymorphisms in the candidate genes for CD associated with oxidative stress (*NCF4*) and autophagy (*ATG16L1*) were selected. Testing of this hypothesis could shed light on CD pathogenesis with regard to the potential application of a supportive antioxidant therapy.

P09.073
CYP2C19 polymorphism and antidepressant response to Citaloperam in Iranian patients with major depression

M. Hasanzad[1], *K. Kahrizi*[2], *S. Hemati*[2], *H. Najafi*[1], *S. S. Sedighi*[3], *M. Sam Zadeh*[4];
[1]*Islamic Azad University; Tehran Medical Branch, Tehran, Islamic Republic of Iran,* [2]*Genetics Research Center,University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [3]*St. Matthew's University; School of medicine, Orlando, FL, United States,* [4]*Shaheed Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Personalized drug therapy based on genotype analysis seems to be a promising approach to reduce adverse effects and enhance drug efficacy. The polymorphic expression of cytochrome P4502C19 (CYP2C19) is known to be one of the determinants responsible for the pronounced interethnic and interindividual differences in response and disposition of clinically important drugs such as citaloperam .On the basis of their ability to metabolize (S)-mephenytoin or other CYP2C19 substrates, individuals can be classified as extensive metabolizers (EMs) or poor metabolizers (PMs). CYP2C19*2 and CYP2C19*3 have been shown as the main polymorphisms contributing to the PM phenotype. This study aimed evaluating the CYP2C19 polymorphism and antidepressant response to Citaloperam in Iranian major depressive population
Methods: 77 patients with major depression were selected according to Hamilton test and then Citaloperam treatment was started. CYP2C19 polymorphism analyses were performed using a Restriction fragment length polymorphism (RFLP) method.
Results and Conclusion: Eight individuals carried two mutated alleles, being homozygous for CYP2C19*2, and thus could be classified as poor metabolizers. Whereas twelve subjects carried one mutated allele (CYP2C19*1/*2) of CYP2C19*2. For CYP2C19*3, we found three subjects with one mutated allele. The rest of subjects have the wild-type alleles that referred to as *1. It seems that there was no sginificant difference in the frequency of CYP2C19 allelic variants between the present study and other studies evaluating this.

P09.074
APOE and CYP2D6 in CNS Disorders

L. Fernandez-Novoa[1], ***R. Cacabelos***[2];
[1]*EBIOTEC, Bergondo, Spain,* [2]*EuroEspes Biomedical Research Center, Institute for CNS Disorders and Genomic Medicine, Bergondo, Spain.*

The APOE and CYP2D6 genes cooperate in the pathogenesis and pharmacogenomics of some CNS disorders as well as in lipid metabolism. The distribution and frequency of polymorphic variants of APOE and CYP2D6 have been studied in the Spanish population, including control subjects (N=315), and patients with anxiety (ANX, N=285), depression (DEP, N=419), psychosis (PSY, N=162), stroke (STR, N=67), Alzheimer's disease (AD, N=231), Parkinson's disease (PAR, N=73), attention-deficit hyperactivity disorder (ADHA, N=42), migraine (MIG, N=217), epilepsy (EPI, N=71), vascular dementia (VD, N=198), vascular encephalopathy (VE, N=380), multiple sclerosis (MS, N=21), cerebrovascular insufficiency (CVI, N?238), brain tumors (BT, N=11), cranial nerve neuropathy (CNN, N=25), mental retardation (MR, N=115), and post-traumatic brain injury (PTBS, N=59). In the control population APOE variants were: APOE-2/2, 0.32%; APOE-2/3, 7.3%; APOE-2/4, 1.27%; APOE-3/3, 71.11%; APOE-3/4, 18.41%; and APOE-4/4, 1.59%. A clear accumulation of APOE-4/4 carriers was observed in AD (6.06%, p<0.001) and VD patients (6.57%, p<0.001). CYP2D6 extensive metabolizers (EM) accounted for 55.71% of the control population; intermediate metabolizers (IM) were 34.7%; poor metabolizers (PM), 2.28%; and ultrarapid metabolizers (UM), 7.31%. Significant differences in CYP2D6 genotypes were observed between DEP vs controls (p<0.02), vs PSY (p<0.02), vs PAR (p<0.05), vs BT (p<0.01); STR vs BT (p<0.05); BT vs Controls (p<0.05); and CNN vs controls (p<0.05). APOE-4 is a major risk factor for AD and VD. The accumulation of CYP2D6-PMs and UMs in different CNS pathologies may influence the therapeutic response to psychotropic drugs.
(Supported by the International Agency for Brain Research and Aging, and the EuroEspes Foundation).

P09.075
Role of CYP1A1 (T6235C) polymorphism and cigarette smoking in the development of coronary heart disease in the Tunisian population

R. Zemni, *A. Achour, E. Chabchoub, F. Ben Hadj Slama;*
Immunogenetics department, Faculty of Medicine "Ibn El Jazzar", Sousse, Tunisia.

Aims: Cytochrome P450 1A1 (CYP1A1) plays an important role in maintaining the homeostasis of the cardiovascular system. This enzyme catalyses the formation and/or metabolism of several endogenous molecules such as arachidonic acid leading to the formation of cardioprotective metabolites. Furthermore, *CYP1A1* activates tobacco mutagens involved in carcinogenesis, atherogenesis, and teratogenesis through DNA adducts formation. This study aimed to evaluate the association between *CYP1A1* (T6235C) polymorphism and the risk of developing coronary heart disease (CHD) in the Tunisian population, and to assess the possible effect of the smoking habit on this association.
Methods: This case-control study consisted of 401 controls and 382 patients with CHD including 264 subjects with myocardial infarction (MI) and 118 with angina pectoris (AP). The genotyping of *CYP1A1* (T6235C) polymorphism was carried out by polymerase chain reaction (PCR) and restriction enzyme digestion.
Results: No significant association was found between *CYP1A1* (T6235C) polymorphism and CHD, MI or AP. However, the CC homozygous subjects may have a lower risk of developing CHD or MI (odds ratio (OR) 0.53; 95% confidence interval (CI) [0.16-1.79] and 0.20; 95% CI [0.02-1.57] respectively) when compared to TT carriers. This did not exceed the significance threshold. When considering the tobacco smoking status, the risk of CHD or MI decreased for the CC genotype carriers even after adjustment for potential confounders but without exceeding the significance threshold.
Conclusion : *CYP1A1* (T6235C) polymorphism does not seem to modify the risk of CHD, MI or AP in the Tunisian population even when considering the tobacco smoking habit.

P09.076
The functional polymorphism of (A-164C) of CYP1A2 gene increases the risk of angina pectoris but not the risk of myocardial infarction in the Tunisian population

***A. Achour**, R. Zemni, E. Chabchoub, F. Ben Hadj Slama;*
Immunogenetics department, Faculty of Medicine "Ibn El Jazzar", Sousse, Tunisia.

Background: Cytochrome P450 1A2 (CYP1A2) enzyme plays an important role in the homeostasis of the cardiovascular system through the metabolism of endogenous molecules such as arachidonic acids which have cardioprotective effects and exogenous molecules like tobacco chemicals that have atherogenic effects. The purpose of this study was to evaluate the association between *CYP1A2* (A-164C) polymorphism and coronary heart disease (CHD) in the Tunisian population and to determine whether smoking habit modifies this association.

Methods: we recruited 400 controls and 379 coronary heart disease patients including 261 subjects with myocardial infarction (MI) and 118 with angina pectoris (AP). The genotyping of *CYP1A2* (A-164C) polymorphism was performed by polymerase chain reaction (PCR)-restriction fragment length polymorphism.

Results: The results did not show any significant association between *CYP1A2* (A-164C) polymorphism and CHD and MI. However, the homozygous genotype CC of the single nucleotide polymorphism (SNP) A-164C was found to be significantly associated with AP (odds ratio (OR) 2.13; 95% confidence interval (CI) [1.20-3.77] p=0.01). We also, found that smokers carrying CC genotype have an increased risk of AP (OR 3.82; 95% CI [1.55-9.39] p=0.004) in comparison to those carrying AA genotype. After adjustment for traditional risk factors, the CC genotype was significantly associated with an increased risk of AP with or without considering the smoking status (OR 7.99; 95% CI [2.24-28.43] p=0.001)/(OR 3.29; 95% CI [1.45-7.84] p=0.004) respectively.

Conclusion: Our findings suggest that the CC genotype of *CYP1A2* (A-164C) polymorphism was associated with AP in the Tunisian population This risk increased significantly among smokers.

P09.077
Genetic markers of inflammation in patients with cardiovascular disease

***Y. R. Timasheva**[1], T. R. Nasibullin[2], O. E. Mustafina[2];*
[1]Institute of Molecular and Cell Biology, Tartu, Estonia, [2]Institute of Biochemistry and Genetics Ufa Science Centre RAS, Ufa, Russian Federation.

Essential hypertension (EH) is a common disease with severe cardiovascular complications (myocardial infarction and stroke), the major cause of mortality and morbidity in the modern societies. Blood pressure is a complex trait with multiple genetic contributors. Inflammation is the core process in pathophysiology of EH, and cytokines are biomediators that are involved in each stage of its development.

Our study was aimed to investigate an association between cytokine genes variants and cardiovascular disease, and to study their expression profile in leucocytes of patients with EH.

DNA and RNA samples were obtained from 364 patients with EH and 273 control subjects. 95 patients with EH had verified myocardial infarction, 45 - ischaemic stroke, and 219 had EH without cardiovascular complications. In our experiment, 11 SNPs in 10 genes analyzed, and an association study between EH patients and control subjects was performed. 84 cytokines and cytokine receptors genes were screened for their expression profile with the RT2ProfilerTM PCR Array (SuperArray Bioscience Corporation, USA).

An association was detected between IL1B T511C (P=0.029) and IL10 C627A (P=0.016) SNPs and EH. IL1B, IL6, IL10, IL12B and TNFA gene variants were found to be associated with cardiovascular complications of EH. Evidence for association with stroke was observed for IL1B T511C (P=0.022), IL-6 G572C (P=0.03), IL12B A1159C (P=0.017) and TNFA G308A. Patients with EH were demonstrated to have altered transcriptional activity of 21 cytokine genes. Our findings suggest that alterations in the genes encoding inflammatory components may have an input to the increased susceptibility to cardiovascular disease.

GJB2 35delG and Mitochondrial A1555G mutations and etiology of deafness at the Gelibolu School for the Deaf in Turkey

***F. Silan**[1], O. Guclu[2], L. E. Kadioglu[3], C. Silan[4], S. Atik[5], A. Uludag[5], A. Demiray[6], F. S. Derekoy[2], O. Ozdemir[5];*
[1]Canakkale Onsekiz Mart University School of MedicineDepartment of Medical Genetics, Canakkale, Turkey, [2]Canakkale Onsekiz Mart University School of Medicine Department of Otorhinolaryngology, Canakkale, Turkey, [3]Canakkale Onsekiz Mart University School of Medicine Department of Paediatrics, Canakkale, Turkey, [4]Canakkale Onsekiz Mart University School of Medicine Department of Pharmacology, Canakkale, Turkey, [5]Canakkale Onsekiz Mart University School of Medicine Department of Medical Genetics, Canakkale, Turkey, [6]Canakkale Onsekiz Mart University School of Medicine Audiometrist, Canakkale, Turkey.

Objective: 35delG mutation in GJB2 (gap junction protein beta 2, connexin 26) gene is the most frequent mutation in patients with non-syndromic autosomal recessive deafness. The A155G mutation in the mitochondrial 12S rRNA is another important genetic alteration, which is associated with aminoglycoside-induced deafness. The aim of this study was to explore the etiology of deafness and the prevalence of both mutations in study cases.

Methods: We examined audiological and dysmorphological features of all children at Gelibolu School for the deaf. A questionnaire investigating prenatal, perinatal and postnatal etiological causes of deafness was prepared, and pedigree analysis was performed for each individual. After ENT examination, audiological tests and mutation analysis with RT PCR method were carried out.

Results: The GJB2 35delG and mitochondrial A1555G mutation was detected in 12% and was10% of all deaf school children, respectively. The percentages of genetic, acquired, both genetic and environmental and unknown etiologies were 62.5, 20.3, 15.6 and 1.6, respectively. One patient had both Waardenburg Syndrome and mitochondrial A1555G mutation, and one patient carried both 35delG and mitochondrial A1555G mutations. Interestingly, one sporadic case, was who developed deafness after fever and aminoglycoside treatment found to have homozygous 35delG mutation. His parents and healthy brother were heterozygous for the mutation.

Conclusion: Our results showed that dysmorphologic examination and mutation analysis are important for clarification of etiology, and thay can be helpful for genetic counselling.

P09.079
Genetic association of adipnectin with type 2 diabetes in Jordanian Arab population

***A. Alkhateeb**, D. Abuarqoub, S. Al-Azzam, R. Zyadine;*
Jordan U of Science and Technology, Irbid, Jordan.

Adiponectin, a protein exclusively secreted by adipose tissue but present at low levels in obese individuals, is now widely recognized as a key determinant of insulin sensitivity and of protection against obesity-associated metabolic syndrome. In Jordan, prevalence of diabetes increased from 13.0% to 17.1% over a period of 10 years, which is twice the prevalence of Diabetes in the US 7.8%. In this study, we examined the contribution of the promoter variant rs266729 (-11377C>G) of ADIPOQ gene as a risk factor for diabetic patients in Jordan. DNA was extracted from blood samples for patients and controls .Polymerase chain reaction and restriction fragment length polymorphism (RFLP) were used to genotype this variant. A total of 420 type 2 diabetic patients and 230 controls were successfully genotyped. The results showed a significant genotypic (p=0.00001) and allelic (p=0.01) association with variant in the diabetic patients as compared to controls. This suggests that ADIPOQ gene plays a role in increasing the risk of diabetes, at least in the Jordanian Arab population.

P09.080
Gene expression analysis in type 1 diabetes prediction

***K. Stechova**[1], R. Blatny[2], Z. Halbhuber[2], J. Vcelakova[1], T. Ulmannova[1], S. Kolouskova[1];*
[1]2nd Medical Faculty of Charles University, Prague, Czech Republic, [2]Central European Biosystems, Prague, Czech Republic.

Background: Type 1 Diabetes (T1D) is considered to be a Th(helper)-1 autoimmune disease but T1D pathogenesis is probably more complex. For the efficient T1D prediction we still lack the sufficient tool for the autoreactive T cell detection. In this study we analysed by gene

expression array the effect of diabetes associated autoantigens on peripheral mononuclear cells (PBMC) with the purpose to identify promising (pre)diabetes cell biomarkers.
Methods: Twelve recent onset T1D patients, 25 their first degree relatives (9/25 autoantibody positive) and 13 healthy controls were tested. Their PBMC were stimulated by the cocktail of diabetes associated autoantigens (proinsulin, IA2 and GAD65 derived peptides). After 72 hours the gene expression was evaluated by high density gene microarray and the data were analysed with the emphasis on search for differences in the cell cascades activation.
Results: The highest number of differences was observed when relatives were compared to controls (69 pathways). Out of these 69 significant pathways 15% of them belong to "immune response pathways". The highest number of significant differences in immune response related pathways was observed when T1D patients were compared to healthy controls (24%). The important seems to be mainly the activation of Th17 and TGF-beta related cell processes.
Conclusions: The important differences were observed when the activation of cell processes after the exposure to diabetes related autoantigens was compared within T1D patients, the first degree relatives and controls. Genes involved in Th17 and TGF-beta cascades represent promising (pre)diabetes biomarkers. Supported by Czech Ministry of Education (NPVII2B06019).

P09.081
Association of *NOS3* with Diabetic Retinopathy in the Azorean population

B. Parreira Amaro[1,2], *A. R. Couto*[1,2], *B. F. Bettencourt*[1,2], *P. Sousa*[1,2], *J. P. Pinheiro*[1,2], *J. Bruges Armas*[1,2];
[1]*HSEAH/SEEBMO, Angra do Heroismo, Portugal,* [2]*IBMC-Universidade do Porto, Porto, Portugal.*

Diabetic Retinopathy (DR) is an ocular manifestation which affects up to 80% of all patients who have had diabetes mellitus (DM) for 10 or more years. It has been suggested that, in diabetes, the increased level of Nitric Oxide in the retina, causes oxidative stress and subsequent pathological changes resulting in DR. Two enzymes which can cause vascular oxidative stress - the ecNOS and ACE - may have important roles in DR.
The objective of this study was to identify possible associations between DR and *NOS3* (T-786C and 4a/4b) and *ACE* (I/D) polymorphisms. 137 DM patients from the Azores were investigated: 76 DM patients with DR were compared with 61 DM controls without DR. *ACE* I/D polymorphism was typed by PCR-RFLP. *NOS3* polymorphisms 4a/4b and T786C were typed by PCR and PCR-RFLP, respectively. Linkage disequilibrium (LD) between *NOS3* polymorphisms was analyzed using Arlequin 3.1.
Allelic frequencies for the *NOS3* and *ACE* polymorphisms did not differ between both groups. All polymorphisms were in Hardy-Weinberg equilibrium with the exception of *ACE* I/D polymorphism in diabetic men (without DR). This HW disequilibrium suggests an association of I/D polymorphism to DM. One *NOS3* haplotype (bbCC) was statistically significant associated to DR (p=0,03;OR=3,625). These polymorphisms were not in LD.
This study identified a clear association of *NOS3* to DR. After testing this association, in a larger sample, this susceptibility haplotype can be used as a molecular marker for DR in DM patients. The sex-specific association of *ACE* to DM needs to be further investigated.

P09.082
Genes, viruses and inflammation in idiopathic (dilated) cardiomyopathy

I. P. C. Krapels*, A. van den Wijngaard, R. J. E. Jongbloed, R. M. Dennert, C. G. M. J. Eurlings, A. T. J. M. Helderman-van den Enden, Y. H. J. M. Arens, S. R. H. Heymans;*
Maastricht University Medical Center, Maastricht, Netherlands.

Background: dilated cardiomyopathy (DCM) is characterized by impaired contractility and ventricular dilatation . Mutations in the currently known DCM-genes are only found in a small number of DCM patients and the clinical phenotype in families with a known DCM mutation varies considerably. Cardiotrophic viruses and/or inflammation also play an important role in DCM and could explain interindivuals clinical variability. We assessed the presence of genetic variants and cardiac viruses/ inflammation in a group of 30 patients with an idiopathic DCM.
Methods: genetic analysis was performed on DNA through CardioCHIP analysis, a CHIP-based high throughput resequencing platform, simultaneously analysing 34 genes involved in inherited cardiomyopathies. The presence of cardiotrophic viruses and/or inflammation was assessed on cardiac biopsies.
Results: 16 of the 30 patients (52%) had genetic variations at CardioCHIP analyses. Cardiac biopsy in these 30 patients revealed ParvoB19 virus infection (>500 copies per mcg isolated DNA) in 7 patients, inflammation (>14 CD45-cells/mm^2) in 4 patients and active myocarditis in 1 patient. Of these 12 patients with viral infection and/ or inflammation (12/30=40%), 6 patients also had genetic alterations (6/12=50%) on cardioCHIP analysis. Family history was positive for sudden death in 3 of these 6 patients. We are currently performing DNA-analysis combined with cardiac biopsies in additional patients.
Conclusion: although based on small numbers, these data demonstrate that viral or inflammatory components as a cause for DCM do not exclude a genetic component and vice versa. These data are important for genetic counseling of individuals with DCM.

Recent bottlenecks at breed creation have led to high levels of inbreeding and linkage disequilibrium within dog breeds, making dogs perfect models for genome-wide association (GWA) mapping of genetic risk factors for inherited diseases.
Dilated cardiomyopathy (DCM) of non-ischemic origin is a heart muscle disease characterized by reduced myocardial contractile function, dilation of cardiac cavities and thinning of the cardiac walls, which may lead to congestive heart failure, arrhythmias or sudden cardiac death. The disease has been shown to be familial in dogs and phenotypically identical to human DCM.
Two dog breeds predisposed to DCM, Great Danes and Newfoundland, were used in this case-control study to identify genetic risk factors predisposing to DCM. Both healthy and affected dogs were thoroughly examined by veterinary cardiologists and characterized using echocardiography. A proportion of dogs also underwent post-mortem histological examination, to confirm or refute the diagnosis of DCM.
GWA study identified different regions of significant association in each breed, indicating different genetic risk factors. Identifying DCM genes in dogs will contribute to identification of causative genes for the corresponding human disease, and lead to advantages for both canine and human health.

P09.084
New susceptibility loci for dilated cardiomyopathy in Irish Wolfhounds

U. Philipp[1], *A. Vollmar*[2], *J. Haggstom*[3], *A. Thomas*[4], *O. Distl*[1];
[1]*Institute for Animal Breeding and Genetics, University of Veterinary Medicine Hannover, Hannover, Germany,* [2]*Veterinary Clinic for small animals, Wissen, Germany,* [3]*Dept of Clinical Sciences Faculty of Veterinary Medicine and Animal Science,The Swedish University of Agricultural Sciences, Uppsala, Sweden,* [4]*ANTAGENE, Animal Genetics Laboratory, Lyon, France.*

Dilated cardiomyopathy (DCM) is a progressive myocardial disease in human and dogs. The disorder is associated with cardiac dilation and reduced systolic function. In human, more than 25 genes are reported whose mutations are related to DCM but they still explain

only a minor part of familial DCM in human. Moreover, many of theses genes were excluded being involved in pathogenesis of DCM in dog breeds. Therefore, identifying susceptibility loci in dogs might identify new DCM causing genes in human. In addition, dogs are excellent models for new therapy concepts e.g. gene therapy which already could be demonstrated.
Irish Wolfhounds show a high prevalence for DCM. In this dog breed, it is a familial adult-onset disease with a dominant major gene model including a sex dependent allele effect.
Here, we present a whole genome linkage analysis using Illumina canine HD beadchip. The linkage data set included 71 dogs from 11 families. Overall, 47 dogs were DCM affected und 24 DCM unaffected. Multipoint linkage and haplotype analysis for SNP sets with different SNP densities were performed as well as non-parametric quantitative trait approaches with Merlin version 1.1.2. Consistent regions for Zmean and LOD score were identified on dog chromosomes 7, 8, 10 and 13. For some regions we identified candidate genes.

P09.085
Intron 3 VNTR polymorhism in XRCC4 DNA repair gene is associated with rehumatoid arthritis in Turkey

S. Pehlivan[1], *S. Oguzkan Balci*[1], *A. Aydeniz*[2], *M. Pehlivan*[3], *T. Sever*[1], *S. Gursoy*[2];
[1]*University of Gaziantep, Faculty of Medicine, Department of Medical Biology, Gaziantep, Turkey,* [2]*University of Gaziantep, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Gaziantep, Turkey,* [3]*University of Gaziantep, Faculty of Medicine, Department of Hematology, Gaziantep, Turkey.*

Objectives of the study: DNA repair genes are involved in several disease such as cancers, autoimmune diseases etc. Rheumatoid arthritis (RA) is a chronic, inflammatory disease that affects 0.5-1.0 % of the adult population. It is estimated, that at least 50 % of the risk of developing RA is determined by genetic factors. In this study, we investigated whether four polymorphisms in DNA repair genes (*XPD*, *XRCC1* and *XRCC4*) are associated with RA.
Methods: Sixty-five patients with RA and 70 healthy controls were examined for *XPD* (A-751G), *XRCC1* (A399G) and *XRCC4* (intron 3 VNTR and G-1394T) polymorphisms. All polymorphisms were genotyped by PCR and/or PCR-RFLP and analyzed statistically.
Results: The intron3 VNTR polymorphism in *XRCC4* showed an association with RA. The distribution of DD, DI and II genotypes for the gene was 20%, 33.8% and 46.2% in RA patients compared with 14.3%, 60% and 25.7% in the controls. The DI genotype was found at lower frequency in RA patients (χ^2=8.227 p=0.0021), while the II genotype was more frequent in RA patients (χ^2=5.285 p=0.010). For both the intron 3 VNTR and G-1394T polymorphisms in the XRCC4 gene region the observed genotype counts deviated from those expected under Hardy-Weinberg equilibrium (p=0.02 and 0.004, respectively), but there was no deviation for other gene polymorphisms. There is no statistical difference between the RA patients and control groups for *XPD* (A-751G), *XRCC1* (A399G), and *XRCC4* (G-1394T) gene polymorphisms (p>0.05).
Conclusion: Our results suggest that the intron 3 VNTR polymorphism in the *XRCC4* gene may be associated with RA ethiopathogenesis.

P09.086***
Targeted re-sequencing of candidate genes for developmental dyslexia: towards the discovery of novel single nucleotide polymorphisms

H. Matsson[1], *M. Peyrard-Janvid*[1], *J. Nopola-Hemmi*[2], *H. Lyytinen*[3], *P. H. T. Leppanen*[3], *J. Kere*[1,4,5];
[1]*Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden,* [2]*Department of Child Neurology, Helsinki University Central Hospital, Helsinki, Finland,* [3]*Department of Psychology, University of Jyväskylä, Jyväskylä, Finland,* [4]*Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [5]*Science for Life Laboratory, Karolinska Institutet, Stockholm, Sweden.*

Current next-generation sequencing platforms are well adapted for high-throughput analysis of sequence variants of many genes in parallel. For this pilot project, we aimed to identify novel single nucleotide polymorphisms (SNPs) and to assess the frequencies of known SNPs in 11 candidate genes for dyslexia, a common childhood learning disability with a large genetic component. Using a pooling strategy, 100 dyslectics of Finnish origin were combined into 10 equal pools. In addition, we used three HapMap DNA samples for methodological quality control. Target regions, including protein-coding exons surrounded by at least 50bp intronic sequence, and UTRs were enriched using the Halo Genomics selector probe technology with average design coverage of 95.9% and amplicon size of 420kb for all regions. Each pool was indexed with a unique barcode whereas the HapMap samples were indexed individually before paired-end sequencing on a SOLiD 4 platform, at Science for Life Laboratory, Stockholm, Sweden.
This approach allowed us to perform deep sequencing in order to detect novel variants with an estimated theoretical coverage of 30-300X per base. Analysis of the preliminary data shows a 99% SNP concordance for the HapMap DNA used in this project. Presently, SNP calling using different software solutions is underway and a panel of SNPs will be verified using the Sequenom MassARRAY iPLEX Gold genotyping methodology.
In summary, we describe a cost-effective approach for assessing the frequencies of sequence variants in selected gene regions using pooled samples of DNA.

P09.087
Genetic overlap of airway obstruction and emphysema

J. Smolonska[1], *P. Zanen*[2], *H. J. M. Groen*[1], *A. E. Dijkstra*[1], *D. S. Postma*[1], *M. Oudkerk*[1], *B. de Hoop*[2], *B. van Ginneken*[2], *W. Mali*[2], *J. Lammers*[2], *M. H. Boezen*[1], *C. Wijmenga*[1];
[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands.*

Airway obstruction and emphysema are two features of chronic obstructive pulmonary disease (COPD). COPD patients can display one phenotype or both at one time. We used the Nelson cohort comprising ~3000 individuals with lung function measurements and CT-scans to determine genes that contribute to both features. We performed genome-wide association studies on both sub-phenotypes. Airway obstruction was investigated in a case-control design (1030 cases with FEV1/FVC<0.7, 953 controls with FEV1/FVC>0.7 and FEV1 >90%pred, both groups being heavy-smokers with >20 pack-years, and 846 blood bank controls). Emphysema was investigated as a quantitative trait. To account for center-derived differences in these measurements we used 15th percentile (p15) of density distribution adjusted for air density in the trachea. p15 was analyzed using linear regression adjusting for age and pack-years smoking in 3047 subjects. To find overlap between these two sub-phenotypes we selected all SNPs with p<0.001 in each analysis, yielding a total of nine SNPs corresponding to four genes. When these genes were investigated in GeneMania they were enriched with an additional 9 genes directly interacting or co-expressed/co-localized with query genes and two of them point to a drug resistance pathway (GATHER p<0.0001, Bayes factor 6).
This is an interesting approach that can help identifying a shared etiology of two distinct sub-phenotypes of a single complex disease.

P09.088
HIF1A, PPARG and PPARGC1B gene variants and physical performance in middle school-age children

I. I. Ahmetov[1,2], *A. V. Malinin*[2], *A. M. Hakimullina*[2], *D. Gavrilov*[2];
[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.*

It has long been recognized that the interindividual variability of physical performance traits and the ability to become an elite athlete have a strong genetic basis. The genetic loci that influence these phenotypes are now being sought. At present, there are few studies related to the search of the associations of gene polymorphisms with physical, physiological and skill parameters in children and adolescents. The aim of the study was to determine the association between HIF1A Pro582Ser, PPARG Pro12Ala, PPARGC1B Ala203Pro gene polymorphisms and performance-related traits in 455 middle school-age children. The assessment of physical performance was conducted with a number of physical and physiological tests. Gene variants were determined by PCR. The discovered correlations concerned primarily sprint performance traits, being in agreement with the generally accepted data: the HIF1A 582Ser, PPARG 12Ala and PPARGC1B 203Pro alleles were associated with the maximal values of standing long-jump and handgrip strength, whereas the HIF1A Pro582, and PPARGC1B 203Pro alleles correlated with the ability to

perform endurance performance (1-min bench trunk-curl testing of abdominal muscular endurance). In conclusion, HIF1A Pro582Ser, PPARG Pro12Ala, PPARGC1B Ala203Pro gene variants are strongly associated with several performance-related traits in physically active middle school-age children.

P09.089
Association between polymorphisms of mannose-binding lectin and Epstein-Barr virus nuclear antigen 1 IgG antibody level

A. Szilagyi[1], *D. Csuka*[2], *H. Farkas*[2], *Z. Illés*[3], *G. Füst*[2];
[1]*Hungarian Academy of Sciences-Semmelweis University, Research Group of Inflammation Biology and Immungenomics, Budapest, Hungary,* [2]*Semmelweis University, 3rd Department of Internal Medicine, Budapest, Hungary,* [3]*University of Pécs, Department of Neurology, Pécs, Hungary.*

Increasing data support that infection by the Epstein-Barr virus (EBV) can be considered as a risk factor for multiple sclerosis (MS). Many studies have suggested a correlation between elevated EBV nuclear antigen 1 IgG (EBNA-1) level, MS and its disease activity. However, scarce data are available on the regulation of EBNA-1 level after EBV infection.

Hence, we decided to follow annual changes of EBNA-1 level in hereditary angioedema patients (as annual control samples of these patients were available for the last seven years). EBNA-1 level was also measured in healthy (N=182) and MS individuals (N=96) in order to analyze its correlation with exon 1 polymorphisms of the mannose-binding lectin (MBL) gene. EBNA-1 level was determined by ELISA; A/0 polymorphisms of MBL were genotyped by real-time PCR.

For the studied period EBNA-1 IgG levels were almost constant in each individual. Lower EBNA-1 IgG level was found in each studied group in carriers of a genotype (0/0) causing functional deficiency of MBL. By summing up data of all the 376 participants we found a significant difference (p=0.043) in the level of EBNA-1 between carriers of the 0/0 genotype (median 100.0 U/ml (IQ range 25.1-243.1)) and non-carriers (192.0 (90.3-421.4), respectively).

Our data indicate that EBNA-1 IgG antibody titer is relatively stable for years denoting a role of genetic factors in the regulation of this antibody. Polymorphisms of MBL may - at least partially - determine EBNA-1 level both in healthy and MS patients.

This work was supported by OTKA-NKTH 80842.

P09.090
Comprehensive study of genetic factors determining the development of rheumatic autoimmune diseases in humans.

V. Y. Dorodnykh*, I. V. Zvyagin, A. V. Chkalina, I. Z. Mamedov, D. M. Chudakov, S. A. Lukyanov, Y. B. Lebedev;*
M.M. Shemyakin and Yu.A. Ovchinnikov Institute of bioorganic chemistry of the Russian Academy of Sciences, Moscow, Russian Federation.

The purpose of our research was to find genetic factors of autoimmune arthropathies. During this research comparative genotyping of two Russian cohorts was performed, both of which combine HLA-B27 positive individuals.

Among a large number of MHC genes it was the HLA-B27, which was strongly associated with autoimmune arthropathies. Also few other candidate genes were involved in the development of pathogenesis. Most of those genes take part in various immunological processes such as differentiation and antigen presentation. In this research we study variability of candidate gene - ERAP1 specially in Russian Caucasian population.

We analyzed an association of several most associated with AS coding-region SNPs in the ERAP1 gene. Was genotyped 5 ERAP1 SNPs (rs2287987, rs30187, rs10050860, rs17482078, rs27044) in 70 AS patients and 83 HLA-B27-positive healthy controls from the Russian Caucasian population by SSP-PCR.

Considerable differences in allele's frequencies within patients vs control cohort were shown for 3 of 5 SNPs under investigation. Using the EM-algorhitm we reconstructed 3-marker haplotypes that distinguish with high probability two cohorts due to differences in the haplotypes frequencies. In such a way both the sensitive, CCT, haplotype and the protective, TTC, one were predicted. To verify the calculation we determined genuine frequencies of 5-marker haplotypes in AS cohort by haplotyping of individual cDNA samples. As a result presumably risk CCT haplotypes of ERAP1 gene was detected in 65 of 69 examined AS patients' genomes.

We forecasted ERAP1 risk haplotype CCT (rs17482078/10050860/2287987) and demonstrated that its frequency detected within AS cohort reaches 88%.

P09.091
Polymorphisms in the factor VII gene and the risk of myocardial infarction in patients with coronary thrombosis: A hospital based study

S. Dayakar[1,2], *K. Iravathy Goud*[3], *T. Parvathi Kumara Reddy*[4], *A. Lakshmi*[1], *B. Shyamala Sesikeran*[2], *M. D Sadhnani*[1];
[1]*Department of Clinical Biochemistry, Institute of Genetics and Hospital for Genetic Diseases,Osmania university, Hyderabad, India,* [2]*Apollo Hospital Educational And Research Foundation, Hyderabad, India,* [3]*Department of Molecular biology and cytogenetics, Hyderabad, India,* [4]*Instituto de Genetica,Dpto.de Biología Molecular Y Genomica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Mexico, Guadalajara, Jalisco, Mexico.*

Factor VII (FVII) is one of the central proteins in the coagulation cascade. High plasma levels of coagulation FVII have been suggested to be the predictors of death due to coronary artery disease. Since polymorphisms in the FVII gene contribute to variations in FVII levels and such polymorphisms may be associated with the risk of myocardial infarction(MI), which is precipitated by thrombosis. We studied a total of 319 patients, 152 of whom had severe angiographically documented for coronary atherosclerosis and no documentation of a previous MI. As a control group, 167 patients with normal coronary arteriograms were also included as healthy controls. We measured the levels of activated FVII and assessed three polymorphisms in the FVII gene, one involving the promoter (*A1*and *A2* alleles), one involving the catalytic region (R353Q), and one involving intron 7. Each of the polymorphisms influenced the FVII levels. To emphasize the contribution of genetic factors, we studied patients with a family history of thrombosis. Patients with the *A2A2* and *QQ* genotypes had the lowest levels of activated FVII (56% and 70 % lower, than the levels in patients with the wild-type genotypes). In the patient group, there were significantly more heterozygotes and homozygotes for the *A2* and *Q* alleles among those who had not had a MI than among those who had an infarction (P=0.007) for the presence of the promoter polymorphism and P=0.01 for the presence of the R353Q polymorphism. Our findings suggest that, certain FVII genotypes have a role in protection against MI.

P09.092
Modeling Parkinson's disease in rats

M. Raisinghani*;*
Sigma-Aldrich, St. Louis, MO, United States.

SAGE Labs has created targeted, homozygous knockouts of Lrrk2, Park2 (Parkin), Park6 (Pink1) and park7 (DJ-1) in rats. The Lrrk2 gene encodes the leucine-rich repeat kinase 2. Lrrk2 mutations account for 5-6% of familial Parkinson's dieases and 1-3% in sporadic PD. Collectively, these mutations result in the most common cause of PD. The Park2 gene, Parkinson disease (autosomal recessive, juvenile) 2, encodes the protein Parkin that localizes to the cytoplasm of neurons and mediates the degradation of improperly folded proteins. Roughly 20% of patients with Parkinson's disease onset before age 40 have mutations within Park2. Park7 (Parkinson disease [autosomal recessive, early onset] 7) gene, synonym DJ-1, belongs to the peptidase C56 family of proteins. In humans, loss of function of Park7 leads to a form of early-onset Parkinson's disease. Pink1 (PTEN-induced putative kinase 1) specifies a serine/threonine protein kinase. Mutations in Pink1 are implicated in early-onset Parkinson's disease. The Pink1 model is being developed in collaboration with the Michael J. Fox Foundation.

The targeted genomic editing for all theses genes was performed using the Zinc Finger Nuclease (ZFN) technology. The availability of genetically modified rat models for Parkinson's disease has opened up new avenues for researchers to better understand the pathophysiology of the disease and explore novel therapeutic avenues for its treatment.

P09.093
A polymorphic miR-155 binding site in AGTR1 is associated with cardiac hypertrophy in patients with Friedreich ataxia

M. Kelly[1,2], *R. D. Bagnall*[1], *R. E. Peverill*[3], *L. Donelan*[3], *L. A. Corben*[4], *M. B. Delatycki*[4,5], *C. Semsarian*[1,2,6];
[1]*Agnes Ginges Centre for Molecular Cardiology, Centenary Institute, Sydney, Australia,* [2]*Sydney Medical School, University of Sydney, Sydney, Australia,* [3]*Monash Cardiovascular Research Centre, MonashHEART and Monash University Department of Medicine (MMC), Victoria, Australia,* [4]*Murdoch Childrens Research Institute, Royal Children's Hospital, Victoria, Australia,* [5]*Clinical Genetics, Austin Health, Victoria, Australia,* [6]*Department of Cardiology, Royal Prince Alfred Hospital, Sydney, Australia.*

Background: Friedreich ataxia (FRDA) is a neurodegenerative condition with a heterogeneous cardiac phenotype caused by an expanded GAA trinucleotide repeat in the *FXN* gene. The number of GAA repeats on the smaller *FXN* allele (GAA1) only accounts for a portion of the observed variability in cardiac phenotype. Genetic modifying factors, such as single nucleotide polymorphisms (SNPs) in the Renin-Angiotensin-Aldosterone system (RAAS), may contribute to phenotype variability. This study investigated variability in the angiotensin-II type-1 receptor (*AGTR1*), angiotensin-converting enzyme (*ACE*), and *ACE2* genes as cardiac phenotype modifying factors in FRDA.

Methods: Review of the *AGTR1*, *ACE* and *ACE2* genes identified twelve haplotype tagging SNPs. Correlation of these SNPs with left-ventricular septal wall thickness (SWT), relative wall thickness, left-ventricular end-diastolic volume index and left-ventricular mass index (LVMI) was examined in a large Australian FRDA cohort (n=79) with adjustments performed for GAA1, sex and systolic blood pressure.

Results: The *AGTR1* polymorphism rs5186 was more common in FRDA patients than in a control population (minor allele frequency: 0.35±0.04 versus 0.22±0.02; p=0.002). Using a recessive model of inheritance, the C allele of rs5186 showed a significant trend with increased SWT (AA+AC=10.7±2.1mm, CC=11.7±2.8mm; p=0.005) and LVMI (AA+AC=99.7±28.6g/m^2, CC=119.6±34.0g/m^2; p=0.001). rs5186 increases expression of *AGTR1* by altering the binding site for miR-155, a regulatory microRNA. No associations were observed for the remaining RAAS polymorphisms.

Conclusions: rs5186 had an increased frequency in a large FRDA population and associated with increased SWT and LVMI. This study supports the role of RAAS polymorphisms as modifiers of cardiac phenotype in FRDA.

P09.094
The common polymorphism of FTO gene is associated with overweight or obesity in Russians

R. R. Shagimardanova*, A. A. Danilova, R. T. Gabbasov, I. I. Ahmetov;*
Kazan State Medical University, Kazan, Russian Federation.

The common rs9939609 A/T polymorphism of the fat mass and obesity-associated gene (FTO) was identified as an obesity-susceptibility gene variant by several independent large-scale genome association studies. The aim of the study was to investigate FTO gene variant with overweight or obesity in Russian population. PCR-restriction fragment length polymorphism was used to determine the rs9939609 polymorphism in 42 patients with overweight or obesity and 135 healthy controls (BMI less than 25 kg/m2) (all Caucasians). The genotype distributions of both groups were in the Hardy-Weinberg equilibrium. The frequencies of AA, AT and TT were 0.381, 0.333 and 0.286 in the overweight or obesity group, and 0.192, 0.489 and 0.319 in the controls (Chi-square = 6.62, P = 0.037). The frequency of AA genotype (with greatest risk for obesity) in case group was significantly higher than that in the controls (Chi-square = 6.28, P = 0.012). In conclusion, the AA genotype of FTO gene might be a risk factor of overweight or obesity in Russian population.

A correlative study of genetic and epigenetic factors associated with cardiovascular pathology

This work is presenting the results of a correlative study of genetic, epigenetic and metabolic factors associated with cardiovascular pathology diagnosed in 100 elderly vs 100 healthy (25 young, 25 adult and 50 aged) persons. HPLC estimation of methylome metabolites and PCR assays of gene polymorphisms as well as methylation sensible restriction estimation of global DNA methylation level associated with the classical karyotyping in limphocyte cultures derived from peripheral blood have been performed. The results showed interesting correlations between the modification of normal S-adenosylmethionine (SAM) to S-adenosylhomocysteine (SAH) ratio towards the increased level of SAH and decreased level of SAM, a pronounced hypomethylation of global DNA. These metabolites levels and epigenetic factors were correlated with genetic aspects in terms of an altered karyotype, as well as high frequency of polymorphism in genes controlling the methylome (methylenetetrahydrofolatereductase gene, *mthfr*) and hypertension (angiotensin-catabolysing gene, *ace*). The study also included the investigation of the above parameters variation when persons took a 3 months inulin containing diet. The results demonstrated that an altered metabolites level (increased SAH concomitant with a lowered SAM concentrations) determined a global DNA hypomethylation and hypercholesterolaemia. The genetic and epigenetic factors are well correlated with a high frequency of abnormal allelic expression of the *mthfr* and *ace* genes.The metabolomic parameters showed an interesting variation towards the decrease of SAH and increase of SAM concentration after three months of the inulin enriched diet.

Using genetic risk models to identify high-risk groups for the prevention of multifactorial diseases: will it work?

R. Mihaescu[1], *R. Moonesinghe*[2], *M. J. Khoury*[3], *C. A. J. W. Janssens*[1];
[1]*Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Office of Minority Health and Health Disparities, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Office of Public Health Genomics, Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Purpose: Genetic risk models could be useful in identifying high-risk groups for the prevention of multifactorial diseases. We investigated epidemiological parameters that may affect the performance of this risk stratification strategy.

Methods: Using simulated data, we assessed sensitivity, specificity, positive and negative predictive value for all possible thresholds of the risk model and investigated how these measures depend on the frequency of disease in the population, the frequency of the high-risk group, and the discriminative accuracy of the risk model, assessed by the area under the receiver-operating characteristic curve (AUC). We modeled genetic risk scores of 50 genes with equal odds ratios and genotype frequencies, which were varied across scenarios.

Results: We show that when the frequency of the high-risk group was lower than the disease frequency, positive predictive value increased with the AUC but sensitivity remained low. When the frequency of the high-risk group was higher than the disease frequency, sensitivity was high but positive predictive value remained low. When both frequencies were equal, both positive predictive value and sensitivity increased with increasing AUC, but higher AUC was needed to maximize both measures.

Conclusion: The performance of risk stratification is strongly determined by the frequency of the high-risk group relative to the frequency of disease in the population. The identification of high-risk groups with appreciable combinations of sensitivity and positive predictive value requires higher AUC.

Two novel loci, EML4/COX7A2L/KCNG3 and *IRF4/EXOC2*, were identified to be associated with Graves' Disease in Han Chinese

J. Wu[1], *F. Tsai*[2], *C. Yang*[1], *C. Chang*[2], *R. Chen*[2], *C. Chen*[2], *T. Wang*[2], *C. Chen*[1], *Y. Chen*[1];
[1]*Inst. of Biomedical Sciences, Taipei, Taiwan,* [2]*China Medical University Hospital, Taichung, Taiwan.*

Graves's disease (GD) is a common autoimmune thyroid disease and displays a strong female predominance. To identify new susceptibility genes that increase the risk of GD in a Han Chinese population, we conducted a genome-wide association study for GD in 596 patients and 804 controls. We found two loci associated with GD, *EML4/COX7A2L/KCNG3* (P = 3.21 × 10^{-6}; odds ratio [OR] = 1.59, 95% confidence interval [CI] =1.31-1.93) and *IRF4/EXOC2* (P = 1.1 × 10^{-5}; allelic OR = 1.44, 95% CI = 1.22-1.69). Within these loci are biological candidate genes that influence self tolerance and the response to estrogen, which may provide a partial explanation as to why women are predisposed to GD. We also confirmed that *HLA* loci (P = 2.75 × 10^{-11}; OR = 2.02, 95% CI = 1.64-2.78) and *TSHR* (P = 1.77 × 10^{-6}; OR = 1.48, 95% CI = 1.26-1.74) were associated with GD risk. In the present study, the HLA-DQB1*0202, HLA-DRB1*0701, HLA-DRB1*1202, and HLA-DRB1*1602 were associated with GD; these HLA alleles were not previously reported to be associated with GD in other Asian or Caucasian populations. Our results may lead to a better understanding of the underlying mechanisms of GD pathogenesis and female-biased autoimmunity.

P09.098
Characterization of the Genomic Risk Profile in Cerebrovascular Diseases

L. Fernandez-Novoa[1], ***J. Carril***[1], *S. Seoane*[1], *R. Cacabelos*[2];
[1]*Department of Genomics, EBIOTEC, A Coruña, Spain,* [2]*Institute for CNS Disorders and Genomic Medicine, EuroEspes Biomedical Research Center, A Coruña, Spain.*

The genomic cerebrovascular panel proposed here deals with the study of genes involved in different events that trigger the atherogenic process, such as: lipid metabolism, endothelial function, immune response, and stability of atherosclerotic plaques (thrombosis).
A total of 20 genetic variants in 15 different genes related to atherogenesis have been determined in 457 individuals, 153 patients with vascular dementia (VaD), 148 with vascular encephalopathy (VaE), 46 stroke patients (ACV) and 110 control subjects without ischemic or hemorrhagic stroke history, or other cerebral diseases, aged over 50 years.
Significant differences between controls and stroke patients were found for APOE*2/3 (6.12% vs. 15.22%, p<0.05), APOE*4/4 (14.29% vs. 10.87%, p<0.05) and IL6*-573GG (29.70% vs. 38.71%, p<0.05). The most informative genotypes in vascular dementia were AGT*235TT (22.83% vs. 6.08%, p<0.001) that showed a protective effect, IL6*-573GG (29.70% vs. 68.29%, p<0.001) and IL6R*1510AA (25.74% vs. 45.12%, p<0.001). Relevant genotypes for VaE were IL6*-573GG (29.70% vs. 51.67%, p<0.001) and IL6R*1510AA (25.74% vs. 45.00%, p<0.001).
The results found in this preliminary study show the relationship between the plasmatic levels of cytokines and the major incidence of cerebral vascular accidents. Increased levels of IL6 and his receptor IL6R increase the recruitment of monocytes and macrophages to the lesion-prone sites contributing to the formation of the plate of atheroma. The potential of other related markers for increased risk to develop atherogenesis associated with lipid metabolism, hypertension or thrombosis, must to be reconsidered when are compared with the high informative capacity showed by genes related with inflammation response.

P09.099
Identification of a novel glaucoma locus in dogs

S. J. Ahonen[1,2], *C. Mellersh*[3], *L. Hansen*[4], *G. Johnson*[4], *H. Lohi*[1,2];
[1]*University of Helsinki, Helsinki, Finland,* [2]*Folkhalsan Institute of Genetics, Helsinki, Finland,* [3]*Animal Health Trust, Suffolk, United Kingdom,* [4]*University of Missouri, Missouri, DC, United States.*

Glaucoma is the second leading cause of blindness and a common eye disease in both human and dogs. Glaucoma is characterized by loss of retinal ganglion cells, damage of the optic nerve and by elevation of the intraocular pressure. Both primary and secondary glaucoma are diagnosed in both species, primary being considered a hereditary complex disease with multiple susceptibility genes combined with environmental factors. No canine glaucoma genes have been identified although the disease affects several breeds including Dandie Dinmont Terrier (DDT). In DDT primary glaucoma develops slowly affecting middle-aged dogs and presents abnormalities in the iridocorneal angle. To map the glaucoma locus, we genotyped 23 affected and 23 control DDTs using canine SNP arrays. The average age of onset in affected dogs was 7 years. Control dogs had been confirmed healthy over the age of 10 years. Association analysis mapped a single locus on CFA8 (P_{raw}=1.6*10^{-7}, P_{genome} =0.001) spanning a region of ~10 Mb. Fine-mapping with 146 additional samples and 111 additional SNPs on 100 kb average spacing narrowed the association to a 2 Mb haplotype with p-value of 1.63*10^{-10}. The identified locus is syntenic with a region associated with human glaucoma, although no genes within the region have implicated. Targeted re-sequencing of the 2 Mb region revealed several possible candidate variants that are may be causal for glaucoma in DDTs. Further analysis of the re-sequencing data will likely identify a novel candidate gene for human glaucoma and establish an important late-onset glaucoma model in a large animal model.

P09.100
CYP1B1 as a modifier gene for two Brazilian families with juvenile-onset open angle glaucoma harboring the C433R mutation in the MYOC gene.

C. A. Braghini, *J. P. C. Vasconcellos, D. Stancato, M. J. Silva, A. Tavares, B. A. C. Santos, V. P. Costa, M. B. Melo;*
State University of Campinas, Campinas, Brazil.

Glaucoma comprises a heterogeneous group of optic neuropathies characterized by accelerated loss of optic nerve ganglion cells, clinically evaluated as increased cup to disc ratio and elevated intraocular pressure (IOP), representing the world's leading cause of irreversible blindness. Mutations in the *MYOC* gene were associated with primary open angle glaucoma (POAG) and juvenile-onset open angle glaucoma (JOAG). In the Brazilian population, the C433R is the most common mutation related to POAG and JOAG. Some authors have suggested the participation of *CYP1B1* gene as a modifier of POAG phenotype in case/control studies. The objective of this study was to evaluate the association between variants of the *CYP1B1* gene and C433R mutation in the *MYOC* gene in modulating glaucomatous phenotype in a family based approach. The individuals of two Brazilian families with JOAG and POAG, harboring the C433R mutation in the *MYOC* gene with incomplete penetrance were clinically assessed and the coding regions of the *CYP1B1* gene were screened. The R48G, A119S, V432L, D449D, and N453S polymorphisms were observed in members from both families. The genotype/phenotype correlation was performed, but the relationship of these polymorphisms with age of onset, IOP and cup to disc ratio was not considered statistically significant. This result may indicate that the *CYP1B1* gene is not responsible for modulating the disease phenotype in these families.

P09.101
Uniparental disomy and progressive clonal selection: a common mechanism causing late onset β-thalassemia major?

C. L. Harteveld[1], *C. Refaldi*[2], *A. Giambona*[3], *C. A. L. Ruivenkamp*[1], *M. J. V. Hoffer*[1], *C. Borgnia-Pignatti*[4], *A. Maggio*[3], *M. Cappellini*[2], *P. C. Giordano*[1];
[1]*The Hemoglobinopathies Laboratory, dpt. of Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Fondazione Ospedale Maggiore Policlinico, Istituto di Ricovero e Cura a Carattere Scientifico, Università di Milano, Milan, Italy,* [3]*U.O.C. Ematologia II con Talassemia, Azienda Ospedaliera Vincenzo Cervello, via Trabucco 180, 90146 Palermo, Palermo, Italy,* [4]*Department of Clinical and Experimental Medicine-Pediatrics, University of Ferrara, Ferrara, Italy.*

We present three cases of "severe late onset β-thalassemia" in three independent subjects, all presenting with the mild phenotype of beta thalassemia minor up to adult age and developing a severe transfusion dependent phenotype in the third and fourth decade of life when a presumed homozygosity for the β-thalassemia mutation is observed. In all three cases molecular analysis shows sequences in which homozygosity for the beta-thalassemia mutation occurs in the presence of a small but consistent wildtype signal in DNA extracted

from peripheral blood, from buccal mucose and from erythroid cultures. Loss of heterozygosity due to a deletion of one allele was excluded by MLPA analysis. Affymetrix SNP-array analysis reveals homozygosity for a large number of SNP's in a region on the short arm of chromosome 11 containing the beta-globin gene with a low background of wildtype SNP's, indicating mosaicism for a partial uniparental isodisomy of chromosome 11p.
Clonal selection for hematopoietic stem cells containing the uniparental isodisomy for the mutant beta-globin gene during life may account for the progressive development of the disease. A similar observation for a single case was made by Chang et al. (Haematologica 2008, 93(6):913-916), who found this in a single patient with late-onset β-thalassemia Major. Our study demonstrates that uniparental isodisomy of chromosome 11p15 is apparently more frequently associated with late-onset transfusion dependent β-thalassemia in presumed carriers at birth, representing a novel mechanism leading to this special form of beta-thalassemia and in other late-onset genetic diseases.

P09.102
Greyhound meningoencephalitis: Major Histocompatibility Complex association highlights a potential model for human neuroinflammatory disease.

*R. E. Shiel[1], C. M. Nolan[1], L. J. Kennedy[2], **J. J. Callanan**[1];*
[1]University College Dublin, Dublin, Ireland, [2]University of Manchester, Manchester, United Kingdom.

Neuroinflammation is common in humans and often has important and devastating consequences. In recent years there has been increased focus on the fact that neuroinflammation may underlie many neurodegenerative disorders such as Alzheimer's disease and Parkinson's disease. Furthermore, the predisposition of certain families to neuroinflammatory disorders such as Viliuisk encephalitis, Rasmussen's encephalitis and multiple sclerosis, highlights the potential of genetic predisposition to neuroinflammation.
We have recently identified a unique breed-associated encephalitis in young greyhounds. Although the underlying cause is unknown, the early onset and high frequency of disease in siblings makes a genetic predisposition likely. This disorder is invariably fatal and the unique pattern of distribution of inflammation within brain tissue made it possible to accurately phenotype this condition and allowed for the collection of diseased siblings, healthy siblings, parents and unrelated control tissues.
In preliminary studies, Major Histocompatibility Complex (MHC) Dog Leukocyte Antigen (DLA) three locus class II haplotypes were determined in 39 diseased dogs with post mortem confirmed disease, and 111 unrelated healthy controls. A significant association was detected between the DLA-DRB1*01802/DQA1*00101/DQB1*00802 haplotype and the development of disease, observed in 38.5% cases in contrast to 11.7% controls (OR=4.7, Chi2=11.9, p<0.0006).
A genome wide association study (GWAS) was performed using 25 unrelated diseased animals and 24 unrelated controls. No regions achieved genome wide significance but results from a larger cohort are pending.
The absence of a strong association in the GWAS study suggests this disease is not monogenic. The DLA association could reflect either an autoimmune or infectious cause.

P09.103
A genome-wide association study for two autoimmune diseases in Sardinia.

***I. Zara**[1], M. Pitzalis[2], M. Zoledziewska[2], E. Cocco[3], F. Deidda[2], J. Frau[3], M. Dei[4], S. Lai[4], F. Poddie[2], R. Cusano[2], M. Marcelli[1], F. Reinier[1], R. Berutti[1,2], C. Sidore[2,5], M. Valentini[1], G. Farina[6], D. Schlessinger[7], G. Rosati[6], S. Sanna[4], F. Cucca[2,4];*
[1]CRS4 (Center for Advanced Studies, Research and Development in Sardinia), Pula, Italy, [2]Dipartimento di Scienze Biomediche, Università di Sassari, Sassari, Italy, [3]Centro Sclerosi Multipla, Dipartimento di Scienze Neurologiche e Cardiovascolari, Università di Cagliari, Cagliari, Italy, [4]Istituto di Ricerca Genetica e Biomedica (ex INN), CNR, Monserrato, Italy, [5]Department of Biostatistics, Center for Statistical Genetics, University of Michigan, Ann Arbor, MI, United States, [6]Clinica Neurologica, Università di Sassari, Sassari, Italy, [7]Laboratory of Genetics, National Institute on Aging, Baltimore, MD, United States.

Autoimmune diseases are extremely common in Sardinians, with the highest incidence worldwide observed for Multiple Sclerosis and Type 1 Diabetes. To detect novel loci associated with both diseases, we analyzed 1,922 controls, 2,280 Multiple Sclerosis (MS) and 1,377 Type 1 Diabetes (T1D) unrelated cases that were genotyped with the Affymetrix 6.0 array. We used Birdseed-v2 to perform genotype calling over a cluster containing all individuals and successively applied standard quality filters to each sample and marker. We then performed three Genome Wide Association Studies (GWAS): two for MS and T1D respectively, and one for shared loci using all available cases. Quality filters were re-applied to each specific data set, leading to a minimum of 471,016 markers available for association. For T1D, only the HLA locus reached genome-wide significance (p=4x10-108), but other known genes were confirmed at lower p-values, including IL2RA and CTLA4. For MS, we confirmed the association at HLA (p=4x10-31), IL2RA, CLEC16A, CD58 and CBLB. SNPs with borderline significance (P<5x10-6) on chr2q13 and chr8q21.12 with nearby strongly functional candidate genes suggest novel potential loci that require further analyses. Finally, the GWAS on shared autoimmunity confirmed the HLA locus and IL2RA gene, and revealed two possible candidates at borderline significance on chr9q21.33 and chr10q26.3. To increase the number of tested variants and to refine the association at known and potentially novel loci, we are performing imputation of un-typed markers using Sardinian and 1000 Genomes sequencing data, while the most associated markers are validated by de-novo genotyping in the entire cohort.

P09.104
Genetic architecture of circulating lipid levels

Genetic architecture of circulating lipid levels

Serum concentrations of low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TG) and total cholesterol (TC) are important heritable risk factors for cardiovascular disease. Although genome-wide association studies (GWAS) of circulating lipid levels have identified numerous loci, a substantial portion of the heritability of these traits remains unexplained. Evidence of unexplained genetic variance can be detected by combining multiple independent markers into additive genetic risk scores. Such polygenic scores, constructed using results from the ENGAGE Consortium GWAS on serum lipids, were applied to predict lipid levels in an independent population-based study, the Rotterdam Study-II (RS-II). We additionally tested for evidence of a shared genetic basis for different lipid phenotypes. Finally, the polygenic score approach was used to identify an alternative genome-wide significance threshold prior to pathway analysis and those results were compared to those based on the classical genome-wide significance threshold. Our study provides evidence suggesting that many loci influencing circulating lipid levels remain undiscovered. Cross-prediction models suggested a small overlap between the polygenic backgrounds involved in determining LDL-C, HDL-C and TG levels. Pathway analysis utilizing the best polygenic score for TC uncovered extra information compared to using only genome-wide significant loci. These results suggest that the genetic architecture of circulating lipids involves a number of undiscovered variants with very small effects, and that increasing GWAS sample sizes will enable the identification of novel variants that regulate lipid levels.

Científicas, Granada, Spain.
Rheumatoid Arthritis (RA) comprises different subsets based on the presence or absence of autoantibodies termed anti-citrullinated peptide antibodies (ACPA). This heterogeneity may reflect important biological differences underlying the disease process. Previous genome-wide association studies mainly addressed ACPA positive RA patients, and consequently detected genetic risk factors primarily associated with ACPA positive disease. The identified genetic factors are typically related to the immune system, pointing to an (auto)-immune disease mechanism in these patients. For ACPA negative RA little is understood about the genetic risk factors, although a substantial part of the disease risk is heritable in this group of patients.
Our goal was to investigate the genetic risk factors in ACPA negative RA. Therefore, we performed a large scale genome wide association study (GWAS) study in a Dutch cohort of 884 ACPA negative RA patients and 4011 controls, and an additional cohort of 699 Caucasian patients and 1653 controls with different nationalities. All patients were screened on the Illumina Human Cyto-12 chip. We will present results of the first analysis of the Dutch cohorts that shows that genetic risk factors for ACPA positive RA indeed differ from ACPA negative RA.

P09.106
A canine model for Hashimoto´s disease

K. Sundberg[1], *K. M. Ahlgren*[2,3], *A. Lobell*[2,3], *O. Kämpe*[2,3], *W. E. R. Ollier*[4], *L. J. Kennedy*[4], *E. Strandberg*[1], *Å. Hedhammar*[6,3], *K. Lindblad-Toh*[6,3], *G. Andersson*[1,3], *G. Rosengren-Pielberg*[3];

Hashimoto's thyroiditis, an autoimmune disease resulting in hypothyroidism, affects millions of people around the world. Even though some familiar cases have been genetically explained, the complete genetic basis of the disease remains largely unknown.
The dog, with its unique genetic structure formed by domestication and recent breed creation, has been proven to be an excellent model for mapping genes. Some breeds, such as the giant schnauzer, show an extraordinary high prevalence of naturally occurring hypothyroidism. We have carefully characterized the canine phenotype and believe there is a strong comparative value because of similar etiology, clinical signs and disease progression.
By a candidate gene approach we have found a strong association to DLA-DRB1*01201/DQA1*00101/DQB1*00201 (corresponding to HLA) in the Giant schnauzer breed (odds ratio of 6.5). We have also performed genome-wide association in the same breed, using the Illumina 174 K canine SNP array for 69 cases and 49 controls. Among the identified candidate regions, several harbour genes with known immuno-regulatory function. Fine-mapping in multiple breeds has confirmed the associations and identified a shared haplotype.
Currently we are performing functional analyses and targeted resequencing of candidate regions and genes in both dogs and humans in order to identify risk factors. We hope that our knowledge will lead to better diagnosis and treatment for both dogs and humans.

P09.107
Gender and dietary factors modulate the effect of the R230C/ ABCA1 variant on HDL-cholesterol levels in Mexican individuals

S. Romero-Hidalgo[1,2], *J. González-Barrios*[3], *M. Villarreal-Molina*[1], *S. Canizales-Quinteros*[4,5], *V. Acuña-Alonzo*[6], *M. Rodríguez-Arellano*[2], *L. Yañez Velazco*[7], *D. Bernal-Alcantara*[7], *A. Carnevale*[1];
[1]*Instituto Nacional de Medicina Genómica (INMEGEN), Mexico City, Mexico,* [2]*Hospital Regional "Lic. Adolfo López Mateos" Instituto de Seguridad Social y Servicios de los Trabajadores del Estado (ISSSTE), Mexico City, Mexico,* [3]*Hospital Regional "1 de Octubre" Instituto de Seguridad Social y Servicios de los Trabajadores del Estado (ISSSTE), Mexico City, Mexico,* [4]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (INCMNSZ), Mexico City, Mexico,* [5]*Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico,* [6]*Escuela Nacional de Antropologı´a e Historia (ENAH), Mexico City, Mexico,* [7]*Medical Division, Instituto de Seguridad Social y Servicios de los Trabajadores del Estado (ISSSTE), Mexico City, Mexico.*
The non-synonymous R230C variant within the ATP-binding cassette transporter A1 gene (ABCA1) has been associated with lower high-density lipoprotein cholesterol (HDL-C) levels in several independent studies. The aim of this project was to analyze whether gender, body mass index and dietary factors modulate the effect of R230C on HDL-C levels. The study included 3630 adults (1173 men and 2457 women) from a nationwide survey conducted by the State's Employees Social Security and Social Services Institute in Mexico (ISSSTE). Genotyping was perfoemd using Taqman probes. The overall risk allele frequency was 9.2%, showing a north to south increasing gradient, consistent with the higher contribution of the Native American gene pool to the populations of Southern Mexico. As expected, the C variant showed a highly significant association with lower HDL-C levels (mean TT:45.5 mg/dL; CT:41.9 mg/dL; CC:39.9 mg/dL; $p=9.2x10^{-13}$). However, there were clear gender differences, as the effect of the C variant was greater and more significant in women (β= -3.6%; $p=2.2x10^{-11}$) than in men (β= -2.8%; $p=1.8x10^{-3}$). In male subjects, increased percentage of dietary carbohydrates was significantly associated with lower HDL-C levels, but this effect was not observed in males with CT or CC genotypes (p= $p=7.3x10^{-4}$). In contrast, in women higher percentage of dietary carbohydrates was significantly associated with lower HDL-C only in in CT or CC genotypes (p=0.027), particularly in premenopausal women ($p=1.3x10^{-9}$). In conclusion, gender, menopausal status and percentage of carbohydrate intake modulate the effect of the ABCA1-R230C variant on HDL-C levels.

P09.108
Allelic polymorphisms of thrombophilic genes in children with brain diseases from Russia.

O. E. Gromyko[1], *N. S. Aver'yanova*[1], *N. V. Zhurkova*[1], *N. L. Nechaeva*[1], *L. M. Kuzenkova*[1], *V. G. Pinelis*[1], *A. Y. Asanov*[1,2];
[1]*Scientific center of Children's Health, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.*
Inherited thrombophilia (IT) can be defined as a genetically determined predisposition to the development of thromboembolic complications. However this problem is not fully clarified. The aim of our study was estimate allelic polymorphisms of different genes involved in IT in children with acute disturbance of brain hemodynamics and neurodegenerative diseases, and to estimate the impact of IT on the risk of stroke in children. The frequencies of polymorphisms -455G>A of the *FBG* gene, 20210G>A of the *FII* gene, 1691G>A of the *FV* gene, 1565T>C of the *GPIIIa* gene, 4G>5G of the *PAI-1*gene and 677C>T of the *MTHFR* gene were investigated in 20 children with ischaemic stroke, 58 children with neurodegenerative diseases and 100 age-matched controls, using hybridization with oligonucleotide biochips.
The frequency of the *FV* Leiden mutation was significantly higher in children with stroke (p=0.0001) compared with the control group. The occurrence of polymorphisms *MTHFR* 677C>T with 4G/5G in *PAI-1* was higher in children with stroke (p=0.05) and children with neurodegenerative diseases (p=0.003) compared with the control group. Thus our data have shown that the *FV* Leiden mutation can be considered as an important risk factor for ischaemic stroke. A combination of the *MTHFR* 677C>T variant and 4G/5G in *PAI-1* increases the risk of ischemic stroke and neurodegenerative diseases. Screening for inherited mutations may be helpful in the prevention of thrombophilic disorders.

P09.109
HHEX is associated with T2D in a South Asian Population

L. K. Towns[1], *M. Attard*[2], *A. J. Walley*[2], *U. L. Fairbrother*[1];
[1]*London Metropolitan University, London, United Kingdom,* [2]*Imperial College, London, United Kingdom.*
The numbers of individuals worldwide developing T2D has increased over the last 30 years, with specific ethnic populations being at a higher risk for developing this complex disease. South Asians are one such population, particularly within an obesogenic environment. A compounding factor for this increased risk is body fat distribution and South Asian (SA) individuals, they have a higher volume of subcutaneous and central visceral adipose tissue but relatively less muscle mass. This contributes to them developing insulin resistance and T2D at a lower BMI, compared to Caucasians. Several genes have

been identified as candidates for T2D through genome wide association scans, including HHEX. Our study was designed to ascertain whether variants in the HHEX locus of 663 SA women influenced the risk of developing T2D. Using the Sequenom iPLEX assay 11 SNPs spanning this region were genotyped. Logistic regression controlling for age and BMI revealed two SNPs significantly associated with development of T2D, rs2488073 (p=0.021, OR 0.181 (0.043 - 0.7710)) and rs4933236 (p=0.004, OR 0.268 (0.109 - 0.66300)). In both cases the minor alleles show a protective effect towards T2D indicating that the risk alleles are the major alleles. Thus we have found an association with SNPs in the HHEX gene region and T2D that is specific to the South Asian population.

P09.110
A new contribution of *PHOX2B* in the pathogenesis of isolated Hirschsprung disease

R. Fernández[1,2], *Y. Mathieu*[3], *R. Nuñez-Torres*[1,2], *M. Acosta*[1,2], *G. Antiñolo*[1,2], *J. Amiel*[3], *S. Borrego*[1,2];
[1]*Unidad de Gestión Clínica de Genética, Reproducción y Medicina Fetal. Instituto de Biomedicina de Sevilla (IBIS), Hospitales Universitarios Virgen del Rocío/CSIC/Universidad de Sevilla, Seville, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Sevilla, Spain,* [3]*INSERM U-781, AP-HP Hôpital Necker-Enfants Malades, Paris, France.*

Hirschsprung disease (HSCR) is a congenital malformation of the hindgut produced by a disruption in neural crest cell migration during embryonic development. HSCR has a complex genetic aetiology with several genes involved in its pathogenesis. *PHOX2B* plays a key function in the development of neural crest derivatives, which has made it an excellent candidate gene for human neurocristopathies. In fact several mutations at this locus cause some syndromic forms of HSCR, as Congenital Central Hypoventilation Syndrome (CCHS) or neuroblastoma (NB). In contrast, to date no mutations had been associated to isolated HSCR and only the common variant g.1364A>G seems to have a predisposing effect in a Chinese series of patients. We sought to determine if *PHOX2B* plays any role in the pathogenesis of isolated HSCR, by both a mutational screening in our series, and the evaluation of its polymorphisms/haplotypes as modifier factors. No association was detected for the common variants tested, including g.1364A>G, which suggests that its association to HSCR is restricted to Chinese population. Our most relevant finding was the identification of a de novo and novel deletion (c.393_411del18) in a HSCR patient without any feature of NB or CCHS. Absence of this variant in 150 normal controls and results of in silico and functional assays support its pathogenic effect related to HSCR. This is the first time that a *PHOX2B* mutation is detected in an isolated HSCR patient, which represents a new perspective of the PHOX2B role in the pathogenesis of the disease.

Hirschsprung disease (HSCR) is a congenital malformation of the hindgut produced by a disruption in the neural crest cells migration during embryonic development. This disorder results in an absence of intramural ganglion cells in the submucosal and myenteric plexuses producing a functional intestinal obstruction. HSCR presents an estimated incidence of 1/5000 live births with sex-dependent penetrance and male predominance of 4:1. *RET* is the major gene associated to HSCR with differential contributions of its rare and common, coding and noncoding mutations to the multifactorial nature of this pathology. In the present study, we have performed a comprehensive study of our HSCR series evaluating the involvement of both *RET* rare variants (RVs) and common variants (CVs) in the context of the disease. RVs were identified by dHPLC and direct sequencing whereas studies of CVs, including the main CV associated to HSCR, the enhancer variant of intron 1 (rs2435357), were performed by Taqman technology. Our results confirm the strongest association to HSCR for the enhancer variant, and demonstrate a significantly higher impact of it in male versus female patients. Integration of the *RET* RVs and CVs analysis showed that in 91.66% of cases with both kinds of mutational events, the enhancer allele is *in trans* with the allele bearing the *RET* RV. Thus, *RET* CVs and RVs seem to act in a synergistic way leading to HSCR phenotype. Furthermore, our results show the existence of a gender effect on both the transmission and distribution of rare coding and common HSCR causing mutations.

Novel identification of *PROKR1* and *PROKR2* genes implicated in the pathogenesis of Hirschsprung´s disease

M. Ruiz-Ferrer[1,2], *A. Torroglosa*[1,2], *R. Núñez-Torres*[1,2], *J. C. de Agustín*[1], *G. Antiñolo*[1,2], *S. Borrego*[1,2];
[1]*Hospital Universitario Virgen del Rocío, Sevilla, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Sevilla, Spain.*

The enteric nervous system (ENS) is entirely derived from migrating neural crest cells and its development strongly depends on specific molecular pathways. Disturbances appearing during theses processes have been demonstrated to affect the proper formation and/or function of the ENS, leading to severe intestinal dysfunctions such as Hirschsprung´s disease (HSCR). Recently, the prokineticin receptor 1 (PROKR1) pathway has been identified to work co-ordinately with the RET/GDNF pathway in the development of mice ENS. In this sense, human ENS progenitors were isolated and characterized from the ganglionic gut obtained from childrens diagnosed with and without HSCR, using full-thickness gut resection specimens or gut biopsy samples, respectively. The expression of both prokineticin receptors, PROKR1 and PROKR2, was then examined. In addition, we also performed a mutational analysis of *PROKR1, PROKR2* and their ligands, *PROK1* and *PROK2*, in a cohort of HSCR patients, evaluating them for the first time as susceptibility genes for the disease. Immunocytochemical analysis showed that the majority of the ENS progenitors isolated and grown like neurosphere were multipotent and neural crest cells in origin. Furthermore, we demonstrated that not only PROKR1, but also PROKR2 might mediate a complementary signalling to the RET/GFRα1/GDNF pathway supporting proliferation/survival and differentiation of precursor cells during ENS development. These results, together with the detection of sequence variants in *PROKR1, PROK1* and *PROKR2* genes associated to HSCR and usually in combination with *RET* or *GDNF* mutations, provide the first evidence to consider them as susceptibility genes for HSCR.

P09.113
HLA-B27 gene study in a paediatric cohort of spondyloarthropathies

A. Militaru[1,2], *O. Belei*[1,2], *C. Daescu*[1,2], *O. Marginean*[3,2], *M. Puiu*[1,2], *I. Simedrea*[1,2], *T. Marcovici*[1,2], *A. Craciun*[1,2], *D. Chiru*[1,2], *R. Stroescu Giurescu*[1];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*"Louis Turcanu" Paediatric Emergency Hospital, Timisoara, Romania,* [3]*University of Medicine and Pharmacy, Timisoara, Romania.*

Background

The spondyloarthropathies (SpA) are a family of related disorders that includes ankylosing spondylitis (AS), reactive arthritis (ReA), psoriatic arthritis (PsA), spondyloarthropathy associated with a inflammatory bowel disease (IBD), undifferentiated spondyloarthropathy (USpA). The spondyloarthropaties are strongly associated with HLA-B27 gene.

Aims

The objective of our study was to observe the correlations between the positivity of HLA-B27 gene and the clinical, biological manifestations of the patients, the response to the treatment and the course of the disease.

Material and methods

We tested for HLA-B27 gene a group of 19 pediatric patients linked by common pathology, including inflammatory back pain and peripheral enthesitis. The evaluation of the patients included complete clinical assessment, laboratory studies, radiological findings and genetic study of HLA-B27.

Results
According to the European Spondyloarthropathy Study Group (ESSG) criteria, we established the diagnoses from the tabel below and the presence of HLA-B27 gene.
Six B27-positive patients from the total 13 children with SpA responded inadequate to non-steroidal anti-inflammatory drugs (NSAID), needing forward treatment (Sulfasalazine, Mesalazine, biologic agents), comparing with the B27-negative children, who had excellent response to NSAID. The course of the disease was more favorable in HLA-B27 negative children.
Discussions
HLA-B27 gene represents a diagnostic criteria in SpA, but could be used as a marker for the treatment response and disease outcome.

HLA-B27 presence in SpA			
	HLA-B27 positive	HLA-B27 negative	Total cases
USpA or Enthesitis-related arthritis	4	1	5
IBD associated SpA	2	1	3
ReA	2	3	5
Patients with cronic back pain, but without criteria for SpA	1	5	6

P09.114
Characterisation of HLA-DQB1 expression demonstrates highly variable expression regulated by SNPs associated with Leprosy susceptibility

***K. Plant**, B. P. Fairfax, S. Makino, J. C. Knight;*
Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

The HLA-DQ1 heterodimer is composed of DQA1 and DQB1 proteins that together form an antigen presentation molecule expressed on most antigen presenting cells. DQA and DQB alleles are strongly associated with susceptibility to multiple diseases, most notably autoimmune conditions including coeliac disease and rheumatoid arthritis. Much of the genetic variation between DQ alleles leads to coding changes resultant in varying abilities to bind and present certain peptides. In addition to structural variation between DQA1 and DQB1 alleles, it has become increasingly apparent that alleles vary in terms of quantitative expression. The highly polymorphic nature of these genes can confound microarray based expression quantitative trait (eQTL) analysis by interference with probe hybridization. With this in mind we performed eQTL analysis of these genes in peripheral blood mononuclear cells from 288 healthy Caucasians using quantitative PCR. Subjects were genotyped at 731,442 markers (Illumina HumanOmniExpress) with subsequent imputation analysis. We identified a haplotype associated with a 5-fold increase in baseline HLA-DQB1 expression (rs9273440, p 3.2*10-66). Whilst this haplotype does not appear to be associated with autoimmune disease, it includes risk alleles for the mycobacterial disease Leprosy. Further analysis of Leprosy associated SNPs demonstrate that in tandem with increased susceptibility noted with increased HLA-DQB1 expression, SNPs associated with reduced HLA-DQB1 expression are protective against Leprosy. These associations were not seen with HLA-DQA1 or HLA-DRB1 expression. This analysis advances our understanding of the strong genetic association of Leprosy with the MHC class II region and provides functional insights into mechanisms of Leprosy susceptibility.

P09.115
Correlation of MTHFR C677T polymorphism with plasma homocysteine concentration in Armenian patients with ishemic stroke and acute myocardial infarction

***L. Safaryan**, T. Sarkisian;*
Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.

In view of the controversy of the role of MTHFR C677T mutation in plasma homocysteine (Hcy) level elevation in patients with cardiovascular diseases and paucity of studies from Armenia, this study has been undertaken. The overall aim was to evaluate MTHFR C677T gene polymorphism in ischemic stroke (IS) and acute myocardial infarction (AMI) patients and correlate these with Hcy level. In a study group of 54 patients (43% male) with confirmed IS, 38 patients with AMI (87% male) and 56 healthy volunteers (50% male), MTHFR polymorphism was detected by SNP-extention assay and determined by ELISA (Prontodiagnostic), and total plasma Hcy was measured by ELISA (Axis-Shield). Significant increase of Hcy was detected in patients with IS (19,18+/-1,49 micromol/L) and AMI (15,59+/-1,76 micromol/L) compared to controls (10,01+/-0,86 micromol/L). The OD for IS in subjects with hyperhomocysteinemia was 16,7 (95%CI=6,05-45,6, p=0.001) and for AMI was 8,3 (95%CI=2,9-24.1, p=0.01). Meantime, the elevation of Hcy level above 15 micromol/L was observed in **56% of cases with IS and in 42% with AMI, while only in 5% of controls.** The plasma Hcy in patients with IS and AMI with MTHFR CC, CT and TT genotypes were 16,6±1,7, 21,20±1,7, 30,12±9,6 micromol/L and 13,11+/-1,24, 18,25+/-3,19, 16,27+/-2,57 micromol/L, respectively. Thus, we showed association of MTHFR polymorphysm in IS and AMI patients with high frequency of elevated homocysteine level in comparison with control group. However, since homocysteine level in latter don't depend on MTHFR polymorphism, e**xponentiation of homocysteine level by other risk factors are quite possible.**

P09.116
RET Mediated Gene Expression Profiling of ENS Precursors

***Y. Sribudiani**[1], R. S. N. Fehrmann[1], E. Binder[2], M. Metzger[2], L. Franke[1], A. J. Burns[2], N. Thapar[2], G. J. te Meerman[1], R. M. W. Hofstra[1];*
[1]University Medical Center Groningen, Groningen, Netherlands,
[2]Gastroenterology and Neural Development Units, Institute of Child Health, University College London, London, United Kingdom.

Signaling of the RET-GDNF receptor triggers many important signal transduction routes crucial for the migration, proliferation, differentiation and survival of the neural crest stem cells (NCSCs), cells that are responsible for the formation of the enteric nervous system (ENS). To identify pathways and genes triggered by RET, we performed gene expression profiling using Microarray Affymetrix GEneChip Mouse Genome 430 2.0 platform on GDNF stimulated and non-stimulated NCSCs. For this we isolated YFP labeled-NCSCs out of embryonic mouse guts E14.5 from Wnt1-Cre/LoxP/R26-YFP transgenic mice by FACs sorting and short term cultured in media with or without GDNF. To identify NCSCs specific genes, we compare the microarray data of NCSCs and embryonic gut E14.5. The data were analyzed by Gene Set Enrichment Analysis (GSEA) and single-gene analysis methods. Pathways that were up-regulated during GDNF stimulation were pathways important for Lipid metabolism, ATP and Steroid synthesis. Several important signaling pathways for ENS and embryonic development were found to be significantly down-regulated upon GDNF stimulation such as the Notch, TGFβ/Smad and Wnt signaling pathways. Genes involved in the cell cycle arrest and apoptosis were down-regulated, pointing toward a model in which NCSC proliferate and survival during ENS development. By single-gene analysis, we identified 429 genes that were differentially expressed between NCSCs treated with GDNF and untreated cells (Bonferoni, $p < 0.05$). In summary, here we provide a profile of pathways and genes that are expressed in ENS precursors and regulated by the RET signaling. These data might helpful in identifying candidate HSCR genes.

P09.117
The role of functional HTR1B variants in alcohol dependence: evidences from haplotype analysis

***V. Contini**, G. Bertuzzi, E. Polina, E. Hendler, M. Hutz, C. Bau;*
Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Alcohol dependence, a common and clinically heterogeneous disease, is frequently comorbid with many other mental illnesses and influenced by genetic and environmental factors. Animal and human studies have suggested that the serotonergic system plays an important role in alcohol consumption and abuse, mainly due to the serotonin receptor 1B (5-HT1B) function in the mesolimbic reward pathway. Association studies between the HTR1B gene variants and alcoholism have found significant results. There is also evidence for a complex balancing regulation of this gene by two functional variants in its promoter region (T-261G and A-161T), which are in linkage disequilibrium. The aim of this study is to investigate the role of the most relevant variants of the HTR1B gene (T-261G, A-161T, G861C and A1997G) in the susceptibility to alcohol dependence. The sample comprised 136 Brazilian alcoholics of European descendent and 237 controls. The results suggest an association between a functional variant of the gene (T-261G) and alcohol dependence (p=0.001). The haplotype analysis,

comprising all studied HTR1B polymorphisms, has shown a different distribution pattern between patients and controls (p<0.0001), which is consistent with the role of the two functional variants of the promoter region. In conclusion, our findings point to an association between functional variants in the promoter region of the HTR1B gene and alcohol dependence, supporting previous neurobiological evidences of the involvement of HTR1B variations in alcohol-related phenotypes.

P09.118
Human *SA* gene polymorphisms are associated with hypertension in the Chinese population: the SAPPHIRe study

M. Lin[1,2], *C. Hwu*[3], *P. Tsai*[1], *C. A. Hsiung*[4], *L. Chuang*[5], *H. W. Sheu*[6], *Y. Hung*[7], *L. Ho*[2];

[1]*Institute of Public Health, National Yang-Ming University, Taipei, Taiwan,* [2]*Department of Medical Research and Education, Taipei Veterans General Hospital, Taipei, Taiwan,* [3]*Section of Endocrinology and Metabolism, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,* [4]*Department of Bioinformatics and Biostatistics, National Health Research Institutes, Zhunan, Taiwan,* [5]*Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan,* [6]*Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan,* [7]*Division of Endocrinology and Metabolism, Tri-Service General Hospital, Taipei, Taiwan.*

Previous studies found significant association of hypertension and hypertension-related phenotypes with genetic variation in the *SAH* (Spontaneously hypertensive rat-clone A - Hypertension-associated) gene. This study aimed to examine whether common *SAH* genetic variations are associated with hypertension in the Chinese population. We genotyped three single-nucleotide polymorphisms (rs55810929, rs11647477, rs5716) of the *SAH* gene in 894 subjects of Chinese origin from the Stanford Asia-Pacific Program for Hypertension and Insulin Resistance (SAPPHIRe) family study. All three SNPs in the *SAH* gene were significantly associated with risk of hypertension in the SAPPHIRe cohort (p= 0.026 for rs55810929, p=0.007 for rs11647477, p=0.009 for rs5716). The subjects carrying with the DI or II genotypes of the rs55810929 SNP was associated with hypertriglycerides (>=150 mg/dL) as compared with the DD genotype (p = 0.039). Moreover, both rs11647477 and rs5716 SNPs were found to be associated with excess waist circumference (p=0.025 and p=0.015 from chi-square for trend test). Furthermore, four haplotypes were constructed based on the rs11647477 and rs5716 polymorphisms. Subjects carried haplotype AC was associated with increased risk of hypertension (p=0.01 from HBAT permutation test); while haplotype GG was conferred protective effect of hypertension (p=0.006 from HBAT permutation test). In conclusion, our results suggest the polymorphisms of the SAH gene are significantly associated with hypertension, elevated levels of tryglycerides, and excess waist circumference. Our study validated the association between SAH gene polymorphisms and hypertension in the Chinese population.

P09.119
Homocysteine level in Ukrainian patients regarding to polymorphic variants of genes, involved in folate metabolism

I. Nazarko, *H. Akopyan, O. Yefimenko, L. Chorna, T. Pryzymirska;*
Institute of Hereditary Pathology of National Academy of Medical Sciences, Lviv, Ukraine.

Hyperhomocysteinemia is generally established etiological factor for arterial and vein thrombosis, and several polymorphic variant's of genes, involved in homocysteine remethylation (C677T and A1298C of MTHFR gene, A2756G of MTR gene and A66G of MTRR gene), are recommended for genetic testing in cases of increased risk of thrombophilia. Among 84 Ukrainian patients with high risk of thrombophilia complications (42 with preeclampsia and 42 with coronary artery disease) the polymorphic variants of genes, involved in folate metabolism, were analyzed regarding to plasma homocysteine level. The homocysteine level was varied between 4,48 to 31,97 mkMol/l in examined cases and there was no significant difference in groups of patients with preeclampsia and coronary artery disease: 9,08±3,06 and 9,88±2,12 mkMol/l respectively (P>0,05). 677TT genotype of MTHFR gene was marked for highest plasma homocysteine concentration and heterozygoes 677CT genotype was the following (11,54±2,76 mkMol/l and 9,92+0,53 mkMol/l respectively, P>0,05), whereas in 677CC carriers homocysteine level was significantly lower (8,57±0,36, P<0,05). No significant differences in homocysteine plasma blood concentration were established in different combinations of C677T and A1298C gaplotypes of MTHFR gene, in cases of AA, AG, GG genotypes of A2756G polymorphic variant of MTR gene (9,45±2,97, 9,54±1,80 and 9,23±2,55, mkMol/l respectively, P>0,05), and also in cases of AA, AG, GG genotypes of A66G polymorphic variant of MTRR gene (9,04±1,90, 9,25±0,47 and 9,81±3,26 mkMol/l, correspondingly P>0,05). In conclusion, significantly increased plasma homocysteine concentration was found in carriers of 677TT and 677CT genotypes of MTHFR gene among Ukrainian patients with preeclampsia and coronary artery disease.

RATIONALE: NSAIDs are actually the compounds most frequently involved in hypersensitivity drug reactions, and there are at least three different mechanisms involved: IgE- mediated, and T cell-mediated (immunological specific mechanisms) and cross-intolerance (CI) (immunological non-specific). In the latter group skin is the main affected organ. Associations between CI and different SNPs in arachidonic acid pathway or prostaglandins receptors (PGsR)-related genes had been described in patients with respiratory symptoms or chronic urticaria, but up today the number of cases is rather limited and selected populations are heterogeneous. In this study, we analysed the association between CI and several SNPs in PGsR in a large group of patients with acute urticaria/angioedema (AUA), defined as skin episode in absence of airways involvement or coexistent chronic urticaria.

METHODS: The population was obtained from several Allergy Services integrated into the Spanish network RIRAAF. Cases included had to have at least two episodes of CI with cutaneous symptoms after the intake of two or more NSAIDs from different chemical groups. We studied several SNPs in *PTGER1*, *PTGER2*, *PTGER3*, *PTGER4*, *PTGDR*, and *PTGFR* genes by using the TaqMan®OpenArray™ System.

RESULTS: We included 249 subjects with AUA, and 247 age- and sex-matched healthy controls. We found statistically significant associations between AUA and *PTGDR* rs8004654, *PTGER1* rs3810255, and *PTGER2* rs1254598.

CONCLUSIONS: Our results suggest the importance of genetic variants in PGsR in NSAIDs-induced AUA. Nevertheless further studies are required to analyze the role of other variations in PGsR and related genes in this clinical entity.

P09.121
Combine effect of Factor V Leiden, MTHFR and Angiotensin converting enzyme (insertion/deletion) gene mutations in hypertensive adult individuals: a population-based study from Sivas and Canakkale, Turkey

A. Uludag[1], *Y. Demirel*[2], *S. Gunes*[2], *C. Silan*[3], *S. Atik*[1], *F. Silan*[1], *O. Ozdemir*[1];

[1]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [2]*Department of Family Medicine, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [3]*Department of Pharmacology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.*

Hypertension is one of the leading causes of mortality and morbidity in the world which influenced by environmental and genetic factors. The MTHFR and Angiotensin converting enzymes (ACE) are possible candidate genes that may influence both body fatness and blood pressure. The purpose of this study was to examine the carriage of gene combinations of the ACE (I/D), MTHFR 677T, 1298C and lipid profiles in patients with essential hypertension (EH) in Turkey.

In a total of150 adult individuals (50 hypertensive, 50 first degree

relatives and 50 healthy control) from Sivas/Turkey with the same age, gender assessed for body composition, lipid profiles, resting blood pressure and gene profiles. Additionally, 149 individuals (99 hypertensive, 50 controls) from Canakkale/Turkey had been investigated for ACE I/D polymorphism. Pheripheric blood samples were genotyped using stripassay reverse hybridisation multiplex PCR tests for target genes.
Heterozygote mutation in FV Leiden was found to be higher in the hypertensive and first degree relatives when compared to the control group($p<0.05$). Homozygous DD allels of ACE gene were also higher than the ACE I/D and control groups ($p<0.05$). The high rates of cholesterol, LDL and low rates of HDL were found in patients with EH when compared with the control.
Current results show that ACE with DD allels, mutated allels of FV Leiden and MTHFR genes were significantly different between genotypes and have a combine effect on EH in Turkish population. Further studies are needed to investigate the genetics of fatness, EH and BP phenotypes in the current adult population.

P09.122
Polymorphism Ile105Val of the *GSTP1* gene is a predictor for ischemic stroke in patients with essential hypertension in Russian population

I. Bulgakova, *A. Polonikov, E. Vyalykh, V. Ivanov, M. Solodilova, O. Vasiljeva, N. Kononykhina, V. Antsupov, O. Belaya, Y. Kupriyanova, D. Ushachev, A. Shestakov;*
Kursk State Medical University, Kursk, Russian Federation.

The present study was designed to test whether two common polymorphisms Ile105Val and Ala114Val of glutathione S-transferase (*GSTP1*) gene are associated with risk of ischemic stroke (IS) in patients with essential hypertension (EH) in population of Central Russia. A total 607 unrelated Russian subjects, including 300 EH patients after MRI-diagnosed cerebral ischemic stroke (EH-IS group) and 307 EH patients having no cerebrovascular events (EH-group) were recruited in the Kursk regional hospital for a period 2008-2010. The polymorphisms were genotyped through PCR-RFLP assays. The frequency of allele 105Val of *GSTP1* gene was significantly higher in EH-IS group (0.418) versus EH one (0.336), odds ration 1.42 95%CI 1.13-1.80 p=0.004. The frequency of genotype 105ValVal of *GSTP1* gene was 19.0% and 9.8% in EH-IS and EH groups, respectively. The genotype 105ValVal of *GSTP1* gene was associated with increased risk of IS in EH patients (odds ration 2.15 95%CI 1.34-3.44, p=0.002). No difference in allele and genotype frequencies between the groups was found for the other genes. This is the first study reporting on the association of polymorphism Ile105Val of the *GSTP1* and ischemic stroke in hypertensive patients. The study was supported by the Federal Targeted Programme “Scientific and Scientific-Pedagogical Personnel of the Innovative Russia in 2009-2013”.

P09.123
Gene-environment interactions as explanation for genetic non-replication in the etiology of hypospadias

L. F. M. van der Zanden, *T. E. Galesloot, W. F. J. Feitz, B. Franke, N. V. A. M. Knoers, N. Roeleveld, I. A. L. M. van Rooij;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Hypospadias is a common congenital malformation of the male external genitalia. In previous studies, hypospadias was associated with single nucleotide polymorphisms (SNPs) in *SRD5A2*, *ESR1*, *ESR2*, and *ATF3*. However, we were unable to replicate these associations in a Dutch study. Therefore, we examined whether this lack of replication could be due to dissimilar environmental exposures, by exploring whether the associations differed when mothers were or were not exposed to exogenous estrogens, suffering from placental insufficiency, or having high estradiol levels. For *ATF3*, we also included occurrence of an infection and/or inflammation and smoking during pregnancy. We genotyped 712 hypospadias cases and their parents, obtained environmental data from postal questionnaires, and tested the presence of gene-environment interactions using the log-linear approach. Gene-environment interactions were identified between rs523349 in *SRD5A2* and maternal estrogen exposure and between rs11119982 in *ATF3* and the occurrence of an infection and/or inflammation. The SNP in *SRD5A2* only increased the risk of hypospadias when the mother was exposed to exogenous estrogens. This could explain why we were unable to confirm the associations found in a Chinese and a Swedish study. Possibly, Chinese and Swedish women experience higher exposures to phytoestrogens than Dutch mothers, because they consume more soy products, rye bread, and berries. The previously reported decreased risk for rs11119982 could not be confirmed, as we found an increased risk of hypospadias when the mother had an infection and/or inflammation and no effect when the mother did not. In conclusion, environmental factors can explain genetic non-replication between studies.

P09.124
High-resolution melting curve analysis for high-throughput genotyping of NOD2/CARD15 and IL23R SNPs and their distribution in Slovenian inflammatory bowel diseases patients

M. Mitrovic[1], *U. Potocnik*[1,2];
[1]*University of Maribor, Medical faculty, Center for human molecular genetics and pharmacogenomics, Maribor, Slovenia,* [2]*University of Maribor, Faculty of Chemistry and Chemical Engineering, Maribor, Slovenia.*

Inflammatory bowel diseases (IBD) are usually classified into Crohn’s disease (CD) and ulcerative colitis (UC). Previous studies in Caucasians have shown that the most potent IBD associated single nucleotide polymorphisms (SNPs) reside in NOD2/CARD15 and IL23R genes (rs2066844, rs2066845, rs2066847 and rs7517847). High-resolution melting analysis (HRMA) was previously reported as a simple, inexpensive, accurate and sensitive method for genotyping and/or scanning of rare polymorphisms. Therefore, qPCR-HRMA was used for genotyping of NOD2/CARD15 and IL23R polymorphisms in 588 Slovenian IBD patients and 256 healthy controls. These results were compared with genotyping results obtained by PCR-RFLP, which were used as a reference method. The optimization of an HRM experiment required careful design and adjustment of main parameters, such as primer concentration, MgCl2 concentration, probe design and template DNA concentration and different HRMA approaches were tested develop reliable and low-cost SNP genotyping assays. Direct HRMA was the fastest and cheapest approach for rs2066847, rs2066844 and 7517847 polymorphisms, yet for rs2066845 polymorphism sufficient reliability was achieved after introduction of unlabeled probe. Association analysis revealed significant associations of rs2066847 ($p = 0.001$, OR = 3.011, CI95% = 1.494-6.071) and rs2066845 ($p = 2.62 \times 10^{-4}$, OR = 14.117, CI95% = 1.884-105.799) polymorphisms with CD patients. The rs7517847 polymorphism was significantly associated with both, CD ($p<0.001$, OR=0.588 CI95% = 1.346-4.797) and UC patients ($p = 0.035$, OR=1.599 CI95% = 1.048-2.439). Applied HRMA assays may contribute to the development of genetic profiles for risk prediction in IBD and for differential diagnosis of CD vs. UC.

Pathological evidence supports a potential role of the pro-and anti-inflammatory cytokine network in the pathogenesis of IBD. In this study, we evaluated the effect of the anti-inflammatory interleukin-10 (IL10) gene on Ulcerative Colitis and Crohn’s Diseasae. Two SNPs in the IL10 promoter, -1082G>A (rs1800896) and -819C>T (rs1800871), were determined in 553 patients (315 UC and 238 CD) and 367 healthy controls from Tuscany (Italy) by HRMA. Statistical analysis was performed using EpiInfo software to assess the risk and using Power Marker software for haplotype frequencies. The -1082G>A SNP followed the HW equilibrium in both UC and CD patients and controls. The HW equilibrium for the -819C>T SNP was respected only in the control group and not in the UC and CD cases. This may be further evidence of the association of the locus with the disease. The IL10-819T allele was weakly associated in UC patients and more significantly with CD patients, compared to controls. The frequency of the IL10-1082A allele was significantly higher both in UC and in CD patients than in controls. In addition, we observed an higher frequency

of the IL10 A/T haplotype in both UC and CD patients, compared to controls. Moreover, we found that -1082G>A SNP was in low LD with -819C>T both in UC and CD cases and controls. In conclusion, the -1082G>A and -819C>T SNPs in the IL10 promoter were significantly associated with risk of UC and CD in a population of Tuscany, suggesting their role in IBD susceptibility at least in this population.

Interleukin-1 β and Interleukin-1 Receptor Antagonist Gene polymorphisms in children not responding to Hepatitis B vaccination

H. Onay[1], *D. Yilmaz Ciftdogan*[2], *S. Tosun*[3], *T. R. Ozdemir*[1], *F. Vardar*[2], *F. Ozkinay*[1];

[1]*Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey,* [2]*Ege University Faculty of Medicine, Department of Pediatrics, Izmir, Turkey,* [3]*Manisa State Hospital, Section of Infectious Diseases, Manisa, Turkey.*

Introduction: Hepatitis B virus (HBV) infection is a major public health issue throughout the world and vaccination of those at risk is the main method of containment. 5-10% of children are not responding to hepatitis B vaccines and probably are not adequately protected against the (HBV) infection. We aimed to investigate the genetic polymorphisms of interleukin-1B (IL-1B) and interleukin-1 receptor antagonist gene (IL-1RN) in children not responding to hepatitis B vaccination, and to determine whether vaccine efficacy is influenced by these gene polymorphisms.

Material and Method: A total of 200 children whose anti-HBs antibody levels lower than 10 IU/L after vaccination against hepatitis B according to a standardized schedule were included in this study as non-responder group. One hundred healthy children who had anti-HBs antibody levels higher than 10 IU/L after vaccination against hepatitis B were included as responder group. IL-1B -511(C/T) and IL-1RN VNTR gene polymorphism were determined using PCR-RLFP and PCR-agarose gel based techniques, respectively.

Results: Frequencies of the genotypes and alleles of IL-1B -511(C/T) polymorphism were similar in both group. Genotype frequencies of IL-1RN VNTR polymorphism were not significantly different between responders and non-responders group. The frequency of allele 2 of IL-1RN VNTR polymorphism was higher in non-responders than responders group (respectively; r= 0,17, r=0,09, p=0,029). The allele 1 and allele 3 frequencies were not different in both group (respectively; p=0,86, p=0,48).

Conclusion: Our results suggest that, allele 2 of IL-1RN gene VNTR polymorphism might be associated with not responding to hepatitis B vaccination.

P09.127
Analysis of copy number variants (CNV) distribution in high scoring impulsive-disinhibited subjects

M. Laplana[1], *A. Aluja*[2], *L. F. Garcia*[3], ***J. Fibla***[1];

[1]*Department of Basic Medical Sciences, University of Lleida, IRBLleida, Lleida, Spain,* [2]*Department of Pedagogy and Psychology, University of Lleida, IRBLleida, Lleida, Spain,* [3]*Department of Biological and Health Psychology, Autonomous University of Madrid, Madrid, Spain.*

Impulsivity/disinhibition trait has been defined as the predisposition to respond to internal or external stimuli without regard to the potentially negative consequences to the individual or to others. The genetic of personality traits has been evaluated in relation to microsatellites and SNPs. Nevertheless, the contribution of CNV is not known. CNVs produces an increase or decrease in the number of copies of one or several genes, which can affect their expression and regulation. We hypothesize that CNV may be part of the genetic component of the impulsivity/disinhibition trait. To test this hypothesis we have performed a comparative genome hybridization (CGH) analysis with the Agilent 2X400K CGH array in a group of subjects whose scores in impulsivity/disinhibition questionnaires were the highest. DNA from each high scoring subject was compared with a pool of DNA obtained from low scoring controls. We used the ADAM2 statistical algorithm to identify CNVs and CNV regions (CNVR) with statistical threshold of 6 and a minimum of 4 probes by using Agilent Genomic Workbench. With these stringent conditions we detected 3310 CNVRs in a subset of 16 subjects that passed array QC. CNVR were distributed according to chromosome size. A total of 4430 GO annotated genes were mapped to 2825 (86%) CNVRs. An overrepresentation of GO:0005488 binding category genes was observed (3200 genes, 72%). In addition, genes included in the GO categories synapse (120 genes, 2,7%) and reproduction (315 genes, 7.1%) were detected with strong statistically significance. The in depth characterization of results is in progress.

P09.128
eQTL analysis of disease associated regions in Slovenian inflammatory bowel disease patients

K. Repnik[1], *U. Potočnik*[1,2];

[1]*Center for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Slovenia, Maribor, Slovenia,* [2]*Laboratory for Biochemistry, Molecular Biology and Genomics, Faculty for Chemistry and Chemical Engineering, University of Maribor, Slovenia, Maribor, Slovenia.*

In many disease associated regions of complex diseases such as inflammatory bowel diseases (IBD) SNPs and haplotypes most significantly associated with disease are located in non-coding regions. The mechanism by which these SNPs contribute to the disease pathogenesis and which genes and proteins they affect is not yet clear. Using method of linking SNP genotype to the level of gene expression (expression quantitative trait loci - eQTL) we wanted to explore the feasibility of eQTL analysis for linking non-coding disease associated SNPs to genes they regulate. Initially we analyzed locus from which non-coding SNP rs3087243 (CTLA4_CT60) showed functional relevance and has been associated with the disease. We further applied our approach to IBD5 region where SNPs are in high linkage disequilibrium and the main contributor from this region is still unknown. We measured expression of genes from selected regions in peripheral blood lymphocytes (PBL) and colon tissue biopsies of 632 Slovenian IBD patients and in PBL of 312 controls and genotyped all patients and controls for selected SNPs. We showed that non-coding SNP rs3087243 affect expression of soluble isoform of CTLA4 gene. Our eQTL analysis of IBD5 region suggested SLC22A5 as a main gene in that region contributing to the IBD pathogenesis where decreased expression of SLC22A5 gene for disease susceptible genotype of SNPs rs1050152 and rs2631372 was detected. Our results suggest genotype/gene expression studies are good approach in linking most significantly disease associated SNPs in non-coding regions with genes they regulate.

P09.129
Genome-wide screen for context-dependant associations reveals an interaction between a locus at 4p15 and waist-to-hip ratio on total cholesterol

A. Isaacs[1,2], *I. Surakka*[3,4], *C. M. van Duijn*[1,2], *Y. S. Aulchenko*[1], *S. Ripatti*[3,4], *on behalf of the ENGAGE Consortium;*

[1]*Genetic Epidemiology Unit, Dept. of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Centre for Medical Systems Biology, Leiden, Netherlands,* [3]*Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland,* [4]*Public Health Genomics Unit, National Institute for Health and Welfare, Helsinki, Finland.*

A large-scale (>100,000 individuals) genome-wide association study recently described numerous loci affecting lipid levels. These common variants explain ~25% of the heritability of these phenotypes. A number of hypotheses have been proposed speculating on the sources of such “missing heritability”, including context-dependant genetic effects due to interactions. In the current analyses, the role of interactions influencing lipids was explored in meta-analysis of genome-wide data from 19 population-based cohorts (n>32,000). Studied lipids were total (TC), high-density lipoprotein, and low-density lipoprotein cholesterol and triglycerides. The interacting variables, chosen for their prior associations with lipids, were alcohol consumption, smoking, sex, waist-to-hip ratio (WHR), and body-mass index. Eight in silico replication cohorts (n>14,000) were available. Interactions were tested using linear regression models including both main effects and a SNP*context interaction term. After meta-analyzing the discovery and replication samples, rs6448771, near the protocadherin 7 gene (PCDH7), showed genome-wide significant interaction with WHR on TC (P-value=9.08e-9). A 10% increase in WHR elevated TC by 0.14 mmol/L (95% CI:0.10-0.18) for the AA genotype, 0.20 mmol/L (CI:0.16-0.24) for AG, and 0.22 mmol/L (CI:0.15-0.29) for GG. The SNP alone did not affect either WHR (P-value=0.46) or TC (P-value=0.51). No other genome-wide associations were observed. Inclusion of suggestive SNP*context interactions in polygenic models marginally improved

the proportion of explained variance. In conclusion, rs6448771 represents the first SNP identified by a genome-wide search for SNP* risk-factor interactions affecting lipids. It is unlikely that large effect-size interactions between common variants and the tested interacting contexts explain a high proportion of "missing heritability".

P09.130

Using canine models in the study of human disease: Genome-wide association mapping identifies a major locus affecting intervertebral disc calcification in Dachshund

M. Mogensen[1], *P. Karlskov-Mortensen*[1], *H. Proschowsky*[1], *F. Lingaas*[2], *H. Lohi*[3], *M. Fredholm*[1];
[1]*Faculty of Life Sciences, University of Copenhagen, Frederiksberg C, Denmark,* [2]*Department of Basic Sciences and Aquatic Medicine, Norwegian School of Veterinary Science, Oslo, Norway,* [3]*Faculty of Medicine, University of Helsinki, Helsinki, Finland.*

In humans, genetic studies of intervertebral disc degeneration have mainly focused on candidate gene studies, but the etiology and pathogenesis of disc degeneration is still poorly understood. Studies of the equivalent disease in dogs offer a relevant animal model to investigate the genetics underlying the phenotype. The predisposition to intervertebral disc disease in Dachshund is caused by an early degenerative process resulting in disc calcification. In Dachshund the number of calcified discs at two years of age determined by a radiographic evaluation is a good indicator of the severity of disc degeneration and thus serves as a measure for the risk of developing intervertebral disc herniation. Since the assessment of disc degeneration in humans often is performed by magnetic resonance imaging where it is difficult to evaluate disc calcifications, it is not possible to make a direct comparison between the etiology of the disease in the two species. However, elucidation of the biological processes involved in disc degeneration in dogs will undoubtedly also shed light on the pathways relevant for the human condition. Based on stringent radiographic examinations 48 affected dogs with ≥6 disc calcifications or surgically treated for disc herniation and 46 unaffected dogs with 0-1 disc calcifications were identified. Genome-wide association using the Illumina CanineHD BeadChip identified a locus on chromosome 12 from 36.8Mb-38.6Mb with 36 markers reaching genome-wide significance with p-values of $1.0x10^{-5}$-0.026 (p-values corrected for multiple testing). These results suggest that a major locus affecting the development of intervertebral disc calcification is present on chromosome 12.

Factor XIII V34L polymorphism and their association with hematoma growth in patients with acute intracerebral hemorrhage

I. Tirado[1], *I. Coll*[1], *B. Cuevas*[1], *J. Mateo*[1], *M. Borrell*[1], *R. Delgado-Mederos*[2], *I. Gich*[3], *J. Martí-Fabregas*[2], *J. Fontcuberta*[1];
[1]*Hemostàsia i Trombosi. Hospital Sant Pau, Barcelona, Spain,* [2]*Neurologia. Hospital Sant Pau, Barcelona, Spain,* [3]*Epidemiologia Clínica. Hospital Sant Pau, Barcelona, Spain.*

We tested the hypothesis that the FXIIIV34L polymorphism is associated with hematoma growth (HG) in patients with acute intracerebral haemorrhage (ICH).

Methods: We studied patients with spontaneous ICH within the first 6 hours after the onset of symptoms. HG was defined as an increase >33% in the volume of hematoma on the computed tomography (CT) obtained 24 to 72 hours after the onset of symptoms in comparison with the CT at admission. We used *Chi-Squared* test to compare frequencies and the risk of HG was assessed as an odds ratio (OR) with a 95 % CI using logistic regression (adjustments for: age, sex, volume haemorrhage at baseline, onset to the first CT, blood glucose, blood pressure, Glasgow score). The FXIIIV34L, Factor V Leiden and *F2G20210A* were genotyped.

Results: We included 90 patients (mean age 71± 10.8y.), 61% were men. HG was observed in 35 (39%) of the patients. The frequency of HG was higher among patients who carried the L34 allele than patients with the V34 allele (51.6% vs 31.6% p=0.072). If patient who carried Factor V Leiden or *F2G20210A* were not included, the difference was significant (53.3% vs 29.6 %, p= 0.039). Carriers of L34allele showed a higher risk of HG (OR= 3.96; 95 % CI:1.4-11.2). Moreover, we found that every year of age increased 5% the risk of HG (OR= 1.05).

Conclusion: The L34 allele increases almost 4 times the risk of developing HG in patients with acute intracerebral haemorrhage.

Background and Purpose - Previous GWA studies have identified 5 loci with strong association (posterior probability of association -PPA>0.5) and further 14 loci with suggestive association (0.1<PPA<0.5) to intracranial aneurysm (IA). However, the pathomechanism by which these loci increase the risk of IA formation remains mostly unknown. Hypertension is one of the strongest traditional risk factors of IA known to date. We hypothesized that some of the loci with strong or suggestive association to IA convey their effect through elevating blood pressure. We further hypothesized that this effect is more likely detectable in a genetically more homogenous population.

Methods - We performed a meta-analysis of four previously described Finnish cohorts consisting of 12,152 individuals. We used a two tier approach; one discovery cohort and three replication cohorts.

Results - We found that the suggestive IA locus at 5q23.2 in PRDM6 is strongly associated with systolic blood pressure (SBP) (p= 0.00016). The risk allele of IA was associated to higher SBP. PRDM6 encodes a protein playing a key role in vascular smooth muscle cell homeostasis. We hypothesize that common variants in PRDM6 may contribute to altered vascular wall structure hence increasing SBP, and predispose to IA.

Conclusions - To our knowledge, this is the first study unambiguously demonstrating replication of a complex disease locus (IA), with its common risk factor (SBP). Further validation is needed to show the significance of this association in other populations.

P09.133

TNF and CCR5 gene polymorphisms are associated with response to anti-TNF treatment in patients with juvenile idiopathic arthritis.

I. V. Pugacheva[1], *A. S. Glotov*[1], *M. V. Aseev*[1], *N. S. Averyanova*[2], *A. A. Grigorieva*[2], *E. I. Alekseeva*[2], *V. G. Pinelis*[2], *A. A. Baranov*[2], *V. S. Baranov*[1];
[1]*D.O.Ott's Research Institute for Obstetrics and Gynecology of Russian Academy of Medical Sciences, St. Petersburg, Russian Federation,* [2]*Scientific Center of children's Health of Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Juvenile idiopathic arthritis (JIA) is a group of chronic arthropathies in children, caused by aberrant immune reactions, with predominance of Th1- over Th2-driven responses. It has been shown that Th1-chemokine receptor CCR5 is important in the recruitment of T-helper cells of children with JIA to the synovium, where they secrete pro-inflammatory cytokines and cause the inflammation. TNF-alpha is one of the major pro-inflammatory cytokines and it plays a key role in pathogenesis of JIA. Anti-TNF therapy has proved to be highly successful in controlling inflammation and is now widely used to

treat JIA. However, large percentage of patients is refractory to anti-TNF treatment. We investigated contribution of TNF-alpha -308 G/A polymorphism (up-regulation of TNF-alpha production) and Th1-chemokine receptor CCR5-delta32 polymorphism (non-functional receptor) on response to infliximab (a monoclonal antibody against TNF-alpha) in patients with JIA. We genotyped the two polymorphisms in 75 Russian patients with JIA and found that TNFA G allele frequency was significantly lower in infliximab responders versus non-responders (83,3%; 96,7%, respectively, p=0,013). The proportion of minor A allele was significantly higher in responders vs. non-responders (33,3% and 6,7%, respectively, p=0,008). Frequency of CCR5-delta32 was significantly lower in infliximab responders (1,4% versus 10,0% in the group of refractory patients; p=0,028). Our data might be useful for determination of management strategy for children with JIA. This work was supported by Russian Foundation for Basic Research, grant No. 09-04-13849.

Two novel genetic factors for CAKUT origin: results from the AGORA project

K. Y. Renkema[1,2], *E. M. H. F. Bongers*[1], *I. A. L. M. van Rooij*[1], *L. F. M. van der Zanden*[1], *N. Roeleveld*[1], *W. F. J. Feitz*[1], *Y. Neirijnck*[3], *A. Reginensi*[3], *A. Schedl*[3], *F. Schaefer*[4], *H. McNeill*[5], *B. Franke*[1], *N. V. A. M. Knoers*[2];
[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Inserm U636, Nice, France,* [4]*Heidelberg University Hospital, Heidelberg, Germany,* [5]*Samuel Lunenfeld Research Institute, Toronto, ON, Canada.*

Congenital anomalies of the kidney and urinary tract (CAKUT) occur frequently in man and comprise the most common cause of end-stage renal disease in children. Structural disorders belonging to the spectrum of these anomalies include renal agenesis, multicystic kidney dysplasia, ureteropelvic junction obstruction, duplex collecting system, and vesico-ureteral reflux. Not much is known about the origin of CAKUT. Alterations in genes expressed during nephrogenesis are considered to be important, with the final phenotypic outcome depending on additional modifying genetic and environmental factors. The aim of this study is to identify new genetic factors involved in CAKUT aetiology. From the AGORA biobank of the Radboud University Nijmegen Medical Centre over 700 well-documented CAKUT case-parent triads and 10 families with multiple affected members were recruited. Mutation analysis of two novel CAKUT candidate genes was performed and revealed interesting genetic variants that were functionally characterized *in vitro*. Genome-wide exome sequencing in CAKUT families identified variants possibly involved in CAKUT aetiology. In addition, linkage analysis of a large CAKUT family demonstrated suggestive linkage for a locus on chromosome 4. The identification of new genetic factors for CAKUT contributes to the understanding of the pathogenesis and the design of genetic diagnostic screening tests, facilitating early detection and recurrence risk estimations for CAKUT.

P09.135

Common genetic variants associated with kidney function and blood pressure are not associated with kidney volume in early life. The Generation R Study

R. Taal*, A. J. van der Heijden, A. Hofman, E. A. P. Steegers, C. M. van Duijn, V. W. V. Jaddoe;*
Erasmus Medical Center, Rotterdam, Netherlands.

It has been postulated that smaller kidneys with reduced number of nephrons lead to impaired kidney function and risk for hypertension and chronic kidney disease. These associations may be explained by common genetic variants that cause lower nephron endowment and smaller kidneys and subsequent increased blood pressure or impaired kidney function. Therefore, the aim of our study was to assess the associations of common genetic variants which have previously shown to be related to adult kidney function and disease (30 common variants, P-value < 5.0*10-8), and blood pressure (23 common variants, P-value < 1.0*10-7), with kidney volume at the age of 6 years. This study was embedded in a population based prospective cohort study among 1233 children aged 6 years. Genotyping was done using the Illumina Human 610 Quad Arrays. If needed, imputation was performed using MACH.

Two of the common variants (in/near STC1, C18orf1) reached the nominal significance threshold (P<0.05) and showed the expected direction of the effect (i.e. lower kidney volume for a SNP previously associated to lower glomerular filtration rate in adults). However, when taking into account multiple testing, none of the common variants were associated with kidney volume at the age of 6 years.

Our results suggest that the underlying mechanisms in which common variants affect kidney function and blood pressure do not include altered kidney growth and development in early life.

P09.136

Role of KIR3D receptor functional variants in ankylosing spondylitis

I. V. Zvyagin*, I. Z. Mamedov, A. V. Chkalina, V. Y. Dorodnykh, D. M. Chudakov, S. A. Lukyanov, Y. B. Lebedev;*
M.M. Shemyakin–Yu.A. Ovchinnikov Institute of Bioorganic Chemistry of RAS, Moscow, Russian Federation.

Some contradictory results on association of activating and inhibitory alleles of killer immunoglobulin-like receptor KIR3D gene with ankylosing spondylitis (AS) were reported. Only one of the studies analyzed the association in the context of functionality of polymorphic KIR3DL1. In our study we analyzed both the frequencies of alleles encoding inhibitory and activating KIR3D receptors and alleles encoding functional (KIR3DL1*F) and non-functional (KIR3DL1*004) inhibitory receptors in two Russian Caucasian cohorts which include 83 AS patients and 107 HLA-B27-positive healthy donors. Presence of low expressed KIR3DL1*005 and KIR3DL1*007 alleles was also detected.

The frequency of KIR3DS1 allele was found to be higher (30.7% vs 18.7%, $p < 0.01$, OR = 1.93) and the frequency of KIR3DL1 allele was found to be lower (69.3% vs 81.3%, $p < 0.01$, OR = 0.52) in the AS cohort. Also it was found that the KIR3DL1*004 allele frequency are near equal in both cohorts, and the decrease of KIR3DL1 allele frequency in the AS cohort is due to the KIR3DL1*F but not KIR3DL1*004 frequencies. Likewise the frequencies of genotypes carrying KIR3DL1*004 was found to be near equal in both cohorts. 9 from 17 KIR3DL1*F/KIR3DL1*F AS patients carry at least one of low expressed allele.

These findings support the hypothesis that KIR3DL1 is not simply a passive counterpart of the segregating KIR3DS1 allele product but play a protective role, although the presence of activating KIR3DS1 allele is more important for AS susceptibility. However individuals carrying two high level expressed inhibitory KIR3DL1*F alleles can be affected by AS.

Predicting development of canine leishmaniasis using genomic selection analysis from genome-wide SNP data

J. Quilez[1], *V. Martínez*[1], *A. Sanchez*[1], *J. A. Woolliams*[2], *R. Pong-Wong*[2], *L. J. Kennedy*[3], *R. Quinnell*[4], *W. Ollier*[3], *X. Roura*[5], *L. Ferrer*[5], *L. Altet*[1], *O. Francino*[1];
[1]*Molecular Genetics Veterinary Service, Dep. of Animal and Food Science, Veterinary School, Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*The Roslin Institute and R(D)SVS, University of Edinburgh, Roslin, United Kingdom,* [3]*Centre for Integrated Genomic Medical Research (CIGMR), Manchester, United Kingdom,* [4]*Institute of Integrative and Comparative Biology, University of Leeds, Leeds, United Kingdom,* [5]*Hospital Clínic Veterinari, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Leishmaniasis affecting humans and dogs constitute a public health and veterinary problem. Leishmaniasis development upon infection from *Leishmania* depends partly on host genetic factors. Genetic-based diagnosis would be a useful tool and therefore we sought to predict affection status in dogs using genomic selection from genome-wide SNP data.

Affection status was defined as healthy infected (>4 years and prior infection, *n*=115) or affected (diagnosed before 4 years, *n*=104). Samples were from Boxer dogs, a breed with higher susceptibility to leishmaniasis. Samples were genotyped with the Illumina's CanineHD and 99,997 SNPs were left for analysis after data cleaning. A modified BayesB method was used under three different models varying on whether covariates were fitted. This produced estimates of markers and covariates effects which were used to calculate predictions for the affection status.

First, the correlation (*r*) between predictions and actual phenotypes was used as measure of predictive power. It was higher in the unpermuted

dataset than in any of 10 permuted sets regardless of the model. When predictions from five cross-validation sets were combined, the highest *r* was obtained for Model-3 and it was greater than for Models 1-2. Second, the area under the ROC curve (AUC) was used to compare sensitivity and specificity, with Model-3 performing better than Models 1-2. Finally, a threshold of 1.5 would produce the highest fraction of correctly diagnosed patients.

P09.138
Association of multiple variants along 6p21.3 region with leprosy susceptibility in two unrelated population groups of India

S. Ali, *S. Aggrawal, R. Chopra, R. Bamezai;*
JAWAHARLAL NEHRU UNIVERSITY, NEW DELHI, India.

Leprosy is a chronic infectious disease caused by Mycobacterium leprae which affects mainly skin and nerve of the host and results in characteristic deformity and disability. Host genetic factors strongly determine susceptibility to leprosy and its subtypes. We studied the selected chromosomal region 6p21.3, which comprises of functionally important genes involved in immune response against M. leprae. Status of 237 SNPs (111 SNPs with MassArray, 120 SNPs with Allele-specific PCR Kit and 6 with Sequencing) within HLA class I, II and III region in 2592 individuals, representing two unrelated population groups, was assessed. The disease associated SNPs were filtered in multiple steps of analysis, either on the whole sample size or a representative sample set, sufficient for statistical and LD analysis. Eight SNPs within BAT1 promoter (rs2523504, p=2.5E-06); exon 3 of NFKBIL1 (rs2230365, p=1.9E-08); LTA 13kb upstream (rs13192469, p=7.2E-07); LTA promoter (rs36221459, p=1.7E-05); TNF intron1 (rs1800610, p=2.8E-4); TNF-LTB downstream (rs769178, p=5.8E-05) and BTNL2-DRA interval (rs3135365, p=4.6E-24 and rs7773756, p=3.3E-18) were significantly associated even after adjustment with sex and the boneferroni correction for multiple testing. In addition to find the role of previously unidentified genes, BAT1 and BTNL2, we also established the functional status of the SNPs in in-vitro reporter assays. Further, an assessment of an interaction of multiple genes in unison within the studied region provided a graded risk to leprosy depending on the combination of genotypes for the significantly associated functional SNPs. These observations dissect the role and help in better understanding of HLA loci involved in disease pathogenesis.

High-throughput omics approach provides clues for novel pathways behind low HDL-cholesterol

P. P. Laurila[1], *S. Ripatti*[2], *J. Naukkarinen*[2], *A. Sarin*[2], *S. Söderlund*[1], *M. Oresic*[3], *M. Jauhiainen*[4], *M. Taskinen*[1], *L. Peltonen*[5];
[1]*University of Helsinki, Helsinki, Finland,* [2]*Finnish Institute for Molecular Medicine, Helsinki, Finland,* [3]*VTT Technical Research Centre of Finland, Espoo, Finland,* [4]*National Institute for Health and Welfare, Helsinki, Finland,* [5]*The Wellcome Trust Sanger Institute, Cambridge, United Kingdom.*

Low HDL-cholesterol is a major risk factor for cardiovascular disease. To elucidate potential novel pathways behind low HDL-C, we have employed 3 different high-throughput omics: genomics, transcriptomics, and lipidomics.
We have performed GWAS on 450 Finnish individuals with low or high HDL-C (10th and 90th population percentiles). Out of subset of these individuals (n=54), we obtained subcutaneous fat biopsies for genome-wide expression analysis, and isolated plasma HDL particles for lipidomics analysis with MS technology.
We first performed gene network analysis for genetic loci associated with low HDL-C observing that SNPs within four inflammatory pathways (e.g. antigen-presentation) were enriched among the low HDL-cholesterol associated genes (p=10^-5). Also, these inflammatory pathways were over-expressed in the adipose tissue of low-HDL-subjects. We then calculated genetic risk scores based on low HDL-cholesterol associating SNPs from these pathways, observing that high risk score resulted in not only decreased HDL-cholesterol-levels but also increased expression of these inflammatory pathways. Moreover, individual genes of these pathways (e.g. HLA-DRB1) exhibited allele specific expression, inversely correlating with HDL-C-levels.
Consistent with enrichment of inflammatory processes in association and expression analyses, the inflammatory nature of the HDL particle itself was evident in the lipidomics analysis. For instance, ceramides with well-established pro-inflammatory function were elevated in HDL-particles from subjects with low HDL-C, and anti-oxidative ether-bond containing plasmalogens down-regulated.
Our findings imply that genetic variation influences the molecular alterations associated with low HDL-cholesterol on both expression and metabolite levels, suggesting a more inflammatory and less vasoprotective role for HDL particles in subjects with low HDL-C.

P09.140
LRRK2 Mutations in sporadic and familial Parkinson disease

L. Fernandez-Novoa[1], *S. Seoane*[1], *J. C. Carril*[1], *J. A. Garcia-Agundez*[2], *R. Cacabelos*[3];
[1]*Genomics Department, EBIOTEC, A Coruna, Spain,* [2]*Pharmacology Department, School of Medicine, University of Extremadura, A Coruna, Spain,* [3]*EuroEspes Biomedical Research Center, Institute for CNS Disorders and Genomic Medicine, Bergondo, Coruna, Spain.*

Parkinson disease (PD) is a chronic and progressive neurodegenerative disorder characterized by 4 cardinal signs: resting tremor, bradykinesia, rigidity and postural instability. Monogenic forms of PD account for only a small percentage of the affected population (<10%). The majority of PD cases are considered to be caused by the interaction of genetic and environmental factors, and susceptibility variants of genes involved in monogenic forms of PD have been identified in sporadic PD in several populations. Recently, mutations in the LRRK2 gene have been implicated in familial dominant and sporadic cases of PD. The G2019S mutation in the LRRK2 gene has been identified in approximatelly 5-6% of familial forms of PD and about 1-2.5% of sporadic cases, and constitutes the most frequent genetic cause of PD known to date. In this study, 6 mutations in the LRRK2 gene were determined in 326 patients with PD and 135 control subjects. The mutations analyzed were G2019S, R1441C/G/H, I2020T and Y1699C. Eleven of 326 patients with PD carrying the G2019S mutation (3.4%). None of the other LRRK2 mutations were found in the remaining patients. The phenotype of the 11 G2019S mutation carriers were similar to those of typical PD. The age of onset was variable, ranged from 37 to 80 years. In conclusion, the G2019S mutation frequency in PD patients was similar to that reported in other European countries, and this mutation was not identified in controls. The R1441C/G/H, I2020T and Y1699C mutations were not found in any of the PD patients or controls.

P09.141
Can mutations in LTBP2 cause Pseudoexfoliation?

R. Haji-Seyed-Javadi[1], *S. Jelodari-Mamaghani*[1], *N. Nilforushan*[2], *S. Yazdani*[3], *E. Elahi*[1];
[1]*School of Biology, University College of Science, University of Tehran, Tehran, Islamic Republic of Iran,* [2]*Department of Ophthalmology, Iran University of Medical Sciences, Hazrat Rasool Hospital, Tehran, Islamic Republic of Iran,* [3]*Ophthalmic Research Center, Shahid Beheshti University MC, Tehran, Islamic Republic of Iran.*

Pseudoexfoliation (PEX) syndrome is a common age-related elastic microfibrillopathy, characterized by deposition of fibrillar extracellular material (PEX material) in the eye, particularly in the anterior segment. PEX is sometimes accompanied by glaucoma, and is considered

the most common cause of secondary glaucoma. Pseudoexfoliation glaucoma (PEXG) may be caused by hindrance of drainage of aqueous humor caused by PEX material. PEX deposits consist of complex cross linked fibrils including components of elastic microfibrils such as fibrillin1 and Latent TGFβ Binding Protein 2 (LTBP2). The genetic basis of PEX remains largely unknown. An association between PEX and a few nucleotide variations in the LOXL1 gene coding lysyl oxidase-like 1 have been reported in some populations. However, the data on LOXL1 from different populations are not all consistent and the role of the gene with respect to PEX is unclear.

LTBP2 was recently identified as a primary congenital glaucoma causing gene. The protein product of the gene may have structural and non-structural functions. As glaucoma often occurs along with PEX, and as LTBP2 is a component of PEX deposits, we queried the possibility that mutations in LTBP2 may cause or predispose individuals to PEX.

Exonic regions of LTBP2 were sequenced in 47 PEX affected individuals. In addition to several previously reported sequence variations, five novel coding variations that cause amino acid changes were observed in the DNA of the patients. At least one of the variations that affects a proline residue is quite likely to be associated with the PEXG phenotype.

P09.142
Copy number variation in 16p11.2 is associated with major depressive disorder

Major depressive disorder (MDD) ranks among the top ten causes of global burden of disease. To our knowledge, only one systematic CNV screening of patients with MDD has been carried out. We performed a genome-wide analysis of CNVs in 575 German patients with a DSM-IV diagnosis of MDD and 1,618 controls. We genotyped all individuals using either Illumina's HumanHap550, Human610 or Human660W arrays. To identify potential CNVs, we analyzed each individual's SNP-chip information with QuantiSNP and PennCNV. To minimize the number of false-positive CNV calls, we developed a stringent quality protocol, requiring CNVs to have a minimum of 30 consecutive SNPs and a confidence value of at least 30. The two datasets generated by QuantiSNP and PennCNV were analyzed separately. Only those regions for which both programs generated nominal significant P-values were included in further analyses.

We discovered a significant overrepresentation of CNVs in four different chromosomal regions (7p21, 15q26, 16p11.2, 18p11) in patients compared to controls. To our knowledge, CNVs in 7p21, 15q26, and 18p11 have not been described in MDD or other psychiatric disorders. The finding on chromosome 16p11.2 is of particular interest as CNVs in this region are associated with autism and schizophrenia. In our sample we observed three rare CNVs in 16p11.2 (one microdeletion, two microduplications) in patients and none in controls (P = 0.0178).

Our study provides evidence for an involvement of CNVs in the development of MDD and indicates an extension of the phenotype associated with CNVs in 16p11.2.

P09.143
Relationship between IKBKE gene and depression and panic disorder

K. Koido[1], *T. Traks*[1], *R. Balotsev*[1], *T. Eller*[1], *S. Koks*[1], *J. Shlik*[2], *E. Maron*[1], *E. Vasar*[1], *V. Vasar*[1];

[1]*University of Tartu, Tartu, Estonia,* [2]*University of Ottawa, Ottawa, ON, Canada.*

Major depressive disorder (MDD) and panic disorder (PD) belong to the most prevalent mental diseases, affecting 10% and 3% of general population, respectively. Alterations in immune system have been implicated in the onset and development of MDD and PD. We studied the relationship between single-nucleotide polymorphisms (SNPs) of IKBKE (inhibitor of kappa light polypeptide gene enhancer in B-cells, kinase epsilon) gene from chromosomal region 1q32 and MDD and PD. The association study design was used: 17 SNPs covering the IKBKE gene were analyzed in 581 unrelated patients and in 389 healthy control subjects. All subjects were individuals of Caucasian origin living in Estonia. Patients were divided into two groups according to diagnosis: comparison of allelic and haplotypic frequencies was performed between control group and MDD patients (n=391), PD patients (n=190), and the whole patient group (n=581). Both MDD and PD groups included 'pure' phenotypes as well as phenotypes comorbid to other mood and anxiety disorders. SNPlex Genotyping System was applied for genotyping, following association and haplotype analyses with Haploview program. Association analysis revealed the most prominent relationship between MDD patient group and SNPs rs1930437 and rs2274902 (allelic p values 0.0007, 0.0013, respectively). Statistically significant differences occurred in the panic and whole group as well. Haplotype analysis revealed five haplotype blocks in all tested groups of patients compared to healthy controls. Significant haplotypic associations confirmed allelic associations in MDD group. These results suggest that IKBKE gene from 1q32 chromosomal region may possibly be related to mood and anxiety disorders.

P09.144
Variants associated with mammographic density are also associated with breast cancer

J. S. Varghese;

Centre for Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom.

Introduction: Mammographic density (MD), is one of the strongest breast cancer risk-factors. However, the mechanism by which this risk is mediated is unclear. Recent genome-wide association studies (GWAS) have demonstrated that a variant in ZNF365 is associated with both breast cancer risk and MD[1;2]. We investigated if other SNPs showing evidence for association with MD in the meta-GWAS were associated, in aggregate, with breast cancer risk.

Method: The SNPs associated with MD were identified through meta-analysis of 5 GWAS(n=4877). For each SNP, Z-statistic for combined effect over all studies was computed and converted into per-allele effect size estimate (β_k). Effect of each SNP on breast cancer risk was then assessed using data from UK2-GWAS study (3628/5190). The combined effect of multiple SNPs was evaluated by multiplying signed MD beta value(β_k) for each of *N* SNPs over given significance threshold in MD meta-GWAS by their number of effect alleles at that SNP, G_{ik}(0, 1 or 2), and summing over all *N* SNPs to create the individual's score($\mathbf{Z}_i$).

$$\mathbf{Z}_i = \sum_{k=1}^{N} \beta_k \, G_{ik}$$

Logistic regression was then used to examine if the individual's score was predictive of breast case-control status.

Results: The top 5% of density SNPs significantly predicted breast cancer case-control status in the UK2-GWAS(P=0.005 & P=0.009 genotyped & imputed SNPs respectively). This predictive effect was not seen when only top 1% of density SNPs were used(P=0.3 & P=0.5 using genotyped & imputed SNPs respectively).

Conclusions: These results suggest that many SNPs associated with MD are also associated with breast cancer.

P09.145
Association between the SNAP25 gene and the extremes in intellectual performance.

G. Beunders[1], P. Rizzu[1,2], E. Sistermans[1], J. W. R. Twisk[3], W. van Mechelen[4], J. B. Deijen[5], P. Heutink[1,2], H. Meijers-Heijboer[1,2], D. Posthuma[1,2];
[1]VU University Medical Center, department of Clinical Genetics, Amsterdam, Netherlands, [2]Neuroscience Campus Amsterdam, Department of Clinical Genetics, Amsterdam, Netherlands, [3]VU University Medical Center, department of epidemiology and biostatistics, Amsterdam, Netherlands, [4]VU University Medical Center, department of Public and Occupational Health, Amsterdam, Netherlands, [5]VU University Medical Center, department of Clinical Neurolpsychology, Amsterdam, Netherlands.

Introduction: Intelligence in the normal and high range is shown to be highly heritable. Low intelligence, mental retardation, is thought to have a heritable cause in about 50%. Association studies have identified some loci and genomic variants associated with variation in intelligence in the normal range. High IQ is thought to be caused by the additive effect of the same genomic variants, but experimental evidence for this hypothesis is lacking. For mental retardation however, known genetic causes are rare and monogenetic.

Aim: We set out to test whether the SNAP25-gene that was previously linked to intelligence in the normal range, is also linked to variation in intelligence at both the lower (mental retardation) and the upper range (high IQ).

Methods: We genotyped two SNP's in SNAP 25 (rs363039 and rs363050), previously linked to variation in normal intelligence (Gosso, et.al. 2006), in a cohort of 644 children with mental retardation and a cohort of 360 participants of the Amsterdam growth and health study, which all were following the highest level of education at the time of recruitment.

Results: We found a significant (p>0.05) lower allele frequency of the allele associated with an higher IQ (gosso et. al.) for both SNP's (rs363039 and rs363050) in SNAP25 in the MR cohort compared to the high IQ cohort. The minor alleles of both SNP's are associated with mental retardation.

Conclusion: Our results suggest that, at least for SNAP-25, the same genomic variants affect both variation in normal or high intelligence and mental retardation.

P09.146
COL1A1 association and otosclerosis: a meta-analysis

I. Schrauwen[1], A. Khalfallah[2], M. Ealy[3], E. Fransen[1], C. Claes[1], A. Huber[4], L. Rodriguez Murillo[5], S. Masmoudi[2], R. J. H. Smith[3], G. Van Camp[1];
[1]Department of Medical Genetics, wilrijk, Belgium, [2]Centre de Biotechnologie de Sfax, Sfax, Tunisia, [3]Molecular Otolaryngology Research Laboratories, University of Iowa, Iowa City, IA, United States, [4]Department of Otorhinolaryngology, University Hospital of Zurich, Zurich, Switzerland, [5]Columbia University Medical Center, New York, New York, USA, New York, NY, United States.

Otosclerosis is a disease of abnormal bone remodeling in the human otic capsule that can lead to progressive hearing loss. Little of the underlying disease etiology has been elucidated thus far, although several studies have suggested that COL1A1 may play a role based on its importance in bone metabolism and other diseases like osteoporosis and osteogenesis imperfecta. Genetic association studies between COL1A1 and otosclerosis, however, have been contradictory. To resolve this issue, we studied a large Belgian-Dutch and a Swiss population for a genetic association between COL1A1 and otosclerosis and additionally performed a meta-analysis to investigate the overall genetic effect of COL1A1 on all otosclerosis populations studied to date. We found a significant association both in the Belgian-Dutch population and in the meta-analysis. In aggregate, our analysis supports evidence for an association between COL1A1 and otosclerosis, although effect sizes of the variants reported in the initial studies are likely to be an overestimate of true effect sizes.

P09.147
A meta-analysis of thyroid-related traits reveals novel loci in the regulation of circulating thyroid stimulating hormone and thyroxine circulating levels

E. Porcu[1], M. Medici[2], G. Pistis[3], A. Cappola[4], C. Volpato[5], S. J. Brown[6,7], M. Gögele[5], S. Wilson[6,8], J. O'Connell[9,10], T. Tanaka[11], M. den Heijer[12], J. Deelen[13,14], D. Toniolo[3], R. Peeters[2], S. Sanna[1], S. Naitza[1];

Thyroid stimulating hormone (TSH) and thyroxine (T4) are key regulators of thyroid function, growth and metabolism. Their dysregulation leads to common endocrine disorders. Despite being relatively highly heritable (65% and 40% respectively), genetic loci so far identified only account for a small proportion of the estimated genetic variation. To identify additional associated regions, we carried out a meta-analysis of up to 12 GWAS using ~2.5 million directly genotyped or imputed autosomal SNPs, corresponding to 18,538 and 13,590 euthyroid subjects of European ancestry for TSH and FT4, respectively. Standard quality filters were applied to each study, and single marker association estimates were combined using inverse-variance weights. For TSH, we confirmed association at PDE8B (rs1382879 p=1.28x10-32) and CAPZB (rs10799824, p=1.0x10-16), and observed 7 novel loci at chr6q27, chr2q35, chr4q31.23, chr9q34.2, chr16q23.2, chr6p21.1 and chr15q26.1 (p<5x10-8). For FT4 we confirmed association at DIO1, for which there was suggestive evidence from candidate gene studies, and observed 2 additional signals at 9q34.3 and 4q33. At 6 genes, including PDE8B, evidence for heterogeneity (p<0.05) was observed, and at 4 of which could be explained by different effects between males and females (p<10-4). We also carried out gender-specific association analyses, but no additional genes were identified. Preliminary analyses on individuals with extreme phenotypic values suggested that TSH associated variants may contribute to thyroid pathologies. Overall, 10 and 3 independent SNPs for TSH and FT4 respectively, explain 3.9% and 1.3% of the heritability, suggesting that several additional loci, remain to be discovered.

Dyslipidemia, hypertension, insulin resistance, and measurements of obesity are key components in definition of the metabolic syndrome (MetS). Genome-wide association studies (GWASs) have identified several susceptibility loci for these MetS component traits, but there is little evidence for genes contributing to the syndrome as an entity rather than to individual component traits.

We conducted a GWAS on MetS and its component traits in four Finnish cohorts (2,637 MetS cases and 7,927controls), and followed the top loci in an independent sample with transcriptome and NMR-based metabolome data. Furthermore, we tested for loci associated with multiple MetS component traits using factor analysis and built a genetic risk score for MetS risk.

A previously known lipid locus, *APOA1/C3/A4/A5* gene cluster region, was associated with MetS in all four study samples (meta-analysis P=7.23x10^{-9}). Primary source of the association was the SNPs effect on triglyceride (TG) (P=2.59x10^{-31}) and high-density lipoprotein (HDL) levels (P=5.83x10^{-8}), which was further supported by serum metabolite analysis, where *rs964184* associated with various VLDL, TG, and HDL metabolites (P=0.024-1.88x10^{-5}). 22 previously identified loci for individual MetS component traits were replicated in our GWAS but none of these loci significantly associated with two or more uncorrelated traits. A genetic risk score (GRS), calculating the number of alleles in loci associated with individual MetS traits, was strongly associated with MetS status.

Our findings suggest that MetS does not have a common genetic background but is likely to result from complex interactions between lifestyle and multiple genetic variants which in combination may predispose to MetS.

P09.149

Metabolic and genetic cardiovascular risk factors in manifestation of metabolic syndrome in males.

***A. N. Voitovich**[1], O. S. Romashkina[1], M. A. Bogdanova[1], B. I. Smirnov[2], A. A. Bystrova[3], T. D. Glebovskaja[4], E. I. Krasilnikova[3], V. I. Larionova[1];*

[1]St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation, [2]St. Petersburg State Electrotechnical University, Saint-Petersburg, Russian Federation, [3]St. Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation, [4]Federal heart, blood end endocrinology center n.a. V.A. Almazov, Saint-Petersburg, Russian Federation.

Metabolic syndrome (MS) is a cluster of metabolic and genetic entities closely associated with the development of cardiovascular disease (CVD) and diabetes mellitus type II (DM2). Male sex is an important factor in the pathogenesis, risk, and prognosis of many known diseases. Therefore, the aim of this study was to investigate the most significant cluster of cardiovascular risk factors specific to males. Patients and methods. The MS patient group consisted of 176 males with abdominal obesity, having at least two of the CVD risk factors (average age 61.7Â±1.0). Among them, 89 patients had DM2, 20 patients had DM2 and survived after myocardial infarction, and 67 patients survived after myocardial infarction but did not have DM2. The control group consisted of 115 males without CVD and DM2 (average age 40.0Â±0.5). Polymorphisms of genes APOA1 G-75A and C+83T, APOC3 Sst1, APOE, APOA5 T-1131C and S19W, ADRB3 W64R, and ACE I/D were studied. Statistical analysis included logistic regression method. Results. We have found cardiovascular risk factors associated with manifestation of MS in males. Factors that increased the probability of MS in males were moderate and severe obesity, and the 19W-allele of the gene APOA5. The normal level of triglycerides appeared to have protective effect. Conclusion. It is evident from the study that the normal triglyceride levels are protective against MS and CVD in males. And the 19W-allele APOA5 that was previously shown to associate with elevated triglyceride levels is the MS risk factor.

P09.150

Genetic variations in tumor necrosis factor alpha, interleukin 10 genes and migraine susceptibility

*O. Ates[1], **J. Altınısık**[2], S. Kurt[3], H. Karaer[3], S. Sezer[1];*

[1]Gaziosmanpasa University, Medical Faculty, Department of Medical Biology, Tokat, Turkey, [2]Balıkesir University Medical Faculty, Department of Medical Biology, Balikesir, Turkey, [3]Gaziosmanpasa University, Medical Faculty, Department of Neurology, Tokat, Turkey.

Migraine is a very common headache disorder and pathogenesis of the disease is still unknown. Cytokine genes have been implicated in migraine susceptibility. The present study was designed to find out whether polymorphisms in the tumor necrosis factor-α (TNF-*α*), interleukin-10 (IL-10) gene and interleukin-10 haplotypes are associated with the risk of migraine.

We analyzed TNF-*α* -308G/A, IL10 -1082G/A, -819C/T, and -592C/A polymorphisms in 203 migraine patients and 202 healthy subjects by using amplification refractory mutation system-polymerase chain reaction.

The -308G/A genotypic and -308A allelic frequency of TNF-α polymorphism was higher in migraine patients than healthy controls and significant association was found between migraine and TNF-α -308G/A polymorphism (Pc: <0.000, OR: 2.16, 95% CI: 1.44-3.28). No statistically significant association was found between IL10 -1082G/A, -819C/T, and -592C/A polymorphisms and haplotypes containing these alleles and migraine.

Our results reflect that TNF-α -308G/A polymorphism may be one of the many genetic factors for migraine susceptibility in Turkish population.

P09.151

Mitochondrial DNA variants (7086 C/haplogroup H/D310 >7C) increased the risk for new-onset diabetes after transplantation

***E. Coto**[1,2], B. Tavira[3], B. Alonso[3], C. Diaz-Corte[3], B. Diaz-Molina[3], J. L. Rodriguez-Lambert[3], E. Suarez[3], M. J. Bernardo[3], M. Martin[3], C. Moris[3], F. Ortega[3], V. Alvarez[3];*

[1]Huca (Hospital Univ. Central Asturias), OVIEDO, Spain, [2]REDINREN, SPAIN, Oviedo, Spain, [3]HUCA, Oviedo, Spain.

Background: New-onset type 2 diabetes (DM2) is a frequent complitation among transplanted patients treated with the immunosuppressor tacrolimus (Tac). Several gene variants associated with the risk DM2 in the general population would also increase the risk of posttransplant DM2 (NODAT). Common mitochondrial DNA variants (haplogroups) were also associated with DM2. We investigated the effect of nine mtDNA polymorphisms on NODAT among heart or kidney transplanted patients treated with Tac.

Methods: The nine mtDNA SNPs that define the common European haplogroups, and the 310 polyC and T16189C SNPs were determined in 120 NODAT and 200 patients who remained non diabetics (no-NODAT) from the same region (Asturias, Northern Spain).

Results: Mitochondrial haplogroup H (7028C) was significantly more frequent in the NODAT group (56% vs. 35%; p=0.001; OR=2.38, 95%CI=1.48-3.72). The mtDNA 16189 SNP was not associated with NODAT-risk. The NODAT group had a higher frequency of D310 >7 C repeats (70% vs. 60%; p=0.012). Haplotype 7028-C/D310- 7C would have a protective effect against the development of NODAT. Sequencing of the mt HVI region from blood leukocytes showed that this haplotype was linked to a lower D310 polyC heteroplasmy compared to the other haplotypes.

Conclusion: Common mtDNA variants were associated with the risk of NODAT. This effect could be due to the higher instability of mtDNA replication among individuals with at risk haplotypes, and this could affect mitochondrial function in beta-pancreatic cells in response to Tac increasing the risk for DM2.

P09.152

A novel m.3395A > G missense mutation in the mitochondrial ND1 gene associated with the new tRNAIle m.4316A > G mutation in a patient with hypertrophic cardiomyopathy and profound hearing loss

I. Chamkha[1], *E. Mkaouar-Rebai*[1], *H. Aloulou*[2], *C. Kifagi*[3], *M. Hachicha*[2], *F. Fakhfakh*[1];

[1]*Laboratoire de Génétique Moléculaire Humaine. Faculté de Mèdecine de Sfax. Tunisie, Sfax, Tunisia,* [2]*Service de Pédiatrie, C.H.U. Habib Bourguiba, Sfax, Tunisia,* [3]*Unité Cible pour le Diagnostic et la Thérapie, Centre de Biotechnologie de Sfax, Sfax, Tunisia.*

Mitochondrial diseases are a clinically heterogeneous group of disorders that arise in young and adult patients at any age, as a result of dysfunction of the mitochondrial respiratory chain. Mitochondrial dysfunction frequently affects the heart and may cause both hypertrophic and dilated cardiomyopathy. The cardiomyopathy is usually a part of a multisystem involvement and may rarely be isolated. In fact, it can be associated with others disorders, such as hearing loss. The state may be stable for many years, but rapid deterioration may occur and often lead to congestive heart failure.

We described a newborn girl with hypertrophic cardiomyopathy and profound hearing loss. The mtDNA mutational analysis revealed the presence of known polymorphisms associated to cardiomyopathy and/or hearing loss, and 2 novel heteroplasmic mutations: m.3395A > G (Y30C) occurring in a highly conserved aminoacid of the ND1 gene and the m.4316A > G located in the residue A54 of the tRNAIle gene. These 2 novel variations were absent in 150 controls. All these variants may act synergistically and exert a cumulative negative effect on heart function to generate the cardiomyopathy.

Genome-wide association study of myxomatous mitral valve disease in Cavalier King Charles Spaniels identifies two candidate loci

M. B. Madsen[1], *L. H. Olsen*[1], *J. Häggström*[2], *K. Höglund*[2], *I. Ljungvall*[2], *G. Wess*[3], *H. Copeland*[4], *V. Chetboul*[5], *H. F. Proschowsky*[1], *S. Cirera*[1], *P. Karlskov-Mortensen*[1], *M. Fredholm*[1];

[1]*Faculty of Life Sciences, University of Copenhagen, Frederiksberg, Denmark,* [2]*Faculty of Veterinary Medicine, The Swedish University of Agricultural Sciences, Uppsala, Sweden,* [3]*Clinic of Animal Medicine, Ludwig-Maximilians-Universität, Munich, Germany,* [4]*Small Animal Teaching Hospital, University of Liverpool, Liverpool, United Kingdom,* [5]*Ecole Nationale Vétérinaire d'Alfort, Paris, France.*

Myxomatous mitral valve disease (MMVD) is a degenerative heart disease with a reported incidence in humans of 1-5%. The disease also has a high prevalence in dogs, especially in Cavalier King Charles Spaniels (CKCS), of which, nearly all are affected at the age of 10 years. In affected individuals the mitral valves become enlarged, lose flexibility and eventually protrude into the left atrium, resulting in mitral regurgitation (MR). Since dog breeds are much more homogeneous than the human population it is more feasible to indentify genetic components underlying complex diseases in dogs. Thus, dogs provide good models for human diseases. We performed a genome-wide association study (GWAS) in CKCS to identify the genes underlying MMVD. Cases and controls were selected using stringent criteria: cases were dogs with early onset of MMVD i.e. murmur ≥1 and MR jet >20% at <4.5 years, or with clinical signs of heart failure; controls were dogs with late onset i.e. murmur ≤2 and MR jet <50% at >8 years. A total of 139 cases and 102 controls were genotyped with the 170k CanineHD BeadChip (Illumina). Genome-wide association analysis using PLINK was performed, and the resulting *p*-values were adjusted for multiple testing. The GWAS revealed two statistically significant regions on canine chromosomes 13 and 14 (*p*-values: $4.0 \cdot 10^{-5}$ - $4.7 \cdot 10^{-2}$ and $7.9 \cdot 10^{-4}$ - $1.7 \cdot 10^{-2}$, respectively). Thus, we have identified two novel candidate regions, in which genetic components of importance for MMVD are located. Studies are currently underway to identify the causative mutations within the two regions.

Somatic Copy Number detection in MZ twins discordant for Congenital Diaphragmatic Hernia (CDH) or Esophageal Atresia (EA) and in affected diaphragm or proximal pouch tissue

D. Veenma, *E. Brosens, L. de Jong, C. van de Ven, C. Meeuwissen, T. Cohen-Overbeek, M. Boter, B. Eussen, H. Douben, D. Tibboel, A. de Klein;*

Erasmus-MC Sophia, Rotterdam, Netherlands.

The occurrence of phenotypic differences between monozygotic (MZ) twins is commonly attributed to environmental factors, assuming that MZ-twins have a 100% identical genetic make-up. Yet, recently several lines of evidence showed that both genetic and epigenetic factors could play a role in phenotypic discordance after all. One report suggested a high occurrence of low-mosaic CNVs within MZ-twin pairs discordant for Parkinson disease, thereby stressing on the importance of post-zygotic mutations as disease-predisposing events.

In this study, we analyzed the prevalence of discrepant somatic CNVs in discordant MZ-twins of the Esophageal Atresia and Congenital Diaphragmatic Hernia cohort in Rotterdam. We used high-resolution SNP-arrays on blood- derived DNA from 11 (4 CDH and 7 EA) pairs of MZ-twins. Paired analysis was executed with specific attention to isolated allelic imbalances as a marker for low-mosaic CNVs. In this way, we showed that somatic CNVs are not the cause of phenotypic discordance in this cohort of MZ-twins. In addition, bead chip genotyping showed no evidence for pathologic SNP differences within each MZ-pair either. To exclude the possibility of somatic mutations restricted to the affected tissues, we screened for CNVs in proximal pouch- and diaphragm tissue of a separate group of patients as well. In line with the twin data, no target-tissue specific CNVs were revealed in DNA from 12 pouch- and 13 diaphragm biopsies. Yet, recurrent, germ-line chromosome 22q11-13 were discovered. In conclusion, post-zygotic structural mutations are not a common cause of OA and CDH.

The investigation of TNF alpha 308G/A polymorphism in mood diseases

O. Ates[1], *J. Altinisik*[2], *B. Elbozan Cumurcu*[3], *A. Rustemoglu*[1], *R. Karlidag*[3], *I. Gogcegoz Gul*[3], *S. Unal*[3];

[1]*Gaziosmanpasa University Medical Faculty Department of Medical Biology, Tokat, Turkey,* [2]*Balıkesir University Medical Faculty Department of Medical Biology, Balıkesir, Turkey,* [3]*Inonu University Medical Faculty Department of Psychiatry, Malatya, Turkey.*

The pathogenesis of mood diseases is still unclear; However an increasing amount of evidence suggests that an imbalance of inflammatory cytokine activity may be a contributing factor in etiology and pathophysiology of mood disorders. Tumor necrosis factor-alpha (TNF-α) is a proinflammatory cytokine with functions in nerve cell growth, differentiation, synaptic scaling, and apoptosis in the central nervous system. Thus TNF-α is considered a plausible candidate gene for mood diseases. The level of TNF-α production in under genetic control and is thought to be influenced by a -308G/A promoter polymorphism. In this study we aimed to investigate the plausible association between TNF-308G/A polymorphism and major depression (MD) and bipolar disorder (BD). We analyzed TNF-308G/A polymorphism in 72 MD, 76 BD patients and 299 healthy subjects by using amplification refractory mutation system-polymerase chain reaction (ARMS-PCR). A significant association was found between TNF-308G/A polymorphism and BD but there are no correlation between MD and this polymorphism (Table 1). Our findings suggest that TNF-308G/A polymorphism may play an important role in susceptibility to BD in Turkish patients.

Table 1. Distribution of TNF-308G/A polymorphism in mood diseases and control

TNF locus n= (%)	**BD** 76	**MD** 72	**Control** 299	P OR: (95%CI)

Somatic mosaicism for FII G20210A and novel FII T20061C polymorphisms in patient with reccurent pulmonary thromboembolism

*V. Djordjevic[1], **I. B. Pruner**[1], G. Mitic[2], M. Kovac[3], D. Radojkovic[1];*
[1]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia, [2]Institute of Laboratory Medicine, Clinical Center of Vojvodina, Novi Sad, Serbia, [3]Blood Transfusion Institute of Serbia, Belgrade, Serbia.

Mosaicism implies the presence of more than one genetically distinct cell line in a single organism. Although it is frequently masked, somatic mosaicism has been implicated in more than 30 monogenetic disorders. Possible role of mosacism in multifactorial diseases is still unknown. Thrombophilia is a multifactorial disorder, involving both genetic and acquired risk factors that lead to increased tendency to thrombosis. The most frequent thrombophilic genetic risk factors are FV Leiden and FII G20201A gene variants.

Here we describe a female patient (48 years) presented with recurrent pulmonary thromboembolism and pulmonary artery hypertension. Routine thrombophilia screening was performed six months after thromboembolic episode. Obtained results were within normal range with exception of conflict results for FII G20210A gene variant. In order to elucidate these results we performed sequencing of 715bp segment of 3`end of prothrombin gene using Applied Biosystems 3130xL Genetic Analyzer. Sequence analysis of DNA from buccal swab cells confirmed presence of heterozygous G20210A gene variant, as well as new C to T transition on 20061 nucleotide. No sequence abnormalities in this region of prothrombin gene were detected in blood and hair bulb cells DNA.

In conclusion, this is the first report of mosaicism for FII G20210A polymorphism and its' possible association with thrombophilia. Current knowledge of potential role of mosaicism in pathogenesis of multifactorial diseases other than cancer is very limited and this area requires further studies.

P09.157
MSX1 gene, as a candidate gene, is not a rik factor for non-syndromic cleft lip and palate formation in Turkish population

*A. I. Guney[1], T. Akcay[2], D. Kırac[3], D. Ergec[4], B. Ersoy[5], O. Celebiler[6], G. Koc[6], **K. Ulucan**[7];*
[1]Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [2]Sisli Etfal, Education and Research Hospital, Istanbul, Turkey, [3]Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, [4]Yeni Yüzyıl University, Faculty of Arts and Science, Department of Molecular Biology and Genetics, Istanbul, Turkey, [5]Marmara University, Faculty of Medicine, Department of Plastic, Reconstructive and Aesthetic Surgery, Istanbul, Turkey, [6]6Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [7]Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey.

Introduction: Nonsyndromic cleft lip with/without palate (NS-CL/P) affects about 1/1000 livebirths with wide variability concerning geographic distribution, ethnic background and socioeconomic status. Gene-gene and gene-environmental interactions have been implicated in NS-CL/P. Studies in mice and humans supported the MSX1 as a strong candidate gene in recent years. But most of the results are contradictory including both case- control and parametric linkage studies. In this study, we aimed to analyze the sequence variations of MSX1 to determine MSX1 mutations that might be etiological to patients with NSCL/P in Turkish population.

Material and Methods: 100 controls and 100 patients without any family history of NS-CL/P were recruited to the study. Mutation analyses of the MSX1 gene was carried out by PCR- SSCP- Sequencing methodology.

Results: According to the SSCP and sequencing analyses, we couldn't detect any sequence variations in patients and control groups.

Conclusion: Our study was based on population- based and case-control design, not case- parent design because of having no information about MSX1 gene alterations in Turkish population. MSX1 gene variants were linked to the NS-CL/P formation in some populations but the same results couldn't be obtained for other populations. In order to clarify the role of MSX1 gene, different population- based studies are needed. Due to our results, MSX1 gene seems not to have target role in NS-CL/P formation, at least alone. More studies including the same and the other gene variation analyses should be carried out inorder to determine the roles of related genes in Turkish population.

P09.158
Study of association of common haplogroup-defining mtDNA polymorphisms with different multifactorial diseases in Russian population

***M. V. Golubenko**[1,2], T. V. Zheykova[1], A. A. Cherednichenko[1,3], O. A. Makeeva[1,2], I. V. Tsimbaliuk[4], I. V. Saltykova[4], E. Y. Bragina[1], N. P. Babushkina[1], A. A. Rudko[1], I. A. Goncharova[1,2], E. V. Beloborodova[4], V. P. Puzyrev[1,4];*
[1]Institute of Medical Genetics, Tomsk, Russian Federation, [2]Institute of Complex Problems of Cardiovascular Diseases, Kemerovo, Russian Federation, [3]Tomsk State University, Tomsk, Russian Federation, [4]Siberian State Medical University, Tomsk, Russian Federation.

Mitochondrial genes encode subunits of respiratory chain complexes which are involved in fundamental cell function. Thus, mtDNA polymorphisms may contribute to susceptibility to common diseases, and there is some evidence for this, mostly for neurodegenerative conditions. It should be noted that genome-wide association studies omit mtDNA because of non-Mendelian inheritance. We have studied patients with multifactorial diseases of different etiology: cardiovascular (coronary heart disease, N=175), allergic (asthma, N=150), and infectious (hepatitis C, N=182; tuberculosis, N=214). Population sample (N=424) has been studied for comparison. All samples were collected in Tomsk (West Siberia) from individuals of Russian origin. Common haplogroup-defining SNPs in mtDNA were genotyped (C7028T for haplogroup H, A12308G for U, A15607G for T, and G13708A for J). In the population, the SNPs frequencies corresponded to those known for most European populations, i.e. H: 38.68%, U: 24.76%, T: 9.91%, J: 7.31% . We have found higher frequency of haplogroup J in asthma (15.33% in the patients; χ^2=7.45; P=0.0063; OR=2.3 with CI 1.24-4.23). The JT cluster also has shown association with asthma (26.67% vs 17.22% in the population; χ^2=5.8; P=0.0160; OR=1.75 with CI 1.1-2.78). In addition, haplogroup T frequency was significantly lower in the hepatitis C group (3.43%; χ^2=6.2; P=0.0128; OR=0.35 with CI 0.15-080). In the samples with coronary heart disease and tuberculosis, no associations have been revealed. Our results suggest that mtDNA polymorphisms may play some role in susceptibility to allergic and infectious diseases, while connections between their pathogenesis and mitochondrial functions are not obvious.

P09.159
C677T polymorphism of the methylenetetrahydrofolate reductase (MTHFR) gene, systolic blood pressure and echocardiographic left ventricular parameters in children with systolic arterial hypertension (AH)

***S. V. Kuzmina**[1], M. A. Bogdanova[2], O. S. Romashkina[2], A. N. Voitovich[2], O. A. Mutafyan[1], V. I. Larionova[2];*
[1]St.Petersburg State Medical Academy of Postgraduate Studies, Saint-Petersburg, Russian Federation, [2]St.Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

Background. Hyperhomocysteinemia is a risk factor for cardiovascular disease. C677T polymorphism of the MTHFR gene may account for increased plasma levels of homocysteine.

Objectives: To investigate distribution of MTHFR genotypes frequency of C677T polymorphism in children with systolic AH. To compare clinical systolic BP levels and values of left ventricular parameters between carriers of various genotypes. **Patients:** 85 children aged 5-17 with systolic AH were studied.

Methods. C677T polymorphism of MTHFR gene was detected with PCR-RFLP. LV mass (LVM), LV mass index (LVMI), interventricular septum thickness in diastole (IVSd), LV posterior wall in diastole (LVPWd), LV end diastolic diameter (LVEDD), and relative wall thickness (RWT) were assessed by echocardiography.

Results. There were identified 21(25%) C/C homozygotes, 55(66%) C/T heterozygotes and 7(8%) TT homozygotes. We have found a significant differences in systolic BP levels and RWT values between carriers of different genotypes. Clinical systolic BP in patients with CC genotype was 135,24±8,7 mm Hg, CT genotype was 131,95 ±10,4 mm Hg, and TT genotype was 131,85±3,3 mm Hg (p<0,05). RWT in patients with CC genotype was 0,36±0,06, CT genotype was 0,34±0,05, and TT genotype was 0,32±0,04 (p<0,05). No significant difference was observed in other echocardiographic LV parameters

among subjects carrying the C/C, C/T, T/T genotypes.
Conclusion. We suggested that the C677T polymorphism of MTHFR gene may be involved in AH and the LV remodeling process.

P09.160
MTHFR C677T and A1298C polymorphism in Iranian patients with migraine

M. Ansari[1], *A. Owji*[2], *M. S. Fallah*[3], *S. Saeidi*[2], *M. Moghadasi*[4], *A. Ebrahimi*[3];
[1]*Department of Clinical Biochemistry, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Biochemistry, Shiraz University of Medical Sciences, School of Medicine, Tehran, Islamic Republic of Iran,* [3]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [4]*Department of Neurology, Iran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Migraine is a common neurologic disorder and familial clustering raises the probability that genetic factor might play a role in migraine susceptibility. Methylene tetra hydrofolate reductase (MTHFR) is a key enzyme in folate metabolic pathway and is suggested to be related to migraine susceptibility. However there are conflicting data on the association between the MTHFR polymorphisms and disease. This study performed to find the association between the MTHFR 677C>T and A1298C polymorphism and migraine.
Material and Methods: Migrainous patient according to the international headache society criteria included in the study. Healthy people without any positive history of periodic headache and no family history of migrainous headache in the family recruited as control group. MTHFR C677T and A1298C polymorphisms were investigated in cases and controls using PCR-RFLP method.
Results: Seventy-five migrainous patient (18 males and 57 females) and 128 healthy controls (43 males and 85 females) were recruited in the study. MTHFR 677TT was more frequent in migrainous patients (17.1% vs, 3.1%, P<0.05) and were associated with higher risk of migraine (OR= 6.5, CI 95%; 2.03-20.76).
Conclusion: It seems MTHFR polymorphism may predict the susceptibility to migraine attach. More studies with more sample is needed in Iranian population.

P09.161
Cytokine genes polymorphism and susceptibility to multiple sclerosis in the republic of Bashkortostan

A. N. Khusainova[1], *T. R. Nasibullin*[1], *I. A. Tuktarova*[1], *A. M. Mikhailova*[1], *O. V. Zaplakhova*[1], *K. Z. Bakhtijarova*[2], *R. V. Magzhanov*[2], *O. E. Mustafina*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Bashkirian State Medical University, Ufa, Russian Federation.*

Multiple sclerosis (MS; MIM 126200) is a demyelinating autoimmune disease of the central nervous system caused by interplay of environmental and genetic factors. Cytokines play an important role in MS pathophysiology, and genes encoding various cytokines are logical candidates to assess possible associations with MS susceptibility and disease course. The study was aimed to evaluate the associations of MS with polymorphisms of tumor necrosis factor alpha gene (*TNFA*, -308 G>A), lymphotoxin alpha gene (*LTA*, 252A>*G),* interleukin 6 gene (*IL6*, -572G>C*)*, interleukin 10 gene (*IL10*, -627C>A, interleukin 12 gene *(IL12B*, -1159A>C) in Russians and Tatars by ethnic origin living in Ufa of the Republic of Bashkortostan, Russia.
DNA was amplified in polymerase chain reaction in 265 patients with MS and 633 controls. It has been revealed that genotype *TNFA*(-308)*G/*G (P=0.045, OR=0.047, CI 0.23-0.97), genotype *LTA*(252)*A/*A (P<0.001, OR=0.31, CI 0.16-0.59) are associated with a decreased risk of the disease development in female from ethnic Tatar, but genotype *LTA*(252)*A/*G is associated with an increased risk of MS (P=0.006, OR=2.62, CI 1.35-5.08). For Russian male genotype *IL6*(-572)*G/*G (P=0.001, OR=12.55, CI 1.68-93.7) is associated with an increased risk of MS, but genotype *IL6*(-572)*G/*C (P=0.003, OR=0.09, CI 0.01-0.67), genotype *IL12B*(-1159)*C/*C (P=0.048, OR=0.12, CI 0.02-0.89) can be considered as a marker of decreased risk for MS. The association of *-627C/A* polymorphism of *IL10* gene with MS has not been detected in both ethnic groups.
Our results suggest contribution of investigated cytokine genes polymorphism in susceptibility to MS in Russians and Tatars.

P09.162**
Do ST-segment elevation and non-ST-segment elevation myocardial infarction have different genetic backgrounds?

P. Salo[1], *J. Sinisalo*[2], *T. Hiekkalinna*[1,3], *J. Kettunen*[3], *M. Lokki*[4], *A. Havulinna*[1], *S. Ripatti*[1,3], *V. Salomaa*[1], *M. Nieminen*[2], *M. Perola*[1,3];
[1]*National Institute for Health and Welfare, Helsinki, Finland,* [2]*Division of Cardiology, Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland,* [3]*Institute for Molecular Medicine Finland, Helsinki, Finland,* [4]*Transplantation Laboratory, Haartman Institute, University of Helsinki, Helsinki, Finland.*

The most robustly replicated common risk allele for myocardial infarction (MI) at 9p21.3 affects gene expression rather than the structure of a protein. This is consistent with the idea that differences in gene expression might explain a significant part of the genetic risk for common diseases. It is also believed that the genetic background differs for different subcategories of complex phenotypes. Taken together, this led us to test two hypotheses: First, many common expression quantitative trait loci (eQTL) are collectively associated with MI. Second, the effects of these loci are not equal for two subtypes of MI, namely ST-segment elevation MI (STEMI) and non-ST-segment elevation MI (NSTEMI).
We performed a GWAS in a sample consisting of acute coronary syndrome patients and healthy controls (n=3373). We selected 20,092 SNP's annotated as eQTL's in a public database and compared them with SNP's randomly selected from the dataset by permutation.
The set of eQTL SNP's is associated with MI (p<0.001). This effect is significantly stronger for NSTEMI (p<0.001) as it is not seen in STEMI (p=0.616). The difference is driven by eQTL SNP's at the HLA locus on 6p21.3. Exclusion of this locus abolishes the difference between NSTEMI and STEMI but not the association of the remaining SNP's with MI.
Our results add to the notion that common differences in gene expression influence the risk for developing MI. We show that the risk conferred by eQTL's is conditional on a clinically relevant classification of MI and identify a locus contributing to this difference.

P09.163
Identification of two SNPs located upstream and intron of CPT1B gene and HLA DQB1*0602 allele in Turkish patients of narcolepsy with and without cataplexy

S. Betinoglu[1], *B. Baklan*[2], *I. Oztura*[2], *D. Karadeniz*[3], *H. Yılmaz*[4], *A. Evlice*[2], *S. Cingoz*[1];
[1]*Dokuz Eylul University, Department of Medical Biology and Genetics, Izmir, Turkey,* [2]*Dokuz Eylül University, Department of Neurology, Sleep Disorders Unit, Faculty of Medicine, Izmir, Turkey,* [3]*University of Istanbul, Cerrahpasa Medical School, Sleep Disorders Unit, Department of Neurology, Istanbul, Turkey,* [4]*Celal Bayar University School of Medicine, Department of Neurology, Manisa, Turkey.*

Narcolepsy is a chronic neurologic disorder characterized by excessive daytime sleepiness, cataplexy and clinical manifestations of abnormal REM sleep. Narcoleptic pathogenesis is triggered by genetic and environmental factors and strongly associated with HLA-DQB1*0602. In recent reports it was established that SNP rs5770917 is associated with susceptibility to narcolepsy and also in strong LD with rs5770911. This study aimed to investigate positivity of HLA-DQB1*0602 allele and detect the differences in allele frequencies of two SNPs among case-control groups.
This study includes 31 narcolepsy with cataplexy (n=19) and without cataplexy (n=12) patients of Neurology Departments in Turkey and 55 healty individuals as a control. Patients and controls were explored for presence of HLA-DQB1*0602 by PCR and screened by sequencing whether the SNP rs5770917 and rs5770911 are associated with narcolepsy. Significance was assessed by chi-square and Fisher's exact test.
The HLA-DQB1*0602 allele was identified in 13 (68.4%) of patients with cataplexy, in 3 (25%) of patients without cataplexy and in 7 (12,7%) of controls. It was significantly more frequent in narcolepsy patients than in controls (p<0.001) and narcolepsy with cataplexy patients than in narcolepsy without cataplexy patients (p<0.05). The comparison of allele frequencies of two SNPs between patient and control groups yielded any significant results.
Recently, HLA-DQB1*0602 allele positivity was significantly high although the rates of the allele was lower in our narcolepsy with/out

cataplexy patients than the results observed in different populations. For further studies, the interaction between SNPs and HLA-DQB1*0602 should be analyzed in a large Turkish patient group.

P09.164
Study of the natriuretic peptide precursor gene $(TTTC)_n$ microsatellite polymorphism and plasma BNP levels in pre-eclampsia

G. Szabo, *A. Molvarec, B. Stenczer, J. Rigo Jr., B. Nagy;*
Semmelweis University, Budapest, Hungary.

Backgound: There is a variable tandem repeat (TTTC) polymorphism of the natriuretic peptide precursor B gene (NPPB), which shows association with essential hypertension. Our aim was to identify this polymorphism in samples of pre-eclamptic patients and healthy controls. We also compared the natriuretic peptide B (BNP) concentrations.

Methods: Blood samples were collected from healthy pregnant normotensive women (n=235) and patients having pre-eclampsia (n=220). DNA was isolated and fluorescent PCR and DNA fragment analysis was performed for the detection of (TTTC) repeats. The plasma BNP concentration was measured by fluorescence immunoassay method.

Results: We detected 12 different repeats on the NPPB gene. The overall distribution of alleles and genotypes was significantly different between the control and pre-eclamptic groups. The number of 10-repeat genotype carriers showed significantly lower frequency in pre-eclamptics than in the healthy pregnants (p=0.032). Adjusted odds ratio: 0.19 (95% CI: 0.04-0.87). Similarly 12-repeat genotype carriers (p=0.037), adjusted OR: 0.53 (95% CI: 0.29-0.96). Contrary, the 11-repeat genotype carrier frequency was significantly higher in the pre-eclamptic group (p<0.001, adjusted OR 2.91 (95% CI: 1.75-4.84)). The concentration of the BNP was 9.75 pg/mL in the healthy controls and 32.40 pg/mL in the pre-eclamptic group (p<0.0001). The 11/11 genotype carriers had significantly higher BNP levels in the pre-clamptic group.

Conclusions: The NPPB gene (TTTC) microsatellite polymorphism showed significant difference in the distribution of alleles and genotypes between healthy pregnants and pre-eclamptic patients in an ethnically homogeneous population. The concentration of the BNP was higher in pre-eclamptics, and it showed association with the genotypes.

P09.165***
Mutations of *VANGL2* gene in human Neural Tube Defects

P. De Marco[1], *E. Merello*[1], *S. Salem*[2], *C. Bosoi*[3], *G. Piatelli*[1], *A. Cama*[1], *Z. Kibar*[3], *V. Capra*[1];
[1]*Neurosurgery Department, G. Gaslini Institute, Genova, Italy,* [2]*Department of Biochemistry, McGill University, Montreal, QC, Canada,* [3]*CHU Sainte Justine Research Center, Department of Obstetrics and Gynecology, University of Montreal, Montreal, QC, Canada.*

Animal models were proven to be instrumental in deciphering the complex causation of Neural Tube Defects (NTDs). Particularly, these models demonstrated an essential role for the planar cell polarity (PCP) pathway, also called the non-canonical Frizzled/Dishevelled pathway, in neurulation. PCP is the process by which cells become polarized within the plane of an epithelium. The *Loop-tail* (*Lp*) mouse, that develops craniorachischisis, has been shown to carry missense mutations in the PCP core gene, *Vangl2.* In vertebrates, *Vangl2* has another homolog called *Vangl1* that has similar biochemical functions based on protein similarity and expression data. Recently, we identified eight novel rare missense mutations in *VANGL1* that were associated with human NTDs. To assess the role of the human ortholog *VANGL2* in the complex etiology of NTDs in humans, we resequenced this gene in a large multi-ethnic cohort of 673 NTD patients. We identified six novel heterozygous missense mutations in seven patients, that could be pathogenic based on genetic and initial validation data. Four of these mutations, p.Arg135Trp, p.Arg177His, p. Leu242Val, p.Arg270His, were predicted to be damaging to protein function using bioinformatics' tools, and two others, p.Thr247Met and p.Arg482His, affect highly conserved residues across evolution. Five mutations were identified in patients affected with closed spinal NTDs, suggesting that *VANGL2* mutations may predispose to thys type of NTDs. Our findings strongly implicate *VANGL2* in the genetic causation of spinal NTDs in a subset of patients and provide additional evidence for a pathogenic role of PCP signaling in these malformations.

P09.166
Sex modulates the effect of *DRD2/ANKK1* polymorphisms in smoking

N. R. Mota, *V. Contini, E. R. Polina, E. S. Vitola, F. A. Picon, E. H. Grevet, P. Belmonte-de-Abreu, C. H. D. Bau;*
Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Several publications, have addressed the relationship between smoking behavior and the *DRD2* gene, especially focusing on the Taq1A polymorphism (which in fact, belongs to a *DRD2* neighbor gene, named *ANKK1*). However, strong heterogeneity among studies has been reported by meta-analysis. Here we analyze the potential role of Taq1A and other three neighbor polymorphisms (rs6277, rs2283265 and rs2734849) in relation to smoking status. Our sample is composed of 463 adult patients with ADHD and 608 non-ADHD adults, totalizing 1071 subjects. Smoking is more common among patients with than without ADHD (43% vs. 18%, respectively; p<0001) but this is not influenced by sex. Logistic Regression analysis, controlling for ADHD status and sex, showed a significant interaction between Taq1A X gender on smoking status (p=0.016). A similar result was observed for the SNP rs6277 in exon 7 of *DRD2* (p=0.076 for interaction). Results of both polymorphisms are suggestive of opposite effects in men and women, with trends towards predisposition in men and protection in women. We did not observe any significant main effect or interaction of the other two polymorphisms studied. Therefore, our results support the hypothesis that the association of the Taq1A and smoking may be modulated by sex, which would help explain the heterogeneity in findings on the Taq1A/smoking association of the last several years. This also seems to be the case involving the rs6277 polymorphism, although further studies are needed to sustain this hypothesis.

P09.167
Polymorphisms in FGF1 gene are associated with nonsyndromic cleft lip and palate

I. Kempa[1,2], *L. Piekuse*[2], *J. Klovins*[1], *B. Barkane*[2], *I. Akota*[2], *A. Krumina*[1], *B. Lace*[1];
[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Riga Stradins University, Riga, Latvia.*

FGFs and their cell surface receptors (Fgfr) are a complex family of signalling molecules that play important roles in a variety of processes of embryogenesis and tissue homeostasis. The published data suggest that the FGF signalling pathway may contribute to as much as 3%-5% of non-syndromic CLP (NSCLP) and will be a consideration in the clinical management of CLP.

The aim of the study was to confirm the role of FGF1 gene in development of NSCLP.

Subjects and Methods: Thirty five SNPs in the FGF1 gene were genotyped using APEX-2 technology for allelic association with NSCLP. The data set consisted of 108 non-syndromic cleft lip and/or cleft palate patients samples and 182 unrelated non-affected and randomly selected individuals from Latvia as control population. Out of the 108 cleft cases, 79 had CLP and 29 had CL. Association analyses of cases and controls were performed using PLINK software version 1.07.

Results: Genotype distributions among study groups were in a Hardy-Weinberg equilibrium. We found very strong evidence that the FGF1 gene plays a significant role in the development of non-syndromic orofacial clefts. Three markers in the FGF1 gene were strongly associated with non-syndromic cleft lip and/or cleft palate (rs33992, p=0.001, OR=1.68, 95% CI=0.051-0.556; rs34010, p=0.0002, OR=0.48, 95% CI= 0.332-0.707; and rs2070715, p=0.025, OR=0.67, 95% CI= 0.465-0.951).

Conclusions: The results show that FGF1 gene contains genetic variations contributing to formation to clefts but additional studies should be made to clarify the possible involvement of these polymorphisms in the etiology of NSCLP.

P09.168
Association of NPBWR1 and NPBWR2 gene polymorphisms with hypertension.

*I. Kalnina[1], G. Latkovskis[2], V. Pirags[3], **J. Klovins**[1];*
[1]Latvian Biomedical Research and Study Centre, Riga, Latvia, [2]Latvian Research Institute of Cardiology, University of Latvia, Riga, Latvia, [3]Department of Endocrinology, Pauls Stradins Clinical University Hospital, Riga, Latvia.

NPBWR1 and NPBWR2 are receptors of neuropeptide B (NPB) and neuropeptide W (NPW). This neuropeptide system is thought to have a role in regulating feeding behaviour, energy homeostasis, neuroendocrine function, however its role in humans remains unknown. The aim of the study was to characterize the genetic variance of NPBWR1 and NPBWR2 and investigate the possible correlation of identified polymorphisms with number of metabolic and cardiovascular traits and phenotypes. In total 6 polymorphisms were indentified in both gene loci from direct sequencing of 100 individuals. Genotype based association was performed in 1500 individuals from Genome Database of Latvian Population. Among 10 different traits included in this analysis hypertension was significantly associated with one missense SNPs from each coding part of NPBWR1 (rs33977775) and NPBWR2 (rs4809401). These SNPs and two SNPs from NPW gene were genotyped in additional group of 500 hypertensives and 500 validated controls. rs33977775 and rs4809401 were significantly associated with presence of hypertension (P=0.0018 and P=0.03 respectively). We have also identified significant epistasis between these SNPs (P=0.005). We also present functional importance of two identified NPBWR1 variants (Ile40Thr and Tyr135Phe) on cAMP inhibition in HEK-293 cells.

P09.169
Genetic polymorphisms in *PXR* associated with alcohol consumption and side effect of methadone maintenance treatment

***H. Tsai**, Y. Liu, J. Tian, O. Chang;*
National Health Research Institutes, Miaoli County, Taiwan.

Objective: Methadone, a synthetic opioid, is well known as a maintenance drug to prevent heroin-addicted patients from experiencing withdrawal symptoms. In addition, nuclear receptor pregnane X receptor (*PXR*) is a xenobiotic nuclear receptor that binds ligands with different structures and is implicated in diverse functions. In this study, we tested whether *PXR* genetic polymorphisms are associated with alcohol consumption and side effect of methadone maintenance treatment.

Methods: A total of 366 heroin addicts undergoing methadone maintenance treatment were recruited in this study. Data were collected using interviewer-administered assessments, including Treatment Outcomes Profile (TOP), and Treatment Emergent Symptoms Scale (TESS). Twenty-five single-nucleotide polymorphisms (SNPs) of *PXR* were genotyped. After adjusting covariates, regression analyses were performed to identify individual association of *PXR* with side effect of methadone maintenance treatment, and joint association of *PXR* and *ALDH2* with alcohol consumption. Permutation-based approach was applied to correct for multiple testing.

Results: We found that 11 *PXR* SNPs were significantly associated with TESS, and 6 *PXR* SNPs were significantly associated with alcohol consumption after multiple testing correction ($P_{corrected}$ < 0.05). In addition, haplotype combination of "rs1523130-rs6785049-rs6438550" was significantly associated with average of alcohol consumption after multiple testing correction ($P_{corrected}$ < 0.05). Furthermore, We found rs6438550 of *PXR* was interacted with rs671 of *ALDH2* on alcohol use ($P < 10^{-4}$).

Conclusion: *PXR* genetic polymorphisms may have impact on the side effect of methadone treatment, moreover influence alcohol consumption through interacting with *ALDH2* gene in heroin addicts.

P09.170
Frequency of genotypes and rare alleles of genes implicated in lipid metabolism in children and adolescents according to family history of obesity.

***A. Khmyrova**[1], A. Vasina[2], A. Voitovich[1], M. Didur[2], V. Larionova[1];*
[1]St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation, [2]St. Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation.

The aim of the study was to estimate the frequency of genotypes and rare alleles of gene polymorphisms 4a4b *eNOS*, I/D *ACE*, W64R *ADRB3*,Q/E27 and G/R16 *ADRB2*,G-75A and C+83T *ApoA1*,S19W and -1131T<C *ApoA5*,L162V *PPARA* in 132 children and adolescents aged 5 to 17. They were divided into 4 groups: (1) 72 individuals whose one or both of the parents suffered from abdominal obesity, (2) 19 individuals whose one or both parents had abdominal fat distribution without obesity, (3) 7 whose one or both parents had obesity but normal fat distribution, and (4) 34 whose parents did not suffer from obesity and had normal fat distribution. The criterion of obesity was body mass index > 27 kg/m^2. Abdominal fat distribution was assessed using waist/hip index, with upper limit of 0.9 for men and 0.85 for women. Gene polymorphism 4a4b *eNOS,* polymorphism of I/D *ACE* were detected by PCR. Polymorphisms G-75A and C+83T *ApoA1*, S19W and -1131T<C *Apo A5*,W64R *ADRB3*, Q/E27, G/R16 *ADRB2*,L162V *PPARA* were determined by PCR-RFLP method. We did not find any significant difference in frequency of genotypes and rare alleles of investigated gene polymorphisms between all studied groups. This might be explained by insufficient samples size. Further studies in larger samples using a different approach, namely a study of combination of genotypes and rare alleles might bring more conclusive results.

P09.171
A clinical and genetic study of childhood and adolescent obesity

***M. A. El-Gammal**[1], I. Mazen[1], A. El-Kotoury[1], K. Amr[1], M. Abdel-Hamid[1], N. Kholoussi[1], G. Anwar[2], G. Ahmed[2], S. Tantawy[1];*
[1]National Research Centre, Cairo, Egypt, [2]Cairo University, Cairo, Egypt.

Obesity is determined by genetic, environmental and behavioral factors acting through the physiological mediators of energy intake and energy expenditure. The aim of this study was to define the most characteristic clinical, genetic, anthropometric and laboratory findings in childhood obesity in an attempt to find the most efficient way to diagnose a genetic cause of obesity. Subjects and Methods: All cases were subjected to full history taking, and full clinical examination including dysmorphology and pubertal assessment. Endocrinal causes were excluded. Serum leptin and insulin where estimated whenever a monogenic cause of obesity was suspected. Conventional and high resolution chromosomal analysis, FISH and molecular studies where done in selected cases. Results: This study included 30 obese children and adolescents. Among the 30 studied cases, 17 had syndromic obesity (56.67%), 7 had simple obesity (23.33%) and 6 had monogenic obesity (20%). Within the 6 diagnosed cases with monogenic obesity, we detect one novel missense mutation in the leptin LEP gene (N103K) and another novel nonsense mutation in the leptin LEP gene (W121X) as well as missense mutation in the Leptin receptor gene LEPR (P316T).

Conclusion: Although genetic causes of obesity are rare autosomal recessive disorders, high consanguinity rate in our society will lead to the discovery of a high number of monogenic and pleiotropic obesity. Early screening and regular follow up for obesity and its complications is particularly indicated for patients with syndromic forms of obesity, together with genetic counseling of the parents.

P09.172
Genotype x nutrient association of single-nucleotide polymorphisms in obesity-related genes with native dietary composition in the Central-European population

***J. A. Bienertova Vasku**[1], P. Bienert[2], J. Tomandl[3], M. Forejt[4], M. Vavrina[2], J. Kudelkova[2], Z. Brazdova[4], A. Vasku[2];*
[1]Masaryk University, Brno, Czech Republic, [2]Department of Pathological Physiology, Masaryk University, Brno, Czech Republic, [3]Department of Biochemistry, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [4]Department of Preventive Medicine, Faculty of Medicine, Masaryk University, Brno, Czech Republic.

As the personal food preferences can either enhance or suppress the development of obesity, we investigated native dietary composition as a specific trait related to obesity and we determined whether genetic variations in leptin (LEP), LEP receptor (LEPR), adiponectin (ADIPOQ), IL-6 and pro-opiomelanocortin (POMC) underlie specific native dietary composition as well as obesity-related anthropometric traits. The total of 520 individuals of Czech Caucasian origin were

enrolled into the present study and 7-d food records were obtained from the study subjects along with selected anthropometric measurements and podometers records. Independently of the BMI of the individuals, common variations in LEP and LEPR genes were associated with specific eating patterns, mainly with respect to timing of eating. The LEP +19A/G polymorphism served as an independent predictor for BMI, percentage of body fat and skinfold thickness and significantly affected the time structure of the daily energy intake. The POMC Rsa I polymorphism was associated with percentage of body fat. The ADIPOQ +45T/G polymorphism was associated with the thickness of the subscapular skinfold. The LEPR Gln223Arg polymorphism was associated with multiple parameters, including diastolic blood pressure, meal sizes during the day and plasma ADIPOQ levels. In a separate sub-analysis, soluble leptin receptor (sObR) plasma levels and LEP:sObR ratio were significantly correlated with systolic blood pressure(beta = - 0.66, P = 0.002; beta = -1.23, P = 0.02). To conclude, we report common allelic variants associated with specific feeding behaviour, obesity-related anthropometric traits and time structure of food intake.

P09.173
Investigation of genome wide association signals for obesity: synthetic association and haplotype analyses at the melanocortin 4 receptor gene locus

A. Hinney[1], *A. Scherag*[2], *I. Jarick*[3], *J. Grothe*[4], *H. Biebermann*[4], *S. Scherag*[1], *A. Volckmar*[1], *C. I. G. Vogel*[1], *B. Greene*[3], *J. Hebebrand*[1];
[1]*Department of Child and Adolescent Psychiatry and Psychotherapy, University of Duisburg-Essen, Essen, Germany,* [2]*Institute of Medical Informatics, Biometry and Epidemiology, University of Duisburg-Essen, Essen, Germany,* [3]*Institute of Medical Biometry and Epidemiology, Philipps-University of Marburg, Marburg, Germany,* [4]*Institute of Experimental Paediatric Endocrinology, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Independent genome-wide association studies (GWAS) showed an obesogenic effect of two single nucleotide polymorphisms (SNPs) more than 150 kb downstream of the melanocortin 4 receptor gene (MC4R). The SNPs might directly influence MC4R function/expression, or they are on a haplotype that predisposes to obesity or includes functionally relevant genetic variation (synthetic association). MC4R is an ideal model to explore synthetic association.

Methodology/Principal Findings: We analyzed a genomic region (364.9 kb) encompassing the MC4R in GWAS data of 424 obesity trios (extremely obese child/adolescent and both parents). SNP rs12970134 showed the lowest p-value (p = 0.004); conditional analyses on this SNP revealed that 7 of 78 analyzed SNPs provided independent signals. These 8 SNPs were used to derive two-marker haplotypes. The confirmed (363 independent obesity trios) obesity effect haplotype comprises the MC4R. Including MC4R coding variants in a joint model had almost no impact on the effect size estimators expected under synthetic association. Haplotype analyses were also conducted for the 31 additional GWAS-derived SNPs; 2 haplotypes revealed better results than the single SNPs, confirmation is ongoing.

Conclusions/Significance: A haplotype reaching from 5' of the MC4R to at least 150 kb from the 3' end of the gene showed a stronger association to obesity than single SNPs. Synthetic association analyses revealed that MC4R coding variants had almost no impact on the association signal. Our data underscore the problems underlying the identification of relevant mutations depicted by GWAS derived SNPs (Scherag et al., PLoS One 2010).

P09.174
Orofacial clefts and MTHFR gene polymorphisms in Slovak population

J. Behunova[1], *M. Zabavnikova*[2], *L. Klimcakova*[3], *L. Podracka*[1];
[1]*I. Department of Pediatrics, Safarik University Children Hospital, Kosice, Slovakia,* [2]*Department of Plastic and Reconstructive Surgery, Safarik University Hospital of Louis Pasteur, Kosice, Slovakia,* [3]*Department of Medical Biology, Safarik University Faculty of Medicine, Kosice, Slovakia.*

Nonsyndromic orofacial clefts are multifactorial birth defects with folate deficiency suspected as one of the risk factors. We evaluated two frequent polymorphisms of MTHFR gene C677T and A1298C in 65 Slovak patients with nonsyndromic orofacial clefts (OFC) (38 males, 27 females); 53 of all had cleft lip or cleft lip and palate (CLP) and 12 had isolated cleft palate (CP). The control group consisted of 290 healthy newborns (147 males, 143 females). The results revealed significantly higher proportion of T allele in C677T polymorphism in the whole OFC patients´ group (p=0.043) as well as in the CLP group 0.037) compared to the controls. Genotype analysis, however, did not show significant prevalence of mutant genotypes (OFC p=0.398, CLP p=0.697), only of heterozygotes (OFC p=0.014, CLP p=0.002). Analysis of the groups according to sex revealed again significant abundance of C677T heterozygotes, but not TT mutants in females. The results in the male groups did not show any significant differences compared to the controls in C677T polymorphism. The analysis of the A1298C polymorphism did not reveal any significant differences between the patients and controls, in the whole OFC group as well as in the CLP group and according to the sex. We can conclude that the two common polymorphisms of MTHFR gene did not pose the risk of OFC in our patients´ group from Slovakia; anyhow, we are aware of a need of a larger patients` sample and continue in the patients´ recruitment.

Genome-wide association study reveals new candidate loci for hand osteoarthritis

A. Näkki[1,2,3], *J. Eriksson*[4,5,6], *E. Widen*[1], *A. Palotie*[1,7], *U. M. Kujala*[8,9], *J. Saarela*[1];
[1]*Institute for Molecular Medicine Finland FIMM, Helsinki, Finland,* [2]*Unit of Public Health Genomics, National Institute for Health and Welfare, Helsinki, Finland,* [3]*Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [4]*Department of General Practice and Primary Health Care, University of Helsinki, Helsinki, Finland,* [5]*Helsinki University Central Hospital, Unit of General Practice, Helsinki, Finland,* [6]*Folkhalsan Research Centre, Helsinki, Finland,* [7]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [8]*ORTON Orthopedic Hospital, Invalid Foundation, Helsinki, Finland,* [9]*Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland.*

Objective. Osteoarthritis (OA) is a complex disease common in the elderly. Our aim was to study single nucleotide polymorphisms (SNPs) using a genome-wide association (GWA) data in a setting of hand OA cases versus healthy controls.

Methods. The study subjects were over 56 years of age and were part of Finnish Helsinki Birth Cohort Study sample genotyped using Illumina HumanHap 610 GWA chip. Hand joints of the study subjects were visually evaluated and individuals with Heberden's nodes in at least one DIP joint were graded as affected (n=524). Individuals graded as healthy (n=970) had visually healthy symptomless finger joints. Association with individual SNPs was monitored using the Plink program. Age, sex and two principal components differed between the cases and controls and were used as covariates.

Results. In our hand OA GWA analysis the most significant results were for SNP flanking the CD28 gene in 2q33 ($p=4.37x10^{-6}$, OR=1.68, 95% CI 1.35-2.10); SNP in the SUCLG2 gene in 3p14 ($p=6.15x10^{-6}$, OR=0.62, 95% CI 0.50-0.76) and SNP in the SLC22A3 gene flanking lipoprotein genes LPAL2 and LPA in 6q25 ($p=1.61x10^{-5}$, OR=1.41, 95% CI 1.20-1.64).

Conclusion. Variants in regions harbouring CD28, SUCLG2, SLC22A3, LPAL2 and LPA genes showed suggestive evidence for association with hand OA. CD28 has been shown to affect T-cell functions and IL2 production. CD28 and LPA genes have been shown to play role in rheumatoid arthritis. Results did not reach genome-wide significance in the initial screening phase but replication effort in a large study set is ongoing.

Osteoarthritis (OA) is the most common degenerative joint disorder in the elderly population. To identify OA-associated genetic variants and candidate genes, we conducted a genome-wide association study (GWAS). A total 3,793 samples from a community-based

epidemiological study were genotyped using the Affymetrix SNP 5.0. An intronic SNP (rs4789934) in the TIMP2 (tissue inhibitor of metalloproteinase-2) showed the most significance with OA (odd ration [OR] = 2.06, 95% confidence interval [CI] = 1.52-2.81, p = 4.01×10^{-6}). Furthermore, a polymorphism (rs1352677) in the NKAIN2 (Na^+/K^+ transporting ATPase interacting 2) was suggestively associated with OA (OR = 1.43, CI = 1.22-1.66, p = 7.01×10^{-6}). The present study provides new insights into the identification of genetic predisposing factors for the prevention of intractable pain from OA.

P09.177**

1,000 genomes based imputation discovers novel locus for osteoarthritis

A. G. Day-Williams[1], *L. Southam*[1], *K. Panoutsopoulou*[1], *S. Doherty*[2], *W. Zhang*[2], *R. Maciewicz*[3], *K. R. Muir*[4], *T. Esko*[5,6,7], *A. Metspalu*[5,6,7], *.. arcOGEN Consortium*[1], *M. Doherty*[2], *A. Valdes*[8], *E. Zeggini*[1];
[1]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [2]*Academic Rheumatology, Nottingham City Hospital, Nottingham, United Kingdom,* [3]*Respiratory & Inflammation Research Area, AstraZeneca, Loughborough, United Kingdom,* [4]*Health Sciences Research Institute, Warwick Medical School, Warwick University, Coventry, United Kingdom,* [5]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [6]*Estonian Biocenter, Tartu, Estonia,* [7]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [8]*Dept of Twin Research & Genetic Epidemiology, King's College London, London, United Kingdom.*

The genetic architecture of osteoarthritis (OA) has not been well characterized yet; to date only two loci have been reproducibly associated with knee OA in Europeans at genome-wide significance levels. As part of the arcOGEN consortium, we have carried out a genome-wide association study (GWAS) in 3,177 cases (knee and/or hip OA) and 4,894 UK controls. We performed genome-wide imputation using the August 2009 release of the 1,000 genomes project and tested for association with OA. We identified 7 loci with p<7E-06 and genotyped them in an independent set of 5,165 arcOGEN cases and 6,155 UK controls. rs11842874 in intron 3 of *MCF2L*, the guanine nucleotide exchange factor DBS, on chr13 showed evidence for replication (p=2.6E-03, MAF ~7%). Based on 8,066 Stage 1 individuals with imputation and directly typed data, there were 24 discordant alleles (overall allelic concordance 99.85%; minor allele concordance 97.93%). Replication was further sought in an independent set of 1,686 knee and/or hip OA cases and 743 UK controls, and in 207 knee and/or hip OA cases and 2,618 controls from Estonia. The fixed-effects meta-analysis odds ratio of the discovery and replication datasets for the major allele A was 1.23 [95%CI 1.14-1.33], p=4.33E-08 (10,235 cases, 14,410 controls in total).

P09.178

The association between serum osteopontin levels and OPN Ala250 polymorphism in urolithiasis

T. Tarhan[1], *F. Atalar*[2], *V. Tugcu*[3], *A. Kural*[4], *A. Bitkin*[3], *T. Altug*[1];
[1]*Istanbul Bilim University,Instituteof Health Sciences ,Medical Biology and Genetics, Istanbul, Turkey,* [2]*Istanbul University,Faculty of Medicine,Pediatric Endocrinology Unit, Istanbul, Turkey,* [3]*Bakirkoy Dr.Sadi Konuk Training and Research Hospital Department of Urology, Istanbul, Turkey,* [4]*Acibadem Hospital Department of Robotical Surgery and Urology, Istanbul, Turkey.*

Background: Osteopontin (OPN) is one of the urinary proteins having an important role in stone formation.Recently,OPN Ala250 (rs1126616) polymorphism along with other OPN SNPs have been investigated in order to define their role in urolithiasis.The aim of our study was to investigate OPN rs1126616 polymorphism and serum OPN levels in 106 urolithiasis patients together with 88 healthy controls.

Material and Methods: Stones were analyzed for their chemical composition by using X-Ray diffraction method.The study groups were genotyped by PCR-RFLP and serum OPN levels were measured by ELISA.

Results:OPN genotype frequencies in urolithiasis patients and control group were shown in Table1. In urolithiasis patients, OPN Ala250 heterozygote and homozygote carriers were almost 2 fold higher compared to controls (p=0.001). Serum OPN levels were higher in control group than urolithiasis patients (p=0.000) (Table1).

Conclusion: Ala250 polymorphism was significantly higher in Turkish urolithiasis patients by contrast their serum OPN levels were significantly lower.These results might be indicating the important predictive role of serum OPN and Ala250 polymorphism in urolithiasis patients.

P09.179

Lack of associations of CALCR and LCT gene polymorphisms with bone mineral density and osteoporotic fractures in the Volga-Ural region of Russia

R. Shakirova, *R. Khusainova, A. Maltzev, E. Khusnutdinova;*
Institute of Biochemistry and Genetics USC RAS, Ufa, Russian Federation.

Determination of bone mineral density (BMD) and formation of osteoporotic fractures are multifactorial and under complex genetic and environmental regulation. Calcitonin receptors (*CALCR*) participate in calcium metabolism and polymorphisms *CALCR* gene contribute to the variation of BMD and underlie osteoporotic fractures. Polymorphisms of LCT gene can lead to indigestion disorders and as a consequence, to disturbance of calcium absorption and reduce of BMD level. We examined associations of polymorphisms c.1377C>T (rs1801197) in the *CALCR* gene and -13910C>T (rs4988235) in the *LCT* gene with fractures and level of BMD in 251 Russian and Tatar women with postmenopausal osteoporosis and 100 Russian men with osteoporotic fractures and matched control (n=399). In Tatar and Russian women with postmenopausal osteoporosis *CALCR*T* allele frequency distribution was lower than in control groups (0.50 and 0.704, respectively), in Russian men with osteoporosis *CALCR*T* allele frequency was higher (0.655) compared with the control group (0.60). The frequency of genotype *LCT*C*C*, determining hypolactasia, was 51.61% in Russian women with fractures and 40% in control group. In this case, *LCT*C*C* genotype frequency in Tatar women of control group (63%) was higher compared with group of patients (45.5%), suggesting the existence of other genetic variants determining the synthesis of lactose in Tatars. Thus, the study of polymorphic loci c.1377C>T in the *CALCR* and -13910C>T in the LCT gens revealed no association of studied loci with fractures development and bone mineral density levels in women with postmenopausal osteoporosis of Russian and Tatar ethnic origin, as well as in Russian men with osteoporosis.

P09.180

Association of VDR, COL1A1, CALCR and BGLAP polymorphisms with susceptibility to steroid osteoporosis in patients with idiopathic pulmonary fibrosis (IPF)

A. S. Ulitina, *D. V. Dzadzua, L. N. Novikova, J. M. Ilkovich, M. V. Dubina;*
I.P.Pavlov State Medical University, Saint-Petersburg, Russian Federation.

Background. Osteoporosis, as complication of glucocorticosteroids (GCS) treatment, is a serious medical and economic problem. Osteoporosis is a polygenic disorder.

Aim. To assess effectiveness of steroid osteoporosis prevention by antiresorptive agents (ARA - calcium, vitamin D, bisphosphonates, calcitonin) in patients with IPF with different genetic predisposition to osteoporosis.

Subjects. 84 Caucasian patients with IPF, 16 men and 68 women, age 56.5±10.9 years, treated with GCS and ARA.

Methods. Bone mineral density (BMD) measuring by DEXA, patients' questionnaires and genotyping approaches were used. We investigated 5 SNPs by PCR-RFLP analysis: 2 sites in vitamin D receptor gene (VDR-BsmI and VDR-FokI), rs1801197 in calcitonin receptor gene, rs1800012 in collagen type1 alpha1 gene and HindIII-polymorphism in osteocalcin gene.

Results. Frequencies of minor alleles were 0.375 (VDR-BsmI), 0.411 (VDR-FokI), 0.185 (COL1A1), 0.280 (CALCR), 0.179 (BGLAP). Associations between VDR-FokI and BGLAP genotypes and BMD

(p=0.02 and p=0.05, respectively), between GCS doses and bone fractures occurrence (p=0.01) were found. Multiple regression analysis showed significant influence of polymorphisms VDR-FokI, COL1A1, CALCR and BGLAP on BMD (p<0.01) but only minor fraction of susceptibility can be explained by these polymorphisms (adjusted R^2=0.238). Environmental factors, firstly ARA intake, seems to have stronger influence on BMD and bone fractures occurrence than genetic predisposition.
Conclusion. ARA administration is an essential way to prevent and treat steroid osteoporosis in patients with IPF, including individuals with genotypes associated with increased risk of osteoporosis progression. Genetic analysis is recommended to reveal subjects with increased risk of osteoporosis.

P09.181
Otitis media prone children: Association with cytokine gene polymorphisms and environmental risk factors

O. Miljanovic[1], *Z. Magic*[2], *D. Vojvodic*[2], *D. Likic*[3];
[1]*Centre for medical genetics and immunology, Clinical centre of Montenegro, Podgorica, Montenegro,* [2]*Institute for medical research, Military medical academy, Belgrade, Serbia,* [3]*Institute for children diseases, Clinical center of Montenegro, Podgorica, Montenegro.*

Otitis media (OM) prone status in children results from complex interactions between genetic factors of the host, exposure to pathogens and environmental risk factors. Cytokine gene polymorphisms, determining the response to infection, may play an important role in multifactorial etiology of this frequent childhood disease. The objective of this study was to investigate the role of specific cytokines gene polymorphisms in OM prone children, as well as significance of association of cytokine gene polymorphisms and environmental risk factors (frequent respiratory infections, passive smoke exposure, day-care attendance and breast feeding practice) in children with recurrent episodes of otitis media. A total of 132 (OM prone and controls), both sex children were enrolled in the study. Single nucleotide polymorphism of IL2, IL6, IL10 and TNFα genes (TaqMan predesigned Genotyping SNP assay) and presence of environmental risk factors, were studied for all children. Results: Explicit bimodal distribution of OM susceptibility appearance, indicate that early childhood and preschool age plays important role in development of OM prone status. Out of 5 examined gene polymorphisms involved in regulation of inflammatory response, significant contribution to genetic predisposition to OM in Montenegro children was found for $IL10_{-1082}$ (G→A) gene. Conclusion: Our study has clearly pointed the significance of $IL10_{-1082}$ gene polymorphism in complex multifactorial pathogenesis of OM susceptibility in Montenegrin children, especially in interaction with environmental risk factors.

P09.182
The glutathione peroxidase 1 (*GPX1*) single nucleotide polymorphism Pro198Leu: association with life span and coronary artery disease in Russian population

T. V. Zheykova[1], *M. V. Golubenko*[1,2], *O. A. Makeeva*[1,2], *O. Y. Botkina*[1], *O. G. Polovkova*[1], *A. A. Lezhnev*[3], *E. V. Kalyanov*[4], *I. V. Tsimbaliuk*[5], *V. M. Shipulin*[3], *V. P. Puzyrev*[1,5];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Institute of Complex Problems of Cardiovascular Diseases, Kemerovo, Russian Federation,* [3]*Institute of Cardiology, Tomsk, Russian Federation,* [4]*Bureau of Forensic Medical Examination of Tomsk Region, Tomsk, Russian Federation,* [5]*Siberian State Medical University, Tomsk, Russian Federation.*

According to the free radical theory of aging, accumulation of oxidative damages determines life span. Also it is suggested that oxidative stress contribute to the development of various diseases including coronary artery disease (CAD). Inactivation of reactive oxygen species is performed by antioxidative enzymes. In this study we genotyped 5 SNPs in 4 genes for antioxidative enzymes (*CAT, SOD2, PON1, GPX1*) in four groups: patients with CAD (n=172), long-livers - above 90 years (n=210), people with early death (before 55 years) from cardiovascular diseases (n=94) and Russian population as control group (n=412). In particular, polymorphism in *GPX1* Pro198Leu (rs 1050450) has shown differences between the groups. The genotype distribution in control group was in Hardy-Weinberg equilibrium. We have found significant higher allele *T* frequency in men with CAD - 34.84% (χ^2=5.228, p=0.022; OR=1.46) and in men with early death from cardiovascular diseases - 38.16% (χ^2=6.461, p=0.011; OR=1.69) compared with control men - 26.8%. Moreover, significantly higher genotype *TT* frequency has been shown in patients with CAD and myocardial infarction (MI) before age 50 - 19.44% compared with control group - 7.28% (χ^2=9.55, p=0.002). The *TT* frequency in long-livers (4.39%) was the lowest and significantly different from CAD group - 12.79% (χ^2=8.07, p=0.0045) and from CAD subgroup with MI before 50 - 19.44% (χ^2=14.49, p=0.0001). Thus our results indicate that allele *T* (Leu) of *GPX1* Leu198Pro polymorphism is unfavorable for successful ageing. It predisposes to coronary heart disease, earlier myocardial infarction (before age 50) and earlier death (before age 55).

P09.183
Paraoxonase 1 gene (PON1) polymorphisms are associated with abdominal aortic aneurysms (AAA) in Polish population

E. Strauss[1], *K. Waliszewski*[2], *W. Majewski*[2], *A. L. Pawlak*[1];
[1]*Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland,* [2]*Department of General and Vascular Surgery, University of Medical Sciences, Poznan, Poland.*

Abdominal aortic aneurysm (AAA) is an age-related vascular disease and an important cause of morbidity and mortality in developed countries. The pathogenesis of AAA is multifactorial with a strong genetic component. Previous studies show that polymorphisms in genes involved in homocysteine metabolism may contribute to risk for AAA developing. However up to now there are very few appropriately powered association studies considered the role of specific genetic variants.
We determined relationship between three functional polymorphisms in paraoxonase 1 (PON1) gene: -108C>T (rs705379), L55M (162T>A; rs854560), Q192R (575A>G, rs662) and AAA occurrence in Poland. PON1 is an antioxidant enzyme, which detoxify homocysteine thiolactone in vascular vessels. The study was conducted in groups of 525 AAA cases, 425 controls and in random population sample of 220 subjects. Polymorphisms were studied by PCR-RFLP method. Haploview was used for haplotype analysis.
Coding region polymorphisms L55M and Q192R were in strong linkage disequilibrium (D'=0,76), which results in relatively low frequency of 55M-192R haplotype in Polish population (0,023). The frequency of this rare haplotype in patients (0,008) was significantly lower as compared to that in controls (0,018, p=0,04). The 5,3-fold higher risk of AAA was noted in homozygotes of 55L-192R haplotype (subjects with -108CT/55LL/192RR genotype; p=0,003). The distribution of 55-192 haplotypes in Polish cohort of AAA patients corresponds to that observed by Giusti et all (2008) in Italian population.
In conclusion, our results confirm observations that functional variants of PON1 gene influence AAA risk.

P09.184
Analysis of mitochondrial haplogroups in patients with Parkinson´s disease in Slovak republic

M. Baldovic[1], *P. Majerová*[1], *L. Kadasi*[1,2];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.*

Parkinson disease is the second most often neurodegenerative progressive dissease with prevalence 1 % in 65 years old persons. It is caused by selective degradation of dopaminergic neurons in substantia nigra pars compacta. Etiology of Parkinson disease can be explained by number of factors, including effect of nuclear genes and mitochondrial DNA variation. The first evidence that mitochondrial polymorphisms could be implicated in etiology of PD came from study of T4366C associated with increased risk of Parkinson disease in Europe. Abnormality of function of mitochondrial electron transfer chain has been reported in many PD cases. Beside haplogroup determining SNPs, may mitochondrial haplotypes and haplogroups share polymorphisms modulating ,,coupling efficiency" of mitochondrion with protective or pathological effect in PD expression. Especially variation in tRNA, 16S RNA and genes for cytochrome b in mtDNA have been identified like possible modulation factors in pathogenesisof PD.
We genotyped 199 PD pacient and 382 control subject and detect

decreased frequencies of haplogroup U (OR= 0, 55; 95% CI: 0,39- 0,90), its subhaplogroup U4 (OR= 0, 26; 95% CI: 0,07- 0,89) and cluster UK (OR= 0,60; 95 % CI: 0,39- 0,92). Decreased frequencies of UK, K + U5b + U4 + J and K + U5a + U4 + J we reported only between men.We also detected increased frequency of T1 (OR= 8,00; 95% CI: 1, 68- 38, 04) in slovak PD pacients. Its protective or possible pathogenic effect of this haplogroup has not been described so far.

P09.185
Stable elevation of FAS mRNA level in peripheral blood lymphocytes of patients with LRRK2-associated Parkinson's disease over time

T. S. Usenko[1,2], *A. F. Yakimovsky*[2], *A. K. Emelyanov*[1,2], *N. A. Boganykova*[3], *T. V. Vavilova*[3], *S. N. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, Saint-Petersburg, Russian Federation,* [2]*St. Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation,* [3]*St. Petersburg State State Medical Academy, Saint-Petersburg, Russian Federation.*

Mutations in the Leucine Reach Repeat Kinase 2 (LRRK2) gene are the most frequent cause of familial Parkinson's disease (PD). Although the precise physiological and pathological role of LRRK2 is unclear, direct link between mutant LRRK2 and apoptosis has been suggested. Earlier we found the increased FAS mRNA level in patients with LRRK2-associated PD compared to controls (persons without neurological disorders). The aim of our present work was to examine the same patients with LRRK2-associated PD over the three-year period and evaluate FAS mRNA level in peripheral blood lymphocytes (PBL) after 1h, 24h, 48h of incubation (37°C, 5% CO2). FAS mRNA levels were estimated in PBL of four patients with LRRK2-associated PD (n=3 G2019S; n=1 V1613A, mean age 65±10) and of nine controls (mean age 61±7). At 1h, 24h, 48h PBLs were harvested, total mRNA extracted and cDNA synthesized. FAS mRNA levels were estimated by means of quantitative real-time PCR with TagMan probes. The level of G protein (GNB2L1) mRNA was used as internal control. At 24h mRNA levels were slightly increased compared to 1h in both groups but this difference was not statistically significant. FAS mRNA level was higher in patients with LRRK2-associated PD compared to controls at 1h ($p<0.03$) and at 24h ($p<0.05$). Our results suggest LRRK2 mutations may lead to the activation of FAS expression in PBL of patients with LRRK2-associated PD and this induction in stable over time.

P09.186
Analysis of exon rearrangements in PARK2, PINK1 and SNCA genes in patients with Parkinson's disease from Russia

E. Semenova[1], *M. Shadrina*[1], *E. Fedotova*[2], *S. Illarioshkin*[2];
[1]*Institute of Molecular Genetics, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

To date, a number of genes involved in the pathogenesis of Parkinson's disease (PD) have been identified. We analyzed rearrangements in exons 1-12 of the PARK2 gene in 170 sporadic early-onset (EOPD, age at onset < 45) and 183 sporadic late-onset (LOPD, age at onset > 45) patients with PD. Exon 7 rearrangements in PINK1 gene were studied in a mixed group of 214 patients with familial and early-onset sporadic PD. Rearrangements in exons 4-6 of the SNCA gene were studied in 61 patients with autosomal dominant PD. All the patients were from Russia. The frequency of EOPD and LOPD patients carrying these mutations in PARK2 gene was 12.4 and 3.8%, respectively. The most frequent rearrangements were detected in exons 3 and 4. The odds ratio for EOPD in individuals carrying PARK2 gene exon deletions and duplications was 3.54 (0.95% CI, 1.465-8.569; P = 0.006). We also found a correlation between exon rearrangements in PARK2 gene and some clinical features of PD. Exon 7 deletion in PINK1 gene was found in 5 patients. The analysis of the SNCA gene revealed no increase in the exon dosage. The results of our study let us conclude that exon rearrangements in PARK2 gene have a significant role in the pathogenesis of sporadic PD in patients from Russia. The role of exon deletions in PINK1 gene remains to be elucidated and multiplications of the SNCA gene play insignificant part in the pathogenesis of autosomal dominant PD in Russia.

P09.187
Androgen levels and metabolic parameters are associated with a genetic variant of F13A1 in women with PCOS

N. Schweighofer, *E. Wehr, O. Trummer, U. Lam, T. R. Pieber, B. Obermayer-Pietsch;*
Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University, Graz, Austria.

Polycystic ovary syndrome (PCOS) affects about 6-15 % of all women and is therefore the most common hormonal disorder among women of reproductive age. PCOS is associated with a variety of clinical problems like infertility, obesity and insulin resistance. This study aimed to evaluate allelic F13A1 variants - a blood coagulation factor gene - for its influence in PCOS patients.

We investigated the effect of an intronic SNP (A/G) in the F13A1 gene in 371 PCOS patients and 133 normal controls. Metabolic and hormonal measurements, oral glucose tolerance tests (oGTT) and a specialised hirsutism score (modified Ferriman-Gallwey method) were determined.

Genotype frequencies of the F13A1 SNP did not deviate from Hardy Weinberg equilibrium and were equivalent in PCOS and controls. In the dominant genotype model, in all PCOS patients and especially in overweight/obese PCOS patients (BMI ≥ 25), the G allele of F13A1 was associated with significantly higher levels of free testosterone and DHEAS as well as decreased levels of SHBG in the overweight/obese group, which was only seen as a trend in all patients. The G allele was additionally associated with insulin metabolism in lean PCOS patients (BMI < 25) since the AUC of insulin was significantly lower compared to the A allele.

We demonstrate an association of F13A1 gene variants with androgen levels in PCOS patients with increased BMI as well as metabolic parameters in lean patients. This might be of high importance for diagnostic and therapeutic aspects in this frequent disease.

P09.188
Pharmacogenetic study of adalimumab treatment in Crohn disease patients

U. Potočnik[1,2], *K. Repnik*[1], *S. Koder*[3];
[1]*University of Maribor, Faculty of Medicine, Maribor, Slovenia,* [2]*University of Maribor, Faculty of Chemistry and Chemical Engineering, Maribor, Slovenia,* [3]*University Clinical Center Maribor, Maribor, Slovenia, Maribor, Slovenia.*

Crohn disease (CD) is one of the two major subtypes of Inflammatory bowel diseases and is characterized with chronic inflammation in whole gastrointestinal tract. Recently biological therapy using, himeric (infliximab (Remicade) or fully humanized (adalimumab (Humira) monoclonal antibodies against TNF-α are used in CD patients not responding to standard treatment or developing adverse drug effects. We have conducted prospective pharmacogenetic study in Slovenian refractory CD patients enrolled in adalimumab treatment. We used IBDQ and CDAI index to monitor therapy response. We have collected blood samples for DNA, RNA and protein isolation and analysis of some biochemical and immunological parameters (CRP) before treatment and in 4, 12, 20 and 30 weeks after first treatment with adalimumab. We have genotyped single nucleotide polymorphisms (SNPs) in selected apoptotic genes (CASP9, FCGR3A, FAS in TIMP-1), previously associated with response to infliximab. We found correlation between SNP in gene CASP-9 and response to treatment with adalimumab. Patients with C/C genotype had worse response after fourth weeks (p = 0,05) and 20 weeks (p = 0,031) of treatment compared to patients with C/T and T/T genotype. Results of our study are comparable with previous study where patients were treated with infliximab and patients with C/C genotype in CASP-9 gene had worse response to therapy. We also found correlation between polymorphisms in genes CASP-9 (SNP rs4645983) and FCGR3A (SNP rs396991) in Slovenian patients with CD involved in this study. Our results provide a step forward to identification of efficient pharmacogenomic biomarkers for individualized therapy in CD patients.

P09.189
Exome sequencing identifies a set of genes that may be associated with escitalopram treatment response in major depression.

A. Tammiste[1,2], *K. Fischer*[3], *T. Jiang*[4,5], *L. Milani*[3], *K. Pettai*[2,3], *K. Krjutškov*[3], *T. Esko*[1,2,3], *R. Mägi*[1,2,6], *Y. Li*[4], *R. Uher*[7], *P. McGuffin*[7], *E. Maron*[8], *J. Wang*[4], *A. Metspalu*[1,2,3];

[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Estonian Biocentre, Tartu, Estonia,* [3]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [4]*BGI-Shenzhen, Shenzhen, China,* [5]*Genome Research Institute, Shenzhen University School of Medicine, Shenzhen, China,* [6]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [7]*Institute of Psychiatry, King's College London, London, United Kingdom,* [8]*Imperial College London, London, United Kingdom.*

Antidepressants are widely used in the treatment of major depression although their efficacy is unsatisfactory - approximately 30% of patients do not fully recover even after several treatment trials. Interindividual genetic differences may contribute to the variability in antidepressant response. Association studies applying the candidate-gene strategy to identify genetic markers influencing antidepressant response in major depression have produced some results, many of which are inconsistent or not transferable to other study samples.

We report on the first application of full exome sequencing to antidepressant pharmacogenetics. From a sample of 126 individuals diagnosed with major depression and treated with escitalopram over 12 weeks, we selected 5 extreme responders and 5 extreme non-responders based on their phenotype - responders were patients who showed good treatment response after 10 mg of escitalopram, non-responders were resistant to treatment even after raising the dose to 20 mg daily. Complete exome sequencing of these patients was performed at the Beijing Genomics Institute using Illumina Genome Analyzer IIx platform.

By comparing the allele counts of previously known SNPs and novel polymorphisms in five responders and five non-responders, we identified a set of genes that may be associated with the difference in response to escitalopram treatment. The most promising findings have been replicated in the remaining 116 patient samples, and in the GENDEP sample which consists of 394 patients treated with escitalopram.

Genome wide association analysis of rheumatoid arthritis patients treated with anti-TNF medication. Results of the DREAM registry

M. J. H. Coenen[1], *M. Umićević-Mirkov*[1], *S. H. Vermeulen*[1], *E. J. M. Toonen*[1], *A. Lee*[2], *F. Batliwalla*[2], *W. Kievit*[1], *H. Scheffer*[1], *T. L. Jansen*[1], *E. A. J. Knijff-Dutmer*[3], *T. R. D. J. Radstake*[1], *M. A. F. J. van de Laar*[4], *P. Barrera*[1], *P. L. C. M. van Riel*[1], *P. K. Gregersen*[2], *B. Franke*[1];

[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*The Feinstein Institute for Medical Research, Manhasset, New York, NY, United States,* [3]*Gelderse Vallei Hospital, Ede, Netherlands,* [4]*University Twente & Medisch Spectrum Twente, Enschede, Netherlands.*

Background: Treatment strategies blocking tumor necrosis factor (anti-TNF) have proven very successful in patients with rheumatoid arthritis (RA). However, a significant subset of patients does not respond for reasons that are unknown, and there is currently no means of identifying these patients.

Objective: We aimed to identify genetic factors predicting anti-TNF treatment outcome in patient with RA using a genome-wide association approach.

Methods: We selected RA patients treated with anti-TNF agents from the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry. Disease activity scores (DAS28) at baseline and after 14 weeks was available of 508 patients. Single nucleotide polymorphisms (SNPs) markers were genotyped using the Illumina HumanHap550-Duo BeadChip or the Human660W-Quad. Association analysis using the relative DAS28 change as outcome was performed using the whole-genome association analysis toolset PLINK.

Results: 511.499 SNPs and 502 patients passed quality control. 75 SNPs showed suggestive association (uncorrected p-value<10^{-4}) with relative DAS change. Candidate genes, among the top ten associated SNPs, that can be linked to anti-TNF or RA are *ASPH* (p=1.36*10^{-6}), a gene involved in calcium homeostasis and regulated by *STAT4*, one of the confirmed risk factors for RA and the genes *TIAM1* (p=2.79*10^{-6}) and *UBE2E2* (p=1.21*10^{-5}), both play a role in cell death, one of the working mechanisms of anti-TNF therapy.

Conclusions: The identified genes may serve as new biomarkers predicting anti-TNF response. However, significant findings need to be replicated in other patient cohorts. Confirmed biomarkers can be used to personalize medication for the individual patient.

P09.191
Assessment of a pharmacogenomic marker panel in a clinical biorepository

M. T. Oetjens, *J. C. Denny, A. R. Baker, H. H. Dilks, M. A. Basford, E. Bowton, N. A. Restrepo, V. M. Youngblood, J. M. Pulley, D. M. Roden, D. R. Masys, M. D. Ritchie, D. C. Crawford;*

Vanderbilt University, Nashville, TN, United States.

Genetic variants associated with adverse events or treatment efficacy are often rare (less than 5% minor allele frequency) or located in difficult-to-assay regions of the genome. Genotyping arrays used for genome-wide association (GWA) studies, which are designed to capture most of the common variation in the human genome, may not be adequate for pharmacogenomics studies. To address this, Illumina has designed the absorption, distribution, metabolism, and excretion (ADME) Core Panel, a fixed content panel of 184 pharmacogenomic-related markers in 34 genes. Because these variants are rare and difficult to assay, there is a lack of reference data in the literature or reference populations such as the International HapMap Project. There is also little data on how well the ADME Core Panel performs.

As a pilot study, we genotyped 320 European Americans prescribed 5 or more unique drugs from BioVU, a de-identified clinical population from Vanderbilt University, to see if certain pharmacogenomic variants may be unequally distributed in patients who received many medications. We also genotyped HapMap samples as well. We abstracted allele frequencies from public repositories as well as the literature for markers targeted by ADME. Preliminary results suggest that 30% of ADME targeted markers do not have reference allele frequency data in HapMap or the literature. Of the 320 samples genotyped on ADME, 98.8% of markers had call rates >95% and HWE p>0.0001. Allele and genotype frequencies differed between reference data and the clinical population for 3 markers (p< 10-5), warranting a follow-up study to explain these results.

P09.192
Genetic and environmental factors influencing the Placental Growth Factor (PlGF) variation in two populations.

R. Sorice[1], *D. Ruggiero*[1], *T. Nutile*[1], *M. Aversano*[1], *L. Husemoen*[2], *A. Linneberg*[2], *C. Bourgain*[3], *A. L. Leutenegger*[4], *M. Ciullo*[1];

[1]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy,* [2]*Research Centre for Prevention and Health, Glostrup, Denmark,* [3]*Inserm / University Paris SUD U669, Villejuif F-94817, France,* [4]*INSERM, U946, Paris F-75010, France.*

Placenta Growth Factor (PlGF), a member of the VEGF family, is a key molecule in angiogenesis and endothelial cell growth and migration. Several studies have been performed to correlate PlGF plasma levels with different pathological conditions (i.e.: pre-eclampsia, inflammation, prognosis of various types of cancers) but, to date, no information is available regarding the genetic basis of PlGF variability. Furthermore, even if the effect of environmental factors (i.e. cigarette smoking) on angiogenesis has been explored, no data on the effect of smoking on the PlGF have been reported so far. We investigated the PlGF variability in two cohorts: a study sample from two isolated villages in Cilento region, South Italy (n=1251) and a replication sample from general Danish population (n=2647). A significant difference in the PlGF mean levels was found between the two populations. However, in both samples, we observed a strong correlation of PlGF levels with ageing and gender, men displaying PlGF levels significantly higher than women. Interestingly, smoking was also found to influence the trait in the two populations, although differently. The association between five single nucleotide polymorphisms (SNPs) located in the PlGF gene and the levels of the protein in the plasma was investigated. We observed a significant association between two polymorphisms and PlGF plasma levels (p<10-2) in the Cilento sample and this association was replicated in the Danish sample (p<10-9). These results, for the first time, support the hypothesis of the presence of genetic and

environmental factors influencing PlGF plasma variability.

P09.193
Association of genetic polymorphisms degradome pathway genes with children chronic lung disease susceptibility

O. Tselousova[1,2], *L. Akhmadishina*[1], *G. Korytyna*[1], *T. Victorova*[1,2];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Proteases a large group of enzymes involved in multiple physiological and pathological processes in lung tissue. Through protein degradation and turnover proteases play an essential role in lung tissue remodeling and repair during the inflammatory response and may be important in the development of chronic lung disease. In our case-control study we investigated role of genetic risk factors to susceptibility of chronic lung disease in children.

The genotypes of MMP1 (-1607G/GG), MMP2 (-735C/T), MMP9 (-1562C/T), MMP12 (-82A/G) genes in 235 patients with chronic respiratory diseases and 323 healthy children were detected by the PCR-RFLP method.

We observed significantly increased susceptibility to chronic lung disease in children for the MMP12 (-82A/G) gene compared with healthy children (x2=5.85, P=0.016). The allele A of was identified as a risk allele for chronic lung disease in children (OR=1,93, 95%CI 1.10-3.40). Whereas the allele G was more frequent in healthy children, and was identified as a protective allele (OR=0,52, 95%CI 0,29-0,91). The A(-82) MMP12 - GG(-1607) MMP1 haplotype was also significantly associated with increased susceptibility to chronic lung disease in both groups (OR=1,40, 95%CI 1,09-1,81). The genotype and allele frequencies of MMP1 (-1607G/GG), MMP2 (-735C/T), MMP9 (-1562C/T) genes do not significantly differ in groups.

The results of the study suggest the genetic polymorphisms in degradome pathway genes may play a significant role in the development of chronic lung disease in children.

P09.194
Comparative study of allele frequencies of PAI-1, MTHFR and FV gene polymorphisms in children with Henoch-Schönlein purpura, Schamberg Disease and in healthy children.

N. V. Shirinbekova[1], *E. V. Voronina*[1], *A. N. Voitovich*[1], *A. M. Smirnov*[2], *G. S. Demin*[2], *V. I. Larionova*[1];
[1]*St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation,* [2]*Gene Ltd., Saint-Petersburg, Russian Federation.*

Objectives: Comparative analysis of alleles and genotypes distribution of plasminogen activator inhibitor 1 (PAI-1) -675 4G/5G insertion-deletion polymorphism, methylenetetrahydrofolate reductase (MTHFR)- 677C/T polymorphism and blood coagulation factor V (FV) 1691G/A polymorphism in (1) children with Henoch-Schönlein purpura (HSP), (2) in children with Schamberg Disease (SD) and (3) in healthy children. Patients and methods. HSP group consisted of 40 patients (20 boys and 20 girls), SD-group consisted of 32 patients (15 boys and 17 girls). Control group was composed of 31 apparently healthy children (20 boys and 11 girls). PAI-1-675 4G/5G insertion-deletion polymorphism was analysed by PCR method, MTHFR 677C/T and FV 1691G/A polymorphisms were analysed by PCR-RFLP method. Statistical significance of differences between groups was assessed using χ2 tests. Results. There was no statistically significant (p>0.05) difference in allele and genotype distribution of analysed polymorphisms between HSP group, SD group and control group. The genotype distribution was in accordance with Hardy-Weinberg equilibrium for all variants. Genotype 5G/5G PAI-1-675 was not found in SD group. 1691A allele of the FV was not found in any group (all children has “normal” GG genotype FV 1691). Conclusion. In this study we did not find PAI-1-675 5G/5G genotype in children with SD and no A -allele FV 1691G/A in any of studied groups.

P09.195
Analysis of polymorphism of COL1A1 and VDR genes in children with congenital scoliosis

I. Kazarian[1], *S. Vissarionov*[1], *G. Demin*[2], *G. Stoyko*[2], *V. Larionova*[3];
[1]*The Turner Scientific and Research Institute for Children's Orthopedics, Saint-Petersburg, Russian Federation,* [2]*Gene Ltd., Saint-Petersburg, Russian Federation,* [3]*St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.*

Vitamin D receptor gene (*VDR*) and the gene encoding alpha chain of collagen type 1 (*COL1A1*) are candidate genes in the development of congenital malformations of the skeleton.

OBJECTIVE: to study the distribution of alleles and genotypes of site Sp1 polymorphism of the *COL1A1* and of TaqI site polymorphism of the *VDR* genes in children with congenital scoliosis.

Patients and methods: the study group included 197 children aged 6 mo to 16 yo with various types of malformations of the spine. Control group included 60 children aged 2 to 17 yo without orthopedic pathology.

Molecular genetic study was carried out using PCR followed by restriction analysis.

RESULTS: Alleles and genotypes frequencies of Sp1 site of *COL1A1* gene and TaqI of *VDR* gene in children with congenital scoliosis and in controls are presented in Table.

Genotypes	Children with congenital scoliosis		The control group		P - value
	N	%	N	%	
COL1A1 Sp1					
SS	131	66,5	51	86,0	0,022
Ss	59	30	8	13,4	
ss	7	3,5	1	0,6	
allele S	321	81,5	110	92,4	0,007
allele s	73	18,5	9	7,6	
TaqI					
TT	78	39,6	39	65,0	0,002
TC	91	46,1	18	30,0	
CC	28	14,3	3	5,0	
allele T	247	62,6	96	78,3	<0,001
allele C	147	37,4	24	21,7	

CONCLUSION: The frequency of the *COL1A1* Ss genotype and s allele were significantly higher in patients with congenital scoliosis than in controls.

There were significant increase in the CC genotype frequency and C allele of *VDR* gene in children with congenital scoliosis compared with control subjects.

P09.196
A coding variant in NLRP1 is associated with autoimmune Addison`s disease

M. Zurawek[1], *M. Fichna*[1,2], *D. Januszkiewicz*[3], *P. Fichna*[4], *M. Gryczynska*[2], *J. Nowak*[1];
[1]*Institute of Human Genetics, Polish Academy of Science, Poznan, Poland,* [2]*Department of Endocrinology and Metabolism Poznan University of Medical Sciences, Poznan, Poland,* [3]*Department of Paediatric Oncology, Haematology and Transplantology, Poznan University of Medical Sciences, Poznan, Poland,* [4]*Department of Paediatric Diabetes and Obesity, Poznan University of Medical Sciences, Poznan, Poland.*

Variations in the NLRP1 (previously, NALP1) gene have recently been reported to confer risk for vitiligo and associated autoimmune conditions. The NLRP1 gene encodes leucine- rich repeat protein 1, a member of a group of cytoplasmic pattern recognition receptors, which recognize microbial lipopolysaccharide, thereby stimulating innate immunity. We hypothesized that polymorphisms in this gene may affect susceptibility to Autoimmune Addison`s disease and Type 1 Diabetes. The aim of this study was to analyse the associations of six NLRP1 SNPs (Single- Nucleotide Polymorphisms) with AAD and T1D within a Polish cohort. The study comprised 101 AAD, 221 T1D patients and 254 healthy control individuals. Genotyping was performed by PCR-RFLP and PCR-SSCP methods. The minor allele of the coding SNP rs12150220 appeared significantly more frequently in AAD compared to healthy individuals (OR=1.5, 95% CI: 1.08-2.08, p=0.015). The distribution of genotypes also demonstrated significant differences. The frequency of high-risk genotype AA of rs12150220 SNP was significantly increased among AAD subjects vs. controls (P=0.006) yielding an OR of 2.96 (95%CI 1.34-6.55). Likewise, the heterozygous genotype TA was observed more frequently in the patient group [OR 3.09 (95%CI 1.53-6.24), P=0.001]. The frequencies of alleles and genotypes of the six SNPs in the NLRP1 region did not

present significant differences between patients with T1D and controls. In conclusion, this study confirms an association between the coding polymorphism in NLRP1 and AAD.

P09.197
Association genes for angiogenic factors and hereditary thrombophilia with preeclampsia in Russian and Yakut populations

E. Trifonova[1], *T. Gabidulina*[2], *K. Pavlova*[3], *V. Stepanov*[1];
[1]*Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [2]*Institute for Obstetrics and Gynecology, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [3]*Yakut Scientific Center of Complex Medical Problems, Siberian Branch of Russian Academy of Medical Sciences, Yakutsk, Russian Federation.*

Several lines of evidence support the hypothesis that angiogenic factor and markers of hereditary thrombophilia play an important role in the pathogenesis of preeclampsia (PE). In the present study we examined 620 women (330 Yakut women [215 cases] and 290 Russian women [140 cases]). Total DNA was extracted, and 8 tagging single nucleotide polymorphisms in 3 genes (*VEGFA, ACVR2a* and *LEP*) and allelic variations C677T and A1298C in *MTHFR* gene, -675 4G/5G in *PAI-1* gene and G1691A in *FV* gene were genotyped. We have detected significant associations for PE with rs3025010 in *VEGFA* (OR=1,98; 95% CI: 1,20-2,36 for genotype TT), rs17742342 in *ACVR2a* (OR=1,68; 95% CI: 1,02-2,76 for genotype AA), rs2167270 in *LEP* (OR=2,38; 95% CI: 1,14-4,97 for genotype AA), genotypes 677TT in *MTHFR* (OR 8,17, CI 2,37-28,17) and -675 4G/4G in *PAI-1* (OR 2,36, CI 1,45-3,84) in Russian population. In Yakut population, we have found that only *PAI-1* 4G/4G genotype carriers have an increased risk of PE (OR 2,02, CI 1,29-3,16). Allelic variations in the *ACVR2a, LEP, MTHFR* and *VEGFA* genes are associated with PE only in Russian women, while polymorphism 4G/4G in *PAI-1* gene shows the association in both ethnic groups. We suppose that these polymorphisms could play a role in the development of PE. Nevertheless, the clinical significance of these findings remains to be determined.

P09.198
Genome-wide linkage and association analyses in nondemented hypertensive individuals suggest association of *PSEN2* with plasma amyloid beta

C. A. Ibrahim-Verbaas[1,2], *I. V. Zorkoltseva*[3], *N. Amin*[2], *M. Schuur*[1], *Y. S. Aulchenko*[2,3], *M. M. B. Breteler*[2], *A. Van der Lugt*[4], *M. A. Ikram*[2,4], *T. I. Axenovich*[3], *M. M. Verbeek*[5], *J. C. Van Swieten*[1], *B. A. Oostra*[2], *C. M. Van Duijn*[2];
[1]*Department of Neurology, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [2]*Department of Epidemiology, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [3]*Institute of Cytology and Genetics, Russian Academy of Science, Novosibirsk, Russian Federation,* [4]*Department of Radiology, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [5]*Departments of Neurology and Laboratory Medicine, Alzheimer Centre Nijmegen, and Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands.*

Plasma amyloid beta (Aβ) is an easily obtained marker for Aβ load in brain. Aβ is highly correlated with hippocampal atrophy, a biomarker for early stages of late-onset Alzheimer's disease (AD). The aim of this study was to find genetic variants associated with plasma Aβ levels. The study included 126 nondemented hypertensive subjects 55 to 75 years old from the Erasmus Rucphen Family (ERF) study. Multipoint variance-component linkage analysis was performed for non-fasting plasma Aβ levels (Aβ40, Aβ42, and truncated forms Aβn40 and Aβn42) in MERLIN. Regions with at least suggestive evidence of linkage were followed up with association analysis using FASTA approximation to linear mixed model in GenABEL. All analyses were adjusted for age and sex. Two regions showed LOD scores >1.9, both for Aβ40: 1q32.3-1q42.13 (LOD = 2.07 at 1q41) and 11q14-11q21 (LOD=2.97 at 11q14.3). At 1q42.13, strongest association was observed at a variant flanking the *PSEN2* gene (p-value $2.5x10^{-4}$). Suggestive association was also observed at 11q14.3 (p-value=$4.8x10^{-3}$) at a variant near the Melatonin Receptor 1B (*MTNR1B)* gene. Our data suggests an association between *PSEN2*, a known gene for familial AD, and plasma Aβ40. The 11q14.3 region for Aβ40 contains the *MTNR1B* gene associated with obesity - a trait linked with plasma Aβ42 levels. Melatonin has an anti-apoptotic effect in neurodegenerative disease in cell and animal models. This region is therefore particularly interesting for further research. Replication efforts in a population-based sample are ongoing.

P09.199
Evaluation of APOE, MTHFR and LOXL1 polymorphisms in pseudoexfoliation syndrome and pseudoexfoliation glaucoma in Epirus (Greece).

D. Chiras[1,2], *S. Oliveira*[3], *M. Grigoriadou*[4], *H. Kokotas*[4], *Z. Petrou*[5], *C. Kroupis*[3], *M. Stefaniotou*[2], *G. Kitsos*[2], *M. B. Petersen*[4];
[1]*Department of Ophthalmology, Hospital of << Ag. Savvas>>, Athens, Greece,* [2]*Department of Ophthalmology, University Hospital of Ioannina, Ioannina, Greece,* [3]*Department of Clinical Biochemistry, Attikon University Hospital, Athens, Greece,* [4]*Department of Genetics, Institute of Child Health, Athens, Greece,* [5]*Department of Ophthalmology, General Hospital << G. Xatzikosta >>, Ioannina, Greece.*

Aim: The purpose of this study is to evaluate *APOE*, *MTHFR* and *LOXL1* polymorphisms as genetic risk factors for pseudoexfoliation syndrome (PXFS) and pseudoexfoliation glaucoma (PXFG) in the Greek population of Epirus.
Material & Methods: Genomic DNA was extracted from 82 PXFG, 69 PXFS and 96 control subjects from Epirus, Greece. *APOE* and *MTHFR* 677C>T genotyping was performed by polymerase chain reaction (PCR), followed by HhaI /HinfI digestion, respectively, and gel electrophoresis. A real-time PCR method with hybridization probes was developed for two *LOXL1* polymorphisms in a single reaction in the LightCycler (Roche-TIB).
Results: No significant differences were observed for the *APOE* and *MTHFR* polymorphisms between PXFS, PXFG and control subjects. The *APOE* e3 allele was found to be the commonest in all groups (88.4%-90.2%-89.1% in PXFS-PXFG-controls). The prevalence of the *MTHFR* 677TT genotype was 13.1%-14.6%-19% in PXFS-PXFG-controls. The *LOXL1* developed method was in 100% concordance with DNA sequencing. The genotyping of the two *LOXL1* polymorphisms is in progress.
Conclusion: Our results suggest that the *APOE* and *MTHFR* polymorphisms are not significant risk factors for the development of PXFS and PXFG. The results of the genotyping of the two *LOXL1* polymorphisms are expected.

P09.200
Serotonin gene receptor (5HT3a) expression in psoriatic patients

S. Ghasemi[1], *G. Ahangari*[1], *H. Mortazavi*[2], *R. Torabi*[1], *M. Mohammadian*[1];
[1]*Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran,* [2]*Department of Dermatology, Razi hospital, Tehran university of medical science, Tehran,Iran, Tehran, Islamic Republic of Iran.*

Serotonin (5HT) plays roles as a neurotransmitter and a neuromodulator with functions in brain and peripheral tissues. Serotonin receptor subtypes are related to depression and also have been shown to be present in certain cells of the immune system. Psoriasis is a hyperprolifrative inflammatory disease. The aim of this study is evaluation of 5HT3a gene expression in peripheral blood mononuclear cells (PBMC) of psoriatic patients in comparison with normal individuals By Real-time PCR.
The PBMC was separated from whole blood by Ficoll-hypaque. The total cellular RNA was extracted and the cDNA was synthesized. This process was followed by real-time PCR using primer pairs specific for 5HT(3a) serotonin receptor mRNA and beta-actin as internal control. Results reveal that relative expression of 5HT(3a) has significant decrease in psoriasis. Considering these results the present study has shown that there is a change in serotonin receptor gene expression in PBMC of psoriatic patients in comparison with healthy individuals. In conclusion, 5HT3a significant decrease may be an important role of this receptor in pathogenesis of psoriasis.

P09.201
Targeted resequencing of susceptibility genomic regions for psoriasis

D. Trujillano, *E. Riveira, C. Tornador, S. Ossowski, A. Puig, M. Gratacòs, X. Estivill;*
Centre for Genomic Regulation (CRG), Barcelona, Spain.

Many recent publications have shown that DNA enrichment in combination with high-throughput sequencing can be successfully applied for the identification of causative genetic variants underlying both rare and common disorders. Psoriasis is a hyperproliferative inflammatory disease that presents several clinical forms and affects the skin, scalp, nails and joints. It is a life-long disease with a prevalence of 2-3% in the general population. The importance of the genetic factors for the susceptibility to psoriasis is supported by the high heritability of the disease, and also by several genome-wide linkage analyses and association studies that have identified multiple loci associated to the susceptibility for psoriasis. However, not all the genetic variants of these regions have been analysed with the same detail.

Therefore, we have re-sequenced six psoriasis candidate genomic regions on ten unrelated patients. The regions of interest were captured with the SureSelect (Agilent) target enrichment technology and sequenced using the Illumina GAII platform. The resulting reads were aligned to the reference sequence. After variant calling, we applied a combination of filters based on frequency and function to discard any variation that is not linked to the disease, and to define a set of candidate protein-altering variants to be associated to psoriasis. This analysis has allowed us to detect more than 300 hundred SNPs and InDels (both novel and known) in 78 different genes. The potential involvement of these variants in psoriasis is currently being evaluated through association studies in additional patients.

Imaging Genetics: tool for gene finding and characterization in psychiatric disorders

B. Franke[1], *A. Arias Vasquez*[1], *J. Bralten*[2], *J. Veltman*[3], *P. Hagoort*[4], *H. G. Brunner*[3], *M. Rijpkema*[5], *G. Fernandez*[6];
[1]*Departments of Human Genetics and Psychiatry, Donders Institute for Brain, Cognition and Behavior, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Departments of Cognitive Neurosciences and Human Genetics, Donders Institute for Brain, Cognition and Behavior, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [4]*Donders Institute for Brain, Cognition and Behavior, Centre for Cognitive Neuroscience, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [5]*Donders Institute for Brain, Cognition and Behavior, Centre for Cognitive Neuroimaging, Radboud University Nijmegen, Nijmegen, Netherlands,* [6]*Department of Cognitive Neurosciences and Donders Centre for Cognitive Neuroimaging, Donders Institute for Brain, Cognition and Behavior, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Alteration of regional brain structure is an inherent feature of neuropsychiatric disorders, but it remains unclear if this is causally related to pathogenesis. If this were the case, alterations of brain structure should also be present in healthy individuals carrying genetic risk factors for such disorders. This, in turn, would imply that brain structure in the healthy population can be used as an intermediate phenotype for gene finding in neuropsychiatric disorders.

We enrolled >1700 young healthy adults in the Brain Imaging Genetics (BIG) study. Structural MRI brain images are available from scans at 1.5 or 3 Tesla. FSL-FIRST is used to assess volumes of specific brain structures. Genotyping of several candidate genes and genome-wide genotyping (Affymetrix 6.0, n=1000) was performed.

Hypothesis-driven testing of candidates for neuropsychiatric disorders lead (among others) to the following findings: By gene-wide (set-based) testing of the Alzheimer's disease (AD) gene SORL1 we found a significant association with hippocampus volume, one of the first structure affected by AD, in a discovery sample of 446 BIG-participants (p=0.0432) and replication in 490 additional subjects (p=0.0093).

Preliminary GWAS of amygdala volume in 600 samples resulted in association findings for several suspected psychiatric risk genes, such as CDH13, featuring among the GWAS top-findings for ADHD, addiction and schizophrenia.In conclusion, risk factors for neuropsychiatric disorders indeed affect brain structure in healthy individuals suggesting that altered brain structure is cause rather than consequence of disease. In addition, healthy brain structure seems a powerful intermediate phenotype for gene discovery in neuropsychiatric disorders.

P09.203
Support for the involvement of the calreticulin gene in the evolution of cognition in humans

T. Farokhashtiani[1], *A. Mirabzadeh*[2], ***M. Ohadi***[1];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Psychiatry, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.*

Development-dependent, tissue-specific expression of calreticulin (CALR) gene in the gray matter coincides with the expression of psychoses phenotypes. We have recently reported instances of mutations within the core promoter sequence of the gene in schizoaffective disorder. In view of the mounting evidence on the genetic overlap in the psychiatric spectrum, we investigated this gene in a spectrum of patients afflicted with schizophrenia, schizoaffective disorder and major affective disorder. We found that a unique mutation at nucleotide -220 from the transcription start site, located at a conserved genomic block in the promoter region of the gene, co-occurs with the spectrum of psychoses ($p<0.005$). This mutation reverts the human promoter sequence to the ancestral types observed in chimpanzee, mouse, and several other species, implying that the genomic block harboring nucleotide -220 may be involved in the evolution of human-specific higher-order functions of the brain (e.g. language, conceptual thinking, and judgment), that are ubiquitously impaired in psychoses. We propose that CALR is not only a promising candidate in the spectrum of psychoses, but also, a gene that may be important in the human-unique brain processes.

P09.204
Molecular characterization of 30 Pulmonary Arterial Hypertension idiopathic Spanish patients

G. Pousada-Fernández[1], *M. Ojeda*[2], *A. Baloira*[3], *C. Vilariño*[4], *D. Valverde*[1];
[1]*Facultad de Biología, Universidad de Vigo, Vigo, Spain,* [2]*IVI Vigo, Vigo, Spain,* [3]*Servicio de Neumología del Complejo Hospitalario de Pontevedra, Vigo, Spain,* [4]*Servicio de Neumología del Complejo Hospitalario de Ourense, Ourense, Spain.*

Pulmonary arterial hypertension (PAH) is characterized by an increase in PA pressure, increased pulmonary vascular resistance, vascular remodeling, and right ventricle failure. Approximately 70% of patients with the familial form of PAH have a mutation in the gene encoding bone morphogenetic protein receptor type II (BMPR-II). However, there is variable phenotypic expression of PAH among carriers of mutated BMPR-II gene. Likely related to a second hit caused by environmental and/or genetic modifiers. Studies have implicated serotonin, the serotonin transporter, endothelin, nitric oxide sintase, and others.

Vasodilators such as nitric oxide (NO) and prostacyclin, along with prolonged overexpression of vasoconstrictors such as endothelin (ET-1) or serotonin (5-HT), not only affect vascular tone but also promote vascular remodelling. All of them have been implicated in the pathogenesis of PAH.

NO is an endothelial-derived relaxing factor that is synthesized from L-arginine by nitric oxide synthase. NOS2 is the major source of NO production and polymorphisms in the *NOS2* gene promoter are thought to regulate its transcription activity.

The mitogenic and co-mitogenic effects of 5-HT require internalization through the serotonin transporter 5-HTT (*SERT*).

The aim of this work was to investigate the association between polymorphisms in the genes *ET-1, NOS2, SERT* and *BMPR-II* (by PCR-Sequencing) and the susceptibility to PAH.

We found 15% of sequence variations in the BMPR-II gene in the HAP patients. The data reveals that the shorter forms of the CCTTT repeat in the *NOS* gene were associated with susceptibility to PAH. No relation has been found with *ET-1* and *SERT*.

P09.205
Analysis of renin-angiotensin-bradykinin system genes polymorphism in preeclampsia, hypertension and metabolic syndrome in children of North-west Russia

E. S. Vashukova[1], *A. S. Glotov*[1], *O. S. Glotov*[1], *I. A. Makchrova*[2], *M. D. Kanaeva*[3], *G. I. Obraztsova*[2];
[1]*Ott's Institute of Obstetrics and Gynecology RAMS, Saint-Petersburg, Russian Federation,* [2]*Saint-Petersburg State Pediatric Academy, Saint-Petersburg, Russian Federation,* [3]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation.*

Renin-angiotensin-bradykinin system (RAS) is a pivotal regulator of arterial blood pressure and water-salt balance in human. It was shown gene polymorphisms of this system is associated with hypertension. The main aim of this study was the analysis RAS genes polymorphism in patients with preeclampsia, hypertension, children with metabolic syndrome. Population group (N=200), children (N=144), children with metabolic syndrome (N=160), children with hypertension (N=179), normal pregnant women (N=100), women with preeclampsia (N=100) were studied by PCR-biochip method including polymorphism of AGT (Met235Thr), AGTR1 (1166A>C), AGTR2 (3123C>A), BDKRB2 (-58T>C), REN (-83G>A) genes. We compared the results in patients groups with relevant data from controls. Only genotypes frequency of AGTR1 polymorphism (1166A>C) was different in children with hypertension from corresponding control group (x2=8.24; p<0.02). Further studies are needed to assess this finding.

The work is supported by grant of Russian Education and Science Ministry - GK N P2387.

P09.206
Genome-wide association study reveals two novel susceptibility loci for restless legs syndrome

B. Schormair[1,2], *D. Czamara*[3], *E. C. Schulte*[1,4], *F. Knauf*[1], *B. Müller-Myhsok*[3], *T. Meitinger*[1,2], *J. Winkelmann*[1,2,4], *for the International RLS Study Consortium;*
[1]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics, Technische Universität München, Munich, Germany,* [3]*Max Planck Insitute of Psychiatry, Munich, Germany,* [4]*Department of Neurology, Technische Universität München, Munich, Germany.*

Restless legs syndrome (RLS) is a sleep-related sensorimotor disorder with an age-dependent prevalence of up to 10% in the general population (> 65 years). It is characterized by the presence of uncomfortable sensations and an urge to move in the lower limbs, occurring in resting situations during the evening or at night. Relief of the symptoms is provided by moving the legs.

Genome-wide association studies (GWAS) have identified a total of four susceptibility loci: *MEIS1*, *BTBD9*, *MAP2K5/SKOR1* and *PTPRD*. However, the number of samples in the GWA stage was small, enabling the discovery of large effect (OR ≥ 1.4) common variants only. We conducted an enlarged GWA for RLS in 922 cases and 1,526 controls, followed by a replication of 76 candidate SNPs in 3,935 cases and 5,754 controls, all of European ancestry.

Herein, we identified two novel susceptibility loci: an intergenic region on chromosome 2p14 (rs6747972, P_{nom}=8.09 x 10^{-11}, OR= 1.2) and a locus on 16q12.1 (rs3104767, P_{nom}=1.96x10^{-19}, OR= 1.3) in a linkage disequilibrium block of 140 kb containing the 5'-end of *TOX3* and the adjacent non-coding RNA *BC034767*. *TOX3* is involved in calcium-dependent neuronal transcription, whereas for *BC034767*, a regulatory function can only be hypothesized at present.

In combination with the four known loci, all susceptibility variants explain about 3.4% of the heritability for RLS, clearly pointing to many more variants remaining to be discovered, until one can sketch the underlying molecular pathways.

P09.207
A copy number variant that provides a 2.3-fold protection against Rheumatoid Arthritis

K. Reekie[1], *L. Padyukov*[2], *J. Worthington*[3], *L. Klareskog*[2], *J. Lorentzen*[2], *C. Veal*[1], *A. Brookes*[1];
[1]*University of Leicester, Leicester, United Kingdom,* [2]*Karolinska Institute, Stockholm, Sweden,* [3]*University of Manchester, Manchester, United Kingdom.*

The genetic component of Rheumatoid Arthritis (RA) risk is estimated at around 60%, a large proportion of which is currently unaccounted for. In part this is due to that fact that, aside from the MHC, RA susceptibility loci so far described have small effect sizes (OR ≤ 1.8). Here we report an allele of a copy number variant (CNV) which is protective against RA, with an odds ratio of 2.3.

This CNV involves part of a large ancient tandem duplication, located within an RA susceptibility region. We assessed copy number in a Swedish RA cohort (cases = 2403, control = 1269), and revealed that a 129 kb deletion within this region occurs at a significantly higher frequency in control samples compared to cases (p = 0.001, OR = 2.3 (95% CI 1.4 - 3.9)), indicating a role protective against RA for this variant. This was replicated in a UK cohort (p = 0.036, OR = 1.90 (95% CI 0.93-3.82)).

Genes within this tandem duplication are involved in important biological processes including the immune response and embryogenesis. Altered expression of these genes has also been implicated in the progression of diseases such as cancer and Alzheimer's Disease. Given the importance of genes within this region, it seems likely that this CNV contributes towards susceptibility for other complex disorders. Indeed, our preliminary investigations have already suggested an association with psoriasis in a Swedish cohort (p=0.013, OR=2.16 (95% CI 1.2-4.1)).

P09.208
Analysis of eNOS gene polymorphisms in Serbian patients with rheumatoid arthritis

T. M. Damnjanovic[1], *B. Jekic*[1], *V. Bunjevacki*[1], *I. Novakovic*[1], *V. Milic*[2], *M. Krajinovic*[3], *L. Lukovic*[1];
[1]*Institute of Human Genetics, School of Medicine, Belgrade, Serbia,* [2]*Institute of Rheumatology, School of Medicine, Belgrade, Serbia,* [3]*Centre de Recherche, CHU Sainte-Justine, Montréal, QC, Canada.*

Nitric oxide (NO), synthesized from L-arginine by NO synthases (NOS). To date, several functionally relevant genetic polymorphisms in the eNOS gene have been associated with various vascular and autoimmune diseases, such as rheumatoid arthritis (RA). The objective of this study was to investigate the influence of the eNOS gene polymorphisms (T-786C in the promoter, intron 4 a/b VNTR and G894T in exon 7) on the susceptibility to RA in the Serbian population. A group of 194 RA patients and 104 healthy subjects were included in this study. The genotype was determined by PCR-RFLPs method.

Our results showed that T-786C genotype distributions in RA patients (TT 46,1%, CT 45,0% and CC 8,9%) were significantly different from healthy controls (TT 49,4%, CT 50,0% and CC 0,96%) (χ2=7,335, p<0.05). We have found a higher frequency of -786C allele in RA patients compared to the controls but without statistically significant association (31, 4% versus 25, 9%) (χ2=2,142, p<0.05, OR=1, 28, and 95%: 0,858-1, 920). Group of patients with -786CC genotype had statistically significant lower number of swollen and tender joints compared with patients with -786TT genotype (t=1,672 p=0,039).

No significant difference in alleles or genotypes frequencies for the 4 a/b VNTR and the G894T polymorphisms was observed between RA patients and controls. Also, no significant differences in three eNOS allele frequencies between groups of patients according to immunological (RF, ANA) and other clinical data were observed. We conclude that there is potential association of C-786T polymorphism with the susceptibility to RA.

P09.209
Association of rs10818488 SNP at TRAF1/C5 region with rheumatoid arthritis in Iranian population

M. Keramatipour[1], *S. Ahmadlou*[1], *M. Akhyani*[2], *A. Salimzadeh*[3];
[1]*Tehran University of Medical Sciences, School of Medicine, Department of Medical Genetics, Tehran, Islamic Republic of Iran,* [2]*Alborz Hospital, Karaj, Islamic Republic of Iran,* [3]*Tehran University of Medical Sciences, Sina Hospital, Rheumatology Section, Tehran, Islamic Republic of Iran.*

Rheumatoid arthritis (RA) is a common autoimmune disease with a complex etiology affecting 1% of the world population. Association studies in various populations have reported a number of genetic variations affecting the individual susceptibility to RA. The strongest association has been reported from genes within the HLA region, particularly the HLA-DRB1 gene.

The association of rs10818488 SNP located near TRAF1 gene, has been recently picked up by genome wide association studies. Following independent studies in different populations revealed inconsistent results. To investigate the possible association of this SNP with RA in Iranian population, a combined family-based (parents-affected child

trios) and population-based case-control study was performed.
In family-based study, 115 trios were recruited. After obtaining their consent, blood samples were taken, and DNA was extracted. Genotyping was done by PCR-RFLP and a set of genotypes were confirmed by sequencing. Analysis of data showed a significant over-transmission of A allele in trios (Transmission Disequilibrium Test, TDT value ≈ 4.3, p-value ≈ 0.03). This resulted in a Haplotype Relative Risk of 1.5.
In case-control design, a total of 362 cases and 422 healthy controls, including samples from family-based study, were genotyped. Genotype and allele frequencies were compared between the two groups. Analysis showed a higher frequency of A allele in cases, although the difference was not significant statistically (Chi-square ≈ 2.8, p-value ≈ 0.09). Comparison of genotype frequencies, revealed higher frequencies of AA and AG genotypes in case group but statistically the difference was not significant (Chi-square ≈ 2.72, p-value ≈ 0.25).

P09.210
The rs2476601 SNP of PTPN22 gene plays no role in susceptibility to rheumatoid arthritis in Iranian population

S. Ahmadlou[1], *M. Akhyani*[2], *A. Salimzadeh*[3], *M. Keramatipour*[1];
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Alborz Hospital, Karaj, Islamic Republic of Iran,* [3]*Rheumatology Section, Sina Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Rheumatoid arthritis (RA) is a common autoimmune disease with a complex etiology affecting 1% of the world population. Association studies in various populations have reported a number of genetic variations affecting the individual susceptibility to RA. The strongest association has been reported from genes within the HLA region, particularly the HLA-DRB1 gene.
The rs2476601 SNP of PTPN22 (protein tyrosine phosphatase nonreceptor 22) gene can be named as the second polymorphism that has been repeatedly reported to be associated with RA. Allelic frequency of 14 - 15% has been reported for A allele (the risk causing allele) in this SNP in Caucasian population. To investigate the possible association of this SNP with RA in Iranian population, we designed a family-based (parents-child trios) and a population-based case-control association studies.
In total 872 blood samples were collected from 405 confirmed RA patients and 467 healthy controls. 115 trios were included in the total samples. DNA was extracted and genotyping was performed by PCR-RFLP method using RsaI restriction enzyme. All samples were genotyped as homozygous GG. Genotyping was repeated for 30% of samples by using XcmI enzyme and for 10% of samples by sequencing. Again all samples showed homozygous GG genotype.
This study strongly suggest that there is no A allele in the gene pool of Iranian population. Therefore it does not play a role in susceptibility to RA and other autoimmune disorders in Iranian population.

P09.211
Strengthening the Reporting of Genetic Risk Prediction Studies: The GRIPS Statement

A. C. J. W. Janssens[1], *J. P. A. Ioannidis*[2], *C. M. van Duijn*[1], *J. Little*[3], *M. J. Khoury*[4];
[1]*Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Stanford University School of Medicine, Stanford, CA, United States,* [3]*University of Ottawa, Ottawa, ON, Canada,* [4]*Centers for Disease Control and Prevention, Atlanta, GA, United States.*

The rapid and continuing progress in gene discovery for complex diseases is fuelling interest in the potential implications of this knowledge for clinical and public health practice. An essential prerequisite for many genome-based health care applications is the predictive ability of the genetic risk model. The number of studies assessing the predictive performance of genetic risk models is steadily increasing, with widely variable completeness of reporting and apparent quality. Transparent reporting of the strengths and weaknesses of empirical studies is important to facilitate the accumulation of evidence on genetic risk prediction. A multidisciplinary panel developed a checklist of 25 items recommended for strengthening the reporting of Genetic RIsk Prediction Studies (GRIPS), building on the STREGA, REMARK and STARD reporting guidelines. The recommendations do not prescribe or dictate how genetic risk prediction studies should be conducted, but offer consensus guidelines to enhance the transparency of their reporting, and thereby to improve the process of synthesizing information from multiple studies with different strategies regarding design, conduct or analysis.

P09.212
ELP4 polymorphisms and rolandic epilepsy in a Greek cohort

L. Fidani[1], *A. Gampeta*[2], *T. Katopodi*[1], *K. Kalinderi*[1], *J. Clarimon*[3], *E. Pavlou*[2];
[1]*Department of Medical Biology-Genetics, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Second Department of Pediatrics, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece,* [3]*Biomedical Research in Neurodegenerative Diseases Center (CIBERNED) and Memory Unit, Neurology Department, Hospital Santa Creu i Sant Pau, Madrid , Barcelona, Spain.*

Rolandic epilepsy (RE) is the most common idiopathic focal epilepsy in childhood characterized by an EEG abnormality of centrotemporal sharp waves. Results from a recent genome-wide linkage analysis have implicated the Elongator protein complex 4 (ELP4) gene, in the pathogenesis of this neurodevelopmental disorder. ELP4 is a component of the elongator complex which regulates the transcription of several genes associated with nerve cell motility and migration during development, however its role is not completely defined up to now.
In an attempt to investigate the previously reported association of ELP4 polymorphisms, rs964112 and rs11031434, with RE, we collected 31 Greek patients (age range: 4-16 years old diagnosed in the AHEPA University Hospital of Thessaloniki, Greece and 47 healthy controls.
The polymorphisms were detected with a PCR-RFLP method, after designation of specific primers. PCR amplification and enzyme digest of the relevant fragment.
Genotype and allelic frequencies were compared with the Chi-square test of independence. Genotype and allele distributions for the two studied polymorphisms were not significantly different between RE and control individuals (for genotypes: P=0.225 and P=0.828 respectively, for alleles: P=0.852 and P=0.993, respectively). Haplotype frequency comparisons did not show any significant difference between RE patients and controls (P=0.649), as well.
Our results do not substantiate ELP4 as a risk locus for Rolandic epilepsy, although an extension of this study to a larger sample is expected to delineate the effect of ELP4 genetic variations on the susceptibility to seizures and neurodevelopmental disorders, such as RE.

P09.213
rs1333040 genotypes on 9p21.3 influence CDKN2A/2B expression in human coronary plaques

N. Marziliano, *F. Orsini, V. Motta, A. Colosimo, F. Marra, E. Araldi, C. Lauricella, S. Veronese, P. Merlini;*
Azienda Ospedaliera Ospedale Cà Granda Niguarda, MILANO, Italy.

Coronary artery disease (CAD) is significantly influenced by genetic background. Genome-wide association studies have shown that common genetic variants located in human chromosomal region 9p21.3 are associated with ischemic heart disease. They are not associated with any established cardiovascular risk factors, and no known protein-coding genes reside within the region. Gene expression studies have shown that gene regulatory elements might be located within the risk interval.
The knock-out mice lacking the CAD locus interval in chromosome 4 shows that this region is critically required for the normal cardiac expression of two neighbouring cyclin-dependent kinase inhibiting genes, Cdkn2a/b.
It is known that CDKN2A/B control cell proliferation by preventing entry to the S-phase of the cell cycle. As the development of human atherosclerotic lesions is characterised by an increase in the rate of replication and death of all mitotic cells in response to injury, it is conceivable that the decreased expression of CDKN2A/B may be associated with altered cell replication, and the start and progression of atherosclerosis.
We investigated the influence of the 9p21.3 variant rs1333040 on CDKN2A/B expression in 30 human coronary atherosclerotic plaques obtained by means of coronary atherectomy from patients with ischemic heart disease. We validated our findings on 20 coronary samples obtained at the heart transplant.

Quantitative PCR showed a significant (p=0.00013) trend of expression levels of both genes with the number of the risk allele (C), the expression in the CT plaques being in between that of CC and TT plaques, for both genes.

Proteome screening in sera of patients with schizophrenia at different stages and courses of drug therapy

B. Rukova[1], *S. Hadjidekova*[1], *I. Dimova*[1], *M. Stamenova*[2], *S. Todinova*[3], *L. Zagorchev*[4], *M. Odjakova*[4], *V. Krumova*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University, Sofia, Bulgaria,* [2]*Department Of Psychiatry, Medical Faculty, Medical University, Sofia, Bulgaria,* [3]*Institute of Biophysics and Biomedical engineering, BAS, Sofia, Bulgaria,* [4]*Faculty of Biology, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria.*

Schizophrenia is a severe chronic mental disorder that affects most of the higher brain functions. Its prevalence is estimated on about 1% worldwide. The classical symptoms also occur in several other psychiatric disorders, which makes difficult the exact diagnostics. The etiology of schizophrenia remains to be elucidated. It is thought to be a result of a complex interaction between genetic and environmental factors. Schizophrenia is a serious social and economic burden to healthcare systems. Currently, there is no etiological treatment. Until now there isn't any proven molecular marker as an objective diagnostic parameter for schizophrenia.

Materials and methods: We have analyzed serum samples from schizophrenic patients at different phases of the disease - before and after treatment, comparing them to a cohort of normal sera. We applied several methods for protein alterations' screening: DSC (Differential scanning calorimetry), protein profiling methods: 2D-SDS PAGE, HPLC techniques. The differences in the profiles were analyzed by mass spectrometric techniques.

Results: Initially we analyzed sera samples with DSC method to detect distinguishing serum profiles. We observed significant differences in the fractions of the more abundant serum proteins- albumin and immunoglobulin. We distinguished different protein profiles: before and after treatment of the patients; according to the medication. We also found considerable concordance between therapy response and protein profiles - normalization in case of remission and marked alterations in non-responders. Because of these differences we proceeded with analyzing serum proteins by more sensitive and precise methods to find a potential marker for drug therapy and disease progression.

Schizophrenia (SCZ) is a severe psychiatric disorder that profoundly affects cognitive, behavioral and emotional processes. The wide spectrum of symptoms and clinical variability in SCZ suggests a complex genetic etiology, which is consistent with the numerous loci thus far identified by family linkage, copy number variation (CNV) and association studies. While SCZ heritability may be as high as ~80% the genes responsible for much of this heritability remain to be identified. Using high-throughput sequencing technologies, we sequenced the exome of 14 patients with schizophrenia and their parents. Each proband had a standardized SCZ diagnostic and every parent was carefully excluded of any psychiatric disorder. A list of high quality variant was validated using traditional Sanger sequencing. We identified 14 DNMs in 8 probands, which is significantly more than expected considering the previously reported DNM rate. Beside, 4 of the 14 identified DNMs are nonsense mutation, suggesting a causal role for those variants. Our study supports the notion that DNMs play a major role in sporadic SCZ while providing a list of genes possibly involved in disease pathogenesis. This report suggests that de novo mutations (DNMs) may account for a substantial fraction of the missing SCZ heritability.

P09.216
Expression QTL analysis of top loci from Psychiatric GWAS Consortium meta analysis reveals additional schizophrenia candidate genes

S. de Jong[1], *D. Zeegers*[1], *K. van Eijk*[1], *E. Strengman*[1], *E. Janson*[1], *J. Veldink*[2], *L. van den Berg*[2], *S. Psychiatric GWAS Consortium*[1], *W. Cahn*[3], *R. Kahn*[3], *M. Boks*[3,4], *R. Ophoff*[1,3,5];
[1]*University Medical Center Utrecht, department of Medical Genetics, Utrecht, Netherlands,* [2]*University Medical Center Utrecht, Rudolf Magnus Institute of Neuroscience, department of Neurology, Utrecht, Netherlands,* [3]*University Medical Center Utrecht, Rudolf Magnus Institute of Neuroscience, department of Psychiatry, Utrecht, Netherlands,* [4]*University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands,* [5]*University of California Los Angeles, Center for Neurobehavioral Genetics, Los Angeles, CA, United States.*

Schizophrenia is a severe psychiatric disorder characterized by delusions and hallucinations, in addition to negative and cognitive symptoms. The disorder affects up to 1% of the population and the genetic contribution is estimated to be around 80%. Thus far, genome-wide association studies of schizophrenia have had limited success, with the best finding at the HLA locus at chromosome 6p. While only a very small number of loci yield genome-wide significance for association, the vast majority of the genetic contribution to disease susceptibility remains uncovered. It is likely to be overrepresented in non-significant top SNPs of large-scale GWAS results. In order to uncover potential interesting candidates, we selected the top 6,000 SNPs with significance threshold at p<0.001 from the international PGC meta-analysis consisting of some 9,000 cases and 12,000 controls and examined their possible involvement in schizophrenia using gene expression data from whole blood. Expression QTLs were calculated for this selection of SNPs in a set of healthy controls (n=437). The transcripts significantly regulated by the top SNPs from were subsequently tested for differential expression in an independent set of schizophrenia cases and controls (n=200). The eQTL analysis yielded significant cis-acting effects, whereas no trans effects were observed. For seven of these transcripts we observed significant differential expression between cases and controls. Results include target genes of interest both in- and outside the HLA region and contain genes that are known to be expressed in brain. These genes are strong candidates for schizophrenia for which further genetic analysis is warranted.

P09.217
Altered expression of Peroxysome proliferator-activated receptor Gamma 2 and serum leptin levels in schizophrenia

G. Akan[1], *O. Ozgen*[2], *T. Acuner*[2], *F. Oncu*[3], *D. Yesilbursa*[3], *S. Turkcan*[3], *F. Atalar*[1];
[1]*Endocrinology Laboratory, Department of Nutrition, Metabolism and Endocrinology, Child Health Institute, Istanbul University, Istanbul, Turkey,* [2]*Department of Genetics, Institute of Health Sciences, Istanbul University, Istanbul, Turkey,* [3]*3Psychiatry Clinics, Turkish Ministry of Health Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Turkey.*

It has long been known that schizophrenia (SCH) is associated with morbidity and mortality rates that far exceed those of the general population. Leptin receptor (LEPR), leptin (LEP) and peroxysome proliferator-activated receptor γ2 (PPARγ2) are the potential genetic determinants which might be liable of metabolic dysregulation in SCH patients. The aim of this study was to evaluate the effect of LEPR gene p.Q223R polymorphism and the impact of mRNA levels of LEPR, LEP, and PPARγ2 along with the serum leptin levels on metabolic adversities in SCH patients (n=80) and controls (n=115).

Methods: Metabolic profiles, LEPR gene polymorphism and the gene expressions of LEPR, LEP and PPARγ2 were studied in SCH patients and controls.

Results: A significant difference was determined between SCH and control groups concerning genotype frequency of LEPR p.Q223R (OR=10.9 95%CI=4.7-25.2) (p=0.000). LEPR p.Q223R was strongly associated with waist circumference (p=0.003) in SCH patients. LEP and LEPR gene expressions and serum leptin levels were higher in SCH patients compared to controls. PPARγ2 gene expression and serum leptin levels were significantly increased in SCH patients carrying LEPR p.Q223R polymorphism (QR+RR) (p=0.003 and

p=0.001, respectively) (Table1).
Conclusion: Leptin receptor, leptin and PPARγ2 genes could be potential risk factors in developing metabolic adversities in SCH.
Table 1: Clinical ,biochemical and genetic characteristics of SCH patients with LEPR p.Q223R genotypes

serotonin receptor genes as markers of intellectual abilities

***A. Timkova**, O. Gumerova, V. Gorbunova;*
Bashcir state pedagogical univercity from name it M.Akmulla, Ufa, Russian Federation.

Important focus in human genetics is the study of genetic determination of individual-personality characteristics, which primarily include a person's ability, so at the forefront search of genetic markers that define these abilities.There is evidence that, for gifted children is characterized by a more rapid transmission of neural information that may be related to the activities of neurotransmitter systems, a special place among them being the serotoninergic system.Serotonin receptor genes HTR2A, HTR1A, HTR2C are one of the major genes determined work of the serotoninergic neurotransmitter systems, and their functional status can be reflected on some aspects of human intellectual activity.Material were DNA samples 184 people.We used cultural-free Kettell test.To analyze the association polymorphisms of serotonin receptor genes with the level of intellectual development was investigated sample was divided into groups according to the gradation level IQ: low- below 90, average- 90-139, and high - above 140.In the group with a high level of intellectual development showed an increase in the frequency of alleles of HTR2A * A (P = 0.002) and genotype of HTR2A * A / * A (P = 0.04) in the serotonin receptor gene HTR2A.In the group with low levels of intellectual development showed an increase in the frequency of alleles of HTR2A * G (P = 0.002) in the gene for serotonin receptor type 2A, as well as genotype HTR1A * G / * G (P = 0.002) in the gene for serotonin receptor HTR1A.This work was funded grant RHSF 10-06-84.609.

Serum Hepcidin levels and association studies of TMPRSS6 and HFE variants provide further insights into regulation of iron homeostasis

***M. Traglia**[1], D. Girelli[2], G. Biino[3,4], N. Campostrini[2], M. Corbella[2], C. Sala[1], C. Masciullo[1], F. Viganò[1], I. Buetti[1], G. Pistis[1], M. Cocca[1], C. Camaschella[1,5], D. Toniolo[1,3];*
[1]Division of Genetics and Cell Biology, San Raffaele Research Institute, Milano, Italy, [2]Department of Medicine, University of Verona, Verona, Italy, [3]Institute of Molecular Genetics-CNR, Pavia, Italy, [4]Institute of Population Genetics-CNR, Sassari, Italy, [5]Vita Salute University, San Raffaele Scientific Institute, Milano, Italy.

Genetic variants of hepcidin-regulatory genes, *TMPRSS6* and *HFE*, affect erythrocyte traits and iron parameters, namely serum iron and transferrin saturation in normal populations. To analyze whether this effect is mediated by the iron regulator hepcidin, we measured serum hepcidin levels in 1657 genotyped individuals from an Italian cohort, the Val Borbera (VB) population. Hepcidin levels showed age and sex dependent variations that correlated with ferritin but not with serum iron or transferrin saturation. We replicated the observation that common variants of the *HFE* (rs1800562, C282Y) and *TMPRSS6* (rs855791,V736A) genes are associated with serum iron and transferrin saturation, but no association was found with hepcidin. Both variants showed a modest effect on the hepcidin/ferritin ratio, and the association was enhanced once iron-deficient and inflammation-positive samples were excluded from the analysis. Interestingly, in such a subset of samples, *HFE* C282Y was associated to ferritin at genome wide significance and the association was further enhanced after adjusting for hepcidin levels. Our results suggest that the main effect of *HFE* C282Y variant is to increase cell iron uptake through increased transferrin saturation. The effect is in part counterbalanced by impaired hepcidin levels which favor cell iron release, especially from macrophages, in this way likely reducing, serum ferritin levels. Finally we show that the effect of *HFE* and *TMPRSS6* variants on erythroid traits is mainly mediated by variations of iron parameters, but not by variations of hepcidin.

P09.220
Differential analysis of molecular profiles between schizophrenia and bipolar affective disorder after genome-wide association study in Bulgarian population

***A. Yosifova**[1,2], E. Betcheva[1,2], T. Mushiroda[3], M. Kubo[4], A. Takahashi[5], Y. Kamatani[6], N. Kamatani[5], D. Stoianov[7], R. Vazharova[1], I. Dimova[1], S. Karachanak[1], I. The major psychotic illnesses - schizophrenia and bipolar disorder, are among the most common debilitating mental conditions that constitute some of the leading causes of disability and pose significant economic burden to society. Although genetic factors make substantial contributions to their etiology, the identification of specific susceptibility genes for both disorders has not been straightforward. In recent years new molecular genetic findings have implicated risk factors for these disorders, thus allowing the possibility of a genetic relationship between them to be directly explored. Findings from genome-wide association studies suggest a partial overlap in the genes that contribute to the susceptibility to schizophrenia and bipolar disorder. To test this statement we have compared our results from genome-wide association studies on bipolar disorder and schizophrenia conducted in 188 BAD patients, 188 schizophrenia subjects and 376 healthy Bulgarians. The analysis of top 100 polymorphisms revealed no genetic overlap between two conditions in our population. The strongest finding in bipolar disorder was not among the top findings after GWAS on schizophrenia. An SNP which revealed the most significant association with schizophrenia did not show any association with bipolar disease. Interestingly, the genome-wide scan on schizophrenia has detected a variant in a gene, which has already been reported as the strongest finding in previous genome-wide association scan on bipolar disorder. Although no genetic overlap between schizophrenia and bipolar disease has been detected in Bulgarian population, this finding supports the hypothesis that common genetic factors may be involved in the etiology of both conditions.

Exercise induced steroid dependent dystonia, ataxia, and alternating hemiplegia associated with epilepsy: a novel phenotype associated with an *SLC2A1* mutation

W. G. Leen[1], *C. M. Weller*[2], *B. de Vries*[2], *B. G. R. Neville*[3], *E. J. Kamsteeg*[4], *M. A. A. P. Willemsen*[5], *G. M. Terwindt*[6], *M. D. Ferrari*[6], *A. M. J. M. van den Maagdenberg*[2], *H. Scheffer*[4];
[1]*Department of Neurology, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Department of Human Genetics, Leiden University Medical Centre, Leiden, Netherlands,* [3]*Neurosciences Unit, Institute of Child Health, UCL medical school and Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom,* [4]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [5]*Department of Paediatric Neurology, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [6]*6Department of Neurology, Leiden University Medical Center, Leiden, Netherlands.*

A 20 year old woman with a combination of a moderate learning disability, seizures, ataxia, exercise-induced dystonia and episodes of alternating hemiplegia was described by Neville et al. in *J Neurol Neurosurg Psychiatry* 1998;65:241-244 (Neville, 1998). Prednisolone improved the ataxia and was associated with cessation of seizures and exercise-induced dystonia. At the time, no diagnosis could be made. Over the last years, the clinical spectrum of *SLC2A1 (GLUT1)* mutations has been expanding. Apart from the classical phenotype which consists of drug resistant seizures, mild to severe developmental delay, and complex movement disorders, such as ataxia and dystonia several non classical presentations have been described as well. Recently, a child with episodes of hemiplegia was found to have a mutation in the *SLC2A1* gene (Rotstein, Neurology 2009). The combination of mental retardation, atypical absences, movement disorders with exercise-induced dystonia and alternating hemiplegia in this patient directed us to the possibility of an *SLC2A1* mutation. Mutation analysis of all 10 exons of the *SLC2A1* gene revealed a novel heterozygous missense mutation in exon 2. The parents did not carry the mutation, indicating that Gly18Arg is a de novo mutation. False paternity was excluded by genetic, multimarker analysis. Screening of 150 subjects from the general Dutch population was performed by sequence analysis of exon 2 and was negative. The Gly18Arg mutation is located in the first transmembrane segment of GLUT1 and is likely to cause disruption of the glucose transport across the aqueous central channel. The Gly18Arg mutation is therefore likely to be pathogenic. This patient presented with symptoms that all have been described in patients with GLUT1 deficiency before, but to the best of our knowledge the combination of a moderate learning disability, epilepsy, ataxia, exercise induced dystonia**,** and alternating hemiplegia has not been associated with *SLC2A1* mutations before. This patient is the first to be described by this specific combination of symptoms and underlines the heterogenic phenotype associated with *SLC2A1* mutations.

P09.222
Bitter taste sensitivity and nicotine dependence in a Romanian population

K. Csep*, G. Dudutz, C. Banescu, N. Argyo, A. Todoran Butila;*
University of Medicine and Pharmacy Tg Mures, Tg Mures, Romania.

TAS2R38 belongs to the TAS2R bitter taste receptor gene family. Three polymorphisms have been described in relationship with differences in bitter taste perception of phenyl-thiocarbamide (PTC). It was hypothesized that taster status is related to smoking, as individuals who perceive PTC as bitter may find the taste of cigarettes aversive, and thus, present a reduced risk to become smokers and nicotine dependent, as compared to non-tasters.

In 226 middle aged (median age: 41 years) Caucasians (53.53 % males, 46.47 % females), we have followed the relationship between the bitter tasting phenotype and genotype (rs713598), respectively, and tobacco dependence as assessed by the NDSS (Nicotine Dependence Syndrome Score), HSI (Heaviness of Smoking Index) and Fagerström Test for Nicotine Dependence.

As compared to a group of non-smokers (n = 112), the percentage of smokers who could taste PTC was lower (57.96 %), and the inability to taste associated with an increased risk for smoking (chi^2 = 3.56, p < 0.05). In smokers, overall scores in the three systems of dependency presented significant association with the TAS2R38 polymorphism (p < 0.01); out of the various traits of tobacco dependence (drive, priority, tolerance, continuity, stereotypy), drive presented a significant correlation with the ability to taste PTC (t = 2.46, 95%CI: 0.14-1.17, p = 0.01).

In conclusion, PTC non-tasters may become more frequently smokers not avoiding the unpleasant taste of cigarettes; however, in those who become smokers, a preference for bitter taste may contribute to the development of dependency.

P09.223
ESR1 polymorphic variants in stroke patients from Ukraine

A. Kucherenko[1,2], *S. Kravchenko*[2], *D. Shulzenko*[3], *S. Kuznetsova*[3], *L. Livshits*[2];
[1]*Taras Shevchenko Kiev National University, Faculty of Biology, Kyiv, Ukraine,* [2]*Institute of Molecular Biology and Genetics of the National Academy of Sciences of Ukraine, Department of Human Genomics, Kyiv, Ukraine,* [3]*Gerontology Institute of the Academy of Medical Sciences of Ukraine, Kyiv, Ukraine.*

Multiple data support the hypothesis of estrogen role in vascular function, lipid metabolism regulation and neuroprotection. Two single nucleotide polymorphisms in intron 1 of estrogene receptor alpha gene (*ESR1)* - c.454-397T>C (*PvuII*) and c.454-351 A>G (*XbaI*) - are thought to influence *ESR1* gene transcription and change cell sensitivity to estrogen-estrogen receptor complex action.

To establish possible involvement of *PvuII* and *XbaI* polymorphisms into stroke development we investigated this SNPs in: case group - patients with ischemic stroke (n=183, men-95, women-88), control group I - individuals from the general population (n=100, men-50, women-50), control group II - healthy individuals elder then 65 years(n=88, men-35, women-53), from different regions of Ukraine. No significant difference between the age of men and women within each group was observed. Blood samples for DNA analysis were obtained after informed consent. Genotyping was performed by PCR followed by RFLP analysis. Obtained data has shown a linkage disequilibrium between studied alleles, CG and TA alleles are in phase (r^2 = 0,557).

We have found no differences in genotype or allelic frequencies between case group and control group I. Interestingly, difference in c.454-351G/G genotype frequency between women (33,7%) and men (20,4%) from case group was observed.

Frequency of c.454-351G/G genotype was higher in women from case group (33,7%) comparing to women from control group II (18%).

Differences were considered significant at P<0.05 value of Fisher exact test.

Our findings suggest a possible role of c.454-351A allele in stroke development in women.

P09.224
Analysis of association of GR gene haplotype and suicidal behavior in population from Bashkortostan (Russia)

A. Zainullina*, D. Zakirov, A. Ishmukhametova, E. Khusnutdinova;*
Institute of Biochemistry and Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation.

Suicidal behaviour (SB) is a complex trait for which the underlying pathophysiology has yet to be fully explained. Hyperactivity of the hypothalamic-pituitary-adrenal axis, leading to increased cortisol levels, has been suggested to play a role in the development of SB. The effects of cortisol, the most important glucocorticoid (GC) in humans are mainly mediated by the GC receptor (GR). Several polymorphisms in the GR gene that alter the GC sensitivity are known. The aim of this study was to study the role of these GR polymorphisms in SB. Three SNPs (9beta, BclI and N363S) in the GR gene were genotyped and haplotypes were constructed. We investigated a total sample of 636 subjects. Cases were 288 persons - hospitalized in the Clinical Republic Hospital (Ufa, Russia) after suicide attempt. Suicide attempts were classified as violent - hanging (4.2%), jumping from a high place or under a vehicle (6.3%), cutting (8.5%), or nonviolent - drug overdose (81%). Forty-seven patients (31.3%) admitted to previous suicide attempts. The most common primary diagnoses in the sample were: personality disorders (29.3%), depressive disorders (17.3%), substance dependence (16%), schizophrenia spectrum disorders (14.7%). Other diagnoses were: bipolar affective disorder (2%); posttraumatic stress disorder (1.33%). The control group consisted of 348 volunteers - without a personal or familial (first degree) history

of neuropsychiatric disorders and SB. The AGA haplotype (P=0.006, OR=1.50) was associated with increased risk of SB. This seems to result from the presence of BclI, and not from the 9beta and N363S polymorphisms.

P09.225

Estrogen receptor α and androgen receptor gene polymorphisms in patients with systemic lupus erythematosus and healthy controls

S. Andonova[1], *D. Tanev*[2], *R. Robeva*[3], *M. Nikolova*[4], *A. Tomova*[3], *R. Rashkov*[2], *A. Savov*[1], *Z. Kolarov*[2];

[1]*National Genetics Laboratory, Sofia, Bulgaria,* [2]*Clinic of Rheumatology, Medical University - Sofia, Sofia, Bulgaria,* [3]*Clinical Center of Endocrinology and Gerontology, Medical University – Sofia, Sofia, Bulgaria,* [4]*Clinic of Nephrology, Medical University - Sofia, Sofia, Bulgaria.*

Background: Systemic lupus erymathosus (SLE) is an autoimmune disease that affects mainly females. Disturbances of estrogen metabolism and decreased androgen levels were found in SLE, however the influence of hormone receptor genetic polymorphisms on the disease progress are still not clarified.

Methods: A total of 109 women with SLE and 47 female controls were genotyped for ER*α* polymorphisms PvuII T/C and XbaI A/G by RFLP analysis. The absence of PvuII and XbaI restriction sites were indicated by “P” and “X” and presence by “p” and “x”, respectively. The CAG repeat length in AR was also investigated by fluorescence-based fragment analysis on an automatic DNA sequencer. Shorter allele (SA), longer allele (LA) and biallelic mean (BM) were determined. SLE disease activity index (SLEDAI) and SLICC/ACR damage index were also calculated and relationships with the genetic parameters were investigated.

Results: No differences were found between the ER*α* alleles distribution in patients and controls. The CAG repeat lengths in the SA, LA and BM were also similar. The (CAG)n number of LA but not SA was inversely related to SLICC index (r=-0.207, p=0.031). In patients with PPXX genotype SLEDAI index was significantly lower than in PpXx patients (p=0.016) but not different in comparison to patients with ppxx (p>0.05).

Conclusions: Our preliminary results showed that AR and ER*α* polymorphisms are not crucial for the development of SLE but probably modulate the activity of the disease and chronic damages in patients.

The study was financially supported by research grant 26/2010, MU - Sofia

P09.226

The autoimmune disease-associated IL2RA locus is involved in the clinical manifestations of systemic sclerosis

F. Carmona[1], *J. Martin*[1], *P. Carreira*[2], *E. Vicente*[3], *L. Rodriguez-Rodriguez*[4], *E. Scleroderma Group*[5], *S. Scleroderma Group*[1], *U. Scleroderma Group*[6], *C. Fonseca*[7], *J. Martin*[1];

[1]*Instituto de Parasitologia y Biomedicina Lopez Neyra, CSIC, Armilla, Spain,* [2]*Hospital 12 Octubre, Madrid, Spain,* [3]*Hospital La Princesa, Madrid, Spain,* [4]*Hospital Clinico San Carlos, Madrid, Spain,* [5]*European Scleroderma Group, Nijmegen, Netherlands,* [6]*The University of Texas Health Science Center–Houston, Houston, TX, United States,* [7]*Royal Free and University College Medical School, London, United Kingdom.*

Objectives: Regulatory T cells (Tregs) are crucial in the maintenance of the immune tolerance and seem to play an important role in systemic sclerosis (SSc),. The interleukin 2 receptor alpha (IL-2RA) is an important Treg marker, and polymorphisms of IL2RA gene are associated with a number of autoimmune diseases. Therefore, we aimed to investigate for the first time the association of the IL2RA locus in SSc.

Methods: A total of 2983 SSc patients and 2652 matched healthy controls, from an initial Spanish cohort and five additional replication European cohorts of Caucasian origin, were genotyped for the IL2RA gene variant rs11594656 using the TaqMan® allelic discrimination technology.

Results: A significant association of IL2RA rs11594656*T with the presence of anti-centromere antibodies (ACA) was first detected in the Spanish cohort (P=6.30x10-3, OR=0.77). The combined analysis of the replication sets showed a clear association with limited cutaneous SSc (lcSSc, P=5.49x10-3 OR=0.84), and the overall meta-analysis including several cohorts evidenced that this variant is consistently associated with both lcSSc (P=1.71x10-3 OR=0.85) and ACA production (P=9.31x10-3 OR=0.86).

Conclusions: Our data strongly suggest that IL2RA is involved in SSc, specifically with lcSSc and ACA subgroups.

P09.227**

Identification of novel genetic markers associated with clinical phenotypes and auto-antibody subsets of systemic sclerosis through a genome wide association strategy

J. Martin[1], *O. Gorlova*[2], *B. Rueda*[1], *B. P. C. Koeleman*[3], *P. Carreira*[4], *E. Vicente*[5], *L. Rodriguez-Rodriguez*[6], *E. Scleroderma Group*[7], *S. Scleroderma Group*[1], *U. Scleroderma Group*[8], *F. C. Arnett*[8], *T. R. D. J. Radstake*[9], *M. D. Mayes*[8], *J. Martin*[1];

[1]*Instituto de Parasitologia y Biomedicina Lopez Neyra, CSIC, Armilla, Spain,* [2]*M.D. Anderson Cancer Center, Houston, TX, United States,* [3]*University Medical Center Utrecht, Utrecht, Netherlands,* [4]*Hospital 12 Octubre, Madrid, Spain,* [5]*Hospital La Princesa, Madrid, Spain,* [6]*Hospital Clinico San Carlos, Madrid, Spain,* [7]*European Scleroderma Group, Nijmegen, Netherlands,* [8]*The University of Texas Health Science Center–Houston, Houston, TX, United States,* [9]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

The aim of this study was to determine the genetic components contributing to different systemic sclerosis (SSc) clinical sub-phenotypes of limited (lcSSc) and diffuse (dcSSc) cutaneous involvement, and with the SSc-specific auto-antibodies, anti-centromere (ACA) and anti-topoisomerase I (ATA) through a genome-wide association study (GWAS). Four GWAS cohorts, comprising 2,296 SSc patients and 5,171 healthy controls, were meta-analyzed looking for associations in the selected subgroups. Eighteen polymorphisms were further tested in nine independent cohorts comprising an additional 3,175 SSc patients and 4,971 controls. Conditional analysis for associated SNPs in the HLA region was performed to explore their independent association in antibody subgroups. Overall analysis showed non-HLA polymorphisms rs11642873 in IRF8 gene (P = 2.32x10-12, OR = 0.75) and rs12540874 in GRB10 gene (P = 1.27x10-6, OR = 1.15) to be associated with lcSSc and rs11047102 in SOX5 gene (P = 1.39x10-7, OR = 1.36) with ACA positive patients. In the HLA region, we observed highly associated allelic combinations in the HLA-DQB1 locus with ACA (P = 1.79x10-61, OR = 2.48), in the HLA-DPA1/B1 loci with ATA (P = 4.57x10-76, OR = 8.84) and in NOTCH4 with ACA P = 8.84x10-21, OR = 0.55) and ATA (P = 1.14x10-8, OR = 0.54). We have identified three new non-HLA genes (IRF8, GRB10, and SOX5) associated with SSc clinical and auto-antibody subgroups. Within the HLA region, HLA-DQB1, HLA-DPA1/B1 and NOTCH4 associations with SSc are likely confined to specific auto-antibodies. These data emphasize the differential genetic components of subphenotypes of SSc.

Studies with mutant animals models can point directly to candidate genes in humans and have been contributing to the knowledge about pathogenesis of cleft lip and palate (CL+/-P). Mice with mutations in TFAP2A and BMP4 genes present the phenotype of clefts. In addition, mutations in BMP4 have been previously described in patients with nonsyndromic CL+/-P. Based on these evidence the aim of our study was to investigate the involvement of BMP4 and TFAP2A genes in the etiology of CL+/-P using mutation screening by direct sequence and enzyme digestion with HphI (PCR-RFLP). The sample included a total of 45 patients, 20 cases of syndromic CL+/-P and 25 cases of nonsyndromic CL+/-P. We found no pathogenic sequence variant in the TFAP2A gene. In the BMP4 gene, we found the rs17563 polymorphism (538T->C variant), previously described as associated with CL+/-P in the Chinese population. In order to investigate whether this same association exists in our sample, we genotyped an additional control group of 169 normal subjects with no antecedent of oral clefts in neither three generations nor oriental ancestrally. We found no significant differences in genotypes or allelic frequencies

between patients and controls (p=0.3347,OR=0.718255,95% CI: 0.4 to 1.27). However, further studies with larger samples are necessary to elucidate this aspect. Financial Support: FAPESP, CNPq

Association of the toll-like receptor 4 Asp299Gly polymorphism with atopic dermatitis in Italian children.

L. Rigoli[1], *M. Miraglia del Giudice*[2], *G. L. Marseglia*[3], *C. Cuppari*[1], *C. Di Bella*[1], *S. Cara*[1], *P. D. Romeo*[1], *M. La Rosa*[4], *C. Salpietro*[1];
[1]*Department of Pediatrics, University Hospital, MESSINA, Italy,* [2]*Department of Pediatrics, II Medical School, Napoli, Italy,* [3]*Department of Pediatrics, Medical School, Pavia, Italy,* [4]*Department of Pediatrics, Medical School, Catania, Italy.*

Background. Atopic dermatitis (AD) is a chronic inflammatory skin disease with a multifattorial pathogenesis. A genetically determined defective function of pattern recognition receptors such as toll-like receptors (TLRs) has been proposed as a candidate mechanism in the pathogenesis of AD.
Aim: To study the impact of genetic predisposition of TLR2 and TLR4 genes encoding for pattern recognition-related molecules for the phenotype of AD.
Methods. We performed a case/control study in which we included 102 Italian AD children (47 males and 55 females, median age 2,4 years) and 50 gender matched non-atopic, healthy individuals (27 males and 23 females, median age 2.5 years). The severity of AD was measured using the SCORing Atopic Dermatitis (SCORAD) Index for the evaluation extensiveness of skin disease. We examined the allelic frequencies of R753Q TLR2 and Asp299Gly TLR4 single nucleotide polymorphisms (SNPs). Genotyping was performed using PCR and restriction fragment length polymorphism analysis.
Results. For the R753Q TLR2 SNP, similar allelic frequencies were found in both groups. Moreover, the allelic frequencies of R753Q TLR2 SNP was no different between the groups with mild, moderate and severe SCORAD. A significantly increased frequency of the Asp299Gly allele TLR4 was present (p<0.001). This SNP was significantly associated with moderate and severe AD.
Conclusion. Our results suggest that in our group of children with AD, the TLR4 gene could play a crucial role in the development of AD, probably with other genetic factors.

HRMA in the TPMT gene study in Polish population

M. Skrzypczak-Zielinska[1], *P. Borun*[1,2], *L. Jakubowska-Burek*[1,3], *O. Zakerska*[2,4], *A. Dobrowolska-Zachwieja*[3], *A. Plawski*[1], *U. Froster*[5], *M. Szalata*[1,2], *R. Slomski*[1,2];
[1]*Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland,* [2]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznan, Poland,* [3]*Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznan, Poland,* [4]*The NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland,* [5]*Institute for Applied Human Genetics and Oncogenetics, Leipzig, Germany.*

Thiopurine methyltransferase (TPMT) is involved in the transformation of thiopurine drugs which are used primarily in the treatment of autoimmune disorders such as inflammatory bowel disease (IBD). Gene TPMT encoding thiopurine methyltransferase is highly polymorphic. In our study we investigated the three most common TPMT alleles responsible for a decreased enzyme activity: TPMT *2 (p.Ala80Pro), *3A (p.Ala154Thr, p.Tyr240Cys) and *3B (p.Ala154Thr). These variants determine 80 - 95% of the intermediate and low enzyme activity, and increase the risk of thiopurine-induced toxicity. The aim of our study was to optimize the HRMA (High Resolution Melting Analysis) to identify main TPMT alleles as a simple alternative method to automatic sequencing and RFLP (Restriction Fragment Length Polymorphism). Moreover, we determined the frequency of these changes in Polish population. We tested 283 DNA samples of Polish population including 91 IBD patients treated with thiopurine drugs. Fragments of exon 4, 6 and 9 of TPMT gene enclosing codon 80, 154 and 240 respectively, were amplified and their melting profiles were analyzed using LightCycler® 480 equipment. The results were confirmed standard sequencing. Identification of sequence variants using HRMA is highly sensitive and less time consuming compared to standard sequencing or RFLP. It can be easily integrated into diagnostic testing. Furthermore, we found TPMT*3A allele frequency of 5,3 % in Polish population. The frequency of TPMT*3B allele in heterozygote is of 1,1%. TPMT*2 allele was not found.

Diabetes impacts approximately 200 million people worldwide, of which type 1 diabetes (T1D) represents approximately 10%. The application of genome wide association studies (GWAS) has robustly revealed dozens of genetic contributors to the pathogenesis of T1D, with the most recent meta-analysis identifying in excess of 40 loci. To identify additional genetic loci for T1D susceptibility, we examined associations in the largest meta-analysis to date between the disease and ~2.54 million SNPs in a combined cohort of 9,934 cases and 16,956 controls. Targeted follow-up of 53 SNPs in 1,120 affect trios uncovered three new loci associated with T1D that reached genome wide significance. The most significantly associated SNP (rs539514, P = 5.66x10-11) resides in an intronic region of the LMO7 (LIM domain only 7) gene on 13q22. The second most significantly associated SNP (rs478222, P = 3.50x10-9) resides in an intronic region of the EFR3B (protein EFR3 homolog B) gene on 2p23; however the region of linkage disequilibrium is approximately 800kb and harbors additional multiple genes, including NCOA1, C2orf79, CENPO, ADCY3, DNAJC27, POMC, and DNMT3A. The third most significantly associated SNP (rs924043, P = 8.06x10-9) lies in an intergenic region on 6q27, where the region of association is approximately 900kb and harbors multiple genes including WDR27, C6orf120, PHF10, TCTE3, C6orf208, LOC154449, DLL1, FAM120B, PSMB1, TBP and PCD2. These latest associated regions add to the growing repertoire of gene networks predisposing to T1D.

The influence of polymorphic positions of the HLA-DRβ1 and HLA-DQβ1 allele heterogeneity on disease risk of type 1 diabetes mellitus in Iranian population

a. sayad[1], *m. zamani*[2], *m. akbari*[1], *a. kazem nejad*[1];
[1]*tarbiat modares university, tehran, Islamic Republic of Iran,* [2]*tehran university, tehran, Islamic Republic of Iran.*

Type 1 Diabetes mellitus (T1D) is a chronic autoimmune and multifactorial disease. The HLA-DRB1and DQB1 loci have the strongest association with T1D. Various HLA-DRB1and DQB1 alleles encode different amino acids in critical positions of HLA-DRβ1and DQβ1 molecules. In this study, we investigated highly polymorphic amino acid residues of HLA-DRβ1and DQβ1 molecules to determine their susceptibility or protective effect in100 Iranian T1D patients and 105 healthy controls. Analysis of the amino acid sequence of HLA-DRβ1 and DQβ1 chains revealed the $DRB\beta1^{Lys71+}$ (p: 10^{-14}; OR: 6.084) and the $DQ\beta1^{Asp57-}$ (p: 10^{-8}; OR: 3.31) were significantly more frequent in patients and had a positive association with T1D. The homozygous $DR\beta1^{Lys71+}$ (p: 2× 10^{-7}; OR: 30.938) and $DQ\beta1^{Asp57-}$ (p: 10^{-5}; OR: 4.111) had the strongest association with T1D susceptibility. According to our results indicating the crucial rule of the $DRB\beta1^{Lys71+}$, we designed allele-specific primers to develop an easy, fast and cost-benefit method to detect the $DR\beta1^{Lys71+}$. We also calculated PcPPV and PcNPV which showed that the person carrying the $DRB1^{Lys71+/+}$ genotype has 1% absolute risk to develop T1D.

Two novel genes were identified as the susceptibility genes of the type 2 diabetes in Han Chinese

C. Yang[1], *F. Tsai*[2], *J. Wu*[1], *C. Chen*[2], *C. Chen*[1], *Y. Chen*[1];
[1]*Academia Sinica, Taipei, Taiwan,* [2]*China Medical University Hospital, Taichung, Taiwan.*

Type 2 diabetes (T2D) is the forth leading cause of death in Taiwan. To identify susceptibility genes that increase the risk of T2D in Han

Chinese that accounts for 98% of the Taiwan population, we conducted a genome-wide association study in which 643 cases and 812 random controls were genotyped using Affymetrix SNP6.0 genechips. In the first stage for genome wide scan, we selected 75 SNPs in 43 regions that had-logP>4 with trend test for subsequent cross-plateform validation using Sequenom. After cross-plateform validation, a total of 72 SNPs in 40 loci yielded consistent results using both Affymetrix and Sequenom, including KCNQ1 and CDKAL1 loci previously reported to be associated with T2D. We took these SNPs forward to replicate in 785 additional samples (stage 2: 597 T2D cases and 188 controls). Of the 72 SNPs in 40 loci selected in stage 1, only two novel loci still showed a strong association in the joint analysis of stage 1 and stage 2, except previously mapped KCNQ1. The strongest new association signal was found for SNP#1 located 2.6 kb upstream of a gene involved in pancreatic islet development (P=5.46x10^{-6}). The second strongest signal was found with SNP#2 (P=8.28x10^{-6}), which lies 24.5kb downstream from a gene involved in the conversion of ketone bodies. Our study may lead to a better understanding of differences in the molecular pathogenesis of T2D among various populations.

P09.234
Visfatin gene mutation may increase tendency to nephropathy among diabetics

S. Demir[1], *A. Ozgoz*[2], *F. M. Icduygu*[2], *K. Hekimler*[2], *T. Koken*[3], *N. Imirzalıoglu*[2];
[1]*Afyon Kocatepe University, School of Medicine, Nephrology Department, Afyonkarahisar, Turkey,* [2]*Afyon Kocatepe University, School of Medicine, Medical Genetics, Afyonkarahisar, Turkey,* [3]*Afyon Kocatepe University, School of Medicine, Biochemistry Department, Afyonkarahisar, Turkey.*

Visfatin is a novel adipocytokine, which is suggested to play a role in kidney diseases. This study was performed to evaluate the association between visfatin gene promoter region SNPs and diabetic nephropathy. SNPs (1001T/G, 423A/G, 1535C/T) of the visfatin gene promoter region were studied for 30 subjects with diabetic nephropathy, 30 subjects without nephropathy and 30 healthy subjects, who served as controls, by real-time PCR method. Routine biochemical parameters, serum insulin, TNF-α, visfatin, urinary protein and microalbumine were tested in subjects. Insulin resistance was evaluated by HOMA method. Heterozygotes for the SNPs 423 A/G and 1001 T/G had significantly more risk to have nephropathy. They had lower serum visfatin levels than the subjects with AA and TT genotypes. There wasn't any relation between serum visfatin levels and the serum insulin, TNF-α, BMI, HbA1c, insulin resistance, proteinuria and creatinine clearence. But, healthy volunteers and diabetics with nephropathy had significantly lower serum visfatin levels compared to the diabetics without nephropathy. The two SNPs, 1001 T/G and 423 A/G were in perfect linkage disequilibrium.

To the best of our knowledge, this is the first study indicating an association between diabetic nephropathy and visfatin gene polymorphism. High visfatin levels may harm the kidney and after development of nephropathy visfatin levels may decrease.

P09.235
Meta-analysis of genome wide association studies reveals new loci associated with childhood obesity

R. Taal[1], *J. P. Bradfield*[2], *V. W. V. Jaddoe*[1], ***S. F. A. Grant***[2], *on behalf of the EGG consortium;*
[1]*Erasmus Medical Center, Rotterdam, Netherlands,* [2]*Children's Hospital of Philadelphia, Philadelphia, PA, United States.*

Genetic determinants of adult obesity have been established through meta-analyses of genome wide association studies (GWAS). However, less progress has been made to establish genetic influences specific to childhood obesity though similar approaches. To identify novel genetic factors that influence early-onset obesity, we performed a meta-analysis of genome-wide genotyped datasets consisting of 5,447 cases (>=95th percentile of BMI achieved any time from age 2 to 18 years old) and 8,185 controls (<50th percentile of BMI consistent throughout all measures during childhood) of European ancestry. Following the meta-analysis of ~2.54 million SNPs (directly genotyped or imputed), variation at seven loci showed notable evidence for association with childhood obesity (P < 5x10-8). All these loci have been previously reported in the context of adult BMI GWAS (FTO, MC4R, TMEM18, POMC, FAIM2, TNNI3K and SEC16B), but their relative magnitude of association were different in the childhood obesity setting.TMEM18 gave the strongest evidence for association while TNNI3K and POMC, which were only detected in adult studies when using hundreds of thousands of participants, were readily detected in our relatively small sample size. We elected to take forward all novel loci yielding association with P < 5x10-6 (n = 11) in order to test for replication in multiple existing datasets. To date, we observe consistent evidence for replication at two loci, harboring the genes encoding alpha-protein kinase 1 (ALPK1) on 4q25 and glypican 5 (GPC5) on 13q31, respectively. As more data for the replication attempt is received, we anticipate additional signals will survive this effort.

J09.01
PON1 phenotype and gene polymorphisms in children with autism

E. Dronca[1], *M. Dronca*[2], *T. Mocanu*[3], *I. V. Pop*[1];
[1]*Department of Medical Genetics, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania,* [2]*Department of Medical Biochemistry, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania,* [3]*Department of Physiology, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania.*

Autism is a neurodevelopmental disorder of unknown etiology. Many genetic and environmental factors are incriminated in its pathogenesis. Subacute exposure to organophosphates (OPs) during critical periods of prenatal neurodevelopment is one of the factors that may trigger autism. Human serum paraoxonase (PON1) is a HDL-associated hydrolase, which in addition to hydrolyzing the OPs, plays a physiological role in reducing LDL oxidation. The PON1 gene shows two functional polymorphisms: M55L and Q192R. These polymorphisms influence the concentration and activity of PON1 towards different substrates, including OPs.

The gene-environment interaction is tested in the present study by assessing the distribution and frequency of M55L and Q192R polymorphisms in 58 autistic children and 43 controls.

No significant difference (p>0.05) in genotypes distribution was found between autistic patients and controls (QQ 51.72%, QR 43.1%, RR 5.17% / MM 12.1%, ML 60.3%, LL 27.6% for autistic group and QQ 51.16%, QR 44.18%, RR 4.65% / MM 9.3%, ML 53.5%, LL 37.2% for control group).

Although, the paraoxonase activity did not present a significant difference between the patients and controls (p>0.05), there was a significant activity increase in the autistic groups with R allele number and both in autistic and control groups with L allele number (p<0.05). The arylesterase activity was significantly decreased (p<0.05) in autistic patients, with no relation to the number of R alleles, but increased in relation with L allele number (p<0.05).

These results provide support for the hypothesis that PON1 arylesterase activity could represent a biochemical/genetic test in estimating autism risk.

J09.02
Assessment of functional impact in lumbar disk disease

D. Stoicanescu[1], *M. Cevei*[2], *A. Belengeanu*[1], *E. Sirbu*[3], *M. Stoian*[1];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*University of Oradea, faculty of Medicine and Pharmacy, Oradea, Romania,* [3]*West University, Timisoara, Romania.*

Lumbar disk disease is a common musculoskeletal disease that has a very strong genetic component, revealed by elevated risks to both near and distant relatives supporting a heritable contribution to the development of the disorder. The aim of this study was to correlate some functional indicators that are used for patients with lumbar disk disease. The lot was formed by 103 cases with clinical diagnosis of low back pain accompanied or not by radiculopathy through lumbar disk hernia, examined in the Medical Rehabilitation Clinical Hospital Felix Spa, between February-November 2010. All patients were investigated by MRI, which confirmed the clinical diagnosis. In order to evidentiate the impact of the lesion on functionality and daily activities, we used pain appreciation and consecutive disability parameters: Oswestry questionnaire. We also used MOS SF-36 Health Survay. Using AMA Guide criteria we have evaluated infirmity that generates disability, measuring mobility of dorso-lumbar column. Correlation between disability, investigated with Oswestry questionnaire, a functional evaluation scale, and infirmity evaluated through AMA Guide criteria, mobility evaluation parameter, was small, but significant (p=0.025).

Life quality indicators registered with MOS SF36 and participation restriction evaluated with AMA, strongly correlate, statistically very significantly (p<0.00001). The strongest correlation was noticed between participation restriction revealed by AMA and variable "physical function" of MOS- SF36 scale (r=0.49) statistically very significant (p<0.00001). Affection of mobility had a moderate functional impact on the organism as a whole, but evaluation of life quality of patients revealed that it decreased to half of the standard value.

Comparison of DRD1-DRD5 Expression Profiles in Rheumatoid arthritis and Systemic Lupus Erythematous Patients

M. Sadeghi koupaei[1], *g. Aangari*[2], *S. Nazari*[3];

[1]*National Institute of Genetic Engineering & Biotechnology(NIGEB)Shaheed Beheshti Medical University (SBMU), Tehran, Islamic Republic of Iran,* [2]*NIGEB, Tehran, Islamic Republic of Iran,* [3]*Shaheed Beheshti University of Medical Sciences, Mofid Hospital,Department of Hematology & Oncology,, Tehran, Islamic Republic of Iran.*

Background and Aims: Rheumatoid arthritis (RA) and Systemic lupus erythematosus (SLE) are both autoimmune disease that their causes are still unknown. It appears that both genetic and environmental factors play a role in their pathogenesis. Dopamine and its receptors are the important components of neurotransmission network. Recent studies reveal that in addition to the CNS, immune cells synthesis neurotransmitters such as dopamines so that these catecholamines can regulate immune functions. The aim of this study is to evalute the dopamine receptor gene expression level on peripheral blood mononuclear cells of RA and SLE patients compared to normal individuals.

Material and Methods: In the present study, we investigated dopamine receptor gene expression in PBMCs of 30 RA and SLE patients and 20 healthy individuals using Real Time-PCR. The specificities of the obtained Real time PCR products for the respective dopamine receptors fragments were confirmed by sequenced analysis capillary system (ABI3700, Applied Bio system, USA).

Results: The results showed that D2 and D4 receptors mRNA Expression significantly altered in PBMC of RA and SLE patients. Compared to normal individuals, D2 receptor mRNA in RA and SLE patients

decreased, whereas D4 receptor mRNA Expression increased. The changes of D1, D3 and D5 receptors mRNA Expression was not significant.

Conclusion: It is suggested that dopamine and its receptors have an effective role in pathophysiology of RA and SLE diseases.

Identification of Novel Mitochondrial Homoplasmic T14512C Mutation in Iranian Brugada Syndrome Patients

M. Khatami[1], ***M. Heidari***[2], *F. Khatami*[3];

[1]*Department of Biology, Science School, Yazd University,, Yazd, Islamic Republic of Iran,* [2]*Department of Biology, Science School, Yazd University, Yazd, Islamic Republic of Iran,* [3]*Department of Biology, Science School, Ferdowsi University, Mashhad, Islamic Republic of Iran.*

Brugada syndrome is a disorder characterized by sudden death associated with one of several ECG patterns characterized by incomplete right bundle branch block and ST elevations in the anterior precordial leads. We identified a homoplasmic T14512C mutation in the mitochondrial ND6 gene in 20 unrelated patients with Brugada syndrome patients by PCR-SSCP. This Mutation causes a change of Met to Val (M54V missense mutation). In this study, the effects of this missense mutation upon transmembrane helixes were assayed by means of PolyPhen database (Polymorphism Phenotyping). **PolyPhen** is an automatic tool for prediction of possible impact of an amino acid substitution on the structure and function of a human protein. The result of this prediction showed that M54V mutation is benign. Thus, further investigations necessary to clarify this correlation.

J09.05

Angiotensin-converting enzyme gene I/D polymorphism and ischemic stroke in Moldavian patients

E. Mocan[1,2], *L. Lisiy*[1], *S. Protopop*[1], *E. Bondarenko*[3], *N. Barbacari*[2], *S. Limborska*[3];

[1]*the State Medical and Pharmaceutical University, Chisinau, Moldova, Republic of,* [2]*Institute of Genetics, Chisinau, Moldova, Republic of,* [3]*Institute of Molecular Genetics, Moscow, Russian Federation.*

The aim of the present study was to examine the possible role of D allele as a risk factor in the development of ischemic stroke. It was analyzed 156 patients with ischemic stroke and 90 controls without cardio-vascular diseases.

The frequency of D allele was 63.8 % in patients and 43.3% in controls (x^2=1.76, p=0.19). The distribution of the ACE gene genotypes frequencies weren't statistically significant between stroke group and controls (x^2=2.70, p=0.26).

But a significant increase in the frequency of ACE DD genotypes has been found in studied elderly male patients with ischemic stroke (OR=3.53; CI, 1.05-11.86, x^2 =4.90, p=0.03) when compared ACE genotypes frequencies in the male of control group.

No increase in ACE DD genotype frequency was seen in all females when compared to the respective control group (x^2=0.81, p=0.67).

Also we have reported the D allele (60%) in hypertensive group of male carriers is more prevalent compared with female patients (50%) and male carriers of control group (48.4%) (x^2=0.3.62, p=0.04). There is significant difference in the correlation of D allele carrier and patient serum total cholesterol, triglyceride with correlation respectively coefficients r = 0.25 (p = 0.03) and r = 0.36 (p = 0.02).

In this study we have demonstrated that DD genotype have some association with hypertensive male individuals, the data shown statistical significance. The ACE D allele in male could be is an independent risk factor of development of the hypertension and ischemic stroke in elderly persons.

J09.06

Thrombosis in young men homozygous for Leiden mutation

M. M. Litvinova;

First Moscow State I.M. Sechenov Medical University, Moscow, Russian Federation.

Hereditary thrombophilia is one of the most important medical and social problems. It is characterized by activation of coagulation system and lead to the propensity to develop thrombosis. It is known that factor V Leiden is one of the main members of coagulation pathway. Factor V Leiden thrombophilia is characterized by a poor anticoagulant response to activated protein C and an increased risk for venous thromboembolism. Mutation G1691A (rs6025) of *F5* gene also called as Leiden mutation is responsible for such condition. In European countries allele 1691A frequency is around 2%. Homozygous genotype for Leiden mutation is very rear.

We report three cases of thrombosis in young male patients homozygous for Leiden mutation. Beside Leiden mutation in *F5* all three patients were genotyped for SNPs in *F2* (G20210A or rs1799963), *MTHFR* (C677T or rs1801133 and A1298C or rs1801131), *MTRR* (A66G or rs1801394), and *MTR* (A2756G or rs1805087). Data on patients is shown in the table 1.

It is important to mention that in all three cases additional exogenous factors as smoking and long hiking together with exposure to cold were presented. Thus thrombosis can occur in very young patients with combination of genetic risk factors of thrombophilia. It is important to detect such predisposition as early as possible to be able to prevent thrombotic complications.

Characteristic of patients (DVT - deep vein thrombosis)

	Genotype							
	F5	F2	MTHFR	MTHFR	MTRR	MTR		
Patients	G1691A	G20210A	C677T	A1298C	A66G	A2756G	Additional risk factors	Age of first DVT

Molecular genetics of severe asthma in children: no association with CFTR gene mutations common to Russian populations

V. S. Tikhonova[1], *A. N. Voitovich*[1], *E. G. Mikhailova*[2], *T. E. Ivaschenko*[2], *A. V. Orlov*[3], *L. A. Zhelenina*[1], *D. S. Korostovsev*[1], *V. I. Larionova*[1];
[1]*St.Petersburg Pediatric Medical Academy, St.Petersburg, Russian Federation,* [2]*Ott's Institute of Obstetrics & Gynecology, St.Petersburg, Russian Federation,* [3]*St-Petersburg Medical Academy of Postgraduate Studies, St.Petersburg, Russian Federation.*

Background: Currently little is known from the literature about a relationship between severe asthma (SA) in children and cystic fibrosis (CF). We hypothesized that children with severe asthma may carry a «mild» and/or a «severe» mutations of cystic fibrosis transmembrane conductance regulator gene. Objective: To detect sixteen CFTR gene mutations most common to Russian populations in children with severe asthma. Patients and methods: SA group included 59 children aged 4 - 17 years old (43 boys and 16 girls) with severe asthma. CF group included 29 children aged 5 - 16 years old with a primary diagnosis of CF confirmed by CFTR genotyping (15 boys and 14 girls). Genotyping of CFTR gene was confirmed by experts Laboratory Ott's Institute of Obstetrics & Gynecology. We used two kits developed by Center for Molecular Genetics (Moscow): "CF - 5" kit (G542X, W1282X, N1303K, 3849+10kbC>T, R334W) and "CF - 11" kit (del21 kb, F508del, I507del, 1677delTA, 2143delT, 2184insA, 394delTT, 3821delT, L138ins, 604insA, 3944delTG). Results: In the group of children with CF, the frequency a major mutation F508del was 79% (48% with genotype F508del/F508del and 31% with compound genotype F508del/others). In 14% of the cases, there were identified some other mutations of the CFTR gene: N1303K, 394delTT, 2143delT, CFTRdele2, 3 (21kb). The rest 7% of the cases were not clarified. We have found neither «mild» nor «severe» the mutations of CFTR gene in the SA group. Conclusion: This study failed to show an association of mutations of CFTR gene with severe asthma in children.

J09.08
What a role vitamin D receptor and its gene polymorphism can play in the development of axial myopia in children?

R. Bannour, *A. N. Voytovich, V. V. Brzhevskii, V. I. Larionova;*
St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

The axial myopia in children caused by the eyeball overgrowth in the anteroposterior direction is an actual problem of pediatric ophthalmology today. The aim of this study was to investigate a probable association of TaqI polymorphism of vitamin D receptor (VDR) gene with the development and severity of axial myopia in children to identify its possible role and the role of its protein product in the eye tissues development. We examined 84 children (168 eyes) aged 4 to 17 yo with emmetropia and axial myopia of various degree. The results of echo biometric evaluation of the axial length, anterior chamber depth (ACD), lens thickness, and vitreous chamber depth of each eye were compared according to the TaqI genotypes polymorphism detected by PCR-RFLP method. We have found a relationship between the TaqI polymorphism of the VDR gene and the size of the ACD that correlated with the axial length of the eyeball. ACD for tt-genotype carriers was 3.73 Â± 0.04 mm, and ACD for b/T-allele carriers was 3.44 Â± 0.05 mm, ($p < 0,001$). TaqI polymorphism affects the vitamin D-binding domain of the receptor. Therefore we hypothesize that VDR gene polymorphism in combination with external factors such as vitamin D and/or ultraviolet deficiency might be a cause of axial myopia in children. Undoubtedly, further studies addressed to the identification of a role of vitamin D receptor and its gene, as well as an implication of vitamin D and ultraviolet exposures, in the development of axial myopia in children are required.

J09.09
No association between functional polymorphisms in MTHFR and childhood schizophrenia in Latvian population

M. Kreile[1,2], *L. Piekuse*[1,2], *D. Bauze*[2], *Y. Stankevich*[1], *A. Zarina*[1], *B. Lace*[3,2], *A. Krumina*[3];
[1]*Riga Stradins University, Riga, Latvia,* [2]*Children's University Hospital, Riga, Latvia,* [3]*Latvian Biomedical Research and Study Centre, Riga, Latvia.*

Introduction Methylenetetrahydrofolate reductase (MTHFR) catalyzes the conversion of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate, a co-substrate for homocysteine re-methylation to methionine. Previously it has been reported, that there is association between MTHFR mutations C677T and A1298C, and increased risk of schizophrenia, there are also publications without any association.

The aim to detect frequency of *MTHFR* polymorphisms C677T and A1298C in children with schizophrenia, and to compare results with control group

Materials and methods The patient group was 53 children with schizophrenia, but the control group consisted of 150 volunteers. DNA was extracted from whole blood and purified by standard phenol/chloroform protocol. The presence of C677T and A1298C mutations was analyzed using PCR with subsequent restriction enzyme *Hinf I* and *MboII* digestion, respectively, and detected in PAGE.

Results The observed frequency of the T allele of the C677T mutation was 0,324. There were no statistically significant differences between patient group and control group- 0,319 (p value 1,0). The observed frequency of the C allele of the A1298C in patients group was 0, 311 whereas in control group - 0,367, the difference was not statistically significant (p value 0,395).

Distribution between genotypes in patients' groups is showed in table

	Wild type (C677T)	Wt/C677T	C677T/C677T
Wild type (A1298C)	6	16	5
Wt/A1298C	12	6	1
A1298C/A1298C	6	1	0

Conclusions

1. The present results suggest that the investigated MTHFR polymorphisms do not influence susceptibility of schizophrenia

2. It is necessary to continue this study with a greater number of patients.

J09.10
The study of a role of genes catechol-O-methyltransferase (Val108Met), tyrosine hydroxylase *TH* (VNTR in 1 exon), and a dopamine receptor DRD4 (VNTR in 5 ' UTR '-areas) in development of disease and neuropsychological abnormalities at Parkinson's disease patients

G. Akhmadeeva, *I. Khidiyatova, I. Gilyazova, A. Baitimerov, A. Sadyikova, R. Magzhanov, E. Khusnutdinova;*
Institute of biochemistry and genetics Ufa Scientic Centre RAS, Ufa, Russian Federation.

The purpose of the study is searching of the genetic factors and neuropsychological abnormalities in Parkinson's disease (PD) development. During our clinic and genetic research of Parkinson's disease we've examined PD patients (N=658) and control individuals (N=538). Psychological investigation of 319 PD was carried out. In the expanded samples of patients and control individuals the association analysis of PD with polymorphic variants of monoamine metabolizing enzyme genes was performed: *TH* (VNTR in 1 exon), COMT (Val108Met) and DRD4 (VNTR in 5 ' UTR '-areas). The most important results have been received in *COMT* gene analysis, giving evidence concerning the influence of Val108Met polymorphism on PD development: genotype *H/*H and allele *H, determining synthesis of the enzyme with high activity, may be considered as genetic markers of the increased risk contributing to development of PD in Bashkortostan Republic as a whole and to the most severe PD form, in particular. Genotype *H/*H and allele *H were also risk markers for the development of such neuropsychological abnormalities as personal anxiety, depression, dementia, whereas the genotype *L/*H, defining average activity of *COMT*, made protective impact, reducing risk of PD development. The comparative analysis of the investigated polymorphic loci of TH and DRD4 genes hasn't revealed significant differences between PD samples and controls.

J09.11
eNOS polymorphism and ACE polymorphism gene in secondary arterial hypertension in a romanian children population

C. Duicu[1], *C. Banescu*[2], *I. Pascanu*[3];
[1]*Pediatric Department No 2, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [3]*Endocrinology*

Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

The aim of our study is to investigate whether genetic polymorphisms in the endothelial nitric oxide synthase (eNOS) gene (in intron 4 (4b/4a)) or insertion/deletion (I/D) polymorphism of the angiotensin-1 converting enzyme (ACE) gene are associated with secondary hypertension (HT) in children.

We genotyped 40 healthy (controls), and 38 hypertensive children and adolescents. We compared the distribution of eNOS and ACE genotypes in the two study groups of subjects. Arterial hypertension was defined as systolic/diastolic blood pressure measurements higher than 95 age-gender-height percentile of the adopted reference values. The 4a/a and 4a/b genotype for the intron 4 polymorphism was more common in normotensive than in hypertensive children. The 4a/b eNOS genotype distribution in patients with secondary hypertension (aa= 0%, ab= 23,68%, bb= 76,32%) did slightly differ from genotype distribution in controls (aa= 5%, ab= 37,5%, bb= 57,5%), and the bb genotype was not associated with secondary hypertension (RR 1.611; CI (0.9-2.88); p = 0.09). Moreover, the I/D ACE genotype distribution in patients with HT (DD= 18,42%, ID= 68,42%, II= 13,16%) did differ significantly (p=0.029) from genotype distribution in controls (DD= 47,5%, ID= 42,5%, II= 10%), and the DD genotype was not associated with HT

(RR 0.4516; 95% CI 0.23-0.88; P = 0.0084). In conclusion, we failed to demonstrate that the 4a/b eNOS polymorphism and the ACE I/D polymorphism are genetic markers for secondary hypertension in children.

Acknowledgments: This study was supported by a CNCSIS Grant - 137/2008 for Young PhD, Romania.

J09.12

ACE gene polymorphism in children with nephrotic syndrome in a Romanian population

Z. Gall[1], *C. Duicu*[1], *C. Banescu*[2], *E. Kiss*[1];

[1]*Pediatric Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

Nephrotic syndrome (NS) is one of the commonest renal problems encountered in children. The role of angiotensin-converting enzyme (ACE) insertion/deletion (I/D) gene polymorphism in various renal disorders has been investigated. We have evaluated the frequency of ACE polymorphisms and their impact on the clinical course of INS in children in a romanian county hospital.

This study comprised 20 pediatric patients with nephrotic syndrome, 11 males (55%) and 9 females (45%). Forty children without previous renal diseases and negative proteinuria were enrolled as a control group (50% males and 50% females). Polymerase chain reaction amplification was performed on genomic DNA isolated from peripheric blood leucocytes.

The distribution of ACE DD, ID, and II genotypes in NS patients were 20; 70 and 10%, respectively; the corresponding numbers for the control group were 47,5; 42,5 and 10%, respectively. Angiotensin-converting enzyme genotypes were no significantly different between patients and control groups (p>0.05).

The study groups consisted of 14 (70%) with steroid-sensitive nephrotic syndrome (SNSS) and 6 (30%) with steroid-resistant nephrotic syndrome (SRNS). The distribution of the ACE genotype was II, 14,29%; ID, 64,29%; and DD, 21,42% in the SSNS population and ID, 83,33% and DD, 16,67% in the SRNS population. No statistically significant difference was found between steroid sensitivity and ACE genotypes.

Conclusion: The current study reveals no association between the ACE gene I/D polymorphism and clinical course and steroid responsiveness. Further studies with a larger number of patients are needed.

J09.13

A/G *CKMM* and C/T *AMPD1* gene polymorphisms in elite Russian athletes and response to endurance training

O. Fedotovskaya[1], *I. Ahmetov*[2], *V. Rogozkin*[1];

[1]*Research Institute of Physical Culture, Saint-Petersburg, Russian Federation,* [2]*Kazan State Medical University, Kazan, Russian Federation.*

There is evidence that athletic performance is influenced by genetic factor. Skeletal muscle isoforms of creatine kinase and AMP-deaminase are important regulators of muscle energy metabolism during exercise. There is a conflicting data concerning whether A/G *CKMM*(rs8111989) and C/T *AMPD1*(rs17602729) gene polymorphisms are associated with endurance performance related phenotypes.

Purpose of the study was to determine whether there is a difference in A/G *CKMM* and C/T *AMPD1* genotypes distributions between elite Russian endurance athletes (EA) and students of Saint-Petersburg Universities without training experience (Con), and to investigate the association of these polymorphisms with VO_{2max} and its response ($deltaVO_{2max}$) to 4 months endurance training program.

The analysis was performed on DNA of 170 EA and 209 Con. VO_{2max} was measured for EA during cycle ergometry tests, for 27 EA - before and after 4 months of endurance training. The A/G *CKMM* and C/T *AMPD1* gene polymorphisms were detected by RFLP-analysis.

There were no differences in genotypic and allelic distributions of A/G *CKMM* SNPs between EA and Con. Frequencies of *AMPD1* CC genotype and C allele were significantly (P<0.01) higher for EA compared with Con. VO_{2max} of EA was genotype-dependent for *CKMM* (AA:59.9±8.2ml/min/kg, AG:54.4±9.3ml/min/kg, GG:43.2±9.2ml/min/kg,P<0.001) and *AMPD1* (CC:54.8±7.9ml/min/kg, CT+TT:47.6±5.4ml/min/kg,P<0.001). A significantly lower mean $deltaVO_{2max}$ was detected in EA with GG genotype (AA+AG:15.5ml/min/kg, GG:8.5ml/min/kg,P<0.04) and in T *AMPD1* allele carriers (CC:15.0ml/min/kg, CT+TT:9.2ml/min/kg,P<0.03).

Results provide evidence that A/G *CKMM*(rs8111989) and C/T *AMPD1*(rs17602729) gene polymorphisms contribute to differences in VO_{2max} and VO_{2max}-response to endurance training and might be molecular markers for endurance performance in athletes.

ADAM33 polymorphisms and overall, cardiovascular and COPD mortality: prospective cohort study

S. M. Figarska*, J. M. Vonk, H. M. Boezen;*

Department of Epidemiology, Groningen, Netherlands.

Background: The *ADAM33* gene is associated with the pathophysiology of COPD and atherosclerosis. This study investigated overall, cardiovascular (CVD) and COPD mortality, in relation to SNPs in *ADAM33*.

Methods: The vital status of 8,465 participants in the Vlagtwedde/Vlaardingen cohort study was assessed at December 31st, 2008. Vlagtwedde/Vlaardingen is a general population based cohort with a follow-up of 25 years (1965-90) with medical surveys every 3 years. We genotyped four *ADAM33* SNPs (S_1, S_2, T_2, Q_1) in 1,390 subjects participating in the last survey. We performed Cox regression to estimate the risk of the SNPs in relation to mortality, with adjustment for gender, age, FEV_1, height, place of residence and packyears of smoking. In addition, stratified analyses according to gender and smoking habits were performed.

Results: At December 31st, 2008, 284 (20.4%) of the included subjects had died (107 due to CVD and 20 due to COPD). Homozygous mutants for SNP T_2 had an increased risk of total and CVD mortality compared to wild types [HR=3.6 (95% CI 2.0- 6.7) and 3.4 (1.2-9.5) respectively]. Individuals homozygous for the minor allele of S_1, S_2, T_2 or Q_1 had a significantly increased risk of COPD mortality. In stratified analyses the risk of total mortality associated with SNP T_2 did not change: females [3.5 (1.5-8.3)], males [3.1 (1.2-7.6)], never smokers [3.8 (0.9-16.3)], ever smokers [3.6 (1.8-7.2)]. **Conclusion:** This study shows for the first time that *ADAM33* is a pleiotropic gene that is associated with total, CVD and COPD mortality, independent of potential confounders.

P10.02
A statistical method for estimation of the age of an admixed population

S. Bhattacharya[1], *A. Ghosh*[1], *A. Basu*[2];
[1]*Indian Statistical Institute, Kolkata, India,* [2]*National Institute of Biomedical Genomics, Kalyani, India.*

Whereas the vast majority of DNA sequence-level variation evolves neutrally and is maintained by a balance between the mutation process and random drift, some parts of the human genome have been subjected to natural selection. Admixed populations are unique in that they represent the sudden confluence of geographically diverged genomes with novel environmental challenges. Thus, genomes from each ancestral population were presented with new challenges. This kind of selection pressure may be quite different from that faced by stationary populations, in which the local environmental changes may occur gradually, allowing for rare advantageous alleles to increase in frequency. Admixed populations therefore offer special opportunities for studying recent selection.

In this study, we propose a method for estimating the 'age' of an admixed population. Using Kimura's (1955) solution of a process of random genetic drift, we developed a novel method of determining the time of a past admixture event based on genetic data comprising of both correlated and independent markers. An extension of the work has been identification of markers exposed to natural selection followed by proposition of a revised time estimator for the admixture event.

Using simulated datasets generated under different assumptions, we have shown that the estimators we propose are robust to fluctuations in the time of the admixture event, proportion of mixing and the genetic divergence between the ancestral populations. However increase in population size and number of markers attributed to a remarkable improvement in the efficiency of the estimators, even under the scenario of natural selection.

P10.03
Interactions between genetic ancestry and socioeconomic status shape self-identification and discrimination among Puerto Ricans

M. Via[1,2], *M. E. Esteban*[1], *L. Fejerman*[2], *L. Avilés*[3], *E. G. Burchard*[2], *J. C. Martínez-Cruzado*[3];
[1]*University of Barcelona, Barcelona, Spain,* [2]*University of California, San Francisco, San Francisco, CA, United States,* [3]*University of Puerto Rico, Mayagüez, Mayagüez, Puerto Rico.*

Puerto Ricans are a complex society resulting from the admixture of the original Taíno Amerindians, Europeans, and Africans. This admixture process was not random and we identified assortative mating based on genetic ancestry in a previous study. Moreover, historical processes have contributed to the geographic heterogeneity in the distribution of admixture across the island of Puerto Rico, which also influenced social differences.

Here, we analyze a census-based sample of 405 Puerto Ricans that fulfilled a comprehensive survey about the concept of race, the use of racial classifications, perception of discrimination, and social class. These individuals were also genotyped using a panel of 106 Ancestry Informative Markers (AIMs) to determine their admixture proportions. Our sample of Puerto Rican individuals showed average proportions of 19.5% African, 64.3% European, and 14.9% Amerindian ancestries, similar to previous studies. There were significant differences in ancestry between individuals that self-identified as "White" or "Black", although both groups overlapped in the distribution of ancestry values. Other variables, such as socioeconomic status, income, or education, contributed to the differences in self-identification and to differences in the perception of race and discrimination. As previously observed for other demographic factors, Amerindian ancestry did not play any substantial role in these processes. These results have substantial implications to understand the social and demographic processes that have formed this population.

P10.04
Grading the credibility of genetic associations in Alzheimer's disease using the Interim Venice Criteria

L. Broer, *M. Schuur, A. C. J. W. Janssens, C. M. van Duijn;*
Erasmus MC, Rotterdam, Netherlands.

The Alzgene database is a valuable resource for researchers working in Alzheimer's disease (AD). In the database, the credibility of genetic associations is graded using the interim Venice Criteria but these criteria have never been formally evaluated. We evaluated the robustness of the Venice grades in Alzgene data in a simulation studies by adding hypothetical results of simulated studies to the meta-analyses in the top list. We further conducted a follow-up study of the interim grades of the top list. The Alzgene 'top list' changed considerably (40%) over the course of one year. A total of 3 genes with strong credibility were graded to weak within this short period. When evaluating the question whether this is due to a high type 1 error (p-values) or type two error (low power), we found that increasing power had very little effect on the positive predictive value of a finding, but the impact of testing with a lower p-value is major. Based on a data-freeze of December 2009 our simulations show that many genes could drop due to a low OR (<1.15; bias criterion), except for APOE and ACE. .Our simulation studies show it is impossible to change the credibility of ACE based on the heterogeneity (I2). However, the credibility for ACE altered empirically due to first study bias. Based on our finding we propose evidence criterion by a criterion based on the p-values and to replace the low summary OR criterion for bias by a criterion based on the presence of replication.

P10.05
Variation at Follicle Stimulating Hormone Receptor (FSHR) gene and age at natural menopause influence the onset of Alzheimer's disease in women.

R. M. Corbo[1], *G. Gambina*[2], *L. Ulizzi*[1], *E. Broggio*[2], *R. Scacchi*[3];
[1]*Biology and Biotechnology Department, La Sapienza University, Rome, Italy,* [2]*Neurology Division, Hospital of Verona, Verona, Italy,* [3]*CNR Institute of Molecular Biology and Pathology, Rome, Italy.*

There is evidence of a higher prevalence of Alzheimer's disease (AD) in women, and it is becoming clear that it may be due not only to their longer life expectancy, but also to biological risk factors. In previous investigations we observed that, in addition to genes involved in estrogen metabolism (ESR1 and CYP19), also gender-specific factors such as past fertility may play a relevant role in the development of AD in women. In the present study we investigated the possible influence on AD onset of FSHR gene, that is involved in the regulation of fertility in women. As a possible AD risk factor, age at natural menopause was examined as well.

In a sample of 212 women with late-onset sporadic AD and 85 control women the FSHR Thr307Ala (rs 6165) polymorphism was examined. A significant excess of FSHR GG genotype (Ala/Ala) (OR = 0.46 , 95% CI 0.24-0.90, p=0.02) was observed in controls suggesting that Ala/Ala genotype could have a protective effect on AD development in women. AD women had an age at natural menopause (49.7± 0.21) lower than controls (50.6± 0.34, p=0.02) and linear regression analysis showed a significant positive relationship (p=0.03) between age at natural menopause and age at AD onset. These observations seem to support the hypothesis that the loss of neuroprotective estrogens after menopause may play a role in AD development in women.

P10.06
Association of genetic polymorphism at the APOAI/CIII/IV/V gene loci with variation in plasma lipid levels among a sample of the general Kuwaiti population

S. A. Al-Bustan, *B. G. Annice, M. A. Alnaqeeb;*
Department of Biological Sciences, Faculty of Science, Kuwait University, Safat, Kuwait.

Apolipoproteins are responsible for the clearance of lipoproteins, failure of which may lead to the development of dyslipidemia. Numerous single nucleotide polymorphisms (SNPs) have been identified at the APOAI/CIII/IV/V gene cluster on chromosome 11q23-24 that may alter the transport and/or metabolism of lipoproteins. As hypercholesterolemia and hypertriglyceridemia have been reported to be highly prevalent in the Kuwait population, the objective of this study was to determine genetic polymorphisms at the APOAI/CIII/IV/V

locus in a sample of the general Kuwaiti population (n=482). A total of 8 SNPs were genotyped and analyzed with regards to plasma lipid levels, BMI and Arab ethnicity. The SNPs included APOAIV Q360H and T347, APOCIII 3238C with APOCIII 3238C›G, -455T›G, -484C›T as well as the APOAV -1131T›C, c.56c›G and c.1259T. Genotype and allele frequencies were determined by simple gene counting methods and tested for Hardy-Weinberg Equilibrium and Linkage disequilibrium using GENEPOP (Version 3.4) while haplotypes were constructed using HAPLOVIEW. Genotype and allele frequencies as well as haplotypes were comparable to those reported in other populations and will be presented. Multivariate analysis was carried out to investigate the association of minor alleles with variation in lipid levels. Preliminary results indicated a genetic component to be involved in predisposing Kuwaiti's to dyslipidemia. Investigating potential direct or indirect involvement of minor alleles in Kuwaiti's could reflect the interaction of environmental factors such as fat-rich diet and sedentary life-style with the diverse ethnicity in Kuwait to promote dyslipidemia. Further analysis of other polymorphisms in a larger sample is currently being analyzed.

P10.07
Association of the APOD gene with cardiovascular and metabolic events

N. Erginel-Ünaltuna[1], *C. Gulec*[1], *N. Coban*[1], *F. Guclu-Geyik*[1], *A. Onat*[2];
[1]*Istanbul University, Institute of Experimental Medical Research, Deperment of Genetics, Istanbul, Turkey,* [2]*Cardiology Society, Istanbul, Turkey.*

ApoD is a lipocalin which plays a role for transport of hydrophobic molecules. While it is well known that ApoD has tissue-specific physiogical ligands and functions, these are still subject for exploration. Transgenic mice over-expressing ApoD show changes in lipid and glucose metabolism.

Our previous findings show that ApoD is present among genes that are expressed mainly in the heart and its expression is significantly decreased on atherosclerotic plaques. Furthermore, as a preliminary finding, variations at the functional regions of ApoD gene on 50 patients with coronary heart disease has been explored using DHPLC and differences in sequences were found on 16 patients. These pilot studies lead us to the hypothesis that ApoD gene polymorphisms and protein may play a role in cardiovascular diseases and metabolic syndrome in humans. We further analyzed one of those SNPs in in our DNA bank of 2235 people specific for Turkish Population, There were significant associations with this genotype and hypertension, physical activity in the whole group. Gender-specific analyses showed that there was an association with ApoA1 levels and physical activity after exclusion of drug usage in women. In men, however, hypertension, physical activity as well as fasting glucose levels, after exclusion of drug usage, were found to be associated.

These is the first study to show that ApoD might play a role in cardiovascular and metabolic event. ApoD-protein analyses can be performed and investigated, if this protein can be specified as a biomarker.

P10.08
Autosomal recessive disorders in the South Mediterranean Region: An overview from North Africa

O. MHAMDI[1], *W. KELMEMI*[1], *M. KHARRAT*[1], *R. MRAD*[1,2], *H. CHAABOUNI BOUHAMED*[1,2];
[1]*Department of Human Genetics. University Tunis El Manar, Faculty of Medicine, Tunis, Tunisia,* [2]*Department of congenital and Hereditary diseases; Charles Nicolle hospital, Tunis, Tunisia.*

Hereditary diseases and congenital abnormalities have been reported to affect 2 - 5 % of all live births. Actual data suggest that genetics disorders are common also in countries of the North Africa. This population is made of a mosaic of communities. This heterogeneity with the same social and economic structure has contributed to increase the rate of endogamy and consanguineous unions. These practices lead to the emergence of autosomal recessive.

Aim: The aim of this study was to report the genetics spectrum of autosomal recessive disorders and analysed their prevalence in North Africa.

Methods: An exhaustive electronic and library research of the recent publications was carried on the biomedical databases Pubmed and OMIM using Keywords "autosomal recessive diseases", "North African patients", "Founder effect".

Results: The distribution of the autosomal recessive disorders was not uniform and some traits are common. Some examples are: Familial Mediterranean Fever, ßthalassemias, cystic fibrosis. The relative homogeneity of populations from North Africa has often been underlined, and several founder mutations have already been suggested. A number of rare diseases described from North Africa have now been few recognised in other countries; this result suggests that the private syndrome does exist such as Andermann Syndrome, Hutchinston-Gilford syndrome and Anderson disease. For theses reasons, our region will continue to be a source of new information's about genetic disorders for the whole world. With the special religious and cultural backgrounds, more work should be given in planning and research ways of prevention and treatment of genetic disorders.

P10.09
STR data from forensics: what can it tell us about human population history?

N. M. Silva[1], *E. S. Poloni*[2], *M. Currat*[2], *L. Pereira*[1,3];
[1]*Institute of Molecular Pathology and Immunology of the University of Porto - IPATIMUP, Porto, Portugal,* [2]*Laboratory of Anthropology, Genetics and Peopling history (AGP), Department of Anthropology, University of Geneva, Geneva, Switzerland,* [3]*Faculdade de Medicina da Universidade do Porto, Porto, Portugal.*

Forensic genetics is prolific in generating genetic profiles based on Short Tandem Repeats (STRs), at a worldwide scale. The most used commercial kits include 13 common autosomal STR loci, being widely screened for consistency and quality control purposes between labs. The availability of such amount of data at a worldwide scale drove us to construct an online database of allele frequency data - Strdna-db - and an online tool comprising genotype profiles - PopAffiliator. Here, we intended to understand how informative these markers used in forensics can be to unravel human demographic history. The analysed datasets included frequency data - 190 populations and 69,229 individuals - and genotype data - 43 populations and 11,181 individuals.

Inter-population comparisons indicate a significant level of population structure, with a global FST value of 4.3-5.0% for both datasets, thus in agreement with levels inferred in non-forensic studies. This agreement further extends to the pattern of within-population diversity, which shows a decrease from sub-Saharan African to American populations, in accordance with the recent African origin of modern humans. Actually, the geographic distance to East Africa explains 55% of the decrease in genotype diversity, a pattern that could be explained by a series of founder effects during the expansions out-of-Africa.

Our results show that extensive datasets from forensics can be used to address population genetics' questions, and the statistical methods used provide reliable results as they account for the particularities and limitations of those markers.

P10.10
Epidemiological study of Beckwith Wiedemann syndrome in European population

L. Odak[1], *I. Barisic*[1], *M. Loane*[2], *E. Calzolari*[3], *E. Garne*[4], *D. Wellesley*[5], *H. Dolk*[6];
[1]*Children's Hospital Zagreb, Clinical Hospital Center Sisters of Mercy Zagreb, Zagreb, Croatia,* [2]*EUROCAT Central Registry, University of Ulster, Newtonbabbey Co Antrim, UK, Ulster, United Kingdom,* [3]*Division of Medical Genetics, Department of Experimental and Diagnostic Medicine, University of, Ferrara, Italy,* [4]*Kolding Hospital, Kolding, Odense, Denmark, Odense, Denmark,* [5]*Wessex Clinical Genetics Service, Princess Ane Hospital, Southampton, United Kingdom, Southampton, United Kingdom,* [6]*EUROCAT Central Raegistry, University of Ulster, Newtonbabbey Co Antrim, UK, Ulster, United Kingdom.*

Beckwith Wiedemann syndrome (BWS) is an overgrowth syndrome characterized by growth disregulation, risk of tumour development and congenital anomalies. In this study we analysed 197 patients registered in EUROCAT network of congenital anomaly registries in 1980-2007 period by monitoring population of 13 546 771 births. The prevalence was 1.45 per 100 000 births. Male to female ratio was 1.3:1. High proportion of patients was diagnosed by prenatal ultrasound examination (70/166; 42.1%), 41 patient was discovered at birth (41/166; 24.69%) and 55 patients (33.3%) were diagnosed during the first month of life. Most patients were live births (177/197;

89.8%), eight were stillbirths (8/166; 4.81%), and twelve pregnancies were terminated after prenatal diagnosis (12/70; 17.4%) due to heart, kidney or limb anomalies. Seven live births didn't survive the first week of life (7/177; 3.9%). In 148 (75.12 %) of patients major malformations were present, with the hallmarks of the syndrome, omphalocele (54.72%; 81/148) and macroglossia (52.7%; 78/148), being the most common. Other associated anomalies were present in 68 (46%) patients: cardiovascular in 20.28 % (30/148), urinary in 17.56% (26/148), limb defects in 9.15% (14/148), and central nervous system malformations and cleft lip in 2.0% (3/148). In thirteen patients more than one congenital anomaly was present. In conclusion, with estimated frequency of 1 in 69930 births, BWS is a rare congenital anomaly disorder, often associated with major congenital anomalies. Pregnancies that are carried out to term mainly result in live births with high survival rate.

P10.11
The relationship between TNF-alpha gene polymorphisms and susceptibility to Behcet's disease in Iran.

***M. Taghizadeh**, Z. Jahan Afruz, M. Jabbarpur Bonyadi, S. Dastgiri, M. Esmaeeli, S. kolahi, A. khabbazi, A. Ebrahimi, M. Haj Ali lu, T. Moharrami;*
Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran.

Background- Behçet is a multisystematic disease which includes recurring mouth and genital ulcers along with inflammation inside the eye and skin problems. BD patients have higher serum levels of Tumor necrosis factor (TNF). The positive response of BD patients to Anti- TNF therapy suggests a pivotal role for TNF-alpha in disease expression.

Aim- The aim of the current study was to investigate the possible relation between TNF- alpha-1031T/C and TNF- alpha -308G/A polymorphisms and susceptibility to Behcet's disease in Iranian Azeri Turkish Patients.

Method- In this study, the distribution of two polymorphisms within TNF gene promoter region was compared in 53 BD patients and 79 healthy controls using PCR-RFLP technique.

Findings- A significant difference was observed with respect to the alleles frequency of TNF-alpha-1031C which was higher in BD patients as compared to controls; while the alleles frequency of TNF alpha-308A revealed no difference in the two groups.

Conclusions- The frequency of CG haplo-type was significantly high in BD patients while the frequency of TA haplo-type was significantly low in these patients. The result reveals that in the North West population of Iran TNF alpha gene is involved in susceptibility of Behçet's disease.

P10.12
Genetic basis of Bombay Blood group

***P. Taskar**, M. Barath, A. Kanugovi;*
Dr.D.Y Patil University, Department of Biotechnology and Bioinformatics, Navi Mumbai, India.

The Bombay Blood phenotype was first discovered in Bombay by Dr.Y.M Bhende, present in about 0.0004% of the world population and in some populations like Mumbai, the occurrance can be as high as 0.01% of inhabitants. This blood group is identified by reverse grouping. The antigens determined by the human ABO blood group locus are oligosaccharide molecules constructed by the sequential action of specific glycosyltransferases, the final step being catalyzed by allelic glycosyltransferases encoded by the ABO locus. These enzymes require an oligosaccharide substrate known as the H blood group antigen, constructed by α-(1,2)-fucosyltransferase; GDP-L-fucose-βD-galactoside 2-α-L-fucosyltransferase, whose expression is determined by H and Secretor (SE) blood group loci known as FUTI and FUT2 genes respectively. Erythrocytes from individuals with rare Bombay and para-Bombay blood group phenotypes are deficient in H determinants, and thus A and B determinants, as a consequence of apparent homozygosity for null alleles at the H locus (h,h) . FUT1 and FUT2 sharing a high degree of sequence homology, are located within a 100 kb region in chromosome 19q13.3 suggesting their common origin. Occurrence of the phenotype among unrelated individuals indicates spontaneous mutations in the gene. A T725G mutation in the coding region of FUT1 and a gene deletion of FUT2 cause classical Indian Bombay phenotype. In para- Bombay blood phenotype (secretor positive), the expression of this variation is due to a missense point mutation at codon 164 in the FUT1 gene. Prior to blood transfusion, people with blood group O should be tested for Bombay phenotype.

P10.13
Genetic-epidemiological study of BRCA1 in an isolated population of South Tyrol. Description of a new mutation.

***C. Platzer**, A. J. Lanthaler, M. Mitterer, H. Heidegger, F. D. Vogl;*
General Hospital Merano, Merano, Italy.

Purpose: Due to its geopolitical situation and socio-cultural heritage South Tyrol can be considered a population isolate. The annual incidence of breast cancer in this region is approximately 300 cases. This is the first study investigating the contribution of the cancer susceptibility gene BRCA1 in this population.

Patients and Methods: Patients were identified from the Tumor Registry. Inclusion criteria were a) all breast (BC) and/or ovarian cancer (OC) patients diagnosed in the year 2002, b) BC patients diagnosed age ≤50 between 1998 and 2001 and c) all OC patients diagnosed between 1998 and 2001. DNA was extracted from peripheral blood and direct sequencing of all exons and exon/intron boundaries was performed.

Results: In total 153 patients were analyzed. We identified two deleterious mutations (c.1687C>T; c.4183C>T) in two BC and one OC patients; both of them non-sense mutations leading to a premature stop codon and previously reported in the BIC database. The missense variation c.83T>C was found in one BC/OC patient. We report a novel germline mutation c.5539_5544del6 in exon 24 in a BC patient. This mutation leads to an in-frame deletion of two amino acids in the highly conserved BRCT-domain and to the best of our knowledge has not been documented before. All of the mutation carriers had a positive family history.

Conclusion: The BRCA1 mutation frequency of 3.3% in unselected breast/ovarian cancer patients from South Tyrol is comparable to that of other European populations. To determine if the newly identified mutation is a founder mutation, further analyses are needed.

P10.14
Science of Breeding and Heredity from Ancient Persia to Modern Iran

***M. M. Kariminejad**, A. Khorshidian;*
Kariminejad & najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.

The prophet Zoroaster declared equal right for women and men to choose their "own ways". There is much evidence that ancient Persians believed in the equal contribution of women and men towards producing a child, and its hereditary characteristics.

The Greek philosophers believed that man's water (Semen) contains all human characteristics, and the female uterus is only responsible for nurturing and development of fetus.

After detection of the ovum Malpigy proposed the preformation theory (ovist) which means there is a miniature human inside ovum, that grows after Semen has entered the uterus and grow into a well developed fetus. This hypothesis was later delegated to spermatozoa. These contradictory and inappropriate beliefs were subject to dicussions and dispute; until C.E.Wolf demonstrated that the embryo is a product of the fertilization of ovum by spermatozoa.

800 years prior the sage Ferdowsi explains nicely the equal participation of man and woman in the production and transmission of characters.

After the renaissance and especially in recent years tremendous achievements have been made in unraveling biological secrets of reproduction. There was no work on genetics in Iran until 1936; when a genetic course to biology curriculum in related colleges and universities was added Iranian Genetics Society was founded in 1966, initiation steady movement in this field.

Although there was an inevitable gap during the revolution and war, now there is great effort by researchers to eliminate the gap and bring us into the mainstream of world science; development in biomedical sciences in the 3rd Millennium.

P10.15
Detection and genotyping of human papillomaviruses in Bulgarian patients for the period of 2009-2010

***P. P. Grozdanov**[1], V. Zlatkov[2], G. Ganchev[3], I. Karagiosov[4], D. Toncheva[5], A. S. Galabov[1];*
[1]Institute of Microbiology "Stephan Angeloff", BAS, Sofia, Bulgaria, [2]G&O

"Majchin Dom" Hospital, Sofia, Sofia, Bulgaria, [3]National Institute of Oncology and Hematology, Sofia, Sofia, Bulgaria, [4]"Tokuda" Hospital, Sofia, Sofia, Bulgaria, [5]Department of Medical Genetics, Medical University, Sofia, Sofia, Bulgaria.

Human papillomavirus (HPV) is now considered as a causative agent of carcinoma of the uterine cervix. Genital human papillomaviruses are classified into low-risk and high-risk groups. The low-risk HPVs are associated with genital warts and lesions, as for the high-risk they are commonly associated with high-grade squamous intraepithelial lesions and cervical cancer. Cervical cancer is the second most frequent cause of death from cancer in women worldwide; however cervical screening programs reduce the incidence of this type of cancer. In this research we have used Roche's LINEAR ARRAY HPV Genotyping Test. This test combines multiplex PCR with 40 pairs of primers with DNA hybridization and analyzes 38 types and subtypes of HPV. The cervical smears were collected from Bulgarian patients with condylata acuminate lesions. One hundred and twenty six cervicovaginal smears and scrapings were tested. Forty two percent of them were found positive for HPV DNA and 58% - negative. We found more then one type of viral DNA in all positive samples. We found in twenty two samples HPV 16 DNA (38%), in eight samples - HPV 18 DNA (18%), in five cases - HPV 6 DNA (10%), in seven cases - HPV 53 DNA (11%), in three cases - HPV 31 DNA (4%), in four cases - HPV 35 (5%) and in two cases we found positive for viral DNA types HPV 61 and HPV 62. Further studies are needed to determine the influence these HPV infections have on the epidemiology of the genital tract of these patients.

P10.16
Upgrading the chimpanzee reference genome

*D. P. Locke[1], **M. Mele**[2], G. Lunter[3,4], W. C. Warren[1], P. Minx[1], L. W. Hillier[1], R. S. Fulton[1], A. Navarro[2], T. A. Graves[1], E. E. Eichler[5], T. Marques-Bonet[2], E. R. Mardis[1], R. K. Wilson[2];*

[1]The Genome Center at Washington University, Washington University School of Medicine, St. Louis, MO, United States, [2]IBE, Institut de Biologia Evolutiva (UPF-CSIC), Universitat Pompeu Fabra. PRBB, Barcelona, Spain, [3]MRC Functional Genomics Unit and Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, United Kingdom, [4]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [5]Department of Genome Sciences, University of Washington School of Medicine, Seattle, WA, United States.

Comparative genomics is an intensive and fruitful field of research that seeks to unravel the main mechanisms underlying the evolution of the different species. Comparisons between the chimpanzee genome and the human genome have already given huge insights to understand adaptive processes that have taken place after the separation of the two species. In 2005 the first draft genome of a Western chimpanzee (*Pan troglodytes verus*) was assembled using a whole genome shotgun approach using Sanger technology and an effective coverage of 3.6x was reached. However, the draft nature of the assembly precludes deeper analyses, and still the genome contained gaps in the sequence every 15.7 Kbps

We are planning to upgrade the chimpanzee assembly by integrating 640 finished BAC clones, making 49.000 contig joins, improving N50 contig length from 26 kbps to 39 kbps and finishing chromosome 7 entirely in BAC clones. We have also sequenced the same individual at a much higher coverage (40x) using the Illumina technology with read length of 100 bp to help gap closure. We have performed an extensive study of the new assembled chimpanzee genome and we have compared it with the human genome (NCBI 37, hg19). We will put special emphasis to detect and resolve spurious indels or SNP variants, and to identify improperly represented duplicated regions using read depth and paired end mapping methodologies. Moreover, we will reanalyze some of the main statements in the initial study such as a detail characterization of the main differences that separate humans from chimpanzees including indels and structural variation.

We believe that this update will be useful for most of the scientific community working in the genomics field and that by comparing the new assembled chimpanzee genome with the human genome/s, we will improve our understanding of human specific genomic features.

P10.17
Variants in the CYP1A1/CYP1A2 locus are associated with coffee drinking

Variants in the CYP1A1/CYP1A2 locus are associated with coffee drinking

Coffee consumption is a model for addictive behaviour. We performed a meta-analysis of genome-wide association scans (GWAS) on coffee intake from eight Caucasian cohorts (N = 18,176) and sought replication of our top findings in a further 7,929 individuals. Significant evidence of association was detected at a variant (p-*value* = $1.6*10^{-11}$) in the 23-kilobases long commonly shared 5-prime flanking region between *CYP1A1* and *CYP1A2* genes. *CYP1A1* was found to be down-regulated in lymphoblastoid cell lines treated with caffeine. *CYP1A1* is known to metabolize polycyclic aromatic hydrocarbons which are important constituents of coffee, while *CYP1A2* is involved in primary metabolism of caffeine. Significant evidence of association was also detected at another variant (p-*value* = $3.9*10^{-09}$) near the *NRCAM* gene -- a gene implicated in vulnerability to addiction -- in the meta-analysis of discovery and replication cohorts. Our results from GWAS and expression analysis also strongly implicate *CAB39L* in coffee drinking. Moreover, the variant in the *CYP1A1*/ *CYP1A2* locus also showed significant positive association with systolic and diastolic blood pressure.

P10.18
Population variability of SNPs associated with common mental and neurological disorders in North Eurasia

***V. A. Stepanov**, K. V. Simonova, A. V. Marusin;*

Institute for Medical Genetics, Tomsk, Russian Federation.

Ethnic background appears to be an important factor in personalized health care and predictive medicine directed to prevention of common diseases. Common psychiatric and neurological disorders including schizophrenia, Alzheimer's diseases (AD), and Parkinson's disease (PD) are now the subject of intensive genome-wide association studies (GWAS). The aim of this study was to estimate the variability of genetic markers strongly associated with neurological and mental diseases across the multiple Eurasian populations. We selected 55 single nucleotide polymorphisms (SNPs) reported in recent GWAS as highly significantly associated with AD, PD, schizophrenia and cognitive performance, and investigated the population variability of these markers in 8 populations representing Eastern Europe, Central Asia, North Asia and Siberia. Considerable between-population variability in allele frequencies was found. The average range of risk allele frequency for 55 SNPs was 24.3%. Population differentiation measured by Fst varied widely across the loci studied (from 0,006 to 0,146). Mean Fst for all 55 SNPs was 0,045. Mean Fst for AD (0,029) proved to be substantially lower than population differentiation for PD (0,044), schizophrenia (0,054) and cognitive performance (0,049). Allele frequencies tend to correlate between populations according their geographical locations. Our data indicate that wide inter-population variation in the frequency of alleles associated with common diseases exists even on a sub-continental level. This variability may play a substantial role in the variation in genetic predisposition to common neurological and mental disorders in ethnically different populations.

This work was supported by the project 242257 ADAMS under the 7th Framework Programme of the EU.

P10.19
CONAN: Analysis Software for Genome-Wide CNV Association Studie

***L. Forer**[1], S. Schönherr[2], H. Weißensteiner[1], C. Gieger[3], H. Wichmann[3], G. Specht[2], F. Kronenberg[1], A. Kloss-Brandstätter[1];*

[1]Division of Genetic Epidemiology, Department of Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria, [2]Department of Database and Information Systems, Institute of Computer Science, University of Innsbruck, Innsbruck, Austria, [3]Institute of Epidemiology, Helmholtz Center Munich, German Research Center for Environmental Health, Neuherberg, Germany.

Genome-wide association studies (GWAS) based on single nucleotide polymorphisms (SNPs) revolutionized our perception of the genetic regulation of complex traits and diseases. Copy number variations (CNVs) are genomic segments which are duplicated or deleted among different individuals, ranging from kilobases to several megabases in length. CNVs promise to shed additional light on the genetic basis of

monogenic as well as complex diseases and phenotypes. However, while several software packages support the determination of CNVs from SNP chip data, the downstream statistical inference of CNV-phenotype associations is still subject to complicated and inefficient in-house solutions, thus strongly limiting the performance of GWAS based on CNVs.
We present CONAN, a freely available software solution which provides an intuitive graphical user interface for categorizing, analyzing and associating CNVs with phenotypes. CONAN assists the evaluation process by visualizing detected associations via Manhattan plots in order to enable a rapid identification of genome-wide significant CNV regions. Various file formats including the information on CNVs in population samples are supported as input data.
CONAN facilitates the performance of GWAS based on CNVs and the visual analysis of calculated results. CONAN provides a rapid, valid and straightforward software solution to identify a part of the genetic variation underlying the 'missing' heritability for complex traits that remained unexplained by recent GWAS. The freely available software can be downloaded at http://genepi-conan.i-med.ac.at.

P10.20
Identification of *p53* and *CYP2C9* gene polymorphisms among Iranian (Turkmen & non-Turkmen) and Iraqi populations

*F. Biramijamal[1], **A. Hossein-Nezhad**[2], M. Soltani[1], S. Al-Awadi[3], A. Al-Zaad[3];*
[1]NIGEB, Tehran, Islamic Republic of Iran, [2]Endocrinology and Metabolism Research Center, Tehran University of Medical Sciences,, Tehran, Islamic Republic of Iran, [3]Baghdad University, Baghdad, Iraq.

The Cytochrome P450 (CYP) 2C9 enzyme is involved in drug metabolism and in detoxification of carcinogenic compounds. It is reported that *CYP2C9* polymorphism is involved in drug resistance. Additionally, the p53 protein is considered a key combination in countering stress messages such as DNA damage. It is reported that *p53* polymorphism at codon 72 is involved in response to chemotherapy. The aim of this study is to determine the prevalence of the *p53* and *CYP2C9* genetic polymorphisms in different ethnic groups in Iran compared with those from Baghdad city in Iraq. After obtaining signed informed consents, blood samples were collected. For this purpose the blood samples were collected from 70 Iraqi healthy individuals and 130 healthy Iranian population (Turkmen and non-Turkmen). We assessed the genotype patterns of *p53* and *CYP2C9* among Iranian ethnic groups. Then, the data was compared with the allele distribution for above genes among Iraqi population. The *p53* genotypes at codon 72 and *CYP2C9* polymorphism at codon 144 were determined by PCR-RFLP analysis and the results were confirmed by DNA sequencing analysis. It is showed that the frequency of Cys allele for *CYP2C9* at codon 144 among Iranian population (10%) was two times higher than Iraqi population (5%). In contrast, Arg allele for p53 gene at codon 72 among Iraqi population (42%) was higher than Iranian population (35%). Thus, these polymorphisms may be a suitable target for research in the field of pharmacogenetics among Iranian and Arab populations.

P10.21
Frequency and origin of 2184insA mutation in CF patients from Ukraine

***S. A. Kravchenko**[1], H. V. Makukh[2], V. M. Pampukha[1], M. Burlova-Vasylieva[3], L. Bober[2], O. Hnateyko[2], L. Livshits[1];*
[1]Institute of Molecular Biology and Genetics NAS of Ukraine, Kyiv, Ukraine, [2]Institute of Hereditary Pathology of the Ukrainian Academy of Medical Sciences, Lviv, Ukraine, [3]Taras Shevchenko National University, Kyiv, Ukraine.

Analysis of mutations in *CFTR* gene among CF patients from different populations revealed that highest frequency of 2184insA mutation was observed in Eastern Europe. In our study we screened mutation 2184insA in 351 CF patients from different regions of Ukraine. The frequency of this mutant allele was 5.5%. This is the second most common CF mutation in Ukraine (F508del - apr. 50%).
To determine origin and distribution of this mutation in Ukraine the haplotype analysis of two intragenic polymorphisms (IVS8CA and IVS17bTA) was performed. For haplotype construction of polymorphic loci the carrier parents and CF individual were analyzed. 28 out of 39 chromosomes with 2184insA mutation carried the haplotype 16-7 for IVS8CA and IVS17bTA loci respectively. In 11 families gametic phase could not be established for one or both markers, but in all these cases alleles 16 and 7 were presented in patient genotype.Our results support single origin of chromosomes with 2184insA mutation in our CF population. However, data on haplotype analysis of CF mutations from other studies revealed that 2184insA mutations originated from multiply events - several haplotypes linked to this mutation were observed in different populations. Our results suggest that the appearance of the 2184insA mutation in the gene pool of Ukraine and reaching such high frequency may have been connected with recent founder effect and slippage has not given rise to any microsatellite variability. To clarify this suggestion analysis of additional polymorphic markers will be necessary.

P10.22
Complete screening of CFTR gene mutations in cystic fibrosis patients from Eastern Hungary

***G. Ivady**[1], L. Madar[1], B. Nagy[1], F. Gonczi[2], E. Ajzner[3], E. Dzsudzsak[1], L. Dvorakova[4], E. Gombos[1], J. Kappelmayer[1], M. Macek[4], I. Balogh[1];*
[1]University of Debrecen, Debrecen, Hungary, [2]Kenezy Gyula County Hosptial, Debrecen, Hungary, [3]Josa Andras County Hospital, Nyiregyhaza, Hungary, [4]Charles University, Prague, Czech Republic.

Introduction. Molecular genetic diagnostic strategies of cystic fibrosis (CF) are dependent of the mutation distribution of the analyzed population. The goal of our study was to establish the mutational spectrum of 40 clinically diagnosed severe CF patients in Eastern Hungary.
Materials and methods. For the mutation testing, a multiplex commercially available diagnostic assay was used together with a specific PCR assay for the detection of the CFTRdele2,3(21kb) enabling to detect 30 CFTR mutations. In patients having mutations not included in this panel, the entire coding region of the CFTR gene was sequenced. Large alterations were analyzed using MLPA.
Results. Using the mutation detection kit only, the detection rate was 81%. Integrating the CFTRdele2,3(21kb) mutation to the panel increased the detection rate to 86%. When DNA sequencing was used, disease-causing mutations could be identified in 79 out of the 80 CFTR alleles. The complete analysis verified four 2184insA (5.0%), two L101X (2.5%) and one Q220X, S466X, Y1092X, E831X alleles (1.25% respectively). No large insertion or deletion was found.
Conclusions. Our results suggest, that in Eastern Hungary the majority of CF-causing mutations are small scale. Presence of six mutations (delta F508, CFTRdele2,3(21kb), 2184insA, N1303K, G542X and L101X) was shown in 91% of CF chromosomes. Two mutations (CFTRdele2,3(21kb), 2184insA) were found in suprisingly high frequency, in four patients each (5.0%).

P10.23
Genetic polimorphism of cytochrome P450 genes in the ethnic groups of Bashkortostan

***G. F. Korytina**[1], L. Akhmadishina[1], O. Kochetova[1], T. Victorova[1,2];*
[1]Institut of biochemistry and genetics, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation.

Aim. To determine the prevalence of the most common allelic variants of CYP1A1, CYP1A2, CYP1B1, CYP2A6, CYP2C9, CYP2E1, CYP2F1, CYP2J2 and CYP2S1 in a representative sample of the three ethnic population from Republic of Bashkortostan (Russia), and to compare these data with exiting published data from other populations.
Methods. CYPs genotypes were determined in DNA samples of healthy unrelated individuals representatives of three ethnic groups (N=319 Russians, N=279 Tatars, and N=144 Bashkirs. The CYPs genes polymorphisms were examined using PCR-RLFP method.
Results. The frequencies of the variant genotypes, alleles and halpotypes of the CYPs genes were determined. Analysis of the CYP1A1 (rs1048943, rs4646903), CYP1A2 (rs762551), CYP2A6 (rs71790353), CYP2E1 (rs2031920) allele, genotype and haplotype frequencies detected significant differences among healthy residents of Republic of Bashkortostan belonging to different ethnicity. Significant differences among Russians, Tatars, and Bashkirs were not detected for CYP1A2 (rs35694136), CYP1B1 (rs1056836), CYP2F1 (rs11399890), CYP2J2 (rs890293), CYP2S1 (rs34971233, rs338583), CYP2C9 (rs1799853, rs1057910) genes. Analysis of the CYPs genes allele frequency distribution patterns among the ethnic groups of the Republic of Bashkortostan in comparison with the worldwide populations were conducted.

Conclusion. The allele and genotype frequencies distributions of the CYPs genes markers among the inhabitants of the Republic of Bashkortostan demonstrate the influence of different ethnic components on contemporary populations occupying the region of interest. The results of present investigation will form the basis for identification of the genetic risk factors to cancer susceptibility, determining the toxic potentials of environmental pollutants and might the genetic background of drug response.

P10.24
Implementation of a recently developed whole genome amplification method on DNA profiling of old skeletal remains

Z. Zafari[1,2], *M. S. Farzad*[2], *A. Shirkavand*[2,3], *A. Ghasemi*[2], *S. Habibi*[4], *M. Tavallaei*[5], *S. Zeinali*[2,6];
[1]*Biology Group, Faculty of Sciences, Khatam University, Tehran, Islamic Republic of Iran,* [2]*Kawsar's Human Genetics Research Center, Tehran, Islamic Republic of Iran,* [3]*Biology Group, Faculty of Sciences, Razi University, Kermanshah, Islamic Republic of Iran,* [4]*Human Genetic Research Center, Baqiyatallah Medical Sciences University, Tehran, Islamic Republic of Iran,* [5]*5Human Genetic Research Center, Baqiyatallah Medical Sciences University, Tehran, Islamic Republic of Iran,* [6]*Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*

An insufficient DNA quantity along with the presence of inhibitors and DNA degradation are of utmost challenges implicated in DNA profiling of old skeletal remains. Apart from approaches using smaller amplicons which have significantly increased the possibility of obtaining DNA profiles from highly degraded DNA samples, amplification of low copy number (LCN) DNA samples and reduction of inhibitory effects are attainable with our recently reported whole genome amplification (WGA) method named KI-PEP PCR. Implementation of this improved degenerate 15-mer primer extension preamplification PCR on the DNA isolated from 44 skeletal remains of Iranian war (1980-1987) victims was followed by specific amplification with specific primers and Real-time PCR. DNA from fresh blood and a mixture of bone and blood DNA samples were also concomitantly examined.
Subsequent to the amplification by KI-PEP PCR, partial DNA profiles were obtained from 15 samples with both Identifiler and minifiler Kits and no superior results were generated in comparison to DNA profiling without prior amplification. These results demonstrated that despite increasing the low quantity of DNA and relieving inhibitors by the utility of KI-PEP PCR, no significant improvement can be achieved in DNA profiling of old skeletal remains on account of the presence of too many degraded DNA and the overall size reduction of DNA by the method.
Keywords: DNA Profiling, Whole genome amplification, Improved primer extension preamplification PCR, Skeletal remains

P10.25
DNA repair gene polymorphisms at XRCC1 (Arg194Trp, Arg280His, and Arg399Gln), XRCC3 (Thr241Met), and XPD (Lys751Gln) in healthy Tunisian population

G. Ben Salah[1], *F. Kallabi*[1], *N. Fendri-Kriaa*[1], *K. Jmel-Hammami*[2], *N. Belghith-Mahfoudh*[1], *A. Fourati*[3], *M. Larbi-Masmoudi*[2], *H. Ayadi*[4], *F. Fakhfakh*[1], *H. Kamoun*[1];
[1]*Laboratory of Human Molecular Genetics, Sfax, Tunisia,* [2]*Occupational Medicine, Hedi Chaker Hospital, Sfax, Tunisia,* [3]*Research Unit, Chemical Tunisian Group, Sfax, Tunisia,* [4]*Centre of Biotechnology, Sfax, Tunisia.*

Reduction in DNA repair capacity is associated with increased rates of birth defects, cancer, and accelerating ageing. Genetic polymorphisms in DNA repair genes might influence the repair activities of the enzymes predisposing individuals to cancer risk. Owing to the presence of these genetic variants, inter-individual and ethnic differences in DNA repair capacity have been observed in various populations. The present study aimed to determine the allele and genotype frequencies of five non-synonymous SNPs, XRCC1 Arg194Trp (C>T, rs1799782), XRCC1 Arg280His (A>G, rs25489) XRCC1 Arg399Gln (A>G, rs25487), XRCC3 Thr241Met (G>A, rs861539), and XPD Lys751Gln (T>G, rs13181) in Tunisian population and to compare them with HapMap populations. The variant alleles of these SNPs have been found to be positively associated with different forms of cancer in several genetic epidemiological studies in other populations. To the best of our knowledge, this is the first report of these DNA repair gene polymorphisms in Tunisians. The basic prevalence of these polymorphisms in the general population must be known to evaluate their significance in risk assessment in cancer and other phenotypes. DNA was isolated from the peripheral blood sample of 154 healthy and unrelated individuals and the genotypes were determined by PCR-RFLP. The allele and genotype frequency distribution at the five SNPs among Tunisians revealed a characteristic pattern may be explained by the fact that the Tunisian population is a mix of ethnic groups. This could assist in high-risk screening of humans exposed to environmental carcinogens and cancer predisposition in Tunisian population.

P10.26
Down syndrome (DS) space clustering suggests fixed geographical exposures

N. V. Kovaleva[1], *M. V. Prozorova*[2], *V. A. Blinova*[2], *D. V. Voronin*[2], *T. V. Kuznetsova*[3];
[1]*St. Petersburg Pediatric Medical Academy, St. Petersburg, Russian Federation,* [2]*St. Petersburg Centre for Medical Genetics, St. Petersburg, Russian Federation,* [3]*Institute of Obstetrics and Gynecology RAMS, St. Petersburg, Russian Federation.*

Space and time clustering of DS has for a long been a matter of controversy. Recent study suggests clustering to be associated with more densely populated urban areas (McNally et al. Int J Epidemiol 37:1169-1179). St.Petersburg is a large densely populated city with comparatively low migration rate. The study included all cases of DS born alive or prenatally diagnosed in 1970-2009, except for twins, both parentally derived trisomy 21 and trisomy 21 suspected to be parentally derived (recurrent cases in the same family). It was found that 2590 DS cases were unevenly distributed throughout the study area. We have identified 253 cases of a multiple occurrence of unrelated DS at the same dwelling, including 223 clusters of two DS, 23 clusters of three DS, 5 clusters of 4 DS, and two clusters of five DS. Clusters of two DS cases were estimated as a chance coincidence predominantly. Analysis of 30 clusters of 3 to 5 DS showed a highly significant excess over expected figures (one case in 714.6 flats) for 16 of them. Mothers of DS individuals from 16 clusters (n=50) were younger compared to mothers of DS from outside the clusters (n=2409): 28.8 vs. 30.8 yo, proportion of mothers aged 35 and older 20% vs. 35.9%, p=0.02. Only 14% of dwelling units inside 16 clusters were located at the ground floor which makes the effect of radon exposure as a major cause of clustering quite improbable. Our data suggests an effect of some geographically fixed exposures other than radon.

P10.27
Molecular diagnosis of Duchenne muscular dystrophy in romanian patients by MLPA method

L. Tamas, *M. Puiu, A. Anghel, E. Seclaman, C. Samoila, C. Gug, L. Pop, I. M. Ciuca;*
University of Medicine and Pharmacy, Timisoara, Romania.

Dystrophinopathies are a group of fatal muscle diseases with X-linked inheritance which have as common cause mutations in the DMD gene. The frequency of the diseases is high - 1:3500 newborns (male). The DMD gene mutations cause in Duchenne muscular dystrophy (DMD) a complete absence of dystrophin synthesis.
Method. 28 patients were analysed and genomic DNA was extracted from blood samples using QIAamp DNA Blood Mini Kit. Samples were collected from DMD patients with clinical diagnosis of DMD, from their relatives and in one case amniotic fluid was collected for prenatal molecular diagnosis. Isolated genomic DNA was analyzed by MLPA technique, which can identify extensive deletions or duplications of gene fragments. The results which were obtained by capillary electrophoresis on AbiPrism 3130XL were quantified and interpreted using Coffalyser program.
Results. In 13 patients were identified extensive deletions (59.1%) and duplications only in two patients (9.1%). 6 female patients with heterozygous genotypes confirmed the previously identified mutations in male patients. In one case prenatal diagnosis was performed on a patient having a child with DMD, confirmed by molecular diagnosis. In 6 patients (27.27%) no deletions or duplications were identified.
Conclusions
Our results confirm literature data that indicate a higher frequency of large deletions and a lower frequency of duplications, the two types together representing over 68% of mutations identified in patients with clinical diagnosis of DMD. MLPA technique is particularly effective if

Duchenne disease, allowing the detection of mutations in most cases and both prenatal diagnosis and diagnosis.

P10.28
FMR1 haplotype analysis in mentally retarded male population

Z. Daneberga[1,2], *B. Lace*[1], *N. Pronina*[1,2], *R. Lugovska*[1,2];
[1]*University Children's Hospital, Medical Genetic Clinic, Riga, Latvia,* [2]*Riga Stradins University, Riga, Latvia.*

DXS548-FRAXAC1-FRAXAC2 microsatellite markers and ATL1 SNP previously have been described as markers associated with Fragile X syndrome (FXS) causing gene FMR1 and CGG repeat instability. Haplotypes linked to FXS are described widely across Western European populations and Scandinavia in contrast to Eastern Europe including Baltic States. The aim of this study was to report specific haplotypes among FXS patients and patients with normal number of CGG repeat in Latvian population.

In our study were included 11 FXS patients and 122 patients with normal CGG repeat alleles. Microsatellite markers were genotyped on ABI 310 genetic analyser and results validated by direct sequencing of random alleles for each locus. ATL1 SNP amplified by allele specific PCR and analyzed on agarose gel. Gray zone alleles (35-50) were analysed for AGG interspersion pattern by direct sequencing.

In total 27 different DXS548-FRAXAC1-ATL1-FRAXAC2 haplotypes were detected - 26 in control group, 3 in FXS group. The prevalent haplotype in control group was 7-4-A-5+ (rel. frequency 0.327). The prevalent haplotype in FXS group was 2-2-G-4 (rel. frequency 0.818). Gray zone alleles with long uninterrupted CGG tract on 3` end were statistically significant associated with 2-2-G-4 haplotype. This finding let us hypothesize instability of these CGG alleles in next generations. Statistical results of our study indicate significant difference among FXS and control group. Most frequent haplotype in FXS group differs from literature data of European populations. Analysis of FXS chromosomes across Baltic States would be desirable.

P10.29
Molecular phylogenetic analysis of the Iranians and other populations

Z. Fazeli, *S. Vallian;*
University of Isfahan, Isfahan, Islamic Republic of Iran.

The allele frequency of polymorphic markers has proven to be useful for survey of human migration and genetic origin. Moreover, the estimation of genetic distance between populations could improve our viewpoint about their genetic origin. In this study, we used allele frequency data of 12 polymorphic markers on 250 (500 alleles) individuals from the Iranian population to estimate genetic distance between the Iranians and other world populations. The phylogenetic trees for three different sets of allele frequency data were constructed. Our results showed that the Iranians had genetic similarity with some European populations, of which the lowest genetic distance of the Iranians with the studied populations was observed with some populations reside in Russia. Furthermore, the high genetic distance was observed between the Iranians and East Asian populations. The data suggest that the Iranians might have relatively close evolutionary history with Europeans, but historically independent from East Asian populations. This study could provide a new insight into the evolutionary history of the Iranian population.

P10.30
Genetic epidemiological study of hereditary disorders in Russian populations

R. A. Zinchenko, *G. I. Elchinova, E. K. Ginter;*
Research Center for Medical Genetics, Moscow, Russian Federation.

Genetic epidemiological study the prevalence's of AD, AR and X-linked disorders in some regions (7 ethnic groups) of Russia was established: Russian from seven populations, Adygean, Maris, Chuvashes, Udmurt, Bashkirs, Tatars (more than 3 millions of inhabitants). Genetic differentiation between populations of different hierarchical levels in the load of Mendelian hereditary diseases (HDs) was established. The prevalence rate of all HDs varied in the investigated populations from 1.34 to 9.78 per 1000 persons. Simultaneously with medical genetic study the population genetic study was performed. Correlation analysis between prevalence rates of AD and AR HDs and random inbreeding F_{st} as well as index endogamy was carried out. It was proposed that the genetic drift is probable one of the factor which determined genetic differentiation of populations by the prevalence of autosomal (AD and AR) HDs. Genetic diversity of HDs in the investigated populations was revealed 480 disorders (7300 affected). Basic part of load (56 % of patients) for all types of inheritance concern to the common 28 forms (15 with AD, 8 with AR and 5 with X-linked inheritance) of the HDs causing only 5,83 % of all registered disorders. However, frequencies of these 28 disorders also varied between regions. The HDs which are finding out locally high frequencies in some populations/ethnic groups were submitted. Specific common diseases and accumulation of some HDs in several populations/ethnic groups were revealed in each population. It has been demonstrated that the genes of HDs are a promising tool for characteristic ethnogenetic processes in populations.

P10.31
Gilbert syndrome molecular diagnostics and clinical characterization in Latvia

L. Piekuse[1], *J. Keiss*[2], *V. Sondore*[2], *I. Micule*[1], *M. Kreile*[1], *B. Lace*[1], *A. Krumina*[3];
[1]*Riga Stradins University, Riga, Latvia,* [2]*Infectology Center of Latvia, Riga, Latvia,* [3]*Latvian Biomedical Study and Research center, Riga, Latvia.*

Gilbert syndrome or benign hyperbilirubinemia is caused by changed number of (TA) repeats in UGT1A1 gene promoter - (TA)5 and (TA)6 is associated with high enzyme activity, but alleles with 7 or 8 repeats - with low activity. Gilbert syndrome is usually described as autosomal recessive disease.

Aims: to characterize Gilbert syndrome patients by biochemical and molecular data. To compare molecular genotyping methods for Gilbert syndrome.

Materials and methods. 500 DNA samples from patients that were sent with elevated bilirubin levels. 400 control individuals. DNA was analyzed by SSCP, direct sequencing and fragment analysis using ABI PRISM 300 (Lin J. P. et al 2006).

Results. Comparing genotyping methods for UGT1A1 gene the best method was found to be fragment analysis using ABI Prism 300. Between patients with changed bilirubin levels diagnose of Gilbert syndrome was approved for 90%. Main clinical complaints were icterus at stress situations, fatigue, very rare as complaints were mentioned pain. Comparing bilirubin levels there were found statistical significance between individuals with genotype (TA)6/(TA)6 and heterozygous and homozygous (TA)7 individuals. Gilbert syndrome frequency in population of Latvia is 10%. There are found alleles (TA)5 and (TA)8 that is uncommon in European descent.

Conclusion: fragment analysis is most cost and time effective method for Gilbert syndrome genotyping. Clinical picture doesn't differ from already described picture from other populations. Alleles that is found in UGT1A1 gene includes alleles that are described in Africa descent.

P10.32
Mutation analysis of the mtDNA A1555G,a3243G,and A7445G mutations in nonsyndromic sensorineural subjects in north Iran .

F. Taji[1], *M. Zohoor*[2], *F. Farrokhi*[3], *M. Hashemzadeh - Chaleshtori*[3];
[1]*Payamenoor university of medical sciences, plant research center, Shahrekord Univ. of Med. Sci. Shahrekord, Shahrecord, Islamic Republic of Iran,* [2]*Cellular and molecular Research center. Shahrekord Univ. of Med. Sci. Shahrekord, Shahrecord, Islamic Republic of Iran,* [3]*Cellular and Molecular Research Center, Shahrekord univ. Of med. Sci. Shahrekord, Shahrecord, Islamic Republic of Iran.*

Three mitochondrial DNA (mtDNA) mutations including A1555G,a3243G,and A7445G occurring in MTRNR1,MTTL1 and MTTS1 genes are considered to be the main causes of mitochondrial hearing loss in some populations. However variouse frequevcies of the mtDNA mutations have been reported from different populations. This study aims to determine the frequency of the A1555G,a3243G,and A7445G mutations in nonsyndromic sensorineural hearing loss subjects in Gilan province in north Iran .

Materials and methods: Fourty six nonsyndromic sensorineural subjects were screened for the presence of mtDNA A1555G,a3243G and A7445G mutations using PCR-RFLP procedure and subsequent direct sequencing.

Result: We found no mtDNA A1555G,A3243G,and A7445G mutations in the cohort of 46 deaf individuals studied .However PCR-RFLP of the MTTL1 gene represented a G3316A mutation due to destroying a

restriction site in the A3243G PCR fragment examined.
Conclusion: Our finding indicate that the association of mitochondrial mutation with deafness is very low in deaf subjects, in north Iran .

P10.33
FV, Prothrombin and *MTHFR* gene mutations in patients with thrombosis risk from Middle Black Sea region of Turkey

*H. Bagci[1], N. Kara[1], S. Gunes[1], **N. Karakus**[1], E. Taskin[1], M. Yuce[1], K. Ozdamar[2];*
[1]Ondokuz Mayis University, Faculty of Medicine, Department of Medical Biology, Samsun, Turkey, [2]Osman Gazi University, Faculty of Medicine, Department of Biostatistics, Eskisehir, Turkey.

FV (Factor V), *Prothrombin* (Factor II) and *MTHFR* (Methylene tetrahydrofolate reductase) genes mutations are listed among the causes of hereditary thrombophilia, so these genes can be used in population-based large-scale genotyping studies. We aimed to determine the frequencies of thrombophilic gene mutations in the middle Black Sea region of Turkey.
In this study we screened 2070 patients (1373 females, 697 males) sent to our laboratory from various clinics of Ondokuz Mayis University, Faculty of Medicine for genetic testing for thrombosis risk between February 2005 - November 2010. *FV* Leiden (G1691A), *Prothrombin* G20210A and *MTHFR* C677T gene mutations were analyzed using reverse hybridization Strip Assay (1818 patients) and real-time PCR (252 patients).
Embolism (32.1%), coronary artery and heart diseases (14.3%), abortion (14.1%), anemia (7.2%), infertility (5.5%), thrombosis (4.9%), malign neoplasia (4.0%) were among the reasons of genetic test request. The percentages for heterozygosity and homozygosity for *FV, Prothrombin,* and *MTHFR* gene mutations were, in order, 18.2, 7.1, 43.0, and 1.9, 0.1, 10.3, respectively.
Determining the distribution of allelic frequencies of *FV, Prothrombin* and *MTHFR* gene mutations that increase the risk of thrombosis, will contribute to understanding of the frequency of these mutations in middle Black Sea region of Turkey.
Keywords: Thrombophilic genes, mutation frequencies

P10.34
Neuromuscular Disorders in Rostov Region (Russia)

***N. Vetrova**[1], S. S. Amelina[1], E. L. Dadali[2], R. A. Zinchenko[2];*
[1]Rostov Region Hospital, Rostov-on-Don, Russian Federation, [2]Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Research of Hereditary Neuromuscular Disorders (HND) is especially important because of their prevalence among neurological disorders is high, most neuromuscular disorders have a progressive course with a lethal outcome. The population of 12 districts was examined to access prevalence of HND in Rostov Region. Total size of investigated population was 497460. Data collection and processing were done according to the protocol of Genetic Epidemiology Laboratory of Medical Centre in Moscow. The HND in Rostov Region's population compose 80% of all hereditary nervous system diseases. Their prevalence is 25,73 per 100,000. Hereditary motor and sensory neuropathy (HMSN) is the most common HND in Rostov Region. This study identified 54 cases of HMSN in 26 families. The prevalence was 10,86 per 100,000. DNA testing was performed to identify duplication of the gene *PMP22* in all patients. The mutations were found in members of 6 families. Myotonic dystrophy (MD) is the most common adult-onset muscular dystrophy. We found 21 cases with clinical manifestations of MD. The prevalence was 4,22 per 100,000. We observed tremendous variability in the phenotypic expression and severity of the disease, especially within families. This study identified 16 cases of Duchenne/Becker muscular dystrophy in 13 families. The prevalence was 6,43 per 100,000 male. DNA testing was performed to identify deletions in gene *DMD*; 3 families with Duchenn/Becker muscular dystrophy had deletions. HMSN, Duchenne/Becker muscular dystrophy, and MD are prevailing HND among Rostov Region's population, which is also true for the Russian Federation neuropathology spectrum.

P10.35
Effective Prediction of HLA Allele Genotypes Using SNP Data for a Han Chinese Population

***S. Chang**[1], P. Chen[2,3], T. Chang[3,4], C. Chang[5], C. S. J. Fann[1];*
[1]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, [2]Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan, [3]Division of Endocrinology & Metabolism, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [4]Department of Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan, [5]Graduate Institute of Clinical Medical Sciences, Chang-Gung University, Taipei, Taiwan.

Genetic variation at classical human leukocyte antigen (HLA) loci has played an important role in the regulation of fundamental molecular or cellular processes and susceptibility to various diseases. Direct typing of HLA alleles can provide insights into complex associations among genomic structure, SNP variation and variation at respective alleles. However, the excessive cost has compelled researchers to adopt more economical approaches, such as SNP-based tagging and allele prediction algorithms. In this study, we modified a statistical methodology developed by Leslie et al. (2008) and applied it to predict alleles at 6 classical HLA loci (HLA-A, -B, -C, -DPB1, -DQB1 and -DRB1) by using commercially available SNP data including Illumina HumanHap550K, Affymetrix 500K SNP, Affymetrix SNP 6.0 genotypes alone and combinations of them within the MHC region for the sample of 437 unrelated Han Chinese individuals residing in Taiwan. Our results indicated that overall, a single panel of ~160 SNPs typed across the region was sufficient for predicting HLA alleles at 6 loci with up to 98% accuracy at 4-digit resolution. In conclusion, the effective prediction algorithm provides a low-cost alternative to direct typing of HLA alleles and sheds light on building a representative estimation background of HLA allele genotypes in the Han Chinese population. Moreover, the specific prediction SNP sets may aid in disease screening and medical treatment in the future.

P10.36
Huntington Disease in Hungary

***E. Sáfrány**[1], L. Balikó[2], J. Nemes[1], E. Baricza[1], B. Duga[1], C. Sáfrány[1], B. Melegh[1];*
[1]Department of Medical Genetics, Pécs, Hungary, [2]Department of Neurology and Stroke, County Hospital, Veszprém, Hungary.

Huntington disease (HD) is a dominantly inherited neurodegenerative disorder that results from a mutation that expands the polymorphic trinucleotide (CAG) tract in the *HTT* gene. Molecular genetic analysis is available since 1997 in our Institute in Hungary. Until the end of 2010 we genotyped 319 subjects originating from 195 families. Amongst them 149 people were tested positive with a repeat length ranging from 40 to 90 CAG repeats (46.7% of all tests). 32 subjects carried an intermediate allele (10.0% of tests), with CAG repeat ranging from 26 to 36.
Epidemiological studies report a wide variation of HD prevalence. Molecular studies suggested that different prevalence rates could be due to differences in other genetic factors responsible for the disease. In this respect, we analysed the CCG length polymorphism that is adjacent to the CAG region and compared our results to those of other European studies. The CCG7 allele was overrepresented among affected chromosomes (94.6%), while we found a low percent of the CCG10 allele (5.38%); this result is in accordance with studies performed previously on other European populations. Since the origin of Hungarian population differs from other European Caucasian ethnical groups, as founders of the ancient Hungarian state were from the eastern side of the Ural Mountains, we might expect different frequencies of the intragenic polymorphisms compared to populations of Western European ancestry. The fact that we found similar frequencies suggests that the founder mutation of HD in Hungary is of Western European and not of Asian origin.

P10.37
Investigation of CAG and CCG repeats in affected patients and risk group of Huntington disease in 61 Brazilian individuals.

***L. A. Agostinho**[1], C. R. Rocha[1], E. Medina-Acosta[2], H. N. Barboza[2], A. F. A. da Silva[2], S. P. Pereira[3], E. R. Paradela[1], A. S. Figueiredo[1], D. Coelho[1], E. M. Nogueira[1], R. P. Alvarenga[1], S. R. dos Santos[1], C. L. A. Paiva[1];*

Brazil, [2]Universidade Estadual do Norte Fluminense Darcy Ribeiro (UENF), Campos dos Goytacazes, Brazil, [3]FAMINAS, Muriaé, Brazil.

Huntington Disease (HD) is a rare fatal neurodegenerative genetic disease. In this study we determined, in 61 Brazilian individuals, the sizes of the polymorphic CAG and CCG regions and correlated these sizes to age at onset of HD. We also investigated the genetic origin of *IT15* gene (4p16.3) and calculated the minimum prevalence of HD for Ervalia City, Brazil. PCR-SSP was used for amplifiying the target regions, and amplicon size was determined by capillary electrophoresis. It was found that 13 subjects had normal alleles. Out of the 48 subjects with abnormal alleles, two had intermediate number of CAG repeats (27-35) and no HD phenotype; and 46 individuals had expanded alleles. The average age of onset of HD was 41.7 years. The correlation between number of CAG repeats and age of onset of clinical manifestations was negative (r = -0.84). There was no statistically significant correlation between CCG repeats and age at onset of HD (r = 0.26). Among those cases that had expanded alleles, 11 had alleles with reduced penetrance (36-39 CAG) and 35 had alleles with complete penetrance (> 39 CAG). Alleles of 7 or 10 CCG repeats are predominant in populations, and strong linkage disequilibrium between the CCG(7) allele and HD has been shown in western HD chromosomes. CCG(7) alleles were found in 78% of 48 individuals who had abnormal alleles. Therefore, the majority the mutated *IT15* genes for HD show putative Western European ancestry. Minimum prevalence of HD for Ervalia was nine times higher than in Europe.

P10.38
Origin and possible ways of evolution of Huntington's disease alleles in Ukrainian population

***N. V. Hryshchenko**, L. A. Livshits;*
Institute of Molecular Biology and Genetics NAS of Ukraine, Kyiv, Ukraine.

Huntington's disease (HD) is a late onset neurodegenerative disorder resulting from an expansion of a CAG-repeats of *HTT* gene on 4p16.3. The frequencies of HD are different in ethnic groups (0,6-100:1000000). The highest ones are found in countries of European origin.

To investigate the *HTT* gene expansion alleles' origin and possible ways of evolution in Ukrainian population the analysis of allelic of CGG-repeats and "del2642" polymorphisms of *HTT* gene was conducted in a group of HD-patients with CAG-expansions (40-52 CAG-repeats) and their relatives from Ukraine. CAG-expansion was found in chromosomes 4 marked by different CCG-allele variants (7, 8, 10, 12 CCG-repeats). Linkage disequilibrium between expanded CAG-alleles and the major $(CGG)_7$-allele (83%) has been displayed. We also found that the frequency of 2642-deletion of *HTT* gene is significantly higher in the group of HD-patients than in controls. Its may be due to "Western Europe founder" effect of HD-chromosomes with $(CCG)_7$-del2642 haplotypes. High frequency of $(CGG)_{10}$-allele in HD-chromosomes (12%) may be a result of migration from populations in which the HD-chromosomes are predominantly marked by this CCG-variant (Asia, ets.). Minor CCG-alleles ($(CCG)_8$ and $(CCG)_{12}$) may appear due to step-by-step mutations of major alleles. We also studied instable intermediate CAG-alleles (27 CAG-repeats of HTT gene). It has been shown that these chromosomes (5% of normal ones) have $(CCG)_7$-del2642 haplotypes (single origin). Our findings suggest that HD-mutation in Ukraine has a recurrent origin. We also found that the *de novo* HD-expansions may arise from intermediate CAG-alleles on chromosomes 4 with $(CCG)_7$-del2642 HTT-haplotypes.

P10.39
A molecular-based estimation of the prevalence of hypophosphatasia in the European population

***E. Mornet**[1,2], A. Yvard[2], A. Taillandier[2], D. Fauvert[1,2], B. Simon-Bouy[2];*
[1]UPRES EA-2493 University of Versailles, Versailles, France, [2]Laboratoire SESEP, Centre Hospitalier de Versailles, Le Chesnay, France.

The prevalence of hypophosphatasia (HP), a rare metabolic disorder due to mutations in the *ALPL* gene, has never been estimated in the European population. Only one published study evaluated the incidence of severe HP at 1/100,000 in Canada 53 years ago. Moderate forms of hypophosphatasia (mHP), including HP with moderate bone features and the mildest form odontohypophosphatasia, reflect both recessive and dominant inheritance, and are therefore expected to be more frequent than severe forms. Here we estimated both the prevalences of severe and mHP in European populations. The prevalence of severe HP was estimated at 1/300,000 on the basis of the number of cases tested in our laboratory and originating from France during the period 2000-2009. We observed a significant discrepancy between North and West Europe where the prevalence was similar to France (1/340,000), and South and East Europe where the value was significantly lower (1/1,360,000). This difference may be due to several factors among which no request of mutation analysis and molecular testing in other laboratories than ours, but also to particular recurrent mutations in North and West Europe reflecting founder effects. The prevalence of mHP was then estimated by using the proportion of dominant mutations among severe alleles and by estimating the penetrance of the disease in heterozygotes for dominant mutations. According to a genetic model with 4 alleles resulting in 10 distinct genotypes, the prevalence of dominant mHP in the European population was estimated at 1/6370, pointing out that mHP is much more frequent than severe HP.

P10.40
Estimating the prevalence of autosomal recessive disorders through mutational records and consanguinity: the Homozygosity Index (HI)

***A. Gialluisi**[1], T. Pippucci[1], Y. Anikster[2], U. Ozbek[3], M. Medlej-Hashim[4,5], A. Mégarbané[4], G. Romeo[1];*
[1]Unità Operativa di Genetica Medica, Dipartimento di Scienze Ginecologiche, Ostetriche e Pediatriche, Bologna, Italy, [2]Metabolic Disease Unit, Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Tel Hashomer, Israel, [3]Genetics Department, Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, [4]Unité de Génétique Médicale and Inserm, Laboratoire International Associé à l'UMR_S 910, Université Saint Joseph, Beirut, Lebanon, [5]Department of Life and Earth Sciences, Faculty of Sciences, Branch II, Lebanese University, Beirut, Lebanon.

Mutational records make it possible to estimate frequencies of disease alleles (q) for autosomal recessive disorders using a novel approach based on the calculation of the **Homozygosity Index** (HI), i.e. the proportion of homozygous patients, which is complementary to the proportion of compound heterozygous patients P(CH). To test this hypothesis, we used mutational records of individuals affected with Familial Mediterranean Fever (FMF) and Phenylketonuria (PKU), born to either consanguineous or apparently unrelated parents from six Mediterranean population samples. Our method gave q estimates very similar to those of previous descriptive epidemiological studies (Table 1). By simulation studies, the minimum sample size needed for this approach is of 25 patients with either unrelated or first cousins parents. These results indicate that the **Homozygosity Index** can give a ranking order of prevalence for autosomal recessive disorders, especially in populations with high frequencies of consanguineous marriages.

Gene	Country	inbreeding coefficient (F)	Sample size	HI	q	P
MEFV	Lebanon	0.0625	34	0.5588	0.123 (0,095[1])	1:66 (**)

Association between K469E and R241G polymorphisms of intercellular adhesion molecule 1 and inflammatory bowel disease in Iran

M. Habibi[1], *N. Naderi*[1], *A. Farnood*[2], *H. Balaii*[1], *T. Dadaei*[1], *S. Almasi*[1], *M. Zali*[1];
[1]*Reserch center of castroenterology and liver diseases shaheed beheshti university of medical science, Tehran, Islamic Republic of Iran,* [2]*Tehran university of medical science, Tehran, Islamic Republic of Iran.*

Introduction: Inflammatory bowel disease (IBD) consists of ulcerative colitis (UC) and Crohn's disease (CD), two chronic idiopathic inflammatory diseases of the gastrointestinal tract. Among various genes contributing in IBD susceptibility, Intercellular adhesion molecule (ICAM)-1 and its polymorphisms are of concern. ICAM-1 gene is located on chromosome 19p13 and plays a pivotal role in the inflammatory processes. There are two single base polymorphisms of ICAM-1 gene (G241R and K469E). In this study, we examined the association between G241R and K469E, and IBD in Iranian patients.
Material and Method: In this case-control designed study, 156 IBD patients (110 UC and 46 CD patients) and 131controls were enrolled. The study was performed in Shaheed Beheshti University during 2006 - 2009. The polymorphisms (G241R and K469E) were assessed by polymerase chain reaction (PCR) followed by restriction fragment length polymorphism (RFLP).
Results: The mutant allele of R241G was more frequent in CD patients compared to controls (33.7% vs. 22.9%; p=0.042; OR=1.71; 95%CI: 1.02-2.88) and K469E mutant allele frequency was significantly higher in CD patients compared to controls (55.4%vs. 40.5%; p=0.013; OR=0.546; 95%CI: 0.34-0.88). No difference was observed among UC patients compared to controls.
Conclusion: Our findings suggest that both mutations of ICAM1 gene may probably participate in pathogenesis of Crohn's disease in Iran

P10.42
Relationship of *iNOS* gene expression with *TNF-α* and *iNOS* gene polymorphisms among Iranian Mazandarani and Turk populations

F. Biramijamal[1], *S. Khoshbakht*[2], *A. Hossein-Nezhad*[3];
[1]*NIGEB, Tehran, Islamic Republic of Iran,* [2]*NIGEB & Azad University, Tehran, Islamic Republic of Iran,* [3]*Endocrinology and Metabolism Research Center, Tehran, Islamic Republic of Iran.*

The identification of genetic alterations in different populations could be useful in recognizing the therapeutic aspects of drugs as well as estimating the prevalence of a variety of diseases. The promoter polymorphisms of -308G/A in *TNF-α* gene as well as -954G/C and CCTTT repeat polymorphism of *iNOS* gene were studied in this research. Due to similar conditions of *TNF-α* and *iNOS* production, the polymorphisms of these genes were studied in both Iranian Turk and Mazandarani ethnic groups. In addition, the expression of *iNOS* gene in transcriptional level has analyzed in comparison with *iNOS* polymorphism genotypes.
To identify the genetic polymorphisms, the PCR-RFLP and sequencing based method were used. The expression of *iNOS* gene was measured by real-time PCR. The results revealed that allele frequency of polymorphic -308A allele of *TNF-α* in Turk and Mazandarani ethnic groups was 15.5% and 16.3% respectively. The polymorphic -954C allele of *iNOS* gene was not observed in both ethnic groups. The most prevalent CCTTT repeat number in promoter region of *iNOS* gene in both groups was shown as 14 repeats. The transcriptional expression of *iNOS* was higher in presence of 15 repeats of CCTTT rather than 14 repeats. Moreover, it was shown that the presence of A allele at -308 position of *TNF-α* gene is associated with lower expression of *iNOS* in transcriptional level (p <0.001). In conclusion, the results of this study suggest the effect of *TNF-α* gene polymorphism on *iNOS* gene expression and this can be modified the inflammation process in the cell.

P10.43
Genetics population flows in the region comprised by the former Kingdom of Granada

M. Saiz[1], *L. Martínez-González*[2], *M. Álvarez-Cubero*[1], *B. Sánchez Martín-Moreno*[1], *J. Álvarez*[1,2], *J. Lorente*[1,2];
[1]*Legal Medicine and Toxicology Department, Faculty of Medicine, University of Granada, Granada, Spain,* [2]*GENYO (Pfizer - University of Granada & Andalusian Government Centre for Genomics & Oncology), Granada, Spain.*

The study of genetic markers allows the characterization of the populations as well as the genetics relationships between them.
A lot of authors have studied the genetic relationships established between North African and South European people as well as the relationships with Iberian Peninsula inhabitants in order to determine the genetic legacy that remains in the present population. But, nowadays, there are not any studies which explain the genetic relationship between the population of Granada, Málaga and Almería (GMA), former Kingdom of Granada; and all those African people who inhabited in this region for more than 700 years and had an influence in its creation and establishment.
That is why, 15 STR genetic markers from 100 non-related individuals (aSTR), residents of Granada, Málaga and Almería, have been studied. Observed-allelic frequencies and common-use forensic parameters have been analyzed. Furthermore, genetic structure and its homogeneity have been studied. For a better characterization of our population, GMA population has been compared with North African, Iberian Peninsula, South European populations. Genetic distances between all the populations have been calculated. Moreover, a correspondence analysis of the allelic frequencies of the genetic markers has been executed.
By the analysis of all the results, it can be affirmed that, owing to the studied genetic markers, the GMA population maintains characteristics that show the genetic influence of North African people, even though our population resembles the rest of the Spanish population.

P10.44
Epidemiological study of Leber's Hereditary Optic Neuropathy in the Novosibirsk District, Russian Federation

I. O. Mazunin[1], *N. V. Volodko*[1], *E. B. Starikovskaya*[1], *I. Y. Bichkov*[2], *I. E. Mikhaylovskaya*[2], *R. I. Sukernik*[1];
[1]*Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation,* [2]*Regional Center of Eye Microsurgery, Novosibirsk, Russian Federation.*

A 10-year epidemiological study of Leber's Hereditary Optic Neuropathy (LHON) in the Novosibirsk District, Russian Federation revealed the prevalence of the disease is at least 1/45,000. We have found primary LHON mutations (3460, 11778 and 14484) in only 44% of LHON pedigrees and only 30% of them are caused by 11778 pathogenic mutation. So-called LHON-like patients with the clinical characteristic of LHON disease (Abu-Amero and Bosley 2006) compose 56% of our sample. Phylogenetic analysis of the entire mtDNA sequences of all patients in this study showed that certain novel and haplogroup-specific mtDNA mutations meet the criteria of the pathologic mutations. Our data imply that genetic modifiers, such as haplogroup-specific mutations in mtDNA and various mutations in nDNA-encoded mitochondrial genes, may promote disease development in Russian LHON patients.

P10.45
Interaction within LPA gene between two multiallelic polymorphisms (5'PNRP and KIV2RP) influences Lp(a) levels and is revealed as a risk factor for Myocardial Infarction in a Spanish family-based sample.

R. Carreras-Torres, *M. Via, E. Esteban, P. Moral;*
Faculty of Biology - University of Barcelona, Barcelona, Spain.

LPA gene codes for apolipoprotein(a) (apo(a)), which constitutes part of lipoprotein(a) (Lp(a)) and influences Lp(a) bloodstream levels, important risk factor for early atherosclerosis and myocardial infarction. LPA gene chromosomal region (6q26-q27) has recently emerged as one of the top 12 loci associated with Coronary Artery Disease/Myocardial Infarction (CAD/MI) in recent Genome-Wide Association Studies (GWAS). In this work we test the influence on Lp(a) levels and the association with MI of two repeat polymorphism, 5' Pentanucleotid (TTTTA) repeat polymorphism (LPA 5'PNRP) and Kringle IV-type2 domain repeat polymorphism (LPA KIV2RP), in 101 family trios from Spain with younger than 55 MI affected descendent (N=302 individuals). The polymorphism were not in LD. Significative correlation showed an inverse relationship between Lp(a) levels and mean repeat number of 5'PNRP and KIV2RP in the whole sample, but only for 5'PNRP in the patients sample. The analyses of variance showed a significative interaction between mean repeats of 5'PNRP

and KIV2RP for Lp(a) levels in the patient sample, explaining the 63,4% of the observed variance of Lp(a) levels. In order to test for Transmition Disequilibrium (TDT) the alleles were grouped into categories. No transmition deviation was observed for the single alleles. But, it was observed overtransmition for the most frequent haplotype (0.197) (p=0.007), which grouped the shorter alleles of both polymorphisms (5'PNRP*8 repeats and KIV2RP*<23 repeats). This results revealed an interaction effect between the shorter repeats of 5'PNRP and KIV2RP on the Lp(a) levels and, in consequence, on the risk of early atherosclerosis and myocardial infarction.

P10.46
Human lymphatic filariaisis: Genetic Polymorphism of Endothelin-1 and TNF receptor II correlate with development of chronic disease

A. K. Panda[1], *P. K. Sahoo*[2], *A. S. Kerketta*[2], *S. K. Kar*[2], *B. Ravindran*[1], *A. K. Satapathy*[2];
[1]*Institute of Lifesciences, Bhubaneswar, India,* [2]*Regional Medical Research Centre, Bhubaneswar, India.*

Background: Hydrocele and elephantiasis are two clinically very diverse and often mutually exclusive chronic manifestations of human bancroftian filariaisis. Plasma levels of Endothelin-1(ET-1), a major angiogenic factor and TNF receptors (TNFRs) that regulate host inflammation have been associated with development of chronic filariasis although their genetic basis are not known.
Methods: We studied polymorphisms of ET-1(Ala288Ser) and TNFRII (Met196Arg) genes by means of polymerase chain reaction confronting two pairs primers method and restriction fragment length polymorphism respectively. Plasma ET-1 levels was measured by Enzyme-linked immunosorbent assay.
Results: Met196Arg genotype frequency of TNFRII polymorphism was significantly more in hydrocele cases in comparison to elephantiasis patients (OR: 4.34 and 95% CI: 2.04 to 9.20). Conversely, significantly high prevalence of Ala288Ser mutation of Endothelin-1 was observed in elephantiasis patients as compared to hydrocele cases (OR: 2.15 and 95% CI: 1.13 to 4.10). Decreased plasma ET-1 levels correlated significantly with Ala288Ser mutation in the study population. A combined analysis indicated a 23 fold for higher risk for developing elephantiasis in subjects with TNFRII (Met196Met) and ET-1(Ser288Ser).
Conclusions: ET-1 (Ala288Ser) and TNFRII (Met196Arg) polymorphisms are associated with development of one or the other forms of chronic disease in bancroftian filariasis.

P10.47
Mannan-binding lectin serine peptidase 2 gene (MASP2) polymorphisms in rheumatoid arthritis patients from Brazil.

I. Goeldner[1], *S. R. R. Utiyama*[1], *T. L. Skare*[2], *A. B. W. Boldt*[1], *I. T. M. Reason*[1];
[1]*Laboratory of Molecular Immunopathology, Clinical Hospital, Federal University of Paraná, Curitiba, Brazil,* [2]*Rheumatology Unit of Evangelic University Hospital, Curitiba, Brazil.*

Aims. Rheumatoid arthritis (RA) is an autoimmune disease (AID) which affects at least 1% of the world's population. The immunopathogenesis of RA is not entirely clarified but the importance of complement system in its development is unquestionable, although still poorly understood. The present study aimed to evaluate the prevalence of MASP2 gene polymorphisms in patients with RA from Brazil.
Methods. Nine MASP2 polymorphisms distributed from the promoter to the last exon were haplotyped through multiplex PCR amplification with sequence-specific primers. A total of 156 RA patients (24 male, 132 female, mean age 51 [24-65] years) and 125 healthy individuals (18 male, 107 female, mean age 43 [24-69] years) were investigated. The study was approved by the local ethics committee.
Results. We identified 10 different MASP2 haplotypes with genotype distributions in Hardy and Weinberg equilibrium. There was a trend for higher frequency of MASP2 haplotypes with the p.D120G and p.P126L polymorphisms, causing low MASP-2 levels in the RA patients (Fisher exact test = 0.06), but no difference was found in the frequencies of high-, low and intermediate MASP-2 producers between patients and controls.
Conclusions. In the present analysis, we did not find an association of MASP2 polymorphisms and haplotypes with RA disease.

P10.48
The utility of commercial STRs beyond forensic purposes: Population relationships in North Africa

M. Gaibar[1], ***M. Esteban***[2], *M. Via*[2], *P. Moral*[2], *M. Kandil*[3], *N. Harich*[4], *A. Fernández-Santander*[5];
[1]*Dpt. de Ciencias Biomédicas Básicas, Facultad de Ciencias Biomédicas, Universidad Europea de Madrid, Villaviciosa de Odon, Spain,* [2]*Secció d'Antropologia, Dpt. Biologia Animal, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain,* [3]*Dpt. Biologie, Faculté des Sciences, Université Chouaïb Doukkali, El Jadida, Morocco,* [4]*Dpt. Biologie, Faculté des Sciences, Université Chouaïbb Doukkali, El Jadida, Morocco,* [5]*Dpt. de Ciencias Biomédicas Básicas, Facultad de Ciencias Biomédicas, Universidad Europea de Madrid, Villaviciosa de Odón, Spain.*

The variability of 15 commercial STRs used for forensic purposes has been employed in this work to analyze the relationships of different Arabic and Berber-speaking North African ethnic groups. A total of 165 individuals from the Doukkala and Khenifra Moroccan regions have been genotyped using the AmpFISTR identifiler kit (Applied Biosystems, Foster City, CA, USA). Data from these two samples completed a previous genetic database of five North African groups genotyped for a variety of autosomal polymorphisms (STRs, Alu, and Alu-STR combinations). The joint use of markers with different mutation rates could be very useful to detect ancient relationships and/or more recent demographic events such as gene flow. Our results underlined the genetic distinctiveness of North African samples (Morocco and Algeria) from North (Spain) and South East Mediterranean groups (Egypt). Differences in genetic heterogeneity estimates strengthened the necessity of taking into account information from genetic markers with different mutation rates to explain properly human population events. In particular, in those populations that share close geographic and historical relationships.

P10.49
Prevalence of rs41274239 polymorphism in the miRNA gene *miR96* in different ethnic groups in Siberia and in patients with common diseases

N. P. Babushkina, *V. Petrov, M. V. Golubenko, A. N. Kucher;*
Institute of Medical Genetics, Tomsk, Russian Federation.

MicroRNAs are short noncoding RNAs which are involved in posttranscriptional regulation of gene expression. The primary transcript of miR96 (7q32.2) generates miR96 and antisense product miR96* (miRBase:MI0000098). SNP rs41274239 (+36A/G) is located in the loop-like structure of pre-miR96; minor allele frequency is 2.8% (NCBI database). We have studied prevalence of this polymorphism in Siberian populations (Russians, Buryats, Yakuts. Tuvinians, 352 individuals in sum). The minor allele frequency in Russians was estimated as 1.05%, with only heterozygous genotypes; in other populations (all of mongoloid origin) the polymorphism was not found. We have studied also this SNP frequency in Russians with different diseases: ischaemic heart disease, hepatitis C, tuberculosis, asthma (126, 173, 207, 144 DNAs, respectively). The polymorphism was very rare in all groups, being registered only in heterozygous state with frequency from 0.24% in tuberculosis to 0.69% in asthma. In the pooled sample of patients, heterozygosity was 0.0094 +/- 0.0035; minor allele G frequency 0.47%. The present study is the first representative work on this SNP. The results show that the G allele of rs41274239is rare in Caucasians and was not registered in Mongoloid Siberian populations.

P10.50
Possible functional differences of the two mitochondrial DNA polymerase gamma (POLG) gene haplogroups

B. Malyarchuk, *M. Perkova, M. Derenko;*
Institute of Biological Problems of the North, Magadan, Russian Federation.

About 150 mutations in the human mitochondrial DNA polymerase gamma (POLG) have been identified in patients with mitochondrial diseases such as Alpers syndrome, progressive external ophthalmoplegia, and ataxia-neuropathy syndromes. However little is known about the haplotypic structure of this gene. Here we have sequenced *POLG1* gene 5'-promotor region and analyzed distribution of this gene haplotypes in two North Eurasian populations - in Russians (n=63) and Buryats (n=90). Only one polymorphic locus, namely rs2856268, was revealed in the 5'-promoter region studied. Comparison with our previous haplotypic data has shown that the alleles

rs2856268-G and -A are strongly associated with haplogroups A and B of the *POLG1* gene. Interestingly that association of the rs2856268 variants with diabetic polyneuropathy (DPN) in type 1 diabetes mellitus has been recently reported in Russians (Spitsina et al. 2009). It was found that the carriers of G-allele and GG-genotype had higher risk of DPN development than the carriers of A-allele and AA-genotype. One may suggest that the polymorphism in the 5'-promotor region can differentially modulate expression of the whole *POLG1* gene, pointing to a higher possibility for G-allele to determine a lower level both of the *POLG1* gene expression and the mtDNA repair. In addition, taking into account that haplogroups A and B could evolve separately for a long time (about 1.5 millions of years), it is important that possibly more accurate form of enzyme is associated with younger and more frequent in humans haplogroup B. This work was supported by the grant from FEB RAS (09-3-A-06-221).

P10.51
HaploGrep - automatic classification of mitochondrial DNA haplogroups

H. Weißensteiner[1], *S. Schönherr*[2], *D. Pacher*[2], *L. Forer*[1], *G. Specht*[2], *F. Kronenberg*[1], *A. Kloss-Brandstätter*[1];

[1]*Division of Genetic Epidemiology, Department of Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria,* [2]*Department of Database and Information Systems, Institute of Computer Science, University of Innsbruck, Innsbruck, Austria.*

Background: Human mitochondrial DNA (mtDNA) is routinely analyzed in various disciplines, such as medical genetics, population genetics and forensic genetics. For studying mechanisms of human evolution, discovering genes involved in complex diseases and quality management, the determination of the mtDNA haplogroup is a critical requirement. However, despite the availability of Phylotree, a regularly updated classification tree of global mtDNA variation, the process of haplogroup classification is still time-consuming and error-prone, as researchers have to manually compare the polymorphisms found in a population sample to those summarized in Phylotree, polymorphism by polymorphism, sample by sample.

Results: To eliminate these shortcomings we designed HaploGrep, a fast and reliable algorithm to determine the haplogroup affiliation of thousands of mtDNA profiles genotyped for the entire mtDNA or any part of it. HaploGrep is implemented as a freely available web application, uses open source technologies and scales well in time and space. For every input sample the top 10 results and the phylogenetic position of the respective haplogroups are displayed, thus providing a detailed explanation of how and why a haplogroup was ranked best. Furthermore, numerous export possibilities are given and all results are visualized in a tree structure, showing the current position in Phylotree with hints for further refinement of the actual haplogroup status and potential errors in the classification process.

Conclusions: HaploGrep uses the latest version of Phylotree and offers an all-in-one solution for quality assessment of mtDNA profiles in clinical genetics, population genetics and forensics. HaploGrep can be accessed freely at http://haplogrep.uibk.ac.at

P10.52
Autosomal and uniparental genetic diversity of the populations of Sakha (Yakutia): Implications for the peopling of Northeast Eurasia

S. A. Fedorova[1], *M. Reidla*[2], *E. Metspalu*[2], *M. Metspalu*[2], *S. Rootsi*[2], *K. Tambets*[2], *B. B. Yunusbayev*[3], *J. Parik*[2], *I. A. Kutuev*[3], *M. I. Tomsky*[1], *E. K. Khusnutdinova*[3], *R. Villems*[2];

[1]*Yakut Research Center of Complex Medical Problems, Russian Academy of Medical Sciences, Yakutsk, Russian Federation,* [2]*Department of Evolutionary Biology, University of Tartu and Estonian Biocentre, Tartu, Estonia,* [3]*Institute of Biochemistry and Genetics, Ufa Research Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Sakha Autonomous Republic occupies a quarter of Siberian total land area in its northeastern part, is an important region for understanding the colonization of the Northern Eurasia by anatomically modern humans. To characterize the genetic variation in Sakha both the haploid mitochondrial DNA (mtDNA) and Y chromosomal as well as diploid autosomal loci (650 000 SNPs) of genome were analyzed in five native populations of Sakha (Yakuts, Evenks, Evens, Dolgans and Yukaghirs).

While striking prevalence of Y chromosome haplogroup N1c in gene pool differentiates Yakuts from other populations, the mtDNA and autosomal analyses demonstrate genetic similarity of all native populations of Sakha, in particular Yakuts and Evenks. The results also demonstrate closest genetic proximity of the populations of Sakha with southern Siberians. Both mtDNA and autosomal analyses reveal deep genetic discontinuity between Siberian and Beringian populations. MtDNA haplogroups A2 and G1b, prevalent in Beringian populations, are either minor or even absent in Sakha, where haplogroups C and D dominate. Autosomal analysis also differentiates Beringian populations from those of Sakha. Our results support the scenario that the territory of Sakha was colonized from the regions west and eastward of Lake Baikal with only minor gene flow from Lower Amur/Southern Okhotsk region and/or Kamchatka.

P10.53
Genetic epidemiology of DFNB1-associated hearing loss in Russia

E. I. Sharonova, *R. A. Zinchenko;*

Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

The major objective of this study was to determine contribution of DFNB1 locus allelic variants to development of non-syndromic hereditary hearing loss (NSHL) among Russian patients of different populations. 228 NSHL patients were analyzed. 35delG mutation was responsible for development of disease in few cases (Chuvash Republic - 28,6%; Republic of Bashkortostan - 0,0%; Republic of Udmurtia - 50,0%; Kirov Region - 26,8%; Rostov Region - 19,2%).

We determined the effect of other mutations in DFNB1 in NSHL progression in different groups of Russians. We analyzed coding exon of Cx26. As the result, the number of patients with identified alleles achieved 35.8% in Kirov Region and 30,8% in Rostov Region. Second mutation has been identified in almost all patients heterozygous for 35delG. However, spectrum of mutations differed in investigated areas. We analyzed noncoding exon of Cx26, but no changes were observed.

We have shown the differences in allele frequencies involved in formation of DFNB1-associated NSHL in different Russian patients. Furthermore, sequencing of coding exon of Cx26 increased the proportion of patients with a confirmed diagnosis beside the analysis of 35delG mutation only. Involvement of Cx30 wasn't confirmed in this type of NSHL development.

Based on our investigation, we could postulate the feasibility of testing of the coding exon of Cx26 in DFNB1-patients of Russian nationality during genetic diagnosis. It's required to search for additional mutations in DFNB1 which are not detected by sequencing of Cx26 and Cx30, as well as in other genes involved in genetic interactions with Cx26.

P10.54
Prevalence monogenetic syndromes of multiple congenital malformations in population of Rostov region (Russia)

T. Ponomareva[1], *S. S. Amelina*[1], *R. A. Zinchenko*[2];

[1]*Rostov regional clinical hospital, Rostov-on-Don, Russian Federation,* [2]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

A total medical genetically study of the population of the Rostov region was carried out (12 districts - 497,460 total investigated persons). Monogenic syndromes of multiple congenital malformations (MMCM) was examined. The overall prevalence of MMCM was 1:2292 persons. Among the syndromes MMCM with autosomal dominant (AD) inheritance type was identified 29 diseases in 129 patients, with autosomal recessive (AR) inheritance type was identified 19 diseases in 32 patients, with X-linked type of inheritance - 6 of diseases in 15 patients. Sporadic syndromes MMCM was identified in 41 patients (6 diseases). Among frequent syndromes MMCM with AD type of inheritance were revealed Noonan syndrome (prevalence of 1:18424), Aarskoga syndrome (1:41455), Opitz BBBG syndrome (1:55273), Klippel-Feil syndrome (1:55273), Greig cephalopolysyndactyly syndrome (1:71066), Waardenburg syndrome, type I (1:82910), hemifacial microsomia (1:82910), EEC syndrome (1:82910), LEOPARD syndrome (1:82910). Some syndromes had met with a lower prevalence (1: 100001-1:200000): camptodactyly with muscular hypoplasia, skeletal dysplasia, and abnormal palmar creases, Pfeiffer

syndrome, Saethre-Chotzen syndrome, Beckwith-Wiedemann syndrome, velocardiofacial syndrome, Williams syndrome, Prader-Willi syndrome, frontonasal dysplasia. Among the most frequent syndromes MMCM with AR inheritance type were identified Dubowitz syndrome (1:99492), Coffin-Siris syndrome (1:165820), Seckel syndrome (1:165820). Among the most frequent syndromes MMCM with X-linked type of inheritance were identified Lujan-Fryns syndrome (1:82910), Coffin-Lowry syndrome (1:165820). Among the frequent sporadic form of syndromes MMCM were identified constricting bands, congenital (1:17154), Pallister-Killian syndrome (1:165820), VATER-association (1:165820). These results agree with data previously surveyed populations of Russia.

P10.55

Association of *OS*, *ESR1*, *COL1A*1 and *CALCR* gene polimorphisms with osteoporosis in postmenopausal women

*S. Tural[1], **N. Kara**[1], G. Alayli[2], L. Tomak[3];*

[1]Ondokuz Mayis University, Faculty of Medicine, Department of Medical Biology and Genetics, Samsun, Turkey, [2]Ondokuz Mayis University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Samsun, Turkey, [3]Ondokuz Mayis University, Faculty of Medicine, Department of Biostatistics, Samsun, Turkey.

Osteoporosis is a common multifactorial disease characterized with reduced bone mass. The purpose of this study was to examine the relationship between osteoporosis and variants of osteocalcin (*OS*) -298 C>T, estrogen receptor 1 (*ESR1*) 397T>C, collagen type 1 alpha 1 (*Col1A1*) 2046G>T and calcitonin receptor (*CALCR)* 1340T>C. Blood samples collected from 158 postmenopausal women with osteoporosis and 108 postmenopausal healthy female controls were analyzed by PCR-RFLP method.

ESR1 CC genotype compared with TT + TC genotypes were found to increase two fold the risk of osteoporosis. [p= 0.039 OR=2.156 %95CI (1.083-4.293)]. *CALCR* CC genotype compared with TT+TC genotypes were found to be protective effect against osteoporosis [p=0.045 OR=0.471 %95CI (0.237-0.9372)]. There was no statistically significant difference in the genotype and allele frequencies of patients and controls for *OS* -298 C>T (p= 0.293, p= 0.437, respectively) and *Col1A1* 2046 G>T polymorphisms (p= 0.283, p= 0.491, respectively). In the combined genotype analysis, *ESR1/CALCR* TCCC combined genotype was found to be protective effect against osteoporosis [p=0.0125 OR=0.323 %95 CI (0.1383-0.755)]. However, *OS/Col1A1* CCTT and *ESR1/CALCR* CCTT combined genotypes were risk factors for osteoporosis (p=0.027, p=0.009).

According to the results of our study, *ESR1* CC genotype and *OS/Col1A1* CCTT, *ESR1/CALCR* CCTT combined genotypes cause a predisposition to osteoporosis. However, CC genotype of *CALCR* gene and *ESR1/CALCR* TCCC combined genotype have a protective effect against osteoporosis. This is the first study in Middle Black Sea region, by enlarging the study population we hope that more explanatory and definitive results can be obtained.

P10.56

Different patterns of TLR2 polymorphisms in populations of various ethnic and geographical origins

***M. Ioana**[1,2,3], A. Cimpoeru[2], B. Ferwerda[1,4], T. S. Plantinga[1], F. Burada[2], M. Oosting[1], N. M. Panduru[3], M. G. Netea[1];*

[1]Department of Internal Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Medicine and Pharmacy Craiova, Craiova, Romania, [3]University of Medicine and Pharmacy "Carol Davila", Bucuresti, Romania, [4]Department of Genetics, University of Pennsylvania, Philadelphia, PA, United States.

BACKGROUND: Innate immunity is triggered upon invasion of the host by microorganisms through pathogen recognition by pattern recognition receptors (PRRs). The best studied class of PRRs, Toll-like receptors (TLRs) recognize specific pathogen-associated molecular patterns (PAMPs) from various microorganisms. Genetic variation in TLRs may influence susceptibility to infections. We studied genetic variation of TLR2 in various populations and whether this variation may be due to genetic drift or natural selection.

MATHERIAL AND METHODS: We have recruited a total of 776 individuals from different populations classified according to geographic and ethnic criteria into 7 groups: Romanians, Vlax-Roma, Dutch (European populations), Han-Chinese (East-Asia), Dogon, Fulani (Africa), and Trio-Indians (America). We genotyped three non-synonymous TLR2 polymorphisms: 1892C>A, 2029C>T and 2258G>A. To avoid false-possitive results for 2029C>T we have also sequenced the TLR2 non-coding exon 3 duplication.

RESULTS AND CONCLUSIONS: The 2029C>T seems to be absent among both European and non-European populations, with the exception of the Vlax-Roma, suggesting that this polymorphisms most likely aroused in Indo-Aryan people after migration into South-Asia. Due to very low frequency of the minor allele (1.3%), it was difficult to identify enough individuals bearing this mutation, in order to perform experiments on its functional effects. 1892C>A was found exclusively in European populations, but not in Asian, African or American volunteers, probably occurred in Proto-Indo-Europeans. Interestingly, 2258G>A was present only in Europeans, but not in Vlax-Roma. The differential pattern of the various TLR2 polymorphisms in various populations may explain some of the differences in susceptibility to infections between these populations.

P10.57

Phylogeographic Analysis of Mitochondrial DNA in the Arabian Peninsula

***V. Fernandes**[1,2], V. Černý[3], F. Alshamali[4], N. M. Silva[1], P. Soares[1], L. Pereira[1,5], M. B. Richards[2];*

[1]Instituto de Patologia e Imunologia Molecular da Universidade do Porto (IPATIMUP), Porto, Portugal, [2]Institute of Integrative and Comparative Biology, Faculty of Biological Sciences, University of Leeds, Leeds, United Kingdom, [3]Institute of Archaeology of the Academy of Sciences of the Czech Republic, Prague, Czech Republic, [4]Dubai Police GHQ, General Department of Forensic Sciences & Criminology,, Dubai, United Arab Emirates, [5]Faculdade de Medicina da Universidade do Porto, Porto, Portugal.

Phylogeographic analyses of mitochondrial DNA (mtDNA) provide insights into modern human evolution. In recent years, worldwide studies of contemporary mtDNAs have indicated that modern humans left Africa ~60,000-70,000 years ago along the "southern coastal route", across the Red Sea and via the Arabian Peninsula. Yet no obvious signs of the passage though Arabia have been found in genetics and archaeology fields. The aims of this work are to seek for possible mtDNA relicts of the initial dispersal from Africa in Arabia and to investigate the origins of lineages that arrived later. We are doing this by sequencing the complete mtDNA molecule (~16,568 bp) from unclassified lineages (referred to as the paraphyletic clusters L3*, N* and R*) and poorly studied haplogroups within the Eurasian macrohaplogroup N, which is predominant in Arabian populations today (86% in Saudi Arabia, 66% in Yemen and 79% in Dubai), in 90 samples from Dubai, Yemen, North/East Africa, the Near East and Europe. Our results will allow to test hypotheses about the settlement of the Arabian Peninsula.

P10.58

Prevalence of hereditary pathology among the childrenâ€™s population of Bashkortostan Republic of Russia

***L. A. Bessonova**, R. A. Zinchenko, E. K. Ginter;*

Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Results of prevalence of a monogenic hereditary pathology (MHP) among the children's population of Republic Bashkortostan (eight Districts) was submitted. The total size of investigated population was made 250110 people (64935 children). All Districts were examined by standard protocol of medical genetic research elaborated in laboratory of genetic epidemiology, Research Centre for Medical Genetics. About 2800 MHP and syndromes of OMIM could be identified by this research. Clinical investigations were performed by neurologists, ophthalmologists, orthopedic, otolaryngologies, dermatologists, pediatricians and clinical geneticists, focused on diagnostic of MHP. The load of children's population by all types MHP - autosomal dominant (AD), autosomal recessive (AR), and X-linked, separately for urban and rural populations was calculated. Total load of AD and AR disorders was 3.87Ã‘Â±0.24 and 2.51Ã‘Â±0.20 per 1000 children, X-linked disorders 0.92Ã‘Â±1.17 per 1000 boys. Our analysis showed that the total load of MHP in children is very high, and close to 1.4%. The spectrum of MHP detected in the eight Districts comprises 113 nosologycal forms. Spectrum of MHP was analyzed according to age of manifestation of disease, life expectancy of patients and fitness. The

total fitness of patients with AD pathology is close to unity (0.87), in families with AR pathology was 0.04, with X-linked disease was 0.16. Patients with low-fitness genotypes are rarely found among patients older than 30 years, and practically do not occur among patients older than 40 years. In this case, the reduction in fitness caused, as a low survival rate and almost zero fecundity.

P10.59
The genome sequence and assembly of world's oldest woman: a longevity reference genome

H. Holstege[1], *D. Sie*[1], *T. Harkins*[2], *C. Lee*[2], *T. Ross*[2], *S. McLaughlin*[2], *M. Shah*[2], *B. Ylstra*[1], *G. Meijer*[1], *H. Meijers-Heijboer*[1], *P. Heutink*[1], *S. Murray*[3], *S. Levy*[3], *G. Holstege*[4], *E. Sistermans*[1];

[1]*VU Medical Center, Amsterdam, Netherlands,* [2]*Life Technologies, Beverly, MA, United States,* [3]*Scripps Translational Science Institute, La Jolla, CA, United States,* [4]*University Medical Center Groningen, Groningen, Netherlands.*

Human genetic diversity has fundamental implications for understanding the genetic basis of diseases. Much effort is currently spent on identifying the genetic variants that are associated with longevity. However, an anonymous reference such as Hg19 can introduce a reference bias in longevity studies; a de novo assembly of a unique genome coding for long healthy life represents a more accurate biological reference genome for such projects.

We had the opportunity to study the genome of a woman who, at the time of her death, was the oldest human being alive in the world. She lived until the age of 115 years without experiencing any problems associated with vascular disease or dementia. At the age of 112-113, she was subjected to neuropsychological examinations, which revealed that her general performance was above average for healthy adults between 60-75 years. Post-mortal examination showed almost no signs of atherosclerotic plaque formation.

We sequenced and assembled the genome of this individual thus generating an independently assembled reference genome. For this, we employed short and long insert paired end reads on the SOLiD™ System. Initial analysis of this genome is focused on identifying the presence or absence of DNA variants associated with atherosclerosis as this is the main cause of death among older people, and the associated vascular dementia is a leading cause of dementia. Ultimately, we will use this genome as an independent reference for larger longevity studies such as the Scripps Wellderly study.

P10.60
MTHFR C667T polymorphism, folate level and hypertension in Croatian elderlies

Ž. Tomas[1], *M. Zajc Petranović*[1], *P. Krajačić*[1], *T. Škarić-Jurić*[2], *J. Miličić*[1], *S. Tomek-Roksandić*[3], *N. Smolej Narančić*[1];

[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Institute for Anthropological Research,, Zagreb, Croatia,* [3]*Dr. Andrija Štampar Institute of Public Health – Department of Gerontology, Zagreb, Croatia.*

The Methylenetetrahydrofolate reductase (MTHFR) enzyme is involved in reducing homocysteine level which, when elevated, has been found to predict cardiovascular events. Adequate blood folate status may decrease the circulating level of homocysteine and lower the incidence of cardiovascular diseases (CVD). We studied MTHFR gene variant C667T, its association with hypertension (HT) and CVD endpoints in Croatian elderly population (85-101 yrs; mean=88.23 yrs; N=303; 65.3% hypertensives). Compared to the previously reported data, the TT genotype frequency was twice as high in senescents as in Croatian general population (12.5% vs. 6%, p=0.023). The results of multiple logistic analysis in elderlies showed significance of younger age (<90 yrs) and TT genotype (OR 2.175, p=0.039) in predicting HT. T allele carriers had increased incidence of stroke in comparison to non-carriers (p=0.027). Further, we evaluated associations between MTHFR genotype, serum folate and HT. Regardless of association of low folate (<7 pmol/l) and TT genotype (p=0.002), we found no association of folate and HT. According to our results, adequate folate levels in blood serum have no protective effect on incidence of HT. Therefore, we suggest that further research of folates - CVD endpoints relation should be directed towards broader spectrum of genes involved in folate and homocysteine metabolism rather than focusing on MTHFR polymorphisms as the main factor. Also, our results indicate that T allele may have some selective advantage that contributes to longevity.

P10.61
Role of some apoptosis genes polymorphisms in aging and longevity

V. V. Erdman, *I. Tuktarova, T. Nasibullin, R. Mustafina, O. Mustafina;*

Institute of Biochemistry and Genetics, Ufa, Russian Federation.

Aim of study was to estimate alleles and genotypes frequencies dynamic of SIRT1 (-1138C>T), NFKB1 (28081564T>A), TP53 (P72R), Casp8 (-652(6)I/D), BAX (919 A>G), BCL2 (140016C>T) genes with age in Tatars (Bashkortostan, Russia).

Total group was composed of 1602 unrelated persons from 16 to 109 years. Gene polymorphism was analyzed by PCR-RFLP. Search of genetic markers associations with age was performed using logistic regression analysis (SPSS18.0). Increase or decrease of certain genotypes with age in periods, defined by applying ROC-analyze, was estimated in odds ratio index - OR (> 1 or <1 respectively).

In male there were increase of genotype frequencies of NFKB1*T/*T in age until 72 years (p=0.028, OR=1.014), TP53*P/*P in 16-80 years (p=0.029, OR=1.012), BAX*A/*A from 17 years (p=0.006, OR=1.01); decrease of genotype frequencies of SIRT1*C/*C in age until 58 years (p=0.026, OR=0.976), NFKB1*T/*T in age until 72 years (p=0.038, OR=0.985), Casp8*I/*I in 15-76 years (p=0.045, OR=0.991), BAX*G/*G from 26 years (p=0.026, OR=0.983), BCL2*T/*T in age until 80 years (p=0.002, OR=0.989). In female SIRT1*C/*C (until 90 years, p=0.002, OR=1.023), BAX*A/*A (from 73 years, p=0.022, OR=1.033), BCL2*T/*T (since 50 year, p=0.002, OR=1.023) genotype frequencies were rises; SIRT1*C/*T genotype frequency until 90 years (p=0.027, OR=0.987) and BCL2*C/*C genotype frequency since 65 years (p=0.009, OR=0.971) were reduces.

Thus, TP53(P72R) and SIRT1(-1138C>T) gene polymorphisms are important for achieve of senile age in men and women respectively; BAX(919A>G) polymorphic marker (in both men and women) and BCL2(140016C>T) gene polymorphism (among women) may be associated with longevity.

Supported by grant RFH 10-04-01614.

P10.62
Genotype and haplotype analysis of TP53 and health related traits in Croatian senescent population

P. Krajačić[1], *Ž. Tomas*[1], *M. Zajc Petranović*[1], *T. Škarić-Jurić*[1], *V. Bišof*[2], *J. Miličić*[1], *S. Tomek-Roksandić*[3], *N. Smolej Narančić*[1];

[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Department of Oncology, Clinical Hospital Centre Zagreb, Zagreb, Croatia,* [3]*Dr. A. Štampar Institute of Public Health, Department of Gerontology, Zagreb, Croatia.*

The TP53 gene has been suggested to be associated with various diseases and with longevity due to its important functions in preserving the genome integrity. In this study we investigated the association of two polymorphisms of TP53 gene - Arg72Pro and PIN3 (+16bp) - with health related traits in 324 persons of very old age (85-101 yrs). The results showed that the health status in elderly is sharply discriminated by PIN3 (+16bp) genotypes: carriers of A1A2 or A2A2 genotype more frequently have cardiovascular diseases (CVD), osteoporosis, risk for undernutrition (weight loss, diarrhea), and they also recently suffered from stress or acute illness. In contrast, for the carriers of A1A1 genotype none disadvantageous condition could be detected. The Arg72Pro polymorphism differentiated the study participants as follows: ArgArg carriers showed more frequently CVD while ArgPro and ProPro carriers had lower body mass index and they more frequently suffered from stress or acute illness. Further analysis showed that the most frequent haplotype ArgArg_A1A1 (48.9% of all haplotypes), although very advantageous for many traits is characterized by increased fasting glucose levels or/and diabetes. The remaining two A1A1 haplotypes (ProPro_A1A1 and ArgPro_A1A1) have lower frequency of CVD and CVD risk factors as well as of osteoporosis; the only disadvantageous characteristic being an increased risk for undernutrition. The present preliminary study exposes A1A1 genotype as the most advantageous TP53 genotype while A2 allele (A1A2 and A2A2 genotypes) bears substantial risk for various health related traits and it is so irrespective of codon72 status.

P10.63
Peroxiredoxin-5 gene polymorphism and human longevity in Russian population

A. Vasilishina[1], *O. Kononova*[2], *O. Semenova*[3], *M. Shavlovsky*[1], *V. Larionova*[2];
[1]*St. Petersburg Medical Academy of Postgraduate Studies, Saint-Petersburg, Russian Federation,* [2]*St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation,* [3]*Research Center for People, who lived in Blockaded Leningrad, Saint-Petersburg, Russian Federation.*

Peroxiredoxin-5 (PRDX5) is a mitochondrial antioxidant enzyme that neutralizes reactive oxygen species (ROS). According to the free radical theory of aging, an accumulation of oxidative damages as a result of ROS attack is probably a reason of aging and age-related pathology. *PRDX5* gene polymorphism may cause a different activity of peroxiredoxin-5 and thus may play a role in human longevity.

The purpose of our study was to reveal associations of *PRDX5* gene polymorphism with human lifespan.

We analysed 2 SNPs in *PRDX5* gene (-540A>C, rs 28364831 and 1955C>T, rs 627425) in two groups of unrelated persons from St-Petersburg: young (4-17 years old, n=123) and elderly (80-106 years old, n=173), including long-livers (90-106 years old, n=85). Genotyping was carried out by PCR-RFLP-analysis. Linkage disequilibrium and haplotype frequencies were estimated by EH program. Allele and genotype frequencies were compared by using Chi-square test, Fisher's exact test.

We have revealed linkage disequilibrium between SNPs (D = 0,12) and only 3 alleles (haplotypes). Allele -540/1955 is absent in our population. No statistically significant differences in allele frequencies between groups were found. The genotype distributions are consistent with Hardy-Weinberg equilibrium in both groups. We found the -540/1955 genotype was significantly less frequent in long-livers compared with young group (11% vs. 24%; =0,012; OR=0,37; 95%CI: 0,16 - 0,82), with group aged 80-89 years (11% vs. 27%; =0,006; OR=0,32; 95%CI: 0,14 - 0,73) and with combined group aged <90 years (11% vs. 26%; =0,004; OR=0,34; 95%CI: 0,16 - 0,73).

P10.64
Molecular, audiological and population features of autosomal recessive deafness 1A (DFNB1A) in Yakut population isolate from Eastern Siberia

N. A. Barashkov[1], *L. U. Dzhemileva*[2], *S. A. Fedorova*[1], *F. M. Teryutin*[1,3], *O. L. Posukh*[4,5], *E. E. Fedotova*[3], *S. L. Lobov*[2], *E. K. Khusnutdinova*[2];
[1]*Yakut Scientific Centre of RAMS, Yakutsk, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [3]*Audiology-Logopaedic Center, Republican Hospital #1, Yakutsk, Russian Federation,* [4]*Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation,* [5]*Novosibirsk State University, Novosibirsk, Russian Federation.*

Hereditary forms of hearing impairment (HI) causing by *GJB2* (Cx26) mutations are the frequent sensory disorders registered among newborns in various human populations. In this study we present data on the molecular, audiological and population features of autosomal recessive deafness 1A (DFNB1A) associated with the donor splicing site q.-3179 (IVS1+1G>A) mutation of *GJB2* gene in Yakut population isolate of the Sakha Republic (Yakutia) located in Eastern Siberia (Russian Federation). The Yakut population exhibits high frequency of some Mendelian disorders which are rare in other populations worldwide. Mutational analysis of *GJB2* gene in 86 unrelated Yakut patients with congenital HI without other clinical features has been performed. In this study we registered a large cohort of Yakut patients homozygous for the q.-3179 (IVS1+1G>A) mutation (70 unrelated deaf subjects in total). Detailed audiological analysis of 40 deaf subjects with genotype q.-3179 (IVS1+1G>A)/q.-3179 (IVS1+1G>A) revealed significant association of this genotype with mostly symmetrical bilateral severe to profound HI (85% severe to profound HI versus 15% mild to moderate HI, p<0.05). The extremely high carrier frequency of the q.-3179 (IVS1+1G>A) mutation (11.7%) from six investigated populations has been found in Yakut population. Reconstruction of 140 haplotypes with q.-3179 (IVS1+1G>A) mutation demonstrates the common origin of all mutant chromosomes found in Yakuts. The age of mutation was estimated to be approximately 800 years. These findings characterize Eastern Siberia as the region with the most extensive accumulation of the q.-3179 (IVS1+1G>A) mutation in the world as a result of founder effect.

P10.65
Reference population database for forensic DNA typing

N. A. Akram[1,2], *S. R. Farooqi*[2];
[1]*Hamdard University, Karachi, Pakistan,* [2]*University of Karachi, Karachi, Pakistan.*

The probability of a random match between two individuals derived from a large heterogeneous population database is likely to have potentially serious errors. It is hypothesized that the genetic variation between larger populations is not different from that between smaller populations and the match probability estimates are not affected by the population substructure. In order to test the first hypothesis, allele frequency data for three STR loci (TPOX, TH01 and CSF1PO) taken from 37 other studies, were analyzed. A hierarchy of the populations (Races→Caucasoids→Caucasoid Asians→Caucasoid Indians) was constructed and statistically analyzed. (A) Significant differences (p<0.05) in the allelic frequency distribution were in order of Races>Caucasoids> Caucasoid Asians = Caucasoid Indians. (B) Significant difference (p<0.05) in average number of alleles (n_a) was observed between Races and between Caucasoids. However significant correlation was observed between sample size and the number of alleles. (C) Ratio of allelic frequencies of > two fold was in order of Races>Caucasoids> Caucasoid Asians > Caucasoid Indians. Ratio of >25 folds were observed only between Races. (D) A frequency differential of > 20% was observed only between Races and between Caucasoid Asians. Second hypothesis was tested through STR genotype data across five Pakistani subpopulations. The match probability estimates of the pooled data differ significantly (p≤0.05) from that of the subpopulations. The combined match probability also shows as much as seven folds difference from the subpopulations. The analyses showed that a reference database from a homogeneous smaller population is more likely to provide reliable estimates of match probability.

P10.66
Vlax Roma in Croatia - signs of endogamy in maternal gene pool

M. Pericic Salihovic[1], *A. Baresic*[1], *I. Martinovic Klaric*[2], *L. Barac Lauc*[3], *B. Janicijevic*[1];
[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Institute for Migration and Ethnic Studies, Zagreb, Croatia,* [3]*Croatian Science Foundation, Zagreb, Croatia.*

Vlax Roma are a branch of Romani people who were enslaved in the historic Romanian states Wallachia and Moldavia between 14th and 19th centuries. After Roma slavery was abolished, larger Vlax Roma groups immigrated to Croatia. Since Roma population is made of numerous socio-cultural endogamous groups, we investigated the extent of fragmentation of Vlax Roma in Croatia by analysing hyper variable segment I (HVS-I) and typing relevant RFLP sites in the mitochondrial DNA of 390 Bayash from two Croatian regions: Baranja (235) and Medjimurje (155). Diversity indexes point to higher level of variation among Vlax Roma settled in Eastern (Baranja) than in Northwestern Croatia (Medjimurje). The analysis of mismatch distribution clearly points to differences in demographic changes of these two subpopulations. Those results are in concordance with field research data on residence patterns indicating higher endogamy in Northwestern than Eastern Croatia. Interestingly, collected socio-cultural data point to absence of marriage unions between Vlax Roma from Eastern and North-western Croatia, indicating that shared mtDNA lineages are a result of common gene pole that predates their separation in Croatia. Despite similar origins and shared demographic history of two Croatian Vlax Roma populations, founder effect followed by strict endogamy shaped their evident population differentiation.

P10.67
A genome-wide analysis of Sardinian population structure

M. Steri[1], *L. Morelli*[2], *M. Pitzalis*[3], *M. Zoledziewska*[3], *F. Busonero*[1], *A. Maschio*[1], *F. Poddie*[3], *M. Uda*[1], *D. Schlessinger*[4], *F. Cucca*[1,3], *S. Sanna*[1];
[1]*Istituto di Ricerca Genetica e Biomedica (ex INN), CNR, Monserrato, Italy,* [2]*Dipartimento di Zoologia e Genetica Evoluzionistica, Università di Sassari, Sassari, Italy,* [3]*Dipartimento di Scienze Biomediche, Università di Sassari, Sassari, Italy,* [4]*Laboratory of Genetics, National Institute on Aging, Baltimore, MD, United States.*

Sardinia is particular attractive for human genetic studies, being one of the larger isolated populations and thus suitable for large-scale

studies. Several attempts have been made to explore its genetic structure, but they either analyzed a large set of markers in very few samples or thousands of individuals at specific loci. Here we genotyped 2,615 individuals with the Affymetrix 6.0 array. Samples were recruited from the north, south and central east areas of the Island, and initially considered as 3 distinct populations. Genotype calling was performed with Birdseed-v2, considering all samples as a unique cluster to avoid batch effects. Subsequently, we applied standard filters for samples and SNP quality, and used IBD sharing to detect, and discard, hidden relatives. Using principal component analysis, we identified outliers and reassigned each individual accordingly. An analysis of molecular variance indicated that only 0.21% of the variability could be attributable to inter-population variation (Fst=0.002), confirming a lack of large-scale substructure. We thus considered the Sardinians as a unique sample. Compared to HapMap3 populations, as expected, higher similarity was observed with Tuscany and CEPH samples (Fst=0.005 and 0.010, respectively). A genome-wide search for SNPs highly differentiated between Sardinians and these European populations confirmed the specialness of HLA and LCT regions, and also showed elevated Fst values (>0.27) at the CR1 gene, known to be related to malaria severity. We are now integrating sequencing data of many individuals to provide a more comprehensive analysis of variants in addition to the common SNPs in current genotyping platforms.

P10.68
The theoretical value of kin in aging theory: a modification of Hamilton's equations of declining selection

S. J. Newman, *S. Easteal;*
Australian National University, Acton, Australia.

The evolutionary theories of aging proposed by Hamilton, Williams and Medawar during the last century remain our dominant explanation for the phenomenon of senescence. Hamilton, Williams and Medawar pointed out numerous shortcomings of these theories in their original papers and subsequent comments, yet since their publication little has been attempted to directly address these issues.
The criticisms levelled at these theories include an inability to explain prolonged post-reproductive survival, the evolution of menopause and early infant mortality, the existence of 'negative' and 'negligible' senescence, positive selection for cellular suicide, and an apparent tautology in defining the likelihood of death. All of these valid criticisms can be addressed using a simple modification of Hamilton's equations. The Eueler-Lotka equation and the Malthusian parameter form the definitional basis of fitness for Williams and Hamilton. Yet these equations carry an implicit and incorrect assumption: that the production of offspring is the measure of fitness for an individual. This assumption creates a situation where fitness must always be a positive, declining vector.
By the simple introduction of an indirect fitness term, and the removal of the dx variable, the traditional equations of Hamilton become more accurate measures of fitness and can account for all of the above phenomena.

P10.69**
Investigating genetic modulation of sudden cardiac death by variants discovered in genome wide association studies for ECG indices of conduction and repolarization

R. Pazoki[1], *R. F. Marsman*[1], *M. W. T. Tanck*[1], *J. S. S. G. de Jong*[1], *L. R. C. Dekker*[2], *A. A. M. Wilde*[1], *C. R. Bezzina*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Catharina Hospital, Eindhoven, Netherlands.*

Background: Sudden cardiac death is a leading mode of death in adults in the Western world and is largely caused by ventricular fibrillation(VF) during acute myocardial ischemia-infarction(MI). Although a genetic component in risk of VF in MI is recognized, underlying genetic factors remain largely unknown. ECG parameters predict risk of sudden death; and recent genome-wide association studies(GWAS) have revealed common single nucleotide polymorphisms(SNPs) associated with variation in ECG indices of conduction and repolarization. In this study we investigated the effect of these SNPs in modulating risk of VF in acute MI.
Methods: Patients studied were from the **Arrhythmia Genetics in the NEtherlands Study (AGNES),** which consists of Dutch Caucasian patients with a first acute MI, with those suffering VF classified as cases(n=515) and those not suffering VF classified as controls(n=457). SNPs associated with ECG conduction and repolarization indices at genome-wide significant p-values ($P<5\times10^{-8}$) in previous GWAS were identified. Genotypes were obtained either by direct genotyping(Illumina610) or were imputed using HapMap build 36. Logistic regression was used to test for association with VF.
Results: Besides previously reported rs6795970 in *SCN10A*, two SNPs, rs11897119 and rs17779747 were found to modulate risk of VF during MI. rs11897119 (OR:1.23, 95%CI:1.03-1.49) is located in *MEIS1*, and was previously shown to be associated with PR-interval in the general population. rs17779747 (OR:1.28, 95%CI:1.05-1.54) is located 600 kb far from *KCNJ2,* and was previously associated with QT-interval in the general population.
Conclusions: SNPs impacting cardiac conduction and repolarization may modulate risk of sudden cardiac death during acute MI.

P10.70
Incidence of Spinal Muscular Atrophy in Chuvashia

V. V. Zabnenkova, *E. L. Dadali, A. V. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

The proximal spinal muscular atrophy is a severe autosomal recessive neuromuscular disease characterized by degeneration of alpha motor neurons in the spinal cord, which results in progressive proximal muscle weakness and paralysis. This disease is caused by mutation in the telomeric copy of the survival motor neuron gene (*SMNt*). Most carriers of SMA have one chromosome 5 with a normal *SMNt* gene and one with a deleted *SMNt* gene.
This study sought to evaluate the incidence of SMA in Chuvashia.
Multiplex Ligation-dependent Probe Amplification was used to assess the copy number of the two survival motor neuron genes (*SMNt* and *SMNc*) on chromosome 5q13. This method allows to determinate accurately the carriers for spinal muscular atrophy (SMA), with one copy of *SMNt*.
Analysis of 260 normal Chuvashia individuals revealed a carrier incidence of 2,7% (1 per 37, 7/260), the calculated incidence of SMA equal to 1 per 5476. These findings are significant comparable with carrier frequency 1 per 40-50 and incidence 1 per 6000-10000 in the general population.

P10.71
Association of single nucleotide polymorphisms in IL-20 and IL-10 with Hepatitis C virus

E. Arbabi Aval, *S. Mohebbi, F. Rostami, P. Azimzadeh, s. Romani, A. Sharifian, F. Derakhshan, M. Zali;*
Research Center for Gastroenterology and Liver Disease, Tehran, Islamic Republic of Iran.

Back ground: Hepatitis C virus (HCV) is an infectious blood-borne pathogen that usually persists as a chronic infection. However, in approximately 15% of cases, patients can clear the virus, indicating that host differences could be critical in determining the course of HCV infection. The inflammatory response is crucial to resolve the virus or progress to chronic infection after acute phase. The aim of this study was to determine effects 5 single nucleotide polymorphisms (SNPs) in the IL10 and IL 20 genes for association with HCV.
Methods: We conducted based case-control study. DNA from 120 patients and 110 controls was investigated. IL-20 gene single nucleotide polymorphisms in (rs1518108), (rs1400986) and IL-10 single nucleotide polymorphisms in (rs1800872) , (rs1800871) and (rs1800896) were evaluated by polymerase chain reaction and the restriction fragment length polymorphism technique.
Result: This study demonstrated a significant association between polymorphism of rs1518108 and HCV infection in the Iranian population. Also no significant differences were found in the polymorphisms of IL-20 and Other IL-10 allele polymorphisms between patients and controls.
Conclusion: The rs1518108 T allele might be a risk factor for HCV in Iranian population.

P10.72
Human chromosome 4p and Malaria Infection

L. C. Pereira[1,2], *J. M. Pescarini*[1,2,3], *R. G. M. Ferreira*[4,2], *A. A. Casseb*[5], *L. M. A. Camargo*[1,2], *H. Krieger*[1,2], *L. M. Garrido*[1,2];
[1]*Instituto de Ciências Biomédicas – Universidade de São Paulo, São Paulo,*

Brazil, [2]Instituto Nacional de Genética Médica Populacional (INAGEMP) – Brazil, Porto Alegre, Brazil, [3]Instituto de Biologia Molecular do Paraná – Paraná - Brazil, Curitiba, Brazil, [4]Fundação Oswaldo Cruz - Rôndonia - Brazil, Porto Velho, Brazil, [5]Fundação Universidade Federal de Rondônia – Rondônia - Brazil, Porto Velho, Brazil.

In the world over 300 million people are infected by malaria each year. In Brazil this cases are concentrated in legal Amazon region. It is known that human genetic factors may contribute to susceptibility and the response to infectious diseases. Genes like HbS, DARC, G6PD and others are responsible for resistance to Malaria infection and the severity of the disease.

Tool-like Receptors (TLRs) are a family of signaling proteins involved in the innate immune response to different kind of pathogens. In the last few years several studies associating TLR genes with infectious diseases were reported.

Recent studies by our group identified a genetic association between the number of malaria infection and a specific region of the human chromosome 4p in Western Amazonian individuals, using a panel of STR markers. It has been postulated that the TLR1 gene may be a good candidate for susceptibility/resistance to malaria infection, since it is related to others infectious diseases and it is located in the 4p human chromosome.

A sample from the Western Amazonian population of Monte Negro (RO) was studied in a Case-Control fashion. Seventy cases and controls were selected through regression analysis, based on the sex, age and the malaria history of 925 individuals. The genotyping assay was made by RFLP of the rs5743618 (I602S).No significant association was detected between the number of malaria infection and the genotype of the analyzed SNP. Other causes for these associations should be searched in order to explain the above findings related to 4p chromosome(CNPq/CAPES).

P10.73
Evaluation the number of carriers of MEFV common mutations in Familial Mediterranean Fever in North-Western area of Iran.

***T. Moharrami**, A. Karimi, M. Jabbarpur Bonyadi, S. Dastgiri, K. Sakha, M. Taghizadeh;*

Department of Medical Genetics and Student Research Center, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.

Background- Familial Mediterranean Fever, one of the most common and recognized periodic fevers syndromes, is a recessive autosomal disorder. This disease is prominently present in the non- Ashkenazi Jews, Arabs, Turks and Armenian people.

Considering the geographic location of North-West of Iran and its neighborhood with two high-risk regions i.e. Armenia and Turkey, the high prevalence of FMF in this area is expected.

Aim- The purpose of this study was to evaluate the number of carriers of MEFV common mutations in healthy controls. The result can be of help in estimating the prevalence of Familial Mediterranean Fever disease and awareness-raising to avoid potential Amiloidosis.

Methods- 200 healthy controls who were not suffering from FMF were selected randomly from North-West area. After obtaining their consent and blood sampling, their DNA was extracted. Then through PCR-RFLP and PCR-ARMS techniques, the mutation was studied.

Findings- Out of 400 studied alleles, 44 mutant alleles for E148Q mutation and 7 mutant alleles for V726A mutation were found. In the other 3 mutations, no mutant allele was found. The frequency of general alleles for these 5 common mutations is 0.1325. The carriers rat was 23.4%.

Conclusions- The result with 23.4% of carriers indicates that FMF is significantly prevalent in North-West of the Iran.

This high number suggests that North-West of Iran, like other high-risk areas, is susceptible to Familial Mediterranean Fever. Like other studies carried out in other countries, this study also suggests that E148Q has reduced influence in the patients of North-West area.

P10.74
Association between SNPs in TNF gene and clinical manifestations of Dengue in Rondonia, Western Brazilian Amazon

***D. Delani**, L. M. Cantanhede, A. Krauze, J. J. O. Amaral, A. A. Casseb, V. E. G. Oliveira;*

Universidade Federal de Rondônia, Porto Velho, Brazil.

TNF gene showed a significant association with severe forms of infection caused by Dengue virus (Sierra 2010). By an extensive variability of SNPs, it has become essential tool for genetic linkage studies or association in composition and frequency within and between different ethnic groups (Vejbaesya, 2009). Aiming to genotype the SNPs -238 and -308 located in the promoter region of this gene and the genetic association observed between individuals infected with dengue, we collected blood samples from 108 individuals living in Cacoal and Jaru, Rondonia's State. DNA extraction was performed using the protocol described by Higuchi and analysis of samples was by PCR and RFLP, followed by electrophoresis on PAGE 6%. Statistical data were obtained using the program GENEPOP (Version 4.0). The allele frequency was 0.936 for -238G, and 0.0640 for -238A, corresponding to that observed in European populations (0.068 and 0.932 respectively, NCBI, 2010). In dengue patients the presence of this mutant allele-238A is associated with protection (Oliveira 2004). In this study, no association was found (p> 0.05). -308G allele had a frequency of 0.878 and -308A of 0.122, similar to described for African-American (0.123 and 0.877 respectively, NCBI, 2010), confirming the ethnic heterogeneity of the study population. Unable to establish a biological basis of susceptibility and resistance in relation to TNF, even though there is data in the literature (Fernández, 2004). New molecular approaches and statistics will be performed for the association dengue / TNF can be analyzed in order to confirm whether or not the literature.

P10.75
Polymorphisms of thiopurine S-methyltransferase (TPMT) gene in the average Roma and Hungarian population samples

***C. Sipeky**[1], A. Maasz[1], E. Saghy[1], G. Tarlos[1], M. Szabo[2], I. Takacs[3], B. Melegh[1];*

[1]Department of Medical Genetics, University of Pécs, Pécs, Hungary, [2]Koch Robert Hospital, Edeleny, Hungary, [3]Department of Institute of Internal Medicine and Haematology, Semmelweis Teaching Hospital, Miskolc, Hungary.

Thiopurine S-methyltransferase (TPMT) gene polymorphisms are the major determinants of interindividual differences in haematological toxicity of 6-mercaptopurine. The purpose of this work was to determine the frequency of *TPMT* polymorphisms, to study the genetic variability and ethnic differences in average Hungarian, and Roma population samples. Total of 370 Hungarian and 271 Roma subjects were genotyped for the *TPMT*2* (G238C, Ala80Pro, rs1800462), *TPMT*3B* (G460A, Ala154Thr, rs1800460), *TPMT*3C* (A719G, Tyr240Cys, rs1142345) and *TPMT*3A* (G460A and A719G) variant alleles by PCR-RFLP assay. Comparing the genotype and allele frequencies of Roma and Hungarian populations differences were found in the *TPMT* 460 GG (93.0 vs. 96.5%), GA genotypes (7.00 vs. 3.50%) and in A allele frequency (0.035 vs. 0.018) between the two studied groups ($p<0.05$). Futhermore, in frequency of *TPMT* 719 AA (91.5 vs. 95.4%), AG (8.50 vs. 4.60%) genotype and in G allele frequency (0.042 vs. 0.023) was significant difference between the Roma and Hungarian population samples ($p<0.05$). Predominant variant alleles were the *TPMT*3A* (7.00 and 3.52%) and the *TPMT*3C* (0.70 and 0.54%) both in Roma and Hungarian populations. Interestingly, the frequency of total variant alleles was almost two times higher in Roma than in Hungarian population samples (7.70 vs. 4.20%). The results of *TPMT* polymorphisms found in the Hungarian population were similar to that observed in other Caucasian populations. By contrast, the Roma population differs from Hungarians, from Caucasians, and from populations of India in common *TPMT* polymorphisms.

P10.76
Analysis of UCPs, PPARs and PGC-1 genes polymorphism in elderly people

***I. V. Tarkovskaya**[1,2], O. S. Glotov[2], L. V. Turjeva[3], L. P. Khorohinina[4], V. S. Baranov[1,2];*

[1]St-Petersburg State University, Saint-Petersburg, Russian Federation, [2]Ott's Institute of Obstetrics and Gynecology RAMS, Saint-Petersburg, Russian

Federation, [3]St-Petersburg State Medical Academy department of internal diseases, Saint-Petersburg, Russian Federation, [4]St-Petersburg Medical Academy of Postgraduate Studies, Saint-Petersburg, Russian Federation.

Our goal was to investigate whether polymorphisms in *UCP2, UCP3, PPARA, PPARD, PPARG* and *PGC-1* genes influence life expectancy. All genes are involved in storage and energy burning and provide opportunity to study energy balance in humans.We have analyzed six polymorphisms of this genes: *UCP2* Ala55Val, *UCP3* C-55T, *PPARA* G/C, *PPARD* +294T/C, *PPARG* Pro12Ala and *PGC-1* Gly482Ser, by RLFP method in 145 elderly people (group1) and 133 control group (25-65 aged people) (group2) from North-West Region of Russia. Distribution of genotypes of *UCP3* gene was significantly different between group1 in comparison to group2 (p=0.009, df=2) for C/C genotype 43.9% and 24.4%, C/T genotype 46.2% and 67.1%, T/T genotype 9.8% and 8.5%, respectively. So as for *PGC-1* (p=0.04, df=2) for Gly/Gly genotype 40.0% and 28.6%, Gly/Ser genotype 47.6% and 62.4%, Ser/Ser genotype 12.4% and 9.0%, respectively. For *PPARD* polymorphism both genotypes and alleles differences were founded between group1 in comparison to group2 (p=0.0007, df=2) for T/T genotype 66.0% and 88.8%, T/C genotype 31.9% and 9.0%, respectively, and increasing of C allele in group1 compared with group2 (18.1% and 6.7%, respectively) and decreasing of T allele in group1 in comparison to group2 (81.9% and 93.3%, respectively). Also increasing of C allele (*PPARA*) in group1 in comparison to group2 (26.3% and 17.5%, respectively, p=0.07) and decreasing of G allele in group1 in comparison to group2 (73.7% and 82.5%, respectively, p=0.07) were founded. Consequently we suggest that *UCP3, PPARD* and *PGC-1* polymorphisms are significant for survival.

P10.77

Vitamin B12 status during pregnancy and cognitive ability of children at age 8: a Mendelian Randomization study in a UK birth cohort

C. Bonilla[1], *D. A. Lawlor*[2], *A. E. Taylor*[1], *D. Gunnell*[1], *Y. Ben-Shlomo*[1], *A. R. Ness*[3], *N. J. Timpson*[2], *B. St. Pourcain*[1], *S. M. Ring*[1], *P. Emmett*[1], *G. Davey Smith*[2], *S. J. Lewis*[1];

[1]School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, [2]MRC Centre for Causal Analyses in Translational Epidemiology, School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, [3]School of Oral and Dental Sciences, University of Bristol, Bristol, United Kingdom.

Vitamin B12 is essential for maintenance of a healthy neuronal system. Brain development occurs primarily in utero and early infancy, but the role of maternal vitamin B12 levels during pregnancy on offspring cognitive function is unclear. In this study we examined the relationship between vitamin B12 status in pregnant women from the UK ALSPAC birth cohort and the cognitive ability of their offspring. First, we conducted an observational study of maternal vitamin B12 dietary intake during pregnancy and child's IQ at 8 years of age. There was a positive observational association between maternal vitamin B12 intake and child's IQ that was attenuated somewhat after adjustment for potential confounders, but remained. We then employed a Mendelian randomization strategy that assessed the association of maternal genotype at SNPs in the genes FUT2 (rs492602) and TCN2 (rs1801198), which have been previously found to be reliably related to serum vitamin B12 in genomewide and candidate gene association studies, with child's IQ. This approach allows us to evaluate the causal relationship between exposure and outcome without confounding from lifestyle and environmental risk factors. In this case, maternal alleles associated with an increase in serum vitamin B12 were also associated with higher IQ scores in children. These associations were present after adjustment for the equivalent offspring SNP and population stratification. Our findings support the hypothesis that low vitamin B12 levels in utero adversely impact children's cognitive function.

P10.78

Allelic determinants of vitamin D insufficiency and bone mineral density

O. Trummer[1], *N. Schweighofer*[1], *U. Lam*[1], *E. Wehr*[1], *V. Schwetz*[1], *H. Dobnig*[1], *M. Gugatschka*[2], *T. Pieber*[1], *W. Renner*[3], *B. Obermayer-Pietsch*[1];

[1]Division of Endocrinology and Metabolism, Department of internal Medicine, Medical University, A-8036 Graz, Austria, [2]ENT University Hospital, Department of Phoniatrics, Medical University, A-8036 Graz, Austria, [3]Clinical Institute of Medical and Chemical Laboratory Diagnostics. Medical University, A-8036 Graz, Austria.

Vitamin D (25(OH)VitD) plays an important role in many areas of health and disease. Prospective studies showed associations between low vitamin D and mortality. Vitamin D insufficiency affects as many as half of otherwise healthy adults in developed countries. The vitamin D binding protein gene GC ("group-specific component") contains an A>C polymorphism, whereby the GG genotype has been associated with an increased risk for vitamin D insufficiency. We investigated the potential role of this GC polymorphism for bone mineral density and bone fractures.

GC genotypes were determined in two independent cohorts, 370 elderly otherwise healthy and in 970 nursing home subjects. Genotypes were related to 25(OH)VitD and fractures in both groups and with bone mineral density (BMD) in healthy elderly subjects.

Mean vitamin D levels were within the lower normal range in the healthy elderly cohort (32,8±13,2 ng/ml) and very low in the nursing home patients (9,3±6,8 ng/ml). The GG genotype was highly associated with lower 25(OH)VitD values (p<0,001). Age-adjusted measurements of BMD expressed as Z-scores (n=356) at the lumbar spine, the total hip and femoral neck were not associated with the GC polymorphism. GC frequencies were not statistically different between persons with fractures (n=583, GG: 8,2%, GT: 42,7% TT: 49,1%) and persons without fractures (n=744, GG: 3,6%, GT: 41,1% TT: 52,3%).

We conclude that the GC polymorphism is a determinant for raised risk of Vitamin D insufficiency but not for bone mineral density and fracture risk, at least in our highly deficient 25(OH)VitD nursing home cohort.

P10.79

The place of the population of Lithuania between Northern and Eastern Europe: Y chromosome analysis

I. Uktveryté[1], *O. Balanovsky*[2,3], *S. Frolova*[3], *M. Kuznetsova*[3], *E. Balanovska*[3], *V. Kučinskas*[1];

[1]Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Vavilov Institute for General Genetics of Russian Academy of Sciences, Moscow, Russian Federation, [3]Research Centre for Medical Genetics of Russian Academy of Medical Sciences, Moscow, Russian Federation.

The population of Lithuania is constituted of 6 dialectal groups which form two major ethno-linguistic groups known as Aukštaitish and Žemaitish, both speaking Baltic languages of Indo-European family. Neighbouring Finno-Ugric (Northern and Eastern Europe), Slavonic (Eastern Europe) and Germanic (Northern Europe) populations surrounding the Baltic sea region influenced historical formation of Lithuanian ethno-linguistic groups. Analysis of the Lithuanian population genetic composition helps to understand the origin, history and place among other populations.

Y chromosome analysis was performed for 301 individuals from 6 dialectal groups. 25 SNPs were genotyped (TaqMan) to determine Y haplogroup and 17 STR were analysed to determine haplotype for each individual. Most frequent haplogroups in the population of Lithuania are R1a1a (42.2%, R1a1a1g compose 8.97% in studied population) and N1c1 (40.5%) and less frequent haplogroups are R1b1b1, I1, I2a, E1b1b1 (<5% each). AMOVA showed no statistically significant differences between two major ethno-linguistic groups Aukštaitish and Žemaitish (among groups p-value=0.897, among population within groups p-value=0.194, within populations p-value=0.282 based on 10100 permutations). MDS of genetic distances based on Y-biallelic markers showed that Lithuanians are closer to Latvian and Estonian populations than to Slavic populations (European part of Russia, Poland, Ukraine, Belorussia, stress=0.029).

According to the frequencies of haplogroups, no statistically significant differences between ethno-linguistic groups were detected (p>0.05), moreover, MDS analysis sets the population of Lithuania between Northern and Eastern European populations.

This study was supported by The Genographic Project.

Y-Chromosome genetic variation of modern Bulgarians

S. Karachanak[1,2], *V. Grugni*[2], *D. Nesheva*[1], *V. Battaglia*[2], *S. Fornarino*[2,3], *N. Al-Zahery*[2], *V. Carossa*[2], *Y. Yordanov*[4], *A. Galabov*[5], *B. Atanasov*[6], *A. Torroni*[2], *D. Toncheva*[1], *O. Semino*[2];

[1]Department of Medical Genetics, Medical Faculty, Medical University, Sofia,

Bulgaria, Sofia, Bulgaria, [2]Dipartimento di Genetica e Microbiologia, Università di Pavia, Pavia, Italy, Pavia, Italy, [3]Human Evolutionary Genetics, CNRS URA 3012, Institut Pasteur, Paris, France, Paris, France, [4]Institute of Experimental Morphology and Anthropology with Museum-Bulgarian Academy of Sciences, Sofia, Bulgaria, Sofia, Bulgaria, [5]The Stephan Angeloff Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, Sofia, Bulgaria, [6]Institute of Organic Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria, Sofia, Bulgaria.

To date, Bulgarian Y chromosomes have been studied only in macrogeographic context or in the lineage-based approach. Therefore, in order to comprehensively characterize Bulgarian Y-chromosome variation, we have performed high-resolution phylogenetic analysis of 812 healthy,unrelated Bulgarian males and compared the results with Y-chromosome data from other Eurasian populations.

The genotyping of 60 biallelic markers was performed in hierarchical order by RFLP and DHPLC analyses. The position of Bulgarians among other populations was visualized by Principal Component (PC) analysis.

About 80% of the total genetic variation in Bulgarians falls within haplogroups E-M35, I-M170, J-M172, R-M17 and R-M269. This finding shows that the Bulgarian haplogroup profile is congruent with those described for most European populations.

Among the prehistoric events marked by the observed haplogroups, the greatest contribution comes from the range expansion of local Mesolithic foragers triggered by adoption of agriculture introduced by a cadre of Near Eastern farmers. The Bulgarian Y chromosome gene pool also bears signals of the recolonization from different glacial refugia, the spread of agriculture from the Near East and the expansion of early farmers along the Central and East European river basins.

As for the interpopulation analysis, similarly to mtDNA, Bulgarians belong to the cluster of European populations, still being slightly distant from them. Bulgarians are distant from Turks (despite geographical proximity), Arabic and Caucasus populations and Indians. These trends in the PCA graph likely reflect not only prehistoric, but also more recent demographic events that have shaped the Y chromosome structure of modern Bulgarians.

P10.81

Eight-year investigation of Yq-microdeletions in azoospermic and severe oligozoospermic men in Iranian population

***H. Imanian**, M. Rostami, M. Azad, N. Almadani, H. Najmabadi;*

Kariminejad-Najmabadi Pathlogy and Genetics, Tehran, Islamic Republic of Iran.

Genes on the long arm of Y-chromosome (Yq), particularly within interval 6, are believed to play a critical role in human spermatogenesis. It has shown that microdeletions of Yq may account for a significant proportion of men with infertility in different populations. Y-chromosome microdeletions are known as the second frequent genetic cause of spermatogenetic failure in infertile men after Klinefelter syndrome.

Over last 8 years, total of 900 infertile individuals referred to our center for Yq-microdeletion analysis. The aim of this study was to determine the proportion of men with idiopathic azoospermia or severe oligozoospermia, who carry microdeletions in Y-q.

EDTA blood was taken from each of patients and DNA extracted according to standard protocol. Yq-microdeletion analysis was performed by PCR method using different STSs multiplex reaction designed for covering three regions of Y-chromosome known as AZFa, AZFb, and AZFc. As the results showed, 4.7% azoospermic and oligozoospermic samples failed to amplify 1 or more STS. Interestingly, 34 out of 42 patients had microdeletions in AZFc region that accounts for 80.95% of all detected microdeletions.

These data suggest a 4.7% prevalence of Yq-microdeletions in Iranian men with idiopathic azoospermia/severe oligozoospermia. The physical locations of these microdeletions provide further support for the concept that a gene(s) on Y-q interval 6 plays an important role in spermatogenesis.

Extremes of sleep duration and timing have been associated with adverse health outcomes that characterise the metabolic syndrome. Body homeostasis and circadian rhythm are though to interact to regulate these phenotypes, but little is known about the molecular mechanism behind it. We thus investigated 7 European populations in relation to their sleep duration habits and genome-wide variability. Meta-analysing the independent genome-wide association results, we identified a variant (P = 3.99 x 10^{-8}) in the *ABCC9* gene that explains ≈ 5 % of the variation in sleep duration. We found supportive evidence for this association in a subgroup of an independent *de novo* replication cohort, which we selected based on gene-environment (time of year) and sleep timing interactions. To investigate the functional relevance of our findings, we knocked down a homologue of the gene in *Drosophila,* which resulted in a night-sleep duration reduction of 3 h. Our study shows that *ABCC9* modulates epidemiological variation in human sleep duration, which is also influenced by inter-individual differences in sleep timing and seasonality (seasonal differences in entrainment of the biological clock). Therefore, scanning only for main effects on sleep duration, one might miss important genetic variants specific to subgroups of the population. *ABCC9* is involved with energy homeostasis, and the susceptibility to overweight and cardiovascular disease, which correlate with sleep duration. The relation of these genes to metabolism and disease indicates a common mechanism for the regulation of these phenotypes and sleep duration.

J10.01

HPV infection prevalence and subtypes‘ distribution among women with cytology findings, attending two private clinics in Larissa (central Greece)

*E. PAPPADA, A. GALMPENIS, M. THANOS, V. STYLOPOULOU, **G. DIMISIANOS**;*

BIOANALYSIS LARISSA, DIAGNOSTIC LABORATORY, LARISSA, Greece.

INTRODUCTION: Infection from Human Papillomavirus has been establisthed as a cause of cervical cancer. HPV screening in women with positive cytology results, helps to identify the women in need for therapy and further screening. The aim of the study was to identify the most prevalent HPV subtypes in Larissa, Greece. The sample population consisted of women attending two private gynaecology clinics and referred to our laboratory for HPV screening due to findings in their cytology test indicating HPV infection.

METHODS: A total of 255 women were studied. All women underwent a regular gynaecological examination including Papanicolaou test. None of the women had been previously diagnosed with an HPV infection. The following 32 HPV types were studied using a commercially available method based on an LCD array hybridization (CHIPRON), following a duplex PCR :

6, 11,16,18,31,33,35,39,42,44,45,51,52,53,54,56,58,59,61,62,66,67,68,70,72,73,81, 82,83,84,90 and 91.

RESULTS: HPV infection was detected in 79.3% of the study population. Among the infected population, 35.8% had a single type

infection with the most prevalent type being type 16 (18%) followed by types 45 (9.7%) and 56 (8.3%).
22% of the infected population had infection with 2 types of hpv, 17% with 3 types, 13,9% 4 types, 5.4% 5 types. The rest had between 7 and 16 types of HPV.
CONCLUSIONS: There is a high prevalence of HPV infection amongst women attending private gynaecology clinics in Larissa. Findings are in accordance with the published literature on the prevalence of each subtype studied.

Population Genetic Study of Russia

***G. I. Elchinova**, R. A. Zinchenko;*
Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Parameters of Barrai calculated in populations: 13 districts of Rostov region (I_r from 0.0005 to 0.0022) , 29 districts of Kirov region (I_r from 0.0017 to 0.0201), 6 districts of Tver region (I_r from 0.0031 to 0.0049), 2 districts of Arkhangelsk region (I_r from 0.0020 to 0.0030), 7 districts of Marii El Republic (I_r from 0.0017 to 0.0133), 33 districts of Yakutia (Sakha) Republic (I_r from 0.0010 to 0.0468), 16 districts of Tatarstan Republic (I_r from 0.0008 to 0.0065). Parameters of Isolation by distance of Malecot calculated in populations: 6 districts of Chuvashia Republic (a from 0.00016 to 0.00054), 5 districts of Marii El Republic (a from 0.00025 to 0.00058), 2 districts of Yakutia (Sakha) Republic (a from 0.0013 to 0.0106), 10 districts of Rostov region (a from 0.00012 to 0.00046), 7 districts of Kirov region (a from 0.00011 to 0.00149), 2 districts of Tver region (a from 0.0009 to 0.0011), 2 districts of Arkhangelsk region (a from 0.00047 to 0.00056), 6 districts of Bashkortostan Republic (a from 0.00015 to 0.00227), 6 districts of Udmurtia Republic (a from 0.00027 to 0.00065), 12 districts of Tatarstan Republic (a from 0.00012 to 0.00041). Crow Index and its components calculated in rural populations: Rostov region (I_m=0.050, I_f=0.211, I_{tot}=0.272), Tver region (I_m=0.029, I_f=0.171, I_{tot}=0.205), Pskov region (I_m=0.019, I_f=0.261, I_{tot}=0.286), Marii El Republic (I_m=0.105, I_f=0.424, I_{tot}=0.575), Chuvashia Republic (I_m=0.068, I_f=0.273, I_{tot}=0.360), Yakutia (Sakha) Republic (I_m=0.072, I_f=0.364, I_{tot}=0.462), Bashkortostan Republic (I_m=0.051, I_f=0.251, I_{tot}=0.315), Udmurtia Republic (I_m=0.046, I_f=0.258, I_{tot}=0.316), Kalmykia Republic (I_m=0.038, I_f=0.300, I_{tot}=0.350).

J10.03
Genetical and epidemiological research of a hereditary ophthalmic pathology among the children‘s population

***V. V. Kadyshev**, O. V. Khlebnikova, R. A. Zinchenko;*
Research Centre for Medical Genetics RAMS, Moscow, Russian Federation.

We carried out genetic and epidemiological research into hereditary ophthalmic pathology (HOP) among children of 9 districts (Bogorodsky, Svechinsky, Nemsky, Uninsky, Shabalinsky, Darovsky, Verhoshizhemsky, Kumensky, Sunsky) of the Kirov province (Russian Federation). The total investigated population was 93,790, of whom 17% were children (0-18 years old inclusive). The prevalence of HOP among children was 2.31±0.38 per 1000 persons. The ophthalmologist in one of the districts actively carried out routine inspections, starting at 2-3 years old. This method allowed detection and registration of disease in an initial stage of illness, without the presentation of subjective complaints, and subsequent monitoring. Considering the high prevalence of isolated HOP, the pronounced clinical variability, genetic heterogeneity, severity of the pathological processes, and the extent of disability in the population, it will be necessary to carry out routine inspections of children. Early diagnosis of disease will help not only to reveal cases, but it will also motivate treatment of illnesses at sub-clinical levels of the pathological process, that considerably postpone long-term disability. It will raise the quality of life and will positively impact on social and economic welfare.

P11 Genomics, Genomic technology including bioinformatics methods, gene structure and gene product function and Epigenetics

Investigation of an atypical 16p11.2 microdeletion as a possible pathogenic rearrangement associated with congenital defects and mental retardation.

***M. A. Ramos-Arroyo**[1], R. Narvaiza-Martinez[1], A. Bengoa-Alonso[1], M. Moreno[1], B. Nieva[2], M. E. Querejeta[2];*
[1]Hospital Virgen del Camino, Pamplona, Spain, [2]Policlínica San Sebastián, San Sebastián, Spain.

Chromosome 16p11.2 deletion is an emerging syndrome associated to a variable phenotype, including autism. The common deleted region extends from genomic location 29.4-31.1Mb and its flanked by low copy repeats. A deletion of the adjacent region has been also described in a boy with mental retardation and his father with learning disabilities. We present an additional case with the same atypical 16p11.2 deletion and speculate about its possible pathogenic effect.
The girl showed facial dysmorphic features, congenital malformations (aortic valve defects, agenesis of the corpus callosum and uretero-vesical reflux), moderate-severe mental retardation and speech disorder. She carried a *de novo* balanced (1;17)(q21;q23) translocation, observed by conventional karyotype. Genome-wide oligonucleotide arrays studies detected a 289kb deletion (location 28.73-29.02Mb), flanking the recurrent 16p11.2 microdeletion/duplication region. The deletion was confirmed by FISH studies and ruled out in both parents. Translocation breakpoints, located at 1q11.1 (a non-containing gene region) and 17q23.1.q23.2, did not present genomic imbalances. It has been shown that around 30% of cases with apparently balanced reciprocal translocations and abnormal phenotype present genomic rearrangements in other chromosomes. We, therefore, hypothesis that the atypical deletion of 16p11.2, present in our patient and previously reported in two cases with intellectual disabilities, may have a pathogenic effect, either as a primary cause or as a contributing factor to the phenotype. Further investigations to rule out the possibility of gene disruption within 17q23 region and characterization of additional cases with 16p11.2 deletions are needed to fully understand the role of this rearrangement.

P11.002
Study of the ACVR1 gene expression and regulation: the 5‘UTR and the promoter region

***F. Giacopelli**[1], S. Cappato[2], M. Mura[2], R. Ravazzolo[1,2], R. Bocciardi[1];*
[1]University of Genoa and CEBR, Genova, Italy, [2]G. Gaslini Institute Laboratory of Molecular Genetics, Genova, Italy.

ACVR1 encodes a BMP type I receptor mutated in Fibrodysplasia Ossificans Progressiva, a severe form of heterotopic ossification. Mechanisms regulating ACVR1 expression are still unknown. According to our analysis, the 5’ genomic region of ACVR1 is subjected to alternative splicing generating several transcripts in which different 5’UTR exons are combined to a common coding sequence, with different expression profiles according to cell type. As assessed by cell transfection with different full length cDNA constructs and western blot analysis, we observed that different splicing isoforms correlated with different quantitative expression of the protein.
Moreover, with the aim to identify regulatory elements involved in the transcriptional control of ACVR1 expression, we focused on a genomic region spanning around 2.9 kb, from position -2.893 to +32 upstream of transcription start site (tss, +1). This region is highly conserved and particularly rich in GC nucleotides. A functional characterization of the ACVR1 promoter was obtained by subcloning the whole fragment and a series of derived deletion segments in a Luciferase expression vector and transfection in different cell lines. The strongest promoter activity was displayed by a 700 bp fragment upstream of tss, but a residual and quite significant activity was still present in a 100 bp fragment.
Our data suggest that besides the transcriptional control of ACVR1 expression operated by the promoter region, other mechanisms involving the 5’UTR region, in particular translational regulation, can take place.
Supported by RFPS-4-631972 grant “Genetic Bases of Birth Defects” from the Italian Ministry of Health.

P11.003
Identification of new putative Alpha globin mutations in Iranian population

N. Bayat, *S. Jalilnejad, F. Daneshimehr, A. Azarkevan, H. Imanian, H. Najmabadi;*
Kariminejad-Najmabadi Pathology & Genetics Center, 14665/154, Tehran, Iran, Tehran, Islamic Republic of Iran.

Alpha thalassemia is usually caused by deletions in alpha globin gene cluster, and the role of point mutations is less investigated.
In present study a total of 3438 individuals with unexplained hypochromic microcytic anemia who did not reveal the most common alpha thalassemia deletions (3.7kb, Med, 4.2kb, 20.5kb) by gap-PCR, were subjected for alpha2 and alpha1 globin gene DNA sequencing, respectively. Total of 2194 alpha2 and 1244 alpha1 globin DNA sequencing assays were performed. In cases of absence of nucleotide change, the sequences were analyzed by CodonCode aligner software (V. 3.7.1), to exclude frame shifts and none sense mutations. Other variations were checked by Polyphen online software to identify whether the mutation is damaging or not.
Seven new mutations have been identified, of which 2 located in alpha2 loci (Cd 83 T>G, Cd43 C>A) and 5 in alpha1 loci (Cd99 A>T, Cd34 T>C, IVSI-4 A>G, Cd44 insC and Cd109 delC). Among alpha1 globin mutations, the Cd99 was nonsense, Cd44 and Cd109 were frameshifts, and the Cd34 was considered as possibly damaging by Polyphen but the role of IVSI-4 needs to be further analyzed.
This study remarks the importance of point mutations in alpha globin gene cluster, and can identify their role in microcytic anemia. Besides, there were plenty of nucleotide variations identified as polymorphisms. Locating these positions and studying their relations with damaging mutations enables us to perform a population study for discovering the origin of the mutations.

Rapid high-throughput Alport diagnosis by next generation sequencing.

R. Artuso[1], *C. Fallerini[1], L. Dosa[1], F. Scionti[1], M. Clementi[2], G. Garosi[3], L. Massella[4], R. Mancini[1], F. Mari[1], I. Longo[1], F. Ariani[1], A. Renieri[1], M. Bruttini[1];*
[1]Medical Genetics, Siena, Italy, [2]Medical Genetics, Padova, Italy, [3]Nephrology, Siena, Italy, [4]Nephrology and Dialysis, Roma, Italy.

Alport syndrome is an hereditary nephropathy often associated with sensorineural hypoacusis and ocular abnormalities. Mutations in the *COL4A5* gene causes X-linked Alport syndrome. Mutations in *COL4A4* and *COL4A3* genes have been reported in both autosomal recessive and autosominal dominant Alport syndrome. The conventional mutation screening, performed by DHPLC and/or Sanger sequencing, is time consuming and has relatively high costs due to the absence of hot spots and to the high number of exons per gene: 51 (*COL4A5*), 48 (*COL4A4*), and 52 (*COL4A3*). Usually, several months are necessary to complete the diagnosis, especially in cases with less informative pedigrees. To overcome these limitations, we designed a next generation sequencing protocol enabling simultaneous detection of all possible variants in the three genes. We used a method coupling selective amplification to the 454 Roche DNA-sequencing platform (GS junior). The application of this technology allowed to identify the second mutation in two Alport patients (p.S1147F in *COL4A3* and p.R1682W in *COL4A4*) and to exclude the diagnosis of Alport in a third patient. This study therefore illustrates the successful application of next generation sequencing to routinely diagnosis of Mendelian disorders with locus heterogeneity.

P11.005
Genotype-phenotype correlation in X-Linked Alport syndrome patients carrying missense mutations in the collagenous domain of COL4A5

D. Tsiakkis[1], P. Koupepidou[1], &. Christodoulakis[2], M. Pieri[1], K. Felekkis[1], G. Papagregoriou[1], P. Demosthenous[1], ***C. Deltas***[1];
[1]University of Cyprus,Department of Biological Sciences, Nicosia, Cyprus, [2]University of Cyprus,Department of Electrical and Computer Engineering, Nicosia, Cyprus.

The X-linked Alport syndrome (XLAS) is caused by mutations in *COL4A5*. More than 400 mutations have been reported in the literature to date and this allelic heterogeneity is also reflected by a phenotypic heterogeneity. Genotype-phenotype correlation remains elusive, although recent analyses have shown that missense mutations (of which the majority are glycine substitutions) give a better prognosis than other types of mutations. A genotype-phenotype correlation was examined with regards to age at onset of ESRD and: (i) distance of mutation from closest natural interruption, (ii) location of mutation along the gene, (iii) change in number of side-chain carbon atoms caused by the mutation, and (iv) change in charge and hydrophobicity caused by the mutation. Trends were evident for all statistical analyses and a statistically significant (p-value: 0.0017) correlation (R square: 0.1362) could be found, with age at onset of ESRD decreasing with increasing number of carbon atoms found in the side chain of the substituting amino acid. We also examined the possibility of interruptions representing subtle mutational hotspots and although a trend could be seen with having less mutations within interruptions, no statistical significance could be reached. Hence, the size of the side chain of the substituting amino acid is an important factor in determining the disease phenotype with regards to age at onset of ESRD. This can be explained by the fact that any other aminoacid substituting glycine is larger and therefore cannot be accommodated where the three chains meet in the collagenous triple helix.

P11.006
Targeted Re-Sequencing in ALS / FTD and patients with neurodegenerative and movement disorders

S. Biskup[1,2], *T. Scheurenbrand[2], H. Pander[3], M. Synofzik[1], C. Wilhelm[2], D. Boehm[2];*
[1]Hertie Institute for Clinical Brain Research, Tübingen, Germany, [2]CeGaT GmbH, Tübingen, Germany, [3]Olgahospital Stuttgart, Tübingen, Germany.

Background: Several genes have been implicated in the pathogenesis of amyotrophic lateral sclerosis (ALS), frontotemporal dementia (FTD) and other types of neurodegeneration. As each gene accounts for only a small fraction of cases, it is crucial to develop an efficient tool for investigating all genes simultaneously. Here we present a very fast and cost-efficient targeted re-sequencing approach to screen for all known ALS / FTD and genes associated with neurodegeneration and potential candidate genes simultaneously. We expect to identify major genetic risk factors in a significantly larger proportion of cases as compared to the cases identified with the conventional sequencing method. In addition, careful collection of all clinically relevant information will allow us to investigate how the genotype determines the phenotype in the different subsets of neurodegenerative diseases.
Methods: Genomic DNA is enriched using a custom made Agilent SureSelect in solution kit. Sequencing of 50 genes (360kb in total) is performed using barcoded libraries on one oct (1/8 slide) on the SOLiD 4 platform generating approximately 5 Million mappable 50 basepair reads per patient. The basic data analysis is performed with Bioscope v1.2. Additionally, we developed a diagnostic pipeline. All variants are then re-sequenced by the gold standard Sanger sequencing or quantitative PCR, respectively.
Results and Conclusion: We introduce a fast and highly efficient screening tool for variants in genes associated with movement disorders and neurodegenerative diseases. Here, we present solved cases and troubleshooting of unsolved cases.

Besta", Milan,

Italy, [11]Epidemiology and Statistics Unit, Institute G. Gaslini, Genoa, Italy, [12]Child Neurology and Psychiatry Unit, Maggiore Hospital, Bologna, Italy, [13]Dipartimento di Scienze Pediatriche, University of Torino, Torino, Italy, [14]Biologia Generale e Genetica Medica, Università di Pavia, Pavia, Italy, [15]Laboratory of Genetics, Oasi Institute for Research on Mental Retardation and Brain Aging, Troina, Italy.

This study show an extensive search for genomic rearrangements by microarray-based comparative genomic hybridization (array-CGH) in patients with epilepsy of unknown etiology.

Two sets of 279 patients with unexplained epilepsy and 246 controls were screened by using a 44K CGH-array. CNVs overlapping >50% with those reported in the Database of Genomic Variant were not followed-up. Validation was performed by FISH, higher density array-CGH, or quantitative-PCR. GeneCodis2.0 software was used to explore the biological function of genes included within the identified CNVs.

Rare CNVs occurred in twenty-six (9.3%) patients and in sixteen (6.5%) controls (p=0.26). CNVs identified in patients were larger (p=0.027) and showed higher gene content (p=0.021) than controls. CNVs sized >1Mb (p=0.002) and including >10 genes (p=0.005) occurred more frequently in patients than controls. Conversely, the two groups did not differ for CNVs smaller than 1Mb (p=0.051) and involving 10 or less genes (p=0.547). Nine (34.6%) patients among those harboring rare CNVs showed rearrangements associated with emerging microdeletion/microduplication syndromes. Mental retardation and neuropsychiatric features were associated with rare CNVs (p=0.004) whereas epilepsy type did not. Significant enrichment of genes involved in ion transport was observed within CNVs identified in patients. Patients with epilepsy have a significantly increased burden of large, rare, gene-rich CNVs, particularly when associated to mental retardation or other neuropsychiatric features. Therefore, we suggest that CNVs screening should be routinely performed for diagnostic purposes only in such patients. Moreover, the implementation of very high resolution screening in clinical practice deserves caution.

Assessing size distribution and integrity of high molecular weight DNA prior to aCGH experiments

***R. Salowsky**, M. Gassmann;*

Agilent Technologies, Waldbronn, Germany.

Multiple genomic applications such as for example aCGH or next-gen sequencing (NGS) require highest DNA quality as the level of DNA degradation can have a significant effect on downstream sample processing and therewith final data quality and interpretation. Over the past years, microfluidic on-chip electrophoresis has become the standard tool for assessing size, quantity and integrity of DNA and RNA starting material in many experimental workflows. With an optimized protocol and improved electrophoresis chemistry, the analytical size range could be extended which resulted in a new prototype assay. This extended size range enables the integrity assessment of high molecular weight DNA isolated from tissues or cell lines by column based extraction methods. In contrast to slab gel analyses, this prototype assay provides standardized information on DNA size distribution, quantity and integrity. Results from a study correlating DNA sample quality with aCGH read-outs are discussed.

P11.009

Diagnostic use of targeted array CGH platforms: 2009-2010 Kocaeli University Experience

***H. Savli**, D. Sunnetci, N. Uzulmez, E. Gumuslu, S. Eren, B. Enguzel, R. Akkoyunlu, D. Yavuz, Z. Ilkay, N. Cine;*

Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.

INTRODUCTION: Array CGH technology is a new method for screening human genetic disorders that cause changes in DNA copy number. This molecular karyotyping technology is remarkable with fast analysis and highly sensitive diagnostic value. We aimed to use this technology as a diagnostic tool in Kocaeli University Hospital. We performed analysis for nine groups of patients, using different targeted array CGH platforms.

MATERIALS and METHOD: Following patient groups were accepted to Kocaeli University Medical Genetics Department; Microdeletion Syndrome(35 patients) Primary Autism(35 patients), 18q21.31 Deletion Syndrome(2 patients), Mental Retardation(52 patients), Prenatal Diagnosis(10 patients), Implantation Failure(50 patients), Primary Amenorrhea(1 patients), IVF improvement(7 patients) and Hematological Malignacy(4 patients). We isolated DNA samples of 514 patients. DNA samples labelled according to the protocols.Samples were hybridized with CytoSure Syndrome Plus(v2) 4x44K microchips and with 24Sure platforms.Hybridised platformes were scanned with Agilent Microarray Scanner.Scanned results were analysed by Cytosure Analysis Software-v.2.0.8 and BlueFuse Multi-v2.1.

RESULTS: We found 7 aberrations in 35 autistic patients, 35 microdeletions in 35 patients, 6 aberrations in 10 prenatal diagnosis investigations, 38 aberrations in 52 mental retardation patients, 4 aberrations in 50 implantation failure patients, and 5 aberrations in 4 hematological malignancy patients.All aberrations were confirmed with FISH analysis.All analysis have been completed less then 72 hours. Starting DNA amounts were between 10ng to 500ng.

CONCLUSION: We conclude that, targeted aCGH platforms have a precious contribution to solve our diagnostic problems in clinical use. This technology is an efficient tool for delineating chromosomal aberrations. It is an indispensable attachment to conventional cytogenetics.

Saudi Biobank experience in enhancing biological and genomic research at King Abdullah international medical research Center

***I. Alabdulkareem**, M. Aljumah;*

KAIMRC, Riyadh, Saudi Arabia.

Biobanks are a new frontier for biomolecular research, clinical genomics and personalized medicine that seeks to integrate collections of bio-specimens with corresponding patient's medical histories, and lifestyle information. Combining and comparing biological tissue samples with genetic and historical patient information, researchers will be able to investigate the fundamental mechanisms of diseases in rich new ways. New insights into molecular and genetic process will lead to better techniques for predicting disease susceptibility, as well as to more targeted and innovative ways to treat serious diseases.

Saudi Biobanking study is designed as a longitudinal study of constitutional and environmental factors influencing the development of most prevalent chronic diseases in Saudi population.

To ensure the value of the stored biological material in serving is main purpose of advancing healthcare of our country through research. Ethical standard and Several quality measures has been implemented to guide the collection process, sample processing, health data acquisition, blinding and retrieving the Saudi Biobank (SB) is designed to store for more than 4 million tubes from 200,000 persons. The blood components, urine, tissue DNA, RNA and dry DNA/blood materials will be accumulate into SB. In addition to that, the banking of purified DNA/RNA from patients will not be limited to the above number; however, DNA and Buffy coat is already in our bank.

This presentation is to summarize the value of biobanking in enhancing biological and genomic research.

BioSHaRE-IT: Solving the bioinformatic challenges of biobanking

*A. J. Brookes[1], P. Burton[1,2], V. Ferretti[3], I. Fortier[3], J. R. Harris[4], R. K. Hastings[1], H. Hillege[5], J. Litton[6], **M. Swertz**[5];*

[1]Department of Genetics, University of Leicester, Leicester, United Kingdom, [2]Department of Health Sciences, University of Leicester, Leicester, United Kingdom, [3]Research Institute of the McGill University Health Center, Public Population Project in Genomics, Montreal, QC, Canada, [4]Norwegian Institute of Public Health, Oslo, Norway, [5]University Medical Center Groningen & University of Groningen, Groningen, Netherlands, [6]Karolinska Institute, Stockholm, Sweden.

Current IT infrastructure in biobanking is imperfect. Biobank databases are often rather basic and almost never interoperable. The project 'Biobank Standardisation and harmonisation for Research Excellence in the European Union' (BioShaRE-EU http://bioshare.eu/) was launched in early 2011. It explicitly addresses the informatics needs of biobanking through its sub-program 'BioSHaRE-IT'.

BioSHaRE-IT will work with other initiatives (e.g., BBMRI, DataSHaPER, ELIXIR, GEN2PHEN, OBiBa, P3G) as part of an open collaboration, to tackle many complex computational and data management challenges

relevant to biobanking. Efforts will exploit 'starting reagents' such as OPAL, MOLGENIS, GWAS Central (HGVbaseG2P), DataShield, DataShaper, etc, with a focus upon;
1) developing data models for core molecular, phenotype, and environmental data along with ontologies so that data can be managed, integrated and represented optimally
2) developing federated databases for local storage and deployment of different types of biobank content, such as sample and research catalogues, genetic/genomic data, detailed phenotype information, epidemiological and environmental data
3) devising data exchange formats and data access mechanisms (based upon digital identifiers) to allow a smooth and secure exchange of data to, from, and between biobanks
4) providing tools and solutions for study design, phenotype harmonisation, data curation, and data visualisation, so that biobanks can adopt these solutions directly and not have to reinvent them
5) developing tools for biobank data searching and remote analysis, along with distributed grid technologies to deal with the data computation and data storage management issues.
BioSHaRE-EU is funded by the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement 261433

P11.012
Identifying knowledge contributors - motivating online sharing of research data

G. A. Thorisson, *O. Lancaster, A. J. Brookes;*
University of Leicester, Leicester, United Kingdom.

Contributor identification is a core challenge in data publication. As in scholarly communication more generally, non-unique person names and the current lack of a global identification infrastructure for producers of scholarly content makes it difficult to establish the identity of authors and other contributors. This in turn makes it difficult to accurately attribute datasets published via online digital repositories to their creators - one of several key requirements for including these important outputs in the scholarly record.
In the GEN2PHEN project (http://www.gen2phen.org) we are developing a series of novel web-based systems and processes for online dissemination of genetic variation and other research data. The core aim is that of ensuring that data creators are recognized and rewarded for publishing data. This work builds on and integrates with recently launched international initiatives to i) extend and adapt the existing DOI infrastructure for identifying, locating and citing online datasets (DataCite: http://www.datacite.org), and ii) create a global registry of unique identifiers for authors and other contributors (ORCID: http://www.orcid.org).
The technical approach we are exploring in this pilot project utilizes this emerging global data citation and contributor identification framework, in order to allow published datasets to be discovered, cited in a scholarly context and unambiguously attributed. We argue that, along with other measures, such an incentive-based approach is key to motivating the sharing of data and other types of digital research outputs in the life sciences.
GEN2PHEN is funded by the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement 200754.

HUGETOOL: A computer-based method for automated identification of gene-environment interactions in human studies including a large number of participants, SNPs and environmental factors

O. Coltell[1], *J. M. Ordovas*[2], *C. Saiz*[3], *M. Forner*[1], *F. Gabriel*[4], *D. Corella*[3];
[1]Universitat Jaume I, Castellon, Spain, [2]Tufts University, Boston, MA, United States, [3]Valencia University, Valencia, Spain, [4]Hospital Clinic de Valencia, Valencia, Spain.

Common diseases are determined by the complex interplay between environmental and genetic factors. However, current methods of data analysis of gene-environment interactions using traditional approaches are inefficient. High-throughput methods of analysis in large scale epidemiological studies including thousands of subjects and hundreds of SNPs and environmental factors should be implemented. We developed an integrative computer tool, HUGETOOL (HUman Gene Environmental inTeraction tOOL), for large-scale analysis of gene-environment interactions, in human studies of complex diseases including a large number of subjects, SNPs, as well as environmental factors. That resource uses standard statistical packages to build and fit the gene-environment interaction models by means of syntax scripts in predicting one or more continuous or dichotomic phenotypes. Codominant, dominant and recessive genetic interaction models including control for covariates are automatically created for each SNP in order to test the best model. Environment variables can be used both as continuous and as categorical. From the standard outputs, HUGETOOL extracts a selected set of parameters (regression coefficients, p-values, adjusted means, etc.), and groups them in a single MS Excel Spreadsheet. The tool allows editing the set of filter parameters, filtering the selected results depending on p-values, as well as plotting the selected gene-environment interactions to check consistency. We implemented our tool in real data obtained in two standard cardiovascular studies carried out in the Mediterranean population, and demonstrated the excellent performance of this tool. In conclusion, HUGETOOL is a very useful and friendly tool for exploring and identifying gene*environment interactions in complex diseases.

P11.014
Evaluation of a novel, single molecule, amplification-free method for the detection of Copy Number Variation (CNV)

T. Guettouche[1,2], *Y. Cardentey*[1], *M. A. Pericak-Vance*[3], *J. R. Gilbert*[2], *D. J. Hedges*[2];
[1]University of Miami, School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL, United States, [2]Hussman Instititute for Human Genomics, Center for Genome Technology, Miami, FL, United States, [3]University of Miami, Hussman Institute for Human Genomics, Miami, FL, United States.

Copy number Variation (CNV) is a major component of the genomic diversity present within the human population. Several methods for genome-wide discovery of structural variants now exist , including array-based genomic hybridization and High throughput SNP genotyping arrays (i.e. GWAS arrays). More recently, structural variation has also been inferred from Second Generation Sequencing data . As CNV calls made from each of these approaches can be subject to appreciable false positive rates, detected variants of interest are generally corroborated by an independent method. The method of choice for CNV confirmation has primarily been real-time qPCR. Here we report the evalution of a novel CNV assay based on the NanoString nCounter Analysis System. The nCounter system uses a hybridization-based single molecule capture approach not requiring amplification of input DNA. Invidual tripartite complexes of the target molecule, a biotin labeled probe and a fluorescently labeled ("barcoded") probe are directly counted. We compared the performance of the nCounter system at 30 putative CNV loci in a set of 96 human samples, all of which have data at these same loci from ABI Taqman CNV assays. A subset of samples also have data available from Agilent aCGH 244k custom and Illumina 1M Infinium arrays. Preliminary results show that the Nanostring method exibits 86% agreement with the Taqman CNV assays across all studied loci and individuals. When three problematic repetitive loci are excluded, concordance rises to 96%. Our initial results suggest the nCounter system will provide a promising alternative for validation of copy number variants.

P11.015
Selection of SNPs to be replicated in GWA investigations: a Bayesian approach

A. De Grandi[1], *M. Modenese*[1], *F. Domingues*[1], *C. Pattaro*[1], *F. Ruggeri*[2], *A. Pastore*[3], *J. Attia*[4,5], *J. Barrett*[6], *M. Boehnke*[7], *G. Borsani*[8], *G. Casari*[9], *C. S. Fox*[10,11], *A. Hicks*[1], *F. Marroni*[12], *G. Parmigiani*[13], *A. Pfeufer*[1], *C. Schwienbacher*[1], *The CKDGen consortium, P. P. Pramstaller*[1,14,15], *J. R. Thompson*[16], *C. Minelli*[1];

Biomedical Sciences and Biotechnology and School of Medicine, University of Brescia, Brescia, Italy, [9]Human Molecular Genetics Unit, Center for Genomics, Bioinformatics, and Biostatistics, San Raffaele University, Milan, Italy, [10]The National Heart, Lung, and Blood Institute's Framingham Heart Study, Framingham, MA, United States, [11]Center for Population Studies, Framingham, MA, United States, [12]Institute of Applied Genomics, Udine, Italy, [13]Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, MA, United States, [14]Department of Neurology, Central Hospital, Bolzano, Italy, [15]15 Department of Neurology, University of Lübeck, Lübeck, Germany, [16]Department of Health Sciences, Centre for Biostatistics and Genetic Epidemiology, University of Leicester, Leicester, United Kingdom.

In GWA investigations, SNPs for replication are selected based either on discovery *p*-values alone or with some consideration of the SNP/gene function. In the former approach, a SNP located within a biologically relevant gene has the same *a priori* probability of being selected as a SNP located in any random genome position. In the latter, inclusion of biological considerations is usually made in a very subjective way. We are developing a Bayesian approach to SNP selection that formally incorporates evidence from different sources supporting the effect of a SNP/gene. We identified 15 sources of evidence, from functional to linkage and association studies, information on which is retrieved from publicly available databases using an *ad-hoc* bioinformatics tool. Since different types of evidence may carry different "weight" in influencing SNP selection, we defined such "weights" through expert-opinion elicitation, using a structured group communication process organised in two Delphi rounds involving 10 anonymous experts. Using as an example a GWA meta-analysis of 20 studies on glomerular filtration rate from the CKDGen consortium (Köttgen et al, *Nat Genet* 2010), we are testing the hypothesis that our approach may help identify true associations in situations with limited sample size. We present the framework of our approach, the types of evidence incorporated in the Bayesian model with "weights" defined by the experts, the bioinformatics tool for evidence retrieval, and preliminary results on the performance of the method.

P11.016

GWAS Central curation tool: solving the bioinformatics challenges of complex data management with MOLGENIS

***S. Gollapudi**[1], M. A. Swertz[2], R. C. Free[1], R. K. Hastings[1], A. J. Brookes[1];*
[1]Department of Genetics, University of Leicester, Leicester, United Kingdom, [2]Genomics Coordination Center, University Medical Center Groningen & University of Groningen, Groningen, Netherlands.

The creation, management and validation of complex biological datasets are time-consuming and error-prone, so software tools are needed to ease the burden on curators. We have therefore developed a curation tool in the GEN2PHEN project (http://www.gen2phen.org) for the genetic association database GWAS Central (http://www.gwascentral.org) using the MOLGENIS tool (http://www.molgenis.org) for rapid development of biomedical database software.

GWAS Central is a comprehensive resource of summary-level findings from >700 genome-wide association studies with >18M p-values. Previous methods for importing study metadata and marker data involved time-consuming construction of custom software pipelines. To solve this, we built a dedicated curation tool with many useful features: a 'quick-add' interface for new studies (to become a submission tool for users to submit data directly to GWAS Central); automatic assignment of stable identifiers for all study components; study 'overview' and 'preview' interfaces for quick data management; a PubMed look-up service for annotating studies with citations; and marker data import and validation. We are now constructing a security layer to track updates and deletions within the database.

We are also exploring the use of the SOAP and REST web services generated by MOLGENIS to develop Taverna workflows, which can then be integrated within the GWAS Central site. This will enable users to enact complex queries over millions of p-values from behind a simple, easy-to-use web portal, without requiring significant bioinformatics expertise.

This research received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement number 200754, GEN2PHEN.

P11.017

GWAS Central: an advanced database for the integration and comparative interrogation of genome-wide association study datasets

***R. C. Free**, R. K. Hastings, S. Gollapudi, T. Beck, G. A. Thorisson, A. J. Brookes;*
University of Leicester, Leicester, United Kingdom.

Comprehensive genome-wide association study (GWAS) data-sets are rarely published in journals or databases, and in the case of negative findings often not reported at all. Consequently, comparing different studies is difficult, and it is impossible to examine a full and unbiased picture of all the data that exist.

To address this deficit, GWAS Central (www.gwascentral.org) (previously HGVbaseG2P) was constructed - representing a free and open access resource for the interrogation of summary-level GWAS data, ultimately combining the features of a database and a scientific journal.

GWAS Central employs powerful graphical and text based data presentation methods for discovery, visualisation and co-examination of many studies, at genome-wide and region-specific levels. Studies of interest can be identified using chromosomal regions/genes and markers. There is also the facility for researchers to securely view their own uploaded datasets alongside many published studies.

Current content includes top p-values from collections; supplementary data; direct researcher submissions; and publicly available data. Consequently, the database now hosts >21 million p-values and 708 studies (vs 3,948 p-values and 798 studies in the NHGRI GWAS catalog), representing an estimated ~5% of all such data yet produced.

A version of GWAS Central will soon be released for research groups to install on their own servers allowing them to manage, analyse and control access to their own data. These installations will be interoperable and searchable as a federated network.

This research received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement number 200754, GEN2PHEN.

P11.018

Non-Disjunction: from a Bioinformatic and Epigenetic Approach towards a clinical validation

***I. Ejarque-Doménech**[1], B. Banelli[2], G. López-Campos[3], F. Vicente-Martín[4], C. Baldo[5], A. Díez-Juan.[6], L. Gil-Alberdi.[7], F. Martín-Sánchez.[4];*
[1]Agencia Valenciana de Salut, Utiel, Spain, [2]Advanced Biotechnology Centre., Genova, Italy, [3]Department of Bioinformatics and Public Health. Institute of Health Carlos III., Majadahonda, Spain, [4]Department of Bioinformatics and Public Health. Institute of Health Carlos III., Majadahonda., Spain, [5]Galliera Genetic Bank. Ospedale Galliera., Genova., Italy, [6]Príncipe Felipe Research Centre., Valencia., Spain, [7]University Alfonso X "El sabio"., Madrid., Spain.

The aim of this work is to present a fully "in silico" approach for the identification of genes that might be involved in the susceptibility for non-disjunction diseases and their regulation by methylation processes.

We have carried out a strategy based on the use of online available bioinformatics databases. Among these the most relevant ones used were OMIM, HUGO, GeneOntology and PubMed. Bioinformatics programs were used to select, retrieve and analyse the genes and their promoters to identify regions susceptible of being methylated, and thus identify those genes susceptible of being epigenetically regulated.

As result we have obtained 34 putative susceptibility genes regulated by methylation processes. We were neither on the need of developing new software nor carrying out clinical laboratory experiments for the identification of these genes. So it would be interesting to analyze the methylation patterns of these genes in the mothers of children with Down syndrome (cases) to compare it with the one of mothers of sound children. MSP (Methylation Specific PCR) is a good method to analyze it.

We consider that this "in silico" methodology is robust enough to provide candidate genes that must be checked "in vivo" due to the clinical relevance of non-disjunction diseases with the aim of providing new tools and criteria for their diagnosis. The molecular origin of constitutional aneuploidies is a classical area of research that could be of great interest if investigated with new approaches: bioinformatics and epigenetics.

ESHG congress non-disjuntion may 2011. Version ENVIADA 20-02-2011.

Using GENCODE annotation to investigate the functional effects of Loss of Function variants identified by the 1000 Genomes Project

G. Mukherjee, *C. Amid, I. Barnes, A. Bignell, D. Carvalho-Silva, A. Frankish, T. Hunt, M. Kay, D. MacArthur, J. Mudge, G. Saunders, C. Snow, M. Suner, C. Tyler-Smith, J. Harrow;*

Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

The GENCODE consortium is producing a reference human gene set rich in alternative splicing and functional annotation that will provide the basis for analysis by the 1000 Genomes project. Manual annotation is supplemented by automated gene predictions from Ensembl to produce the GENCODE gene set, the default annotation in the Ensembl browser. A catalogue of variants in protein coding genes predicted to result in Loss of Function (LOF), based on 1000 genomes data, were identified by investigating the intersection of SNPs and indels from the three pilot phases, together with GENCODE gene models. We have manually analysed 885 SNPs/indels that introduce premature termination codons or splice site disruptions, firstly to validate and ensure completeness of the gene models on which LOF calls are based. One third of all variants investigated were miscalled due to errors in genome sequence or computational gene predictions. Secondly, we have assessed whether the exon containing a LOF variant is constitutive or alternatively spliced, and finally we predict the functional impact of the variant. Of the valid calls, 36% affected exons that showed transcriptional evidence of being skipped in splice variants. Furthermore, 17% are predicted to effect changes in the protein product that may not result in LOF; producing for example small CDS truncations. We will describe how high quality annotation of gene models are essential to accurately predict the consequences of a SNP, and we propose a model whereby LOF may be considered at the level of the transcript and not the overall locus.

P11.020

Automated nucleic acid purification with Thermo Scientific KingFisher magnetic particle processors and KingFisher Kits

S. Suomalainen, *M. Suomalainen, N. Lindholm, V. Puro, A. Lamberg;*

Thermo Fisher Scientific, Vantaa, Finland.

The pure and intact DNA and RNA are doubtless the most important sample materials for various experiments in molecular biology. The magnetic particle technology combines the speed and efficiency of automation with high quality nucleic acid purification capability. Thermo Scientific KingFisher processors offer a patented technology based on the use of magnetic rods with specially designed plastic consumables, and the process can be combined with optimized KingFisher Kits. This automated nucleic acid purification method is described in the poster. Additionally, the process is compared with the competitors' purification systems.

KingFisher Kits are available for genomic and viral nucleic acid purification from wide variety of sample types e.g. blood, cells and animal or plant tissues. We analysed the performance of the purification process with five different KingFisher Kits. The KingFisher Blood DNA Kit was compared to three competitive methods or instruments, and the KingFisher Plant DNA Kit to four competitors. In each case the KingFisher Kits performed as well as or better than the competitors, and the performance was excellent. With the KingFisher Cell and Tissue DNA Kit and Total RNA Kit different sample materials and variable lysis times were tested. The results indicate the sensitivity of the purification process. In addition the performance of KingFisher Viral NA was tested in different applications.

The KingFisher processors together with the KingFisher nucleic acid purification kits and the Thermo Scientific BindIt software constitute an exceptional purification system for obtaining high yield and purity of DNA and RNA.

P11.021***

Integrative analysis of whole-genome and transcriptome sequence data for identification of treatment options for metastatic triple negative breast cancer

*A. Siddiqui[1], D. Craig[2], J. O'Shaughnessy[3], J. Kieffer[2], T. Moses[2], C. Barbacioru[1], S. Sirani[2], **O. Sakarya**[1], T. Izatt[2], S. Wong[2], J. Paquette[1], L. Hoang[1], J. Aldrich[2], A. Christoforides[2], J. Dinh[2], A. Kurdoglu[2], S. Mousses[2], D. Von Hoff[2], J. D. Carpten[2];*

[1]Life Technologies, Foster City, CA, United States, [2]TGEN, Phoenix, AZ, United States, [3]Baylor-Sammons Cancer Center, Houston, TX, United States.

Triple negative breast cancer (TNBC) is characterized by the absence of expression of estrogen receptor, progesterone receptor and Her2-neu, accounting for 15% of all breast cancer diagnosis. Targeted therapies have a reasonable likelihood of improving the cure rate of early stage TNBC, and promising therapies discovered in the metastatic setting are rapidly advancing through clinical trials. We present integrated analysis of matched normal and tumor whole genome data, along with tumor transcriptome sequencing data of multiple individuals with metastatic chemo-resistant TNBC.

In each case, two independent 1.5kb Mate-pair libraries were generated for both tumor and germ-line derived genomic DNA and sequenced using SOLiD version 4.0 paired 50mers to a target of 30x depth. The tumor transcriptome was sequenced on four replicates and compared to transcriptome sequencing from ethnicity-matched population-based control hyperplastic breast tissue. Genome analysis was performed using multiple aligners and variant callers. Transcriptome alignment was performed using Life Technologies Bioscope pipeline, and differential expression analysis was performed using EdgeR and DESeq. We prioritized annotated germline and somatic variants by integrative analysis with differential expression results. Several striking examples of intronic events correlating with either altered splicing or differential expression were observed in genes relevant to cancer treatment, suggesting that transcriptomic data may have high value in interpreting somatic events that fall outside of coding regions. Final integration of data was validated through knowledge mining and convergence of somatic events and expression.

For Research Use Only. Not intended for any animal or human therapeutic or diagnostic use.

P11.022

Using high-throughput SNP data to define the relationship between self-reported ethnicity and genetic identity in three Australian breast cancer studies

G. Athanasiadis[1], *M. Bui[2], E. Makalic[2], D. Schmidt[2], J. Stone[2], D. Park[3], K. Aujard[2], M. Southey[3], J. Hopper[2];*

[1]Unitat de Genòmica de Malalties Complexes, Institut de Recerca, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Centre for Molecular, Environmental, Genetic and Analytic Epidemiology, Melbourne School of Population Health, The University of Melbourne, Melbourne, Australia, [3]Department of Pathology, Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne, Melbourne, Australia.

Background.- Choosing the right subjects for a genome-wide association study implies, among other things, obtaining a sample with little or ideally no population structure. Even though efficient methods correcting for stratification now exist, these may fail when cases and controls come from entirely different populations. Subject recruitment is often based only on self-reported information about ethnic origin, but how well does this strategy deal with population structure issues?

Aim.- Here, we evaluate self-reported ethnicity as a predictor of genetic identity with respect to more objective information, such as patient/ parent/ grandparent place of birth in three Australian breast cancer studies.

Methods.- A total of 412 subjects from the (i) Australian Breast Cancer Family Study; (ii) Multiple Case Breast Cancer Families; and (iii) Australian Mammographic Density of Twins and Sisters were considered. Genotypes for 552,131 SNPs were determined with the Infinium® HD Human610-Quad BeadChip. Major population clusters were defined by means of principal component analysis (PCA) using EIGENSOFT. A naïve Bayes (NB) classifier was developed using self-reported ethnicity and place of birth as attributes and PCA clusters as the target value. Accuracy measures were used for the evaluation of the classification.

Results.- The sample showed a considerable level of stratification. PCA also revealed several inconsistencies, mostly concerning self-reported ethnicity, whereas the NB classifier indicated grandparent place of birth as the best predictor of genetic identity.

Conclusion.- Self-reported ethnicity, as opposed to grandparent place of birth, may not be the best guide for subject recruitment in epidemiological studies.

P11.023
Loss-of-Function Exomic Analysis in the identification of predisposition genes

E. Ruark, *K. Snape, S. Hanks, J. Douglas, N. Rahman;*
Institute of Cancer Research, Sutton, United Kingdom.

Exome sequencing has proved to be a powerful approach in the identification of causative variants underlying several Mendelian disorders. Two of the challenges that currently limit the widespread application of exome sequencing in disease gene identification are 1) the requirement for extensive, experienced statistical and bioinformatic infrastructure for sequence analysis and 2) the identification of insertion-deletion variants in short read data which impedes the ability to detect one of the commonest types of pathogenic mutation in human disease. We have been developing strategies to address these challenges. To address the first challenge we have been utilising and optimising a commercially available software, known as NextGENe, which uses a Burrows-Wheeler alignment algorithm to align short read data. We have analysed over 75 exomes from individuals with a variety of genetic conditions and to address the second challenge we have optimised indel calling and we have undertaken validation experiments. These showed that 48/54 (89%) insertion-deletion variants chosen randomly across our sample series were real. We have also developed a loss-of-function (LOF) script which identifies all variants predicted to result in premature protein truncation and have applied the script to all of the exomes. This has led to the identification of six truncating mutations that are pathogenic and several others that we are currently investigating. Our scripts allow the accurate detection and prioritisation of variants in exome sequencing that are most likely to be pathogenic and may be of value to other groups.

P11.024
A breast-cancer DNA methylation signature associated with field defect

S. Kumar Botla[1], A. Moghaddas Gholami[1], M. Malekpour[2], E. A. Moskalev[1], A. Aghajani[3], I. S. Bondar[4], R. Omranipour[2], F. Malekpour[5], A. Jahangiri Babadi[1], V. V. Bubnov[6], H. Najmabadi[3], J. D. Hoheisel[1], ***Y. Riazalhosseini[1];***
[1]Division of Functional Genome Analysis, German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]Cancer Institute, Imam Khomeini Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [3]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [4]Regional Oncology Clinic, Odessa, Ukraine, [5]Shohada Tajrish Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [6]Department of Genomics and Immunology, Odessa State Medical University, Odessa, Ukraine.

DNA methylation patterns have been recognised as cancer-specific markers with potential clinical application. We aimed at identifying differential methylation patterns between breast cancers and other breast lesions to establish a DNA methylation signature for breast cancer diagnosis. 117 fresh-frozen breast specimens including cancer, benign, normal-appearing breast tissue from patients and healthy individuals were analysed. Candidate genomic loci were isolated from DNA following bisulfite treatment and were hybridised to specialised oligonucleotide microarrays. A DNA methylation signature was identified by unsupervised analysis on the screening set, and its performance was assessed through bisulfite pyrosequencing in an independent validation set. The DNA methylation signature discriminates breast cancers from other samples in the screening set (10-12< adjusted p<10-6) (n=52) and is validated against an independent set of breast tissue samples (adjusted p<1.92e-07) (n=65). High sensitivity and specificity of the signature to detect breast cancer is demonstrated by Receiver Operating Characteristic (ROC) curves and the corresponding area under the curve (AUC) analysis (AUC> 0.90). This signature is constituted of 12 CpG sites associated with SFRP2 and GHSR genes, and show significant hypermethylation in cancers. Strikingly, the normal-appearing breast tissues from cancer patients are also methylated in these loci but at lower extent. This study reports a highly sensitive and specific molecular classifier for breast cancer detection based on DNA methylation. Furthermore, detection of methylated DNA in the normal-appearing breast tissues of cancer patients indicates an epigenetic field defect.

P11.025
Copy number variation and aberrations derived from cancer targeted exome resequencing

P. Flaherty[1,2], B. Kim[2], J. Buenrostro[1], G. Natsoulis[2], D. Burgess[3], M. Rodesch[3], ***X. Zhang[3]****, T. Albert[3], H. P. Ji[1,2];*
[1]Stanford University, Stanford Genome Technology Center, Palo Alto, CA, United States, [2]Stanford University School of Medicine, Stanford, CA, United States, [3]Roche NimbleGen, Madison, WI, United States.

Next generation DNA sequencing is rapidly becoming the platform of choice for numerous genomic applications. Complete genome sequencing is used to derive germline copy number variation (CNVs) and cancer copy number aberrations (CNAs) but its genomic resolution is limited by the extent of sequencing. Targeted resequencing (sequence capture) provides an option to increase the resolution and sensitivity of CNV and CNA analysis in a highly accurate and cost effective manner. For cancer genome analysis, targeted resequencing substantially increased the fold coverage over regions of interest, which is useful in more sensitive applications like CNA discrimination in complex tumor-normal tissue mixtures.

We have developed an experimental and statistical algorithmic solution to derive copy number variation from targeted resequencing on the scale of gene subsets up to whole exomes. We focused on four cancer samples with matched normal-tumor pairs including breast adenocarcinoma, colorectal carcinoma and lymphoma. To minimize experimental variance from the sequencing process, we used a novel indexing approach where matched tumor-normal pairs are sequenced together in a single sequencing lane. We enriched either gene subsets or whole exomes from these cancer samples. We then developed a statistical approach that incorporates absolute depth of coverage to provide a confidence in the tumor-normal read ratio. Using these combined procedures, we not only were able to confirm CNVs on the resolution of exons but also could discriminate indels smaller than 150 bases. Overall, our approach for CNV and CNA analysis on exome and exon subsets is robust and straightforward to implement.

Identification of low prevalence somatic mutations in heterogenous tumor samples

J. Warner[1]*, S. Kotsopoulos[1], O. Harismendy[2], L. Bao[2], D. Amorese[3], M. Stapleton[3], J. Olson[1], M. Nakano[2], B. Crain[2], K. Messer[2], P. Chen[3], V. Sementchenko[3], R. Schwab[2], K. A. Frazer[2], D. R. Link[1];*
[1]RainDance Technologies, Lexington, MA, United States, [2]Moores UCSD Cancer Center, University of California San Diego, La Jolla, CA, United States, [3]NuGEN Technologies, San Carlos, CA, United States.

To understand the progression and prognosis of cancer, researchers face a number of unique challenges. Current whole-genome sequencing studies are unable to cost-effectively achieve the required depth of coverage to discover rare mutations that represent 1% of a heterogeneous sample. Researchers have also been unable to routinely apply next-generation sequencing (NGS) technology to Formalin-Fixed Paraffin-Embedded (FFPE) samples, which are the standard archival method for nearly all solid tumors, due to challenges with low yield, degraded DNA, and sample extraction methodologies.

The RainDance DeepSeq™ FFPE Solution is the first ultra-deep targeted sequencing system for fresh-frozen and FFPE samples. Researchers can now interrogate as many as 500 targets across extensive collections of well-annotated clinical samples to discover rare cancer and other disease-specific mutations that represent as little as 1% of a heterogeneous sample.

To test the performance of the DeepSeq FFPE Solution, two matched breast and colon tumor samples from Fresh-Frozen Normal Adjacent, Fresh Frozen (FF), and FFPE Tissue were validated against a primer library targeting known cancer mutation hotspots across 46 genes. All samples were processed with the RainDance 2-Step Tailed Primer Assay and sequenced using the Illumina GAII with 100 base-pair reads. The data was analyzed and evaluated for sequence coverage and uniformity, along with the SNP detection and concordance between the FF and the FFPE tumor samples. Results demonstrate the ability for the RainDance DeepSeq FFPE solution to detect low prevalence mutations present in the FF and FFPE samples in both types of tissue.

Expression profiling of rectal tumors defines genetic determinants of response to treatment

M. Cuadros[1], *C. Cano*[1], *C. Olmedo*[2], *I. Segura*[3], *R. Conde*[3], *A. Blanco*[1], *P. Bueno*[2], *J. A. Ferrón*[3], *P. Palma*[3];

[1]*Department of Computer Science and Artificial Intelligence, University of Granada, Granada, Spain,* [2]*Department of Surgical Research, Virgen de las Nieves Hospital, Granada, Spain,* [3]*Division of Colon & Rectal Surgery – Department of Surgery, Virgen de las Nieves Hospital, Granada, Spain.*

BACKGROUND. To date, none of the identified signatures or molecular markers related to response to pre-operative chemoradiation (CRT) in locally advanced rectal cancer (LARC) has been successfully validated as a diagnostic or prognostic tool applicable to routine clinical practice. We applied DNA microarrays to gain insight into the molecular signatures associated with response to treatment after CRT.
METHODS. RNAs from patients with LARC without metastasis were obtained and subsequently cDNA and cRNA were synthesised for hybridization on *Human WG CodeLink bioarrays*. Tumor tissue biopsies were obtained before CRT. Significant genes were found using *Significance Analysis of Microarrays*. Real time quantitative RT-PCR (qRT-PCR) was used to confirm the results from the arrays. Results were correlated with pathological response (*Mansard's* criteria).
RESULTS. We used a t-test to find those genes that have an expression significantly different between responders and non-responders patients. We found 257 genes with an adjusted p<0.05, which clearly differentiate these two groups of patients after CRT. A detailed analysis identified genes encoding proteins associated with several canonical pathways, such as Pyrimidine and Purine Metabolism, and Colorectal Cancer Metastasis Signaling. As occurred in the microarrays, the level of expression of MYC determined by qRT-PCR, showed significant differences between Responder and Non-Responder subgroups.
CONCLUSIONS: Molecular signatures could provide the basis for improved treatment stratification of patients with LARC and define novel prediction of response to CRT treatment. Elevated levels of MYC not only induce growth and proliferation but also strongly could sensitize tumor cells toward pro-apoptotic stimuli including DNA damaging agents.

Identification of post-transcriptional regulatory elements in CDK5R1 3'UTR gene involved in CNS development and functioning

P. Zuccotti[1], *A. Barbieri*[1], *C. Colombrita*[2], *S. De Palma*[3], *S. Moncini*[1], *C. Gelfi*[3], *A. Ratti*[2], *M. Venturin*[1], *P. Riva*[1];

CDK5R1 encodes p35, an activator of CDK5, which is involved in neuronal migration and differentiation during CNS development. It has been implicated in some neurodegenerative disorders and candidate for the non-specific mental retardation. The considerable size of CDK5R1 3'UTR and the high level of sequence conservation suggests a role in post-transcriptional regulation. We recently reported that the large CDK5R1 3'UTR contains some regulatory elements affecting transcript stability. Precisely, a 138 bp region was shown to be the most destabilizing region within the 3'UTR. We search for post-transcriptional destabilizing factors in this region by UV-cross-linking that showed the binding of some RBPs among which the strongest band had a molecular weight compatible with that of the nELAV confirmed by immunoprecipitation. The fragment has been further divided in four regions for UV-crosslinking experiment that allowed to identify a stretch of 7 bp binding region and through the site-directed mutagenesis we identified the binding sequence. Silencing and overexpression of this factor are in progress in order to validate its destabilizing activity on CDK5R1 expression. To verify the binding of further regulatory elements the four regions of the 138 bp fragment have been transcribed and used for pulldown experiment of protein extracts from SK-N-BE cells. Following mass spectrometry analysis we identified the hnRNPA2/B1 for which the cytoplasmatic function is unknown and should be confirmed by immunoprecipitation assays. This study, besides defining the regulatory mechanisms of CDK5R1 expression, may help to identifying the pathogenetic implications of the gene in neurodegenerative and cognitive diseases.

Methylation status of the cyclin-dependent kinase 2A (p16INK4a/CDKN2A) promoter in human atherosclerotic plaques

M. S. Nazarenko[1,2], *V. P. Puzyrev*[1,2], *I. N. Lebedev*[1,2], *A. V. Markov*[1], *A. A. Sleptsov*[1], *A. V. Frolov*[3], *O. L. Barbarash*[3], *L. S. Barbarash*[3];

[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Research Institute for complex studying of cardiovascular diseases, Kemerovo, Russian Federation.*

Genome-wide association studies have linked common single nucleotide polymorphisms on chromosome 9p21.3 with risk of atherosclerotic diseases; however the underlying mechanism remains unknown. This genomic region contains several genes including the *CDKN2B* (p15INK4b) and *CDKN2A* (p16INK4a and p14ARF), which are key regulators of the cell cycle. Epigenetic inactivation of the *CDKN2A* gene by CpG islands methylation is well known in cancerogenesis and aging. The aim of the present research was to determine whether such methylation occurs in the atherosclerotic disease. Methylation-sensitive PCR using Hpa II restriction was employed in studying of the p16INK4a/CDKN2A promoter methylation in tissue samples of carotid artery (54 atherosclerotic tissues and 54 paired macroscopically normal specimens from the same patients). The promoter was not methylated in all studied tissue samples. This research was supported by Grant of Russian Foundation of Basic Research (10-04-00674).

Microarray-based DNA methylation analysis of human atherosclerotic plaques

V. P. Puzyrev[1,2], *M. S. Nazarenko*[1,2], *I. N. Lebedev*[1,2], *A. V. Frolov*[3], *O. L. Barbarash*[3], *L. S. Barbarash*[3];

[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Research Institute for complex studying of cardiovascular diseases, Kemerovo, Russian Federation.*

The contribution of epigenetic mechanisms to cardiovascular diseases remains poorly understood. Hypomethylation of genomic DNA is present in human atherosclerotic lesions and methylation changes also detect at the promoter level of several genes involved in the atherogenesis. In the current study for the first time quantitative microarray-based methylation profiling of 1505 CpG-sites across 807 genes was performed in two samples of atherosclerotic aorta and carotid artery wall lesions using the GoldenGate Methylation Cancer Panel I (Illumina). We identified 103 CpG sites (associated with 90 genes) that varied significantly in the DNA methylation level between the tissue samples. The most pronounced differences in the DNA methylation level were registered for a site which is located -541 bp from the transcription start site of imprinted gene *H19*. In particular, promoter's site showed a low level of methylation in the sample from the aorta's plaque area (0.02) compared to carotid artery (0.66). By comparing 90 genes that were differentially methylated between tissue samples in our study, 10 genes (*ICAM1*, *GSTM1*, *IGFBP1*, *POMC*, *APOA1*, *IL1RN*, *INS*, *LTA*, *MMP3*, *THBS2*) were overlapped with data from Human Genome Epidemiology Network (HuGENet), in which they were identified as candidates for cardiovascular disease continuum. This study was supported by state contract of the Ministry of Education and Science (Russia) for Science and Educational Centers (N 02.740.11.0281).

Haplotype analysis of MCP-1/CCL2 with essential hypertension in tatars from Russia

V. Belonogova, *O. Mustafina, I. Tuktarova, T. Nasibullin;*

Institute of Biochemistry and Genetics Ufa Science Centre of Russian Academy of Science, Ufa, Russia, Ufa, Russian Federation.

Objective: Inflammation play an important role in the initiation essential hypertension (EH). Evidence suggests that the chemokine, monocyte chemoattractant protein-1 (MCP-1; gene name, CCL2, previously SCYA2) is involved in EH. In the present study, we examined a possible association between polymorphic variants -5796A>T(rs1860190),

-2581A>G(rs1024611), 704(14)I/D (rs3917887) and 5357C>T (rs991804) of the CCL2 gene and EH.
Subjects and methods: We analyzed the association of genetic variation in the CCL2 gene in groups of hypertensive patients and healthy subjects from Tatar ethnic group (Bashkortostan, Russia). MCP-1 genotypes were determined in 164 and 209 individuals, respectively. DNA was isolated from whole venous blood using phenol-chloroform extraction by standard method. Genotypic frequencies in control subjects for each SNP were tested for departure from Hardy-Weinberg equilibrium using a Fisher`s exact test. Haplotype block structure was determined with Haploview 4.2 program using EM algorithm.
Results: In this study, we have successfully genotyped four SNPs of the CCL2 gene in 373 individuals. To test the association between MCP-1 and risk of EH, we determined 12 common haplotypes , that accounted for 75% of all haplotypes. The EH patient group showed a significant higher frequency of the CCL2*A*G*D*T haplotype compared to the controls (20.5% versus 13.5%, respectively; χ2=6.662, P=0.0099 Pperm=0.0472, OR=1.53). Thus, CCL2*A*G*D*T haplotype has association with EH.
Conclusion: Our data demonstrate that MCP-1 is significantly associated with the risk of occurrence EH, but the certain mechanism of this influence remains to be elucidated.

A study of the Insertion-Deletion polymorphism of the gene β-2 receptor of bradykinin (BDKRB2)

G. Gumerova, *D. Shamova, E. Vorobjeva, V. Gorbunova;*
Bashkir State Pedagogical University of M. Akmulla, Ufa, Russian Federation.

INTRODUCTION. Described in the literature that polymorphic variants of genes encoding components of the kallikrein-kinin system are associated with physical performance rights. The presence of favorable alleles of this system provides a more effective implementation of physical work and, therefore, contributes to better results in various sports. The study aims to estimate the frequency distribution of genotypes and alleles of gene ß2-bradykinin receptor (BDKRB2) in individuals with different coefficients of endurance. MATERIALS AND METHODS. We studied samples DNA of 199 of individuals with different values of endurance aged 18-30 years. Endurance coefficient (EC) is determined to assess the state of the cardiovascular system in accordance with formula Kvaasa: EC=heart rate×10/pulse pressure. The analysis genetic polymorphism is realized by polymerase chain reaction (PCR). Statistical data processing was carried out using a software package ANOVA (spss v13). RESULTS. Analysis of the frequencies of genotypes and alleles of gene ß2-bradykinin receptor (BDKRB2) between groups with different endurance factor revealed a significant increase in the frequency of the genotype *D/*D and allele *D in the group with increased activity of the cardiovascular system (P=0.04,x2=3.951). The data obtained are of interest for understanding the molecular and genetic mechanisms of predisposition to perform physical activity. This work was partially funded by the grant of Russian Foundation for Humanities 10-06-84609.

Cardiovascular malformations (CVMs) have a higher incidence in patients with NF1 microdeletion syndrome, compared to classical NF1 patients (18% vs 2%), presumably owing to haploinsufficiency of genes lying in the deletion interval and important for cardiac morphogenesis. One of the possible candidate genes for CVMs onset inside the deletion, CENTA2, was found, by WISH (Whole-mount In Situ Hybridization) on mouse embryos, to be turned on in heart at 9-9.5 dpc, when the heart tube is looping and the valves and septa are forming, suggesting a role in heart development. In order to provide further evidence on a possible role of CENTA2 in cardiac development, we employed zebrafish as a model system. Zebrafish is a useful model that allows a detailed cardio-vascular analysis even in embryos with severe defects that would be lethal in other organisms. We performed loss-of-function experiments injecting a morpholino that is able to block the mRNA translation of the zebrafish CENTA2 orthologue, *centa2-like*. At 2 dpf the injected embryos displayed *in vivo* circulatory and cardiac defects, such as blood stases in the head and caudal region, block of circulation and heart shape defects. A preliminary molecular characterization on morphants at 2 dpf showed that the injection of the *centa2-like* morpholino caused heart looping defects, in particular the formation of a tubular heart or an inverted heart looping. WISH analysis on morpholino-injected embryos at different developmental stages with different cardiac markers will allow further investigation of the role of *centa2-like* during zebrafish cardiac morphogenesis.

Host-retrovirus interactions influence the genomic landscape and have contributed substantially to mammalian genome evolution. The dog has emerged as an excellent model for complex disease genetics in human. Therefore, we analyzed a female boxer (Canis familiaris) genome for complexity and integration pattern of canine endogenous retroviruses (CfERV) to gain further insights into comparative evolution regarding the human genome. Intriguingly, we could only identify 407 CfERVs constituting 0.15% of the dog genome, compared to six times more ERVs identified in the human genome. Primates and canines have likely different mechanisms to purge, restrict and protect their genomes against retroviruses. The CfERV integration landscape showed a non-uniform intra- and inter-chromosomal distribution in agreement with distinct selective pressures at different loci. Evidence for selection against CfERVs in sense orientation relative to chromosomal genes was supported by a majority of CfERVs integrated in antisense orientation within 100 kb from annotated protein-coding genes. Finally, a novel group of gammaretrovirus-like CfERVs with high similarity to HERV-Fc1 was found to have potential for active retrotransposition and possibly result from lateral transmissions between dog and human as a consequence of at least 10.000 years of close interactions. In conclusion, this ERV analysis of the first sequenced carnivorous species supports the notion that different mammals interact distinctively with endogenous retroviruses and suggests that retroviral lateral transmissions have occurred between dogs and. This comprehensive CfERV study will provide an excellent resource for dog-to-human comparative genomics.

P11.035
Impact of cis-regulatory motifs in non-coding regions on CFTR expression

V. Viart[1,2], *J. Varilh*[1,3], *M. Claustres*[1,2,4], *M. Taulan*[1,2];
[1]*INSERM - U827, Montpellier, France,* [2]*Université Montpellier I, Faculté de Médecine, Montpellier, France,* [3]*Université Montpellier II, Faculté des Sciences, Montpellier, France,* [4]*CHU Arnaud de Villeneuve, Montpellier, France.*

Cystic Fibrosis is a rare and lethal autosomal recessive disease. Although *CFTR* shows all the features of a housekeeping gene, it is tightly regulated both spatially and temporally. In addition to several regulatory motifs identified within the minimal promoter, (Pittman et al. 1995, Taulan et al. 2007, René et al. 2010, Lopez et al. 2010), this gene is also post-transcriptionally regulated by ARE (AU-rich elements) motifs in its 3'UTR region (Baudoin-Legros et al. 2005).
However, tissue- and developmental-specific regulatory elements governing *CFTR* gene expression are still not defined. The aim of this work is to identify the most of functional motifs involved in the basal *CFTR* gene expression control.
Use of bioinformatic tools leads to the identification of new putative regulatory sites, binding sites for transcription factors in 5'UTR (TFsearch, consite...), and for specific proteins (AREsite) and

microRNA (TargetScan, miRBase...) in non-coding 3'UTR part.
To assess impact of each motif, we have carried out many constructs, countaining or not, natural or experimental mutants. Reporter gene assays, quantification of *CFTR* transcript level, RNA stability studies..., were performed to test functional significance of each mutation.
Here, we have identified new binding sites for essential transcription factors in the promoting part (as C/EBP proteins, another motif as previously described by Pittman et al. 1995). We have also shown the role of some microRNA (as hsa-miR-101) on the *CFTR* gene expression regulation. These *cis*-regulatory motifs might constitute new therapeutic stategies to modulate transcriptional and post-transcriptional regulation of *CFTR* gene.

Integrative analysis of gene coexpression networks identifies novel ciliary proteins in human tissues

A. E. Ivliev[1,2], *P. A. C. 't Hoen*[3], *D. J. M. Peters*[3], *M. G. Sergeeva*[2];
[1]Department of Bioengineering and Bioinformatics, Moscow State University, Moscow, Russian Federation, [2]A.N. Belozersky Institute of Physico-Chemical Biology, Moscow State University, Moscow, Russian Federation, [3]Center for Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.

Cilia are multifunctional cell organelles whose dysfunctions cause ciliopathies - an emerging group of human genetic diseases. Understanding molecular biology of cilia requires genome-wide identification of proteins involved in biogenesis and function of this organelle. Here, we explored the human ciliome by constructing gene coexpression networks in 10 public microarray datasets from 3 tissues containing cells with motile cilia (airways, fallopian tubes and brain). The network analysis identified a cilia-related module of coordinately expressed genes shared by the tissues. This transcriptomic signature recapitulated 294 known ciliary genes (including ciliopathy genes DNAH11, DPCD, HYDIN, LCA5, MDM1, RSPH4A, RSPH9) and identified 77 novel genes with expression patterns specific to ciliated cells. We used data from the Protein Atlas project to validate their expression at the protein level: for 138 proteins we found an increased staining in the ciliary subcellular compartment or the apical region of the cytoplasm. We finally searched for genes with differences in expression between the ciliated tissues and found SLC47A2 as a gene highly expressed in ciliated cells in brain only. SLC47A2 represents one of the few known examples of differences between ciliated cells across tissues. This protein belongs to multidrug and toxin extrusion transporters (MATE) and may play a role in efflux of metabolites and xenobiotics from brain. Our analysis provides novel insights into the human ciliome and illustrates how combinations of open-access transcriptomic and proteomic resources can be utilized to annotate protein function at a genome-wide scale. This work is partly supported by grant RFBR 10-04-01385-a.

P11.037
Copy number variation and chromatin structure

R. M. Witwicki, *E. Migliavacca, G. Didelot, A. Reymond, N. Gheldof;*
Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland.

The functional consequences of structural variation in the human genome range from adaptation, to phenotypic variation, to predisposition to diseases. We, and others, have previously shown that alteration in copy number of a given genomic region influences the expression of genes mapping within, but also on its flanks. To assess the possible mechanism(s) behind this neighboring effect, we gauged the histone modification status by ChIP-seq in human lymphoblastoid cell lines from patients affected by Williams-Beuren, Williams-Beuren region duplication, Smith-Magenis or DiGeorge Syndrome and control individuals. We monitored monomethylation of histone H4 K20 and trimethylation of histone H3 K27, as proxies for open and condensed chromatin, respectively.
Sequences were mapped using Bowtie, while SICER and DESeq were used to define regions with modified histones. Upon comparison between samples we observed that the rearranged regions (22q11.2, 17p11.2 and 7q11.23) were significantly modified in their chromatin structure. Consistent with the changes in expression levels of multiple genes mapping on the entire length of the chromosomes affected by structural variants, we also detected regions with modified histone status between samples, up- and downstream from the critical regions, up to the end of the rearranged chromosome. Coherently, we pinpointed alteration of chromosomal looping interactions between affected gene loci and the rearranged interval using an unbiased variant of chromosome conformation capture (3C-seq).
We conclude that large genomic rearrangements can lead to changes in the state of the chromatin spreading far away from the critical region, thus possibly affecting expression globally.

P11.038
A practical method for high-resolution CNV estimation and validation using digital PCR

J. Regan, *P. Belgrader, B. Hindson, S. Saxonov;*
QuantaLife, Pleasanton, CA, United States.

Digital PCR (dPCR) is a practical solution for validating copy number variations identified by next generation sequencers and microarrays. The dPCR method we developed empowers one person to screen hundreds of samples for CNV analysis in a single work shift. The dPCR workflow involves using restriction enzymes to separate tandem copies of a target gene prior to assembling a duplex TaqMan assay that includes reagents to detect both the target gene and a single-copy reference gene. The reaction mixture is then partitioned into 20,000 nanoliter droplets that are thermo-cycled to end-point before being analyzed in a two-color reader. The fraction of positive-counted droplets enables the absolute concentrations for the target and reference genes to be measured, from which, a relative copy number is determined. 20,000 PCR replicates per well provide the statistical power to resolve higher-order copy number differences. This low-cost method reliably generates copy number measurements that cluster near integer values without overlap with adjacent copy number states allowing consistent discrimination between four and five copies at 95% confidence level. Lastly, to our knowledge, this technology is the first to be capable of phasing copy number variants, as we can easily determine whether all copies of a target locus are on the same or different chromosomes. Applications of this technology include: validation of CNV discoveries from GWAS, follow-ups to next generation sequencing experiments, cytogenetic analyses, copy number alterations in cancer, and CNV phasing.

P11.039
The Effect of Sulforaphane on Transcriptional Repression and Gene Expression of CoREST

M. Yucebas, *C. Biray Avci, Z. O. Dogan Sigva, S. Yilmaz, T. Balci, C. Gunduz;*
Medical School, Izmir, Turkey.

Sulforaphone (SFN), a compound derived from cruciferous vegetables like broccoli, is reported to inhibit HDAC activity in prostate cancer cells. Aberrant activity of HDACs has been documented in several types of cancers and HDAC inhibitors (HDACi) have been employed for therapeutic purposes. CoREST, a subunit of HDAC1, HDAC2 and LSD1, plays a role in blocking the expression of key target genes. In this study, we aimed to investigate the effect of sulforaphane on the transcriptional repression of CoREST in prostate cancer cell lines PC3 and V-CAP, by chromatin immunopresipitation method (ChIP) and gene expression analysis. The cytotoxicity (IC50) of sulforaphane was found as 31.95 and 27.5 µg/ml in V-CAP and PC3 respectively, by XTT method. The CoREST ChIP relative ratios in control and IC50 dose groups were 19.08 and 9.87 in PC-3, while it was 17.37 and 6.28 in V-CAP cell lines. The gene expression analysis of CoREST in control and IC50 dose group was found as 0.0036 and 0.0028 in PC-3 cell line and 0.00026 and 0.00022 in V-CAP cell line. The transcriptional repression of CoREST was decreased by 51.74% and 36.16% and gene expression was decreased by 79.3% and 84.90% in PC-3 and V-CAP cell lines.
The HDAC inhibitor effect of Sulforaphane may depend on the decrease of the CoREST gene expression in PC-3 and V-CAP cells, and additional studies with a wide range of cell lines are needed to evaluate this compound as a new approach for the treatment of prostate cancer.

P11.040

Molecular Profiling of Human Sporadic Craniosynostosis

*C. Bernardini[1], M. Barba[1], F. Novegno[2], L. Massimi[2], G. Tamburrini[2], F. Michetti[1], C. Di Rocco[2], **W. Lattanzi**[1];*
[1]Inst. Anatomy and Cell Biology, Università Cattolica S. Cuore, Rome, Italy, [2]Dept Pediatric Neurosurgery, Policlinico Universitario A. Gemelli, Rome, Italy.

Craniosynostoses (CRS), the premature fusion of cranial sutures, are the more prevalent human craniofacial malformation, often associated to brain abnormalities, mental retardation and relevant morbidity. The molecular pathogenesis of CRS is still largely unknown. This study attempted to clarify the molecular mechanisms underlying the premature ossification of calvarial sutures. Ten sporadic non-syndromic CRS patients were enrolled in the study upon obtaining informed consent and excluding known mutations in the FGFRs and TWIST genes. Calvarial cells (CC) were isolated from prematurely fused and normal unfused suture surgical specimens. CC displayed a homogenous mesenchymal IP (CD29+,CD44 +,CD105 +,CD73 +,CD34-. CC morphological features and in vitro osteogenic potential, along with the expression of osteospecific genes was analyzed comparatively in fused and unfused suture-samples. CC isolated from pathological sutures showed a premature osteogenic commitment along with the augmented expression of upstream osteogenic genes (LMP, RUNX2, NELL-1 and OC). Moreover, genome-wide expression profiling was performed at the exon level using microarray analysis on total RNA isolated from matched suture specimens of each patient. Up-regulated genes included ADAM21, involved in cell-cell/cell-matrix interactions during tissue development; CLCF1, a potent neurotrophic factor implicated in structural head and spine abnormalities. Interestingly, FGFR1, FGFR2, FGFR3 and TWIST1 were among significantly alternatively spliced genes. This suggested that possible post-transcriptional regulation of gene expression occurring at the somatic level could be one possible pathogenic mechanism in sporadic CRS. The identification of genes, whose function is impaired at the somatic level in CRS, would help the future development of targeted molecular therapy.

P11.041

Identification of cRSS with close structural similarity to RSS of Ig and TCR genes in the human genome

***A. Y. Gubsky**[1], V. G. Zinkovsky[2];*
[1]Odessa National I.I. Mechnikov University, Odessa, Ukraine, [2]University of Opole, Opole, Poland.

Cryptic recombination signal sequences (cRSS) are motives that potentially can mediate instability of mammalian genome, when V(D)J recombination system gets out of control. It is known that there are a lot of cRSS in the human genome outside the Ig and TCR loci. However, at present no information is available about origin, quantity and genomic location of cRSS with close structural similarity to RSS of functional V, D, J segments of Ig and TCR genes (fRSS).

Using specially developed program algorithms we found that there are 580 cRSS in the human genome (Build 37.1), which have close structural similarity to fRSS. Only 67 of these cRSS were found in duplicated V, D segments of Ig and TCR genes. Appearance of 32 % cRSS in the genome may be explained by random nucleotide combinations. We observed that 27, 14, 3, 3 and about 1 % cRSS are structural elements of non-LTR retrotransposons (AluJb, L1MDa, etc.), endogenous retroviruses and LTR retrotransposons (ERVL-E-int, MER65B, etc.), simple repeats ((CA)n, (CAGA)n, etc.), DNA transposons (Charlie25, MER5B, etc.) and other repeats respectively. In 85 % cases the nucleotide sequences of motives are fully localized inside repeats. 195 (34 %) cRSS were found in 189 (0,8 %) protein-coding genes (GRIP1, PDE8A, etc.).

Our study shows that cRSS with close structural similarity to fRSS can be found in many human protein-coding genes. Their appearance in the human genome can be explained by duplications of Ig and TCR gene fragments, spread of repeats and random nucleotide combinations.

P11.042

Epigenetic regulation of the X chromosomal macrosatellite repeat encoding for the cancer testis gene CT47

***J. Balog**[1], D. Miller[2], E. Sanchez-Curtailles[1], J. Carbo-Marques[1], G. Block[2], M. Potman[1], P. de Knijff[1], R. J. L. F. Lemmers[1], S. J. Tapscott[3], S. M. van der Maarel[1];*
[1]Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Pediatrics, University of Washington, Seattle, WA, United States, [3]Division of Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

Macrosatellite repeats (MSR) present an extreme example of copy number variation, yet their epigenetic regulation is largely understudied. The CT47 cancer-testis antigen array on human Xq24 consists of 4.8kb-large units and the CT47 gene encoded in each unit is expressed in testis and in certain types of cancer, but not in non-malignant somatic tissue. We studied CT47 for possible correlations between copy number variation, epigenetic regulation and transcriptional activity in normal and malignant cells. In lymphoblastoid cell lines and in primary fibroblasts CT47 transcripts were absent, corroborating the observed heterochromatic structure and DNA hypermethylation of the CT47 promoter. Heterochromatinization of CT47 occurs early in human embryonic stem cells showing high levels of DNA methylation and repressive chromatin modifications in the absence of CT47 expression. In small cell lung carcinoma cell lines showing low levels of CT47 transcripts we observed reduced levels of H3K9me3 and H3K27me3 without increase in euchromatic histone modifications. DNA methylation levels in the CT47 promoter region are also significantly reduced in these cells. Apparently during oncogenic transformation there is a relative loss of repressive markers resulting in leaky expression of CT47. Comparing the epigenetic regulation of CT47 with other published MSR like the autosomal MSRs TAF11-Like, PRR20, ZAV and D4Z4 which is involved in facioscapulohumeral muscular dystrophy, a model emerges in which some MSR seem to be governed by common regulatory mechanisms with their abundant expression mostly being restricted to the germ line.

Automatization of CYP2D6 genotyping in patients under paroxetine treatment

***J. Zrustova**[1], E. Pindurova[2,3], A. Zourkova[4,5], J. Jurica[6];*
[1]Department of medical genetics, Faculty hospital, Brno, Czech Republic, [2]BioVendor - Laboratory medicine, Brno, Czech Republic, [3]Faculty of Medicine, Masaryk University, Brno, Czech Republic, [4]Faculty of medicine, Masaryk University, Brno, Czech Republic, [5]Psychiatric clinic, Faculty Hospital, Brno, Czech Republic, [6]Department of pharmacology, Masaryk University, Brno, Czech Republic.

Cytochrome P450 (CYP) 2D6 is one of the most investigated from CYP family in relation to genetic polymorphism. There is a wide interindividual variability in the enzyme activity of CYP2D6. Typical substrates for CYP2D6 are largely lipophilic bases and include antidepressants, antipsychotics, antiarrhythmics, antiemetics, ß-blockers and opioids. The CYP2D6 activity vary within a population and includes ultrarapid metabolizers (UMs), extensive metabolizers (EMs), intermediate metabolizers (IMs) and poor metabolizers (PMs). There is a considerable variability in the *CYP2D6* alelles distribution among different ethnic groups, resulting in variable percentages of PMs, IMs, EMs and UMs in a given population.

In our study psychiatric patients under the paroxetine therapy have been automatically genotyped by using INFINITI Analyzer (Autogenomics Inc). The INFINITI™ Analyzer is an automated, multiplexing, continuous flow, random access microarray platform that integrates all the discrete test processes such as sample handling, reagent management, hybridization, stringency and detection for analyses of DNA into totally self-contained system. It can be used for clinical multiplex systems intended to measure and sort multiple signals from clinical sample. INFINITI analyzer is designed to measure fluorescence signals of labeled DNA target hybridized to BioFilmChip™ microarrays. It automates assay and integrates all the discrete processes of sample handling, reagent management, hybridization, detection, and results analysis. Assays are processed automatically and read by the built-in confocal microscope. Results are analyzed and presented in numerical and graphical format. The genotype has been determined and compared with clinical data, phenotype, drug dosages and compliance. The results are described in included tables.

Assessing DNA copy numbers in large-scale studies using genomic arrays

I. Ruczinski;
Johns Hopkins University, Baltimore, MD, United States.

Oligonucleotide-based arrays are commonly used to assess genotype-phenotype association on a genomic scale, and studies involving DNA copy numbers are becoming more common. While genotyping algorithms are largely concordant when for example assessed on HapMap samples, methods to assess DNA copy number alterations often yield discordant results. One explanation for the discordance is that DNA copy number estimates are particularly susceptible to systematic differences that arise across batches of samples that were processed at different times or by different labs. Analysis algorithms that do not account for such systematic biases are more prone to spurious findings that will not replicate in other studies. This presentation describes statistical methods and software for the locus-level estimation of DNA copy number that specifically adjust for batch effects. We illustrate a workflow for copy number analysis using HapMap Phase 3 data, including normalization, genotyping, adjusting for batch effects in copy number estimation, visualizations to inform downstream processing, and smoothing point estimates as a function of physical position via segmentation and hidden Markov models. We also discuss the importance of GC content, and show a case study on inferred and validated (via RT-PCR) de-novo deletions in trios with cleft-palate probands. We also provide a performance assessment of four different copy number microarray platforms using a spike-in experiment.

P11.045
ICF syndrome, a model to investigate how DNA hypomethylation affects DNA replication

E. Lana[1], A. Mégarbané[2,3], G. Lefranc[4,5], P. Sarda[6], M. Claustres[1,6,7], ***A. DE SARIO***[1];
[1]INSERM U827, Montpellier, France, [2]Saint-Joseph University, Beirut, Lebanon, [3]Institut Jérôme Lejeune, Paris, France, [4]UM2, Montpellier, France, [5]CNRS UPR1142, Montpellier, France, [6]CHRU, Montpellier, France, [7]UM1, Montpellier, France.

In addition to regulating gene expression, epigenetic modifications contribute to the control of other biological processes, such as DNA replication, but their relationships is not well understood. Using cells from ICF (Immunodeficiency, Centromeric instability and Facial anomalies) patients, we investigated how a DNA methylation defect affects DNA replication in human cells. ICF is a rare autosomal recessive disorder resulting from impairment of the DNMT3B protein, a *de novo* DNA methylating enzyme. ICF patients suffer from a severe immunodeficiency and are characterized by loss of DNA methylation in repetitive sequences and decondensation of constitutive heterochromatin and chromosome instability. Previously, we showed that heterochromatic genes undergo hypomethylation and escape silencing in ICF cells. DNA hypomethylation was generalized to all the heterochromatic genes and to all the ICF cell lines, whereas gene expression was restricted to some genes, every patient having his own group of activated genes. Herein, we showed that heterochromatic genes replicate earlier in the S phase in ICF compared to control cell lines. The change in the replication timing was not correlated with gene activation. Next, to investigate further the effect of DNA hypomethylation on DNA replication, we measured fork speed by molecular combing and S-phase length by flow cytometry. Replication fork speed was higher and the S-phase was shorter in ICF cells suggesting that the alteration of DNA replication is not restricted to heterochromatin but is generalized to the whole genome. ICF cells are an ideal model to investigate DNA methylation changes and their molecular and pathological consequences.

P11.046
Analysis of DNA Lesions Induced by Ultraviolet Radiation with Two-Dimensional Electrophoresis

B. Gudmundsson[1,2], *W. Dankers[1], G. H. Gunnarsson[1,2], H. G. Thormar[1,2], J. J. Jonsson[1,3];*
[1]Univ. of Iceland, Reykjavik, Iceland, [2]Lifeind ehf., Reykjavik, Iceland, [3]Landspitali - University Hospital, Reykjavik, Iceland.

Background. The main DNA damage caused by ultraviolet radiation (UV) are base changes that cause bending of DNA molecules. They include cyclobutane pyrimidine dimers, pyrimidine (6-4) pyrimidone photoproducts and its Dewar isomers. Two-dimensional electrophoresis, a method that can separate bent DNA from normal DNA, was used to analyse DNA lesions in complex DNA samples and cell cultures after UV radiation.

Methods. Human genomic DNA was digested with MboI and radiated with UVB (312 nm, 5-30 J/cm2) in a droplet on a Petri dish. HeLa cell culture was radiated with UVB (15-45 J/cm2), the DNA isolated and digested with MboI. The samples were analysed using Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE) and Two-Dimensional Conformation-Dependent Electrophoresis (2D-CDE). AvaI digested lambda DNA was UVA radiated (44 J/cm2) and analyzed in the same manner.

Results. DNA induced by UVB migrated in front of normal DNA on 2D-CDE gel, due to bending caused by the DNA lesions. UVA radiation of lambda DNA also caused migration of DNA in front of normal DNA with 2D-SDE. Surprisingly, 2D-SDE analysis of DNA radiated with UVB revealed formation of a DNA arc behind normal DNA. The ratio of this arc increased with increased UVB dosage up to 43%. The same effect was detected in DNA from UVB induced cell culture.

Conclusions. 2D-SDE and 2D-CDE can be used to assess DNA lesions associated with UV-radiation. The DNA arc caused by UVB radiation may be explained by cross-links or formation of A-helix DNA due to either base lesions or deoxyribose oxidation to ribose.

LUPA: Discovering human disease susceptibility loci via the power of dog genetics

M. Ramos Pamplona[1], *T. LUPA consortium[2];*
[1]Unit of Animal Genomics, GIGA-R, University of Liège, Liège, Belgium, [2]EU large-scale integrating project, FP7-HEALTH-n201370, Brussels, Belgium.

Given the many human diseases that exert increasing social and economic burdens on society, there is a compelling need to propose novel therapeutic strategies. As innovative therapies are best designed based on the underlying genetic and molecular mechanisms of the disease, state-of-the-art research must be conducted on animal models of human pathologies. The domestic dog is an exemplary genetic resource for the dissection of human disease pathways. Due to intensive selection for desirable traits in a pet animal, each dog breed is characterized by a highly homogenous genetic structure. A spectrum of equivalent diseases afflicts both man and dog and exhibits very similar pathological symptoms. The EU-funded project LUPA has conducted extensive genome-wide association studies on a collection of dog cohorts diagnosed with a range of disease conditions including cancer, cardiovascular, inflammatory, neurological and monogenic diseases. Given its collaborative nature, LUPA has leveraged on a network of veterinarians for diagnosis and sample collection, a centralized high-throughput genotyping facility, and geneticists and computational biologists for data analyses. Since 2008, with ~10,000 samples genotyped, a number of associated loci have been identified for various diseases, including a region on CFA 5 for cardiovascular, DLA class II alleles for immunological and *CCDC39* for respiratory disorders. LUPA has successfully built an infrastructure of resources, most notably a new SNP array and a comprehensive database of well-characterized phenotypes and SNP genotypes. The achievements of LUPA are key to facilitating investigations in comparative and translational studies in partnership with the human disease research community.

P11.048
High resolution map of canine copy number variation

E. Nevalainen[1,2], *C. Hitte[3,4], J. Berglund[5], M. Webster[6], C. André[3,4], K. Lindblad-Toh[5,6], H. Lohi[1,2], and the LUPA Consortium;*
[1]Department of Medical genetics and Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland, [2]Department of Molecular Genetics, Folkhälsan Institute of Genetics, Helsinki, Finland, [3]CNRS, UMR6061, Institut de Génétique et Développement de Rennes, Rennes, France, [4]Université de Rennes 1, Rennes, France, [5]Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden, [6]Broad Institute of Harvard

and Massachusetts Institute of Technology, Cambridge, MA, United States.
Copy number variations (CNVs) are an important form of structural variation in mammalian genomes. Substantial amount of phenotypic differences between healthy individuals have been attributed to CNVs and they also contribute to disease risk in several human disorders including autism spectrum disorders, schizophrenia and epilepsy. Dog breeds as genetic isolates have recently emerged as a new model for human inherited diseases. Hundreds of genetic diseases have been identified in dogs, many of which are similar to human diseases and are likely to have a similar genetic background. CNVs are expected to play a role in several disease conditions in dogs and contribute to breed-specific characters. This study aims to map and catalogue CNVs in 50 dogs from 17 breeds (2-10 dogs/breed) and 3 wolves by comparative genome hybridization (aCGH) using Nimblegen's arrays with 2.1 million probes giving a high resolution of approximately 1 kb median probe spacing across the canine genome. This density gives considerably higher resolution than previously published studies. A Finnish Boxer DNA was used as a reference for other breeds. The results of this high resolution analysis of the CNVs in a large number of breeds provide important discoveries likely to contribute to several phenotypes in dogs and are being followed up in many cohorts available in the European canine genomics effort, LUPA consortium. Furthermore, findings associated with genetic diseases can be tested on human cohorts and eventually this will improve the health of both species. The new CNV data will be discussed in the meeting.

P11.049
Evaluation of global DNA methylation and twelve polymorphisms of folate pathway on Down syndrome etilogy

B. L. Zampieri[1]*, C. C. Mendes*[1]*, J. M. Biselli*[1]*, M. N. Eberlin*[2]*, R. Haddad*[2]*, M. F. Riccio*[2]*, V. M. Carvalho*[3]*, H. Vannucchi*[4]*, E. M. Goloni-Bertollo*[1]*, E. C. Pavarino*[1]*;*
[1]Faculdade de Medicina de São José do Rio Preto - FAMERP, São José do Rio Preto, Brazil, [2]Laboratório Thomson de Espectrometria de Massas, Universidade Estadual de Campinas – UNICAMP, Campinas, Brazil, [3]Centro de Medicina Diagnóstica Fleury, São Paulo, São Paulo, Brazil, [4]Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo – USP, São Paulo, Brazil.
Down syndrome (DS) is, in most cases, attributed to maternal non-disjunction which occurrence is associated with DNA hypomethylation as consequence of abnormal folate metabolism. Thus, global methylation was compared between 10 mothers of individuals with DS and 10 of individuals without the syndrome. Association between DNA methylation, *Methylenetetrahydrofolate reductase (MTHFR)* C677T and A1298C, *Methionine synthase* (*MTR)* A2756G, *Reduced folate carrier 1 (RFC1)* A80G, *Transcobalamin 2 (TC2)* A67G and C776G, *Cystathionine beta-synthase (CβS)* 844ins68, *Methylenetetrahydrofolate dehydrogenase 1* (*MTHFD1)* G1958A, *Serine hydroxymethyltransferase* (*SHMT)* C1420T, *Methionine synthase reductase* (*MTRR)* A66G, *Betaine-homocysteine methyltransferase (BHMT)* G742A and *Dihydrofolate reductase* (*DHFR*) deletion of 19 base pair (bp) polymorphisms, serum folate and plasma homocysteine (Hcy) and methylmalonic acid (MMA) concentrations was also evaluated. Global methylation analysis was carried out by *Imprint Methylated DNA Quantification Kit* (*Sigma Aldrich*). The investigation of polymorphisms was performed by Polymerase Chain Reaction (PCR), Real time PCR and PCR followed by digestion. Plasma MMA and Hcy concentrations were determined by liquid chromatography-tandem mass spectrometry and folate by chemiluminescence. Percentage of methylation between DS mothers and non-DS mothers did not differ (P=0.19). *DHFR* 19 pb polymorphism was asscociated with global DNA methylation with a mean of DNA methylation percentage in heterozygous genotype mothers (ID) of 24.67 ± 6.51%, mothers DD 18.73 ± 5.65% and II, 14.32 ± 9.62% (P=0.05). This work is the first to measure global methylation in DS mothers and association between *DHFR* 19 bp polymorphism and DNA methylation shows the importance of abnormal folate metabolism on DS etiology.

P11.050
The transcription factor MEIS1 marks a megakaryocyte-specific alternative promoter of the DNM3 locus at the position of a GWAS sequence variant for platelet volume

S. Nürnberg*;*
University of Cambridge, Cambridge, United Kingdom.
We recently identified 12 quantitative trait loci for mean platelet volume and three for platelets count by a Genome-Wide Association Study (GWAS). One of the association single nucleotide polymorphisms (SNPs), rs10914144, lies in intron 2 of the DNM3 gene on chromosome 1q24.3.
We set out to elucidate the mechanism by which sequence variation in the DNM3 locus exerts its effect on platelet volume.
First we reproduced the GWAS association in platelets from two groups of 19 healthy individuals each, who were homozygous for the major and minor alleles of the association SNP (P<0.05, unpaired t-test). We then measured DNM3 transcript abundance and observed significant differences between the groups. Chromatin immunoprecipitation (ChIP) with massive parallel sequencing for the MK-specific transcription factor MEIS1 in the MK-like cell line CHRF-288-11 identified four MEIS1 binding sites within the DNM3 locus. One site in intron 2 of DNM3 harbours a SNP (rs2038479) 10,600 bp downstream of the original association SNP, with which it is in strong linkage disequilibrium (r2=0.941). Sequencing of MK mRNA and 5' RACE identified a novel, alternative DNM3 transcript that lacks the first two exons and instead contains a novel exon, named 2B, which is located in intron 2. Real-time qPCR analysis demonstrated that in MKs transcript 2B is predominant whilst being virtually absent from neuronal cells. Promoter studies identified an alternative promoter upstream of exon 2B which is only active in MKs but not in neuronal cells. Studies are currently underway to assess DNM3 protein function in megakaryopoiesis and platelet formation.

P11.051
Using an EMT in vitro model to approach novel intronic based-mechanisms underlying pathological cadherin impairment

P. Oliveira[1]*, A. Moussavi*[2]*, A. Burleigh*[2]*, C. Roskelley*[3]*, E. Stupka*[4]*, R. Seruca*[1]*, D. Huntsman*[2]*, C. Oliveira*[1]*;*
[1]IPATIMUP, Porto, Portugal, [2]BCCA, Vancouver, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada, [4]UCL, London, United Kingdom.
Epithelial mesenchymal transition (EMT) is a fundamental mechanism controlling multiple events during embryonic development and cancer. The loss of E-cadherin expression, and consequently of cellular adhesion, is a key event in this phenomena. Cancerous cells undergoing EMT, exhibit a mesenchymal-like phenotype with concomitant polarity loss, increased invasibility and apoptosis resistance, enabling metastization. Many proteins have been proved to induce EMT and others to be modulated by EMT, but nothing has been explores in terms of intronic transcription modulation during this process.
To better understand the role of intronic-based transcription during EMT, we have reproduced this process in vitro by treating a normal mouse mammary cell line with TGF-β1. DNAse treated RNA extracted at distinct EMT-timepoints was then subjected to RNA-sequencing. We confirmed the occurrence of EMT via analysis of the differential transcription of epithelial and mesenchymal markers and the activation of the TGF-beta pathway underlying EMT. Moreover, we were able to identify both differential and constantly transcriptionally active intronic areas within cadherin genes, which putatively underlie novel cis-regulatory elements. In addition we have detected a differential rate of transcription from within introns and exons of both CDH1 and CDH2 genes, both hallmarks of epithelial and mesenchymal states of EMT. These observations point out a specific role for CDH1 and CDH2 intronic transcription in EMT.

P11.052
Epigenetic effects of prenatal exposure to ethanol: a specific effect on the H19 gene methylation in sperm

A. Paoloni-Giacobino[1,2]*, C. Stouder*[1]*;*
[1]Geneva University Medical School, Geneva, Switzerland, [2]Swiss Center for Applied Human Toxicology, Geneva, Switzerland.
Alcohol exposure during pregnancy, in humans and mice, induces a wide range of disorders in the offspring referred to as the fetal alcohol

syndrome (FAS). Epigenetic alterations like, in particular, methylation changes in some imprinted genes may play a role in the teratogenic effects of alcohol. The aim of our study was to evaluate the possible effects of alcohol administration in pregnant mice on the methylation pattern of 5 imprinted genes (H19, Gtl2, Peg1, Snrpn and Peg3) in the tail, liver, skeletal muscle, hippocampus and sperm DNAs of the male offspring over 2 generations. The effect observed on the imprinted genes was a small (3 %) but highly significant decrease in the number of methylated CpGs of H19, in the F1 generation. The effect disappeared in the F2 generation. The prenatal exposure also induced a decrease (26%) in the mean sperm concentration of the F1 that was not detected anymore in the F2 offspring. The CpGs of the H19 CTCF-binding site 2, were analyzed. A correct methylation of H19 CTCF-binding sites is indeed known to be important for the production of mitogen factors controlling fetal growth. The 1st, 2nd and 6th CpGs exhibited significant methylation percentage losses in alcohol-exposed offspring as compared to the same positions in control mice whereas the 3th, 4th and 5th CpG methylation patterns were unaffected. A link can be hypothesized between the hypomethylation of a fraction of the H19 CpGs and the decreased spermatogenesis observed in the alcohol-administered female offspring.

P11.053

Epigenetic signatures of the human extraembryonic tissues reflect the common principles of genome reprogramming during early embryogenesis

***E. N. Tolmacheva**, A. A. Kashevarova, N. A. Skryabin, I. N. Lebedev;*
Institute of Medical Genetics, Tomsk, Russian Federation.

Initiation of tissue-specific differentiation in the early ontogeny is considered as a result of global epigenetic modifications. Studies in model mammals have shown a clear difference in the DNA methylation level between embryonic ectoderm and mesoderm in comparison with primitive endoderm and trophoblast. However, there is sparse information about the mode of epigenetic reprogramming during human development because of tissues unavailability after implantation. The first accessible samples can be obtained from early miscarriages only. We have performed genome-wide DNA methylation analysis of the cytotrophoblast (CT) and extraembryonic mesoderm (EM) from 2 induced abortions, 5 miscarriages with normal karyotype and 6 spontaneous abortions with diploid-aneuploid mosaicism using HumanMethylation27 BeadChip (Illumina, USA) covering 27,578 CpG sites of 14,495 genes. All samples regardless the karyotype and developmental results were clearly separated by two clusters specific to the studied tissues. This finding can be explained by higher methylation of CpG-sites in EM (16,450) vs. CT (10,138). Differentially methylated CpGs were observed in 4,898 genes (FDR<0.01, P<0.01). To determine the biological relevance of these genes a Gene Set Enrichment Analysis using hypergeometric testing for KEGG pathways and Gene Ontology categories was performed. The selected genes were related to cytokine-cytokine receptor interactions (120 genes, P=0.0003), neuroactive ligand-receptor interactions (116 genes, P=0.0005), cell-cell signaling (275 genes, P=0.0002), cellular homeostasis (275 genes, P<0.0001), and others. Our results provide first evidence for the significant impact of epigenetic modifications into tissue specificity and confirm the common principles of genome reprogramming. This study was supported by Federal Program P806 and P1161.

P11.054

Tissue specific epigenetics mechanisms of the I.4 promoter of the CYP19A1 gene in human adipocytes

*T. J. McNab[1,2], J. R. Lewis[1,2], J. Tan[2], P. Hudson[3], J. Wang[1,2], **R. L. Prince**[1,2];*
[1]University of Western Australia, Perth, Australia, [2]Sir Charles Gairdner Hospital, Perth, Australia, [3]Qiagen, Doncaster, Australia.

Background: Aromatase encoded by the gene CYP19A1, catalyses the synthesis of oestrogens from androgens. In adipose tissue, basal transcription is in part driven by promoter I.4. We sought to determine whether methylation of CpG sites within this region is associated with aromatase RNA expression.

Methods: Omental and subcutaneous adipose tissue samples were taken from 31 obese subjects undergoing bariatric surgery. DNA and RNA were extracted from purified mature adipocytes. Methylation status of CpG sites was determined using quantitative pyrosequencing (QIAGEN Pyromark Q24 at -350 (I.4.1) and -316 (I.4.2) bases upstream of the transcription start site (TSS) of promoter I.4 and +152 (I.4.3) bases downstream of the TSS within an SP1 binding site. Total aromatase expression was determined using qRT-PCR, with primers binding to the coding region.

Results: There were no differences in methylation at I.4.1 and I.4.3 in either omental or subcutaneous tissue with mean values between 75.8% and 79.2% (range 2.0 - 98.0%). I.4.2 methylation was significantly lower with mean values between 21.9% and 36.8% (range 3.0 - 96.0%). In omental tissue percentage methylation at I.4.1 and I.4.2 were positively correlated with each other and negatively correlated with total aromatase RNA expression (R = -0.516, P = 0.017 and R = -0.522, P = 0.015). In subcutaneous tissue methylation of the I.4.3 was positively correlated with aromatase expression (R = 0.549, P = 0.004).

Discussion: Methylation of CPG sites in the promoter region of human adipose tissue aromatase have both positive (I.4.3) and negative (I.4.1and I.4.2) effects on transcription.

P11.055

DNA methylation and gene expression changes in monozygotic twins discordant for psoriasis: identification of functionally important genes involved in immune response

*K. Gervin[1], M. D. Vigeland[1], M. Mattingsdal[2], M. Hammerø[1], H. Akselsen[1], H. Nygaard[1], A. O. Olsen[1], J. R. Harris[3], D. E. Undlien[1], **R. Lyle**[1];*
[1]Oslo University Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway, [3]Norwegian Institute of Public Health, Oslo, Norway.

Psoriasis is a common chronic inflammatory disease affecting the skin, scalp, nails and joints. Psoriasis has a strong genetic component with ~20 susceptibility loci, but epigenetic changes are involved since concordance rates among monozygotic (MZ) twins are 35-70%.

Here we used MZ twins (n=20 pairs) discordant for psoriasis to explore genome-wide differences in DNA methylation and gene expression. The study of discordant MZ twins is an attractive model to investigate epigenetic mechanisms in disease. Discordance in this context can be interpreted as a result of external factors that shape the epigenetic profile and thereby the susceptibility for disease through altered gene expression. We isolated different lymphocyte subpopulations and studied single-cell types (CD4+ and CD8+) to overcome the issue of epigenetic heterogeneity in whole blood. In order to detect gene specific DNA methylation differences, we used the 27K Infinium methylation assay (Illumina). To integrate the analysis of global methylation status and gene expression of approximately all associated genes we used HumanHT gene expression assays (Illumina). Analysis of these data identified genes where differences in DNA methylation between twins were correlated with gene expression in CD4+ cells, thus identification of genes where DNA methylation has a functional role in development of psoriasis. We also present preliminary data on genome-wide DNA methylation (RRBS) and ChIP.

To our knowledge this is the first study using MZ twins discordant for psoriasis in order to reveal epigenetic alterations which potentially contributes to the development of disease.

P11.056

Finding the Genetic Cause of Bladder Epispadias-Exstrophy-Complex (BEEC)

***C. J. Jorgez**, S. Bian, H. Vangapandu, D. J. Lamb;*
Baylor College of Medicine, Houston, TX, United States.

The Bladder Epispadias-Exstrophy-Complex(BEEC) includes urological anomalies with different degrees of anterior midline defects that include epispadias(E), bladder exstrophy(BE), and cloacal exstrophy(CE). The incidence of these conditions varies from 1:30,000 for BE, 1:100,000 for epispadias, to 1:300,000 for CE. Although rare, treatment for these birth defects requires numerous surgeries over the first years of life that can be traumatic and costly. The majority of cases are sporadic, nonsyndromic, with a normal karyotype, and unknown etiology. Although most genetic studies failed to identify specific genes defects that underlie the disorder, there is evidence of strong genetic component. We used array comparative genomic hybridization (aCGH) to find submicroscopic regions of chromosome gains or losses in BEEC. DNA from 6-epispadias, 14-BE, and 3-CE patients were analyzed using a 3x720K aCGH from NimbleGen. Analysis was performed with Nexus Copy Number and SignalMap software. Each

suspected CNV (copy number variation) was validated by Taqman-QPCR. Sequence analysis of selected genes was then performed. We identified microduplications in chromosome 7 that include genes important in urinary tract development, such as HOXA1-11(7p15.2) and a novel gene PHF14 (7p21.3). Also in other affected patients, we found several microdeletions in novel genes located at chromosome 13(13q14.2 and 13q32). Additionally, we found CNV-losses in the developmental genes DLG2(11q14.1) and NOTCH2(1p12) that display interesting expression profiles in the genitourinary system. Further studies of these genes and their expression profiles will help us to understand the genetic cause of BEEC that may lead to advances in the diagnosis, counseling, and treatment of these patients.

P11.057

The effect of sample mixups in genome-wide studies

H. Westra[1], *R. C. Jansen*[2], *R. S. N. Fehrmann*[1], *G. te Meerman*[1], *D. van Heel*[3], *C. Wijmenga*[1], *L. Franke*[1];

[1]*UMCG, Groningen, Netherlands,* [2]*Rijksuniversiteit Groningen, Groningen, Netherlands,* [3]*Blizard Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom.*

Sample mix-ups can arise during sample collection, handling, genotyping or data management, and might account for part of the missing heritability of complex diseases. However, it is unclear how often sample mix-ups occur in genome-wide studies, as there are no post-hoc methods that can identify these mix-ups in unrelated samples. We have therefore developed an algorithm (MixupMapper) that can both detect and correct sample mix-ups in genome-wide studies by looking at gene expression levels. Our method utilizes the principle that some genetic variants strongly affect expression phenotypes, permitting us to check for every sample whether its phenotypic measurements correspond to the genetic variants that affect these phenotypes.

We show that sample mix-ups are common in genome-wide studies by applying our method to five publicly available human datasets on the genetics of gene expression. On average, 3% of all analyzed samples had been assigned incorrect expression phenotypes; in one of the datasets 23% of the samples had incorrect expression phenotypes. The consequences of these sample mix-ups are substantial: when we corrected these sample mix-ups, we identified on average 15% more significant cis-expression quantitative trait loci (eQTLs). In one dataset, we identified three times as many significant cis-eQTLs after correction.

Through simulations we show that a low percentage of sample mix-ups may lead to an underestimation of the explained heritability of complex traits in genome-wide datasets as well. Sample mix-ups should therefore call for serious attention in past and future genome-wide studies.

Disease gene identification by exome sequencing

C. Gilissen*, A. Hoischen, L. Vissers, B. van Bon, J. de Ligt, H. Arts, B. van Lier, M. Steehouwer, P. de Vries, I. Janssen, N. Wieskamp, M. del Rosario, B. de Vries, H. Brunner, J. Veltman;*

Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Classical positional cloning techniques for disease gene identification have benefited from the recent advancements of next generation sequencing technology. In this presentation we discuss three whole exome sequencing strategies for disease gene identification in rare and sporadic disorders where classical genetic approaches do not apply.

1) Rare sporadic disorders lack large pedigrees due to reduced fecundity. For this we hypothesize that de novo mutations in a single gene are the underlying genetic cause. We resolved the genetic cause in two of such disorders (Schinzel-Giedion syndrome and Bohring syndrome) by identifying rare coding variants that affect the same gene in multiple patients.

2) In case of more frequent (genetically heterogeneous) sporadic disorders, the underlying cause might be attributed to single de novo mutations in a large mutational target. The amount of patients required to find an overlap however increases exponentially with the amount of disease loci. By sequencing a patient as well as the unaffected parents we identified de novo mutations in 6 out of 10 patients as the potential cause for mental retardation.

3) When dealing with a rare recessive monogenic disorder the identification of the disease gene is intrinsically easier because the search is for two independent events in a single gene. We have shown for patients with Sensenbrenner syndrome that a single patient and a sufficient amount of control data can suffice to determine the cause of the disease.

We conclude that exome sequencing allows robust and unbiased disease gene identification in both rare and common genetic disorders.

P11.059

A common micro-deletion in intron 2 of the human GLA gene identified by a fast PCR - Sanger sequencing workflow

E. Schreiber*;*

Life Technologies - Applied Biosystems, Foster City, CA, United States.

Aberrations in the X-linked human GLA gene cause Fabry disease and a large number of mutations have been described. Given this multitude of mutations the only comprehensive mode of detection is DNA sequencing of the exons and intron-junctions.

During testing of published primer pairs for amplification and subsequent sequencing of the seven exons in the GLA gene I have found that a micro-deletion of the pentamer CAGCC is frequently found upstream of exon 3 in the bona fide healthy population. Of the 95 specimen of a “normal” human DNA control panel tested, 79 were found to be homozygous intact, 11 were heterozygous for the deletion and 5 were homozygous carriers of the deletion. The significance of this unusually frequent micro-deletion is unknown; does it point to a “mutational faultline” in the GLA gene ?

The poster also describes a novel, fast workflow for re-sequencing exon/intron portions of the human genome: fast PCR (ca. 50 min), followed by amplicon purification using preparative e-gel electrophoresis (ca. 20 min) and subsequent fast Sanger cycle sequencing (ca. 40 min), electrophoresis on an Applied Biosystems capillary Genetic Analyzer (ca. 60 min) finalized by sequence detection using Variant Reporter™ data analysis software.

P11.060

New approaches for Familial Hypercholesterolemia (FH) genetic diagnosis

L. Palacios, S. Catarino, L. Osaba, D. Arteta, D. Tejedor, ***M. Stef****;*

Progenika Biopharma SA, Derio, Spain.

Familial Hypercholesterolemia (FH) is an autosomal dominant disorder caused by mutations in the *LDLR*, *APOB* and *PCSK9* genes. Classically, FH mutation detection is carried out by Sanger sequencing and MLPA, since Copy Number Variations (CNVs) account for 5-10% of *LDLR* mutations.

We have developed the LIPOchip® tool, a DNA-array that detects point mutations and CNVs simultaneously and has been used to diagnose more than 5,000 index cases. LIPOchip® current versions detect more than 80% of the Spanish, Dutch, Italian and British mutations but, due to the LDLR heterogeneity and the lack of frequency studies, LIPOchip® is not viable worldwide.

Two technical approaches have been tested to produce a new, rapid, economic and universal FH genetic diagnosis tool: the Affymetrix resequencing chip and the Next Generation Sequencing Genome Sequencer Roche GS Junior. We have developed protocols to allow these tools detecting substitutions, small indels and CNVs in the *LDLR*, *APOB* and *PCSK9* genes.

Our first results revealed the potential of our Affymetrix array design in detecting FH causing variants (even small indels and CNVs). However, there are two main issues to improve: the number of no calls and the robustness of the results.

Regarding the GS Junior, the accuracy of the obtained results was high and we have managed to sequence the whole *LDLR* gene and target exons of the *APOB* and *PCSK9* genes. CNV detection was also analyzed and we expect to reach a routine tool able to analyze 40 patients by run, obtaining their final result in a week.

P11.061
Multiplexed targeted next-generation sequencing as a comprehensive mutation screening approach for Fanconi anemia

***N. Ameziane**, D. Sie, S. Dentro, H. J. P. Gille, J. P. de Winter, E. A. Sistermans; Vrije Universiteit Medical Center, Amsterdam, Netherlands.*

Background: Fanconi anemia (FA) is a recessive chromosomal instability syndrome characterized by congenital malformations, bone failure, and susceptibility to malignancies. Mutations in 15 genes have been shown to cause FA. Since FA patients require special treatment, and syndromes with overlapping clinical symptoms exist, molecular diagnosis is required. The current screening approach is neither time- nor cost-effective and may miss various aberrations, such as large deletions. Here we evaluate the use of a multiplexed targeted next-generation sequencing (NGS) approach in the diagnosis of FA.

Methods: We selected samples from 12 FA patients with various hetero-/homozygous variations including large deletions and small deletions/insertions. For one sample, only one pathogenic mutation had been found by Sanger sequencing. We used a custom Agilent in-solution SureSelect kit to enrich for the known FA genes. The 12 resulting sequence libraries were tagged with a unique barcode and pooled before sequencing 74 cycles paired-end in one lane on the Illumina GAIIx platform. An in-house variation detection pipeline, including a tool for large deletion detection, was used to score for relevant mutations.

Results: An average of 2.8 million unique reads were obtained per sample, resulting in a median coverage of ~100 fold. All disease causing mutations have been detected in our validation panel. In addition, a novel large deletion mutation in an unresolved case has been detected and validated through conventional sequencing.

Conclusion: Multiplexed targeted NGS offers a fast and reliable method for molecular

diagnosis, without the need for preselection by complementation studies.

P11.062
Transcriptional regulation of Fanconi anemia (FA) genes containing NLS-encoding sequences controls nuclear FA pathway activity

*A. Haitjema, J. Jørgensen, D. A. P. Rockx, H. Joenje, **J. C. Dorsman**; VUmc, Amsterdam, Netherlands.*

The study of the FA/BRCA pathway in the last decade has added increasing insight in the function of individual FA proteins as well in their role in DNA damage repair. Few studies, however, have focused on the transcriptional regulation of the genes themselves. Since the FA pathway plays a role in the cell cycle, one can expect that (a subset of) the FA genes will be cell-cycle regulated. The aim of this study is to determine the behavior of all FA genes during the cell cycle combined with an *in silico* analysis of their promoter elements.

We could separate the pathway genes into two groups based on their mRNA expression during the cell cycle and/or response to serum in the human glioblastoma cell line T98G. The responsive group consists of four core-complex members (*FANCA, -B, -E*, and *-M*), the ID-complex members (*FANCD2* and, *-I*), and the downstream genes *BRCA2*, and *-J*. The non-responsive group consist of the subcomplex partners of *FANCA*, *-G*, of *FANCB*, *-L*, of *FANCE*, *-C* and *-F*, and of *BRCA2*, *PALB2*. The promoters of each group were analyzed to identify common transcription factor models with Genomatix. For both groups, models containing homeodomain TF families, known to be involved in development were identified. The responsive genes are furthermore characterized by SP1 and E2F sites in the vicinity of their transcription start sites.

The responsive genes contain Nuclear Localization Signals (NLSs)-encoding sequences, suggesting that these constitute the driving forces for nuclear import when necessary during DNA replication.

P11.063
Applying Massive Parallel Sequencing to Molecular Diagnosis of Marfan and Loeys-Dietz Syndrome

*M. Baetens[1], L. Van Laer[2], K. De Leeneer[1], M. Renard[1], J. Hellemans[1], J. De Backer[1], A. De Paepe[1], B. Loeys[2], **P. Coucke**[1];*

[1]Center for Medical Genetics, Gent, Belgium, [2]Center for Medical Genetics, Antwerp, Belgium.

The Marfan (MFS) and Loeys-Dietz (LDS) syndromes are caused by a wide variety of mutations in the Fibrillin 1 (FBN1) and Transforming Growth Factor Receptor 1/2 genes (TGFBR1/2), respectively. With conventional mutation screening technologies, analysis of this set of genes is time-consuming and expensive.

We have optimized a cost-effective and reliable mutation discovery strategy using Next Generation Sequencing technology. In a first phase, five MFS or LDS patient samples with previously identified mutations and/or polymorphisms in FBN1 or TGFBR1/2 were amplified using a multiplex PCR reaction and sequenced on a Genome Sequencer FLX (Roche). All expected mutations could be identified. In a second phase, we validated the technique on 87 samples from MFS patients fulfilling the Ghent criteria using two GS-LR70 runs and one Amplicon Titanium XLR70 run (Roche). To differentiate the samples within a single run, we have used up to 30 different Multiplex Identifiers (MIDs). This resulted in the identification of 66 different FBN1 mutations in a total of 74 patients. Multiplex Ligation-dependent Probe Amplification (MLPA) analysis of the remaining 13 negative samples identified one duplication and two deletions in FBN1. For the remaining 9 negative samples, Sanger sequencing of the coding sequences which were investigated with NGS, did not reveal additional variants.

Our data support that multiplex PCR of all coding exons of FBN1 and TGFBR1/2 followed by Next Generation Sequencing analysis and complemented with MLPA, is a clear-cut strategy for a time- and cost-effective identification of mutations.

P11.064
Evaluation of single-step homogenous screening assays for rapid detection of *FMR1* CGG repeat expansions

***S. S. Chong**[1,2], C. R. L. Teo[1], H. Y. Law[3], C. G. L. Lee[1,4,5];*

[1]National University of Singapore, Singapore, Singapore, [2]National University Hospital, Singapore, Singapore, [3]KK Women's and Children's Hospital, Singapore, Singapore, [4]National Cancer Center, Singapore, Singapore, [5]Duke-NUS Graduate Medical School, Singapore, Singapore.

Fragile X syndrome is one of the most common genetic causes of mental retardation, second only to Down syndrome. It is predominantly caused by hyperexpansion (>200 repeats) and hypermethylation of CGG repeats in the *FMR1* promoter region, which results in gene silencing. Smaller unmethylated expansions in the gray zone and premutation range (45 - 200 repeats) have been associated with premature ovarian failure (POF) and fragile X-associated tremor ataxia syndrome (FXTAS). We previously developed several methylation-specific and direct triplet-primed PCR based assays for analysis of the *FMR1* CGG repeat structure and expansion. We have now adapted these assays for single-step homogeneous screening of *FMR1* CGG repeat expansions by melting curve analysis in the presence of SYBR Green I nucleic acid dye. Melting peak profiles from 5'-anchored and 3'-anchored triplet-primed PCRs were evaluated. For 3'-anchored triplet-primed PCRs, the melt peak profiles or normal and expanded alleles were distinctly different. In contrast, 5'-anchored triplet-primed PCRs produced similar melting peak morphologies from normal and expanded alleles, although melting peak temperatures from expanded alleles were slightly increased compared with normal alleles. Therefore, 3'-anchored triplet-primed PCRs are more sensitive compared with 5'-anchored triplet-primed PCRs in distinguishing normal from expanded alleles by melting curve analysis. This difference likely stems from the position(s) of the AGG interruption(s) in most expanded alleles. We conclude that melting curve analysis represents a viable single-step strategy for rapid screening of *FMR1* CGG repeat expansions.

P11.065
Evaluation of MGMT gene promoter methylation by comparing qMS-PCR and MS-HRM analysis in GBM

*C. B. Avci[1], S. Yilmaz[1], Z. O. D. Sıgva[1], M. Yucebas[1], T. Balci[1], O. Cogulu[2], N. Oktar[3], T. Dalbasti[3], T. Akalin[4], **C. Gunduz**[1];*

[1]Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey, [2]Ege University Medical Faculty Department of Medical Genetics, Izmir, Turkey, [3]Ege University Medical Faculty Department of Neurosurgery, Izmir, Turkey, [4]Ege University Medical Faculty Department of Medical Pahtology, Izmir,

Turkey.
Current therapeutic options for patients with glioblastoma multiforme (GBM) consist of surgical resection followed by radiation and chemotherapy. Despite this aggressive multimodality approach, patients continue to have a poor prognosis, indicating the need for an individual molecular drug therapy for each case as a novel therapeutic modality. Expression of the O(6)-methylguanine-DNA methyltransferase (MGMT) gene has shown to correlate with the clinical outcome in GBM patients treated with alkylating agents. HRM is an extended melting curve analysis method, but it requires additional analysis software and special reagents. The aim of the study is to evaluate the effectiveness of qMS-PCR and MS-HRM, two distinctive methods for identifying methylation in GBM patients. We evaluated the status of MGMT gene promoter methylation in 20 primary glioblastoma patients and 2 GBM cell lines (U-87MG, U-118MG) and analyzed the correlation between qMS-PCR and MS-HRM methods by individually designed primers and probes.
In qMS-PCR, 5 cases were found to be unmethylated. According to the analysis of the MS-HRM results; 3 of the 5 cases were correlated with qMS-PCR and 2 cases were heterogenous. Methylation status was correlated in both cell lines, 55-65% methylated and 75-85% methylated groups in these two analysis.
The results indicated the importance of determining individual genetic differences by using both qMS-PCR and MS-HRM analysis for inactivation of MGMT is indispensible.

P11.066
Whole transcriptome expression microarray profiling of cancerous and adjacent normal total RNA

***A. Bergstrom Lucas**, B. Mullinax, J. Venneri, E. Lin, V. Kulkarni, M. Janis, J. Ghosh, J. Gao, E. Leproust, S. Fulmer-Smentek;*
Agilent Technologies, Santa Clara, CA, United States.
Whole transcriptome expression profiling by microarray analysis is an important tool for classifying tissue and tumor types and understanding biological mechanisms. This profiling measures the alternative splicing of exons from RNA leading to the translation of different proteins. To address the need for whole transcriptome expression profiling we have developed an exon workflow which includes catalog and custom microarrays, a whole transcript labeling method, and data analysis software. The Low Input Quick Amp Whole Transcriptome Labeling Kit employs a mixture of random nucleotide and oligo dT-based T7 promoter primers resulting in high cRNA yields and Cy-labeled specific activities from nanogram amounts of RNA. The probes on the SurePrint G3 microarrays were designed from the high quality content of public databases including RefSeq and Ensembl. Exon arrays were analyzed for gene level and exon level expression using GeneSpring GX 11.5 software, thus enabling whole transcript profile comparisons within two days. Comparisons of technical replicate samples demonstrate high reproducibility with wide dynamic range across a broad range of RNA input. High correlations were also demonstrated in comparisons to orthogonal expression measurement techniques including RNA-Seq. The whole transcriptome workflow was used to detect alternative splicing of exons between cancerous and normal cells resulting in gene and exon expression profiles consistent with the current literature. SurePrint G3 microarrays were also used to assess differential expression of non-coding RNAs (lincRNAs) in these samples. The combined results demonstrate the value of identifying known exons and showcase the importance of including non-coding RNA profiling in cancer research.

P11.067
Using HGNC to improve and expand Gene Family resources

***L. C. Daugherty**, R. L. Seal, S. M. Gordon, M. J. Lush, M. W. Wright, E. A. Bruford;*
HGNC, European Bioinformatics Institute, Hinxton, United Kingdom.
The HUGO Gene Nomenclature Committee (HGNC) has assigned unique approved gene symbols and names to over 30000 human loci, over 19000 of which represent protein coding genes. We also name pseudogenes, phenotypic loci, genomic features and non-coding RNAs. Our website: genenames.org is an online repository of HGNC-approved gene nomenclature and associated resources including links to genomic, proteomic and phenotypic information, as well as dedicated Gene Family pages.
Approved gene symbols are based on names describing the structure, function or homology and the HGNC organise genes into gene groups and gene families where possible. Previously the HGNC has created dedicated Gene Family web pages many of which have specialist advisors that both check their accuracy and help to maintain them. However, these pages currently only represent a subset of human gene families. We now intend to expand and generate more Gene Family pages using data curated by the HGNC combined with external resources that specialise in particular gene families. These new Gene Family pages will be sorted into meaningful categories including functions, structure, homology or a mixture. We will provide links from our Symbol Reports to our improved Gene Family resources.
If you have a gene family that you think should be represented, contact us hgnc@genenames.org.
The work of the HGNC is supported by the NHGRI and the Wellcome Trust.

P11.068
Genomic imprinting of canine *MAS1*, a component of the renin-angiotensin system

***C. M. Nolan**, S. O'Boyle, R. E. Shiel, J. J. Callanan;*
University College Dublin, Belfield, Dublin 4, Ireland.
Genomic imprinting occurs in mammals and refers to parent of origin specific epigenetic modifications of genes. The consequence of these modifications is that the two alleles of imprinted genes are differentially expressed. Although few in number, the function of imprinted genes is essential for normal growth and development, and they also regulate aspects of adult behaviour. Aberrant regulation of imprinted genes contributes to a variety of clinical conditions in humans, including somatic undergrowth and overgrowth, behavioural disorders and cancer.
Imprinted genes have mostly been studied in mice and humans. For comparative purposes, and because the dog is now considered an excellent model of human disease, we examined genomic imprinting in the canine. For canine orthologs of three well-characterized imprinted genes (*IGF2*, *H19* and *IGF2R*), we have shown parent of origin specific effects on expression. Imprinted genes usually occur in genomic clusters that are co-regulated by a common imprint. The *MAS1* gene lies upstream of *IGF2R* in mammals and its imprint status in humans is somewhat controversial. Here we report that canine *MAS1* is imprinted, with expression of the maternally-derived allele in several fetal tissues and in neonatal umbilical cord. The protein encoded by *MAS1* is a component of the renin-angiotensin system, a complex regulatory network that is essential for normal human physiology and is altered in several disease states. If *MAS1* (or other RAS components) is imprinted in humans, this could have implications for human health and disease. We suggest that the imprint status of human *MAS1* should be re-evaluated.

P11.069**
Towards a comprehensive overview of genomic variation in patient-parent trios

***J. de Ligt**, J. Y. Hehir-Kwa, L. E. L. M. Vissers, C. Gilissen, H. G. Brunner, J. A. Veltman;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.
We performed exome sequencing on 10 patient-parent trios to obtain a comprehensive overview of genomic variation. These patients were selected based on the presence of unexplained mental retardation in the absence of *de novo* or rare Copy Number Variations (CNVs) and syndromic diagnosis.
Initial array data (250k) provided a low-resolution insight in the patients common CNVs (on average 3, with an average size of 648 kb). Furthermore we detected on average 7,098 common (based on dbSNP130), 100 uniquely inherited, and 1.2 *de novo* Single Nucleotide Variants and 1,953 Insertions/Deletions (InDels) per patient.
Currently, different algorithms are being tested for the detection of Structural Variation (SV), including CNVs and inversions, and their concordance with high-resolution array data (Affymetrix 2.7M arrays) which will provide a detailed overview of the larger SVs. In combination with the extensive analysis on InDels and SNVs, our analysis will provide a comprehensive overview of the genomic variation within an individual, including *de novo* and inherited variants.

P11.070***

G2P Knowledge Centre: An integrated genotype-phenotype data access portal and online collaborative network

***A. J. Webb**, A. J. Brookes;*
University of Leicester, Leicester, United Kingdom.

The unprecedented quantity and complexity of genotype-phenotype (G2P) data currently being generated by research and diagnostic labs worldwide, together with a shift toward online data dissemination and collaborative work patterns, has spawned the need for new data handling, integration and online community workspace tools. To tackle data handling issues, the GEN2PHEN Project has spearheaded the creation of a hybrid federated-centralised database network where disparate G2P data (for both Mendelian traits, and data from genome-wide association studies (GWAS)) are held in multiple distributed databases. These independent databases are then interlinked using common exchange formats and data standards.

The 'G2P Knowledge Centre' (http://www.gen2phen.org) leverages this broad yet complex network, and enables valuable distributed G2P data to be quickly located through an intuitive yet powerful holistic search tool. Allied to the data search is the provision of a user annotation system whereby any user may leave comments or feedback on any search result, dataset or resource. These annotations are then made available to the original data provider and the wider G2P community, adding real value to the data and a second-level peer-review system. To further foster an online collaborative G2P community, the 'G2P Knowledge Centre' provides discrete online workspaces (Interest Groups) as well as blogs, news items, events listings, training materials and full access to the many outputs of the GEN2PHEN project.

P11.071

GNAS NESP and XL hypermethylation in pseudopseudohypoparathyroidism patients.

***B. Izzi**[1], K. Devriendt[2], D. Lambrechts[3], C. Van Geet[1,4], K. Freson[1];*
[1]Center for Molecular and Vascular Biology- KULeuven, Leuven, Belgium, [2]Center for Human Genetics- KULeuven, Leuven, Belgium, [3]Vesalius Research Center- KULeuven, Leuven, Belgium, [4]Pediatrics Department-University Hospital Leuven, Leuven, Belgium.

Endocrinopathies in patients with hypocalcemia and hyperphosphatemia that share resistance to parathyroid hormone (PTH) are named pseudohypoparathyroidism (PHP). Most PHP types are caused by defects in GNAS, an imprinted gene locus consisting of maternal, paternal and biallelic transcripts. PHPIb patients have isolated PTH resistance and GNAS epidefects while PHPIa presents with hormonal resistance and characteristic physical features such as mental problems, brachydactyly, shortness, round face and subcutaneous ossifications, jointly termed as having Albright's Hereditary Osteodystrophy (AHO) due to maternally inherited GNAS mutations. PPHP patients have AHO without hormone resistance and paternally inherited GNAS mutations. This classification of PHP was made years ago but was recently questioned since GNAS epidefects were also identified in PHPIa. Our present study further complicates this (epi)genotype/phenotype relation as we found for the first time GNAS epidefects in PPHP. We quantified 3 differentially methylated regions in GNAS: NESP (2 regions of 13 and 20 CpGs), XL (24 CpGs) and exon A/B (20 CpGs) methylation via the Sequenom EpiTYPER in 3 PPHP patients with variable degree of AHO (shortness, brachydactyly, behavior problems, round face) but no GNAS coding mutation. These patients showed significant hypermethylation of preferential CpGs in NESP and XL (Z-test, p<0,05) and one patient also had significant A/B hypermethylation. This is a novel imprint pattern that has not been described since PHPIb/PHPIa epidefects are characterized by A/B and XL hypomethylation and NESP hypermethylation. Further studies are needed to unravel this novel methylation pattern in relation to an AHO phenotype by including more patients.

P11.072

Noninvasive detection of GSTP1 gene in urine samples from prostate cancer patients

***R. Dumache**, B. Bumbacila, S. Negru, A. Tudor, M. Puiu;*
University of Medicine and Pharmacy"Victor Babes", Timisoara, Romania.

Purpose: Methylation of the GSTP1 gene promoter region is the most common epigenetic change in prostate carcinogenesis. In our study, we want to analyse the methylation status of gene GSTP1 in urine samples from prostate cancer (PCa) patients, as a noninvasive method to detect PCa from urine.

Material and method: We collected voided urine specimens from 75 men who underwent transrectal ultrasound-guided biopsy of the prostate for suspected malignancy, and from 58 men with benign prostatic hyperplasia (BPH), representing the control subjects. We isolated genomic DNA from urine specimens and after, subjected them to sodium bisulfite modification.

Analysis of the methylation status of GSTP1 gene was done by methylation-specific PCR (MSP) method, and we correlated them with Gleason score and PSA levels.

Results: Using methylation-specific PCR (MSP) method, we found GSTP1 gene hypermethylated in 69 of 75 (92 %) PCa patients , and in 5 of 58 (8.62%) patients with BPH.

Conclusion: From the obtained results we can conclude that, the detection of aberrant methylation of gene GSTP1 in urine may offer a promising approach for the noninvasive diagnosis of prostate cancer.

P11.073

Molecular Diagnosis of the BRCA genes in Hereditary Breast and Ovarian Cancer families, using Roche/454 Pyrosequencing technology.

*B. Yannick[1], **N. Uhrhammer**[2], L. Lafarge[2], Y. Bignon[2];*
[1]Université d'Auvergne, Clermont-Ferrand, France, [2]Centre Jean Perrin, Clermont-Ferrand, France.

Screening for deleterious mutations in the *BRCA* genes is an essential service to women with familial risk of breast or ovarian cancer. To offer this service as widely as possible, it is necessary to develop faster and less expensive methods. New high-throughput genotyping technologies give high-quality sequence data with quick turnaround and low cost. We evaluated Roche-454 technology for genetic diagnosis.

Sixty-four familial breast cancer cases were analyzed by amplicon pyrosequencing and Sanger dideoxy sequencing, plus 14 by pryosequencing only.

Pyrosequencing was validated for up to 97 % of amplicons in each of four standard runs of 16 cases, and up to 98 % using Titanium chemistry. A minimum coverage depth of 40 reads was required to validate an amplicon as 'analysed'. All variants detected by dideoxy sequencing were also detected by pyrosequencing, including eleven deleterious mutations.

Six of the 84 amplicons contained homopolymer tracts in the coding sequence systematically misread by the Amplicon Variant Analysis software. Development of in-house software for the reanalysis of homopolymer data showed that most misread sequences were the result of intermediate pyrosequencing signals: histograms of read data aided the analysis considerably and allowed validation of the majority of homopolymers.

This pilot study on the *BRCA* genes indicated that pyrosequencing was as sensitive as dideoxy sequencing, and the effort and cost involved were comparable. Moving to Titanium chemistry, with more and longer reads and the multiplexing of samples, permits analysis of 64 or more samples simultaneously, giving pyrosequencing an advantage over classic techniques.

P11.074***

An inflammasome genome screen to detect novel disease genes in hereditary autoinflammatory disorders.

***M. E. van Gijn**[1], W. Kloosterman[1], J. Frenkel[2], I. Nijman[1], J. van de Belt[1], K. Duran[1], R. van der Burgh[3], L. H. Jongeneel[4], M. L. Boes[3], E. P. J. G. Cuppen[1];*
[1]Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of General Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Pediatric Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [4]Department of Pediatric Immunology, University Medical Center Utrecht, Utrecht, Netherlands.

Hereditary autoinflammatory disorders, for example Familial Mediterranean Fever (FMF), and the cryopyrinopathies (CAPS) are caused by mutations in 'inflammation-related genes', which include genes in which a mutation can trigger an uncontrolled, aimless activation of the inflammatory process in response to innocuous stimuli.

A large number of patients with autoinflammatory diseases, remain

genetically unexplained. Several studies have shown that aberrant activation of the IL-1β pathway via the inflammasome is a common mechanism in the pathogenesis of autoinflammatory diseases. We hypothesize that mutations in a variety of genes involved in the control of inflammasome function can result in autoinflammatory disease in a specific patient.
To test this hypothesis an 'inflammasome genome' was designed. This 'inflammasome genome' consists of 120 genes known to be involved in, or associated with proteins functioning in the inflammasome. Next Generation Sequencing was used to efficiently screen the 'inflammasome genome' in 60 selected patients, for novel disease associated variations. A combination of 60 barcoded-patient-DNA-libraries was pooled and enriched on a single custom Agilent CGH 1M array followed by SOLID sequencing. Sanger Sequencing confirmed 50 novel candidate disease associated variations found in 34 different patients.
We are currently in the process of functionally testing the identified candidates for their effect on inflammasome function in human cells to determine their implication in the disease. The identification of new disease-causing genes are expected to not only help diagnostics but also future therapies. Moreover, this study will shed more light on the function of various inflammasomes, which are still poorly understood.

P11.075
Identification of the causative gene for SPG27 by Exome capture

A. Noreau[1], *S. L. Girard*[1], *A. Szuto*[1], *I. A. Meijer*[1], *P. Cossette*[1], *P. A. Dion*[1,2], *G. A. Rouleau*[1,3,4];
[1]*Center of Excellence in Neuromics of Université de Montréal (CENUM), Centre de Recherche du Centre H, Montreal, QC, Canada,* [2]*Université de Montréal, Department of pathology and cellular biology, Montreal, QC, Canada,* [3]*University of Montreal, Faculty of Medicine, Department of Medicine, Montreal, QC, Canada,* [4]*Research Center, CHU Sainte-Justine, Montreal, QC, Canada.*

Hereditary spastic paraplegia (HSP) is a motor neuron disease for which the key symptoms are lower limb spasticity and weakness because of progressive neurodegeneration events. The group of HSP is particularly heterogeneous because different modes of inheritance were observed (dominant, recessive and X-linked) as well as various levels of symptoms complexity; pure and complicated forms were described. To date, over 45 spastic paraplegia locus were identified and 20 genes identified. A previous linkage analysis on an autosomal recessive pure HSP family identified a new locus (*SPG27*) on the 10q22.1-10q24.1 region; a locus partially overlapping the *SPG9* locus. We proposed to perform use an exome capture approach with the Agilent Technology SureSelect Human All Exon Kit (50MB) and proceed to resequencing with ABI SOLID4 DNA sequencer. Four affected individuals, the unaffected-carrier father and another unaffected sibling carrying the same disease-allele as the father will be used. As we may be looking for compound-heterozygote mutations, we will develop an algorithm to determine the parental origin of variants and the more promising mutations will be validated through Sanger sequencing. By this method, it will be possible to cover the 40 genes, find the causative mutation and maybe solve the *SPG9* clue.

P11.076
Integration of GWAS data using Gene Ontologies and "2-step analysis" to select disease genes candidates for HSCR.

B. Luzón-Toro[1,2], *M. Marbá*[2,3], *R. Fernández*[1,2], *I. Medina*[2,3], *M. Acosta*[1,2], *D. Montaner*[2,3], *G. Antiñolo*[1,2], *J. Dopazo*[2,3], *S. Borrego*[1,2];
[1]*Hospital Universitario Virgen del Rocio, Sevilla, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Sevilla and Valencia, Spain,* [3]*Bioinformatics Department, Centro de Investigación Príncipe Felipe, Valencia, Spain.*

Hirschsprung's disease (HSCR) is a congenital malformation of the hindgut with low sex-dependent penetrance, variable expression and involvement of one or more genes.
One of the most innovative tools for the identification of additional genomic regions associated with HSCR is a Genome Wide Association study (GWAS). An International Consortium (ICHSCR) was settled in 2004 to achieve this goal. Using this strategy, several loci have been described as "HSCR-associated regions" and their "HSCR gene". We propose a new approach based in an innovative data processing of the results obtained from a GWAS performed on 213 S-HSCR trios worldwide recruited by ICHSCR. Such approach leads the identification of specific terms from the Gene Ontology database (GOs) associated with the pathogenesis of HSCR. We have used a new bioinformatic tool: http://gesbap.bioinfo.cipf.es, to compare Spanish patients (reference group) with the rest of populations (Consortium) from ICHSCR through 2 consecutive methods:
1) Using the p value (<0.05) of the GOs obtained from gesbap from both populations, we got 17 significant GOs in Spanish population of which just 11 were significant in all the populations.
2) "2-step functional analysis": we calculate the adjusted p value from the nominal one applied to Consortium populations. Results: 27 significant GOs in all the populations (Spanish and Consortium).
We have established a new tool to select a wide spectrum of genes as candidates in the context of HSCR. Further analyses are needed to elucidate the complex nature of HSCR.

Immunostaining of acetylated histone H3 on metaphase chromosomes reveals band-specific patterns differing in pre- and postnatal human development

A. V. Tikhonov[1], *O. A. Efimova*[2], *J. G. Lezhnina*[1], *A. A. Pendina*[2], *I. A. Galembo*[1], *O. G. Chiryaeva*[2], *L. I. Petrova*[2], *V. S. Dudkina*[2], *V. S. Dudkina*[2], *N. A. Sadik*[2], *T. V. Kuznetzova*[2], *V. S. Baranov*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*D.O.Ott's Research Institute of Obstetrics and Gynecology, laboratory for Prenatal Diagnosis of Human Inborn and Inherited Diseases, Saint-Petersburg, Russian Federation.*

Acetylation of 9th lysine residue in histone H3 (AcH3K9) is an epigenetic modification of human genome involved in gene regulation and generally associated with transcriptionally active, or potentially active, chromatin.
We aimed at analysis of acetylated histone H3 distribution in metaphase chromosomes from PHA-stimulated fetal cord blood lymphocytes compared to that from adult lymphocytes. Study was performed on 79 metaphases from 3 embryos (20-24-weeks gestation) and 60 metaphases from 5 adults fixed with 2% acetic acid in ethanol.
Distribution of AcH3K9 on metaphase chromosomes was studied by indirect immunofluorescence with specific monoclonal antibodies against AcH3K9 (Abcam, USA). Chromosomes were identified by centromeric index and DAPI banding. Immunostaining of metaphase chromosomes revealed regions of different fluorescence intensity, with most bright fluorescence in R-bands and absence of signal in pericentromeric heterochromatin.
Signal distribution in chromosomes from fetal lymphocytes demonstrated difference in fluorescence intensity between homologous chromosomes in bands 1p36.3, 2p23, 2q33, 10p11.2, 11p15. These differences may be determined by genomic imprinting.
Five bands - 5p13, 5p15, 9q13,16p13,18p11.32 - showed differences in AcH3K9 level between fetal and adult chromosomes. Bands 5p13, 5p15and16p13 were hypoacetylated; bands 9q13and18p11.32 demonstrated higher acetylation level in fetuses compared to adults.
Thus, pattern of AcH3K9 distribution along metaphase chromosomes of both fetal and adult lymphocytes corresponds to a band-specific manner, resembling R-banding. Differences in AcH3K9 of some bands between fetal homologous chromosomes as well as between fetal and adult chromosomes might be attributed to stage-specific epigenetic patterns in the same cell types of humans.

Holoprosencephaly and Notch signalling pathway: transcriptomic approach using chick model

L. Ratié[1], *I. Gicquel*[1], *S. Mercier*[1], *C. Dubourg*[1,2], *S. Odent*[1,3], *V. David*[1,2], *V. Dupé*[1];
[1]*UMR 6061, Université de Rennes1, Rennes, France,* [2]*Génétique Moléculaire, CHU, Rennes, France,* [3]*Service de Génétique médicale, CHU Hôpital Sud, Rennes, France.*

Holoprosencephaly (HPE) is a congenital malformation of the human brain due to an imperfect division of forebrain during early development. It is now currently admitted that HPE is a multihit pathology caused by at least two or more dysfunctional events involving genes from more than one signalling pathway.
The Shh and Nodal pathways have been presented to be the main signalling pathways involved in human HPE. To a lesser extend, FGF

has also been identified to be implicated. Importantly, by CGH array we have recently identified a component of the Notch pathway, *Dll1*, as a new HPE candidate gene. This result suggests that a dysregulation of Notch pathway may well confer a susceptibility to HPE.
However, if previous studies have showed the importance of Notch throughout the neurogenic phase of forebrain development, a link with HPE has never been described. To assess this question, we have implemented an *ex ovo* chick embryos culture system with a pharmacological inhibitor known to block specifically Notch pathway. Subsequently, the molecular reprogramming of the treated brain has been tested using expression microarray and *in situ* hybridization approaches. These analyses provide functional data about the Notch pathway during HPE appearance as well as throughout normal forebrain development.

Reactivating the foetal haemoglobin (HbF) program of development to raise the level of HbF in sickle cell disease or β-thalassemia patients would greatly ameliorate the symptoms of these diseases. This can only be achieved by first understanding fully the genetic switch from foetal to adult haemoglobin. Substantial progress has recently been made in this field, however the exact mechanism remains elusive. Using a combination of clinical research coupled with basic research using state-of-the-art technologies generated data and knowledge that addresses parts of this intricate mechanism. A unique and large Maltese family with elevated levels of HbF was identified through the National Screening Program conducted in Malta. An extensive molecular study revealed a novel mutation in the human EKLF/KLF1 transcription factor that was responsible for an overall dominant HbF increase in this family from Malta. Gene expression array analysis delivered a list of KLF1-target genes that might also be implicated in the globin biosynthesis pathway. The same study showed how BCL11A is developmentally regulated by KLF1 and that diminished levels of BCL11A as a result of KLF1 haploinsufficiency resulted in higher HbF levels. A different Maltese family carrying the same mutations has recently been identified, but these individuals displayed much lower foetal haemoglobin levels. This suggested the presence of modifier genes strongly affecting the Hereditary Persistence of Foetal Haemoglobin (HPFH) phenotype in conjunction with the KLF1 mutations and therefore we device methods at the genomic, transcriptomic and proteomic levels to identify these modifier genes acting in conjuction with KLF1.

Re-Sequencing of human samples: comparing and combining different libraries, sequencing technologies and software tools

K. A. Stangier*, H. Hegele;*
GATC Biotech AG, Konstanz, Germany.

Strategies for sequencing human genomes and transcriptomes need to be designed based on the goals of the project.
Genomic libraries with small (300 bp) and large(up to 8 kb) inserts to identify SNPs and rearrangements can be prepared. Different enrichment technologies are applied to sequence specific subsets of genes or the whole exon.
Transcribing RNA into cDNA is another procedure for transcriptome analysis.For a quantitative analysis, UTR libraries are used to generate expression profiles. Regulatory studies are performed withChIP-, and small RNA libraries.
The Illumina HiSeq 2000 provides the industry's highest **sequencing** output, quality and fastest data generation rate for resequencing and quantitative analysis.
Amplicons can be sequenced on the Roche GS FLX or with the classical Sanger technology to obtain longer reads.
With the Pacific Biosciences PacBio RS real time single molecule sequencer, long reads in the range of Sanger sequencing and so-called strobe readscan reveal multiple types of genetic variation, such as large-scale rearrangements, as observed in cancer.
In addition, direct sequencing of methylated and other modified bases will be possible.
Proprietary tools are used for the analysis of Next Gen sequencing data, while third party tools are available for optimised *de novo* assembly or improved hybrid assemblies..
Conclusion
High quality results will be obtained by optimally combining several library preparation methods and the newest Next Gen technologies with state-of-the-art bioinformatics.Thus, the deepest analysis of data and as a consequence, the most robust analysis of the sequence you are working on, will be achieved.

A novel mutation in alpha-Actinin-2 responsible for Hypertrophic Cardiomyopathy identified by massively parallel next generation sequencing

M. Iascone[1], *S. Bardi*[2], *F. Girolami*[3], *L. Berti*[3], *L. Pezzoli*[1], *F. Cecchi*[2], *I. Olivotto*[2], *F. Torricelli*[2];
[1]*USSD Medical Genetic Laboratory, Ospedali Riuniti di Bergamo, Italy, Bergamo, Italy,* [2]*Referral Center for Myocardial Diseases, Genetic Diagnostic Unit, Careggi University Hospital, Florence, Italy;, Florence, Italy,* [3]*Referral Center for Myocardial Diseases, Genetic Diagnostic Unit, Careggi University Hospital, Flore, Florence, Italy.*

Aim of the present study was to evaluate the capacity of sequence enrichment and next generation sequencing (NGS) to successfully identify mutations in a large family with an atypical variant of hypertrophic cardiomyopathy (HCM). Sequence capture target enrichment and massively parallel NGS might be particularly advantageous in testing for genetically heterogeneous hereditary conditions, such as HCM. Current diagnostic evaluation proceeds by sequencing a large number of genes, based mainly on the relative frequency of the mutations. In more than 35% of patients, the pathogenic mutation is unknown even after very extensive and expensive molecular testing.
We designed a custom in-solution SureSelect enrichment system covering 36 genes. The genes were chosen based on reports of identified mutations in at least one patient. We tested the proband, an 82 year-old man with a mild, asymmetric LV hypertrophy localized to the apex, marked bi-atrial dilatation, restrictive LV filling patter and juvenile onset of atrial fibrillation. After the run on GAIIx and bioinformatics analysis, three variants were identified: TTNchr2:17918115C>T; p.Arg13823Gln ACTN2 chr1:234961223T>C; p.Met228Thr and MYH3 chr11:47313204C>G; p.Ala1198Thr. Of these, only ACTN2 chr1:234961223T>C; p.Met228Thr co-segregated with the disease manifestations in the proband's pedigree .
This is the first study that showed the feasibility of using genomic enrichment by sequence capture followed by NGS to investigate genetic causes of HCM. Such strategy allows simultaneous, efficient and low-cost sequencing of all genes implicated in a particular genetic disorder, with potential implications for other monogenic cardiovascular disorders.

Immunodeficiency, centromeric instability and facial anomalies syndrome (ICF; MIM 242860) is an autosomal recessive immune disorder that is characterized by recurrent, often fatal, respiratory and gastrointestinal infections due to greatly reduced serum immunoglobulin levels. About 50% of ICF patients (ICF1) carry mutations in the DNA methyltransferase 3B (*DNMT3B*) gene rendering specific repetitive DNA sequences in their genome hypomethylated. The remaining patients carry unknown genetic defects (ICF2), but share with ICF1 patients similar immunological and epigenetic features including hypomethylation of juxtacentromeric heterochromatin regions. By homozygosity mapping and whole exome sequencing we identified nonsense mutations in the zinc finger and BTB domain containing 24 (*ZBTB24*) gene in four consanguineous ICF2 patients, in an affected sibling pair and in one patient of whom consanguineous descent was unknown.

ZBTB24 belongs to a large family of transcriptional repressors including members with regulatory roles in hematopoietic development and malignancy. By the combinatorial use of FACS analysis and quantitative RT-PCR we demonstrated that *ZBTB24* is ubiquitously expressed in human tissues and cell lines and that the highest *ZBTB24* mRNA levels are observed in human peripheral blood B cell subpopulations, especially in naive B cells. Altogether this argues that ZBTB24 is not only involved in the methylation of juxtacentromeric heterochromatic regions, but that it also regulates the development and/or differentiation of B cells.

P11.083

Implicit conceptual links in the literature: a large untapped reservoir of gene discovery

***H. van Haagen**;*
LUMC, Leiden, Netherlands.

The published literature and bioinformatic data are growing faster than individual researchers can track. Text- and data-mining tools have been developed to retrieve explicit links between pairs of concepts (e.g. genes and disease). However, in addition to explicit links, text also contains a complex network of indirect (implied) links containing useful information. We applied concept profiling to probe this vast network of implied information. In a retrospective analysis of 18 gene-disease relationships, implicit information alone could prioritize the causative gene on average within the top 13 out of 200 genes located in a specified linkage interval, at least one year before publication of the landmark paper. The concepts shared between gene and disease enabled the evaluation of the plausibility of the inferred relationship. Of the 40,404,412 possible gene disease pairs, 120,246 (47%, $p < 0.003$) arose exclusively from implicit relations. These results reveal an enormous untapped discovery potential in the implied information of biomedical literature .

P11.084

Next generation sequencing in a family with infantile onset spinocerebellar ataxia identified a novel missense mutation in *C10orf2* gene

***H. Dündar**[1], R. K. Özgül[1], D. Yalnızoğlu[2], S. E. Özdamar[3], D. Tuncel[4], N. Akarsu[5], A. Dursun[1];*
[1]Hacettepe University, Department of Pediatrics, Nutrition and Metabolism Unit, Ankara, Turkey, [2]Hacettepe University, Department of Pediatrics, Neurology Unit, Ankara, Turkey, [3]Hacettepe University, Department of Neurology, Ankara, Turkey, [4]Sütçü İmam University, Department of Neurology, Kahramanmaraş, Turkey, [5]Hacettepe University, Department of Medical Genetics, Ankara, Turkey.

Infantile Onset Spino Cerebellar Ataxia (IOSCA) is a quietly rare disorders characterized ataxia associated with peripheral sensory neuropathy, athetosis, epilepsy, deafness, opthalmoplegia and optic atrophy, and primary hypogonadism in female. Typically, the progressive symptoms developed after upper tract infection in a child with normal developmental milestones until 9-18 months.

In this study, next generation sequencing together with homozygosity mapping identified the disease causing mutation in effected individuals in a Turkish family with spinocerebellar ataxia. Homozygous missense mutation c.1366C>G (L456V) in *C10orf2* gene encoding the Twinkle protein was identified as the disease causing mutation. The open reading frame of *C10orf2* spans five exons and encodes 684 amino acids Twinkle protein, which is a helicase responsible for the replication and maintenance of mitochondrial DNA in mammalian cells. While recessive mutations in the *C10orf2* gene result in IOSCA and hepatocellular encephalopathy syndrome accompanied by mitochondrial depletion, autosomal dominant mutations in the gene cause autosomal dominant progressive external ophthalmoplegia (adPEO) mainly manifesting itself in adulthood.

Pathogenic effect of this amino acid change (L456V) was supported by several lines of evidence. Firstly, c.1366C>G nucleotide change was not detected in 150 Turkish individuals and has not been reported in dbSNP. Secondly, the ClustalW alignment of the amino acid sequence indicated that L456V homozygous missense mutation was at highly conserved position in *C10orf2* shown by comparison to the corresponding sequence of six vertabrates. Lastly, PolyPhen analysis showed that this amino acid change is possibly damaging on the function of the protein.

P11.085

Identification of the *IRXB* gene cluster as candidate genes in severe dysgenesis of the ocular anterior segment.

***M. Chaabouni**[1,2], H. Etchevers[3,4], M. De Blois[2], P. Calvas[4], M. Waill-Perrier[2], M. Vekemans[2], S. Romana[2];*
[1]Department of Hereditary and congenital disorders, Charles Nicolle Hospital, Tunis, Tunisia, [2]Service de Cytogenetique Hopital Necker Enfants Malades, Paris, France, [3]INSERM U781, Hopital Necker Enfants Malades, Paris, France, [4]INSERM U563, Hopital Purpan, Toulouse, France.

PURPOSE: Anterior segment ocular dysgenesis (ASOD) is a broad heterogeneous group of diseases detectable at the clinical and molecular level. In a patient with bilateral congenital ASOD including aniridia and aphakia, a complex chromosomal rearrangement, inv(2)(p22.3q12.1)t(2;16)(q12.1;q12.2), was characterized at the molecular level, to identify candidate genes implicated in ASOD.

METHODS: After negative sequencing of the PAX6, FOXC1, and PITX2 genes, we used fluorescence in situ hybridization (FISH) and Southern blot analysis to characterize the chromosomal breakpoints. Candidate genes were selected, and in situ tissue expression analysis was performed on human fetuses and embryos.

RESULTS: Molecular analyses showed that the 16q12.2 breakpoint in this rearrangement occurs in a 625-bp region centromeric to the IRX3 gene, which belongs to the IRXB cluster. In situ hybridization expression studies showed that during early human embryonic development, the IRX3 gene is expressed in the anterior segment of the eye. Of interest, it has been shown previously that a highly conserved noncoding region (HCNCR) is located 300 kb centromeric to the IRX3 gene and induces, in a murine transgenic assay, an expression pattern fitting that of the IRX3 gene.

CONCLUSIONS: The authors propose that the 16q12.2 breakpoint of this complex translocation is causally related to the ocular anterior segment dysgenesis observed in this patient. This translocation is assumed to separate the HCNCR from the IRXB cluster genes, thus

deregulating the IRXB cluster and leading to the ASOD observed by a positional effect.

P11.086
Genetic analysis of a glomerulonephropathy segregating in a pedigree of French Mastiff

G. F. J. S. Battaille[1], *R. Lavoué*[2], *D. Peeters*[3], *F. Farnir*[4], *M. Georges*[1], *C. Charlier*[1], *A. Lequarré*[1];
[1]*Animal Genomics Unit, GIGA-R, University of Liège, Liege, Belgium,* [2]*2Small Animal Medicine, Ecole Nationale Vétérinaire de Toulouse, Toulouse, France,* [3]*Clinical Sciences, Faculty of Veterinary Medicine, University of Liège, Liege, Belgium,* [4]*Biostatistics and Bioinformatics applied to veterinary sciences, University of Liège, Liege, Belgium.*

Human primary glomerulopathies have a high incidence (~6/1000). Several have suspected or confirmed genetic basis. Implicated genes encode structural proteins such as collagen type IV (Alport syndrome) or the laminin β2. A dozen genes are responsible for alterations of podocyte function, of which three involved in juvenile disorders (*NPHS1, NPHS2 and WT1*). Other glomerulopathies have a genetic component but the causative genes are not yet discovered.
Juvenile glomerulonephropathy has been reported in a pedigree of French Mastiffs. Affected dogs develop symptoms during the first year of life with polyuria, polydipsia and signs of azotemia. Diseased dogs are born from clinically healthy parents, without gender predisposition. The proportion of affected dogs within a litter suggests an autosomal recessive mode of transmission. A genome wide association (GWA) study using the 50K canine SNPs Affymetrix array on 30 healthy and 10 affected dogs did not reveal any region significantly associated with the disease. In one chromosome region, however, affected dogs carried one of only two haplotypes over a 4Mb segment. Candidate genes lying within the interval are currently under investigation in conjunction with expression studies in kidney samples from affected dogs versus healthy ones. A new genome wide scan with data coming from the 170K Illumina array is statistically studied at the moment. The genome of two affected dogs (representing the two haplotypes) has been completely sequenced and the resulting traces are being analyzed. RNA-seq experiments of affected and healthy kidney samples are also in progress. Latest results will be presented.

Characterization of a novel transcript of the *EHMT1* gene reveals important diagnostic implications for Kleefstra Syndrome

W. M. Nillesen[1], *H. G. Yntema*[1], *M. Moscardo*[2], *N. E. Verbeek*[3], *L. C. Wilson*[4], *F. Cowan*[5], *M. Schepens*[1], *A. Raas-Rothschild*[6], *O. Gafni-Weinstein*[6], *M. Zollino*[2], *R. Vijzelaar*[7], *G. Neri*[2], *M. Nelen*[1], *H. van Bokhoven*[1], *J. Giltay*[3], *T. Kleefstra*[1];
[1]*Department of Human Genetics, Nijmegen, Netherlands,* [2]*Institute of Medical Genetics, Catholic University, Rome, Italy,* [3]*Department of Medical Genetics UMC Utrecht, Utrecht, Netherlands,* [4]*Clinical Genetics Unit Great Ormond Street Hospital for children NHS trust and Institute of Child Health University College, London, United Kingdom,* [5]*Perinatal Neurology Department of Paediatrics Imperial College Healthcare Trust, London, United Kingdom,* [6]*Department of Human Genetics and Metabolic Diseases, Hadassah Hebrew University Medical Center, Jerusalem, Israel,* [7]*MRC Holland bv, Amsterdam, Netherlands.*

Kleefstra syndrome is characterized by intellectual disability, childhood hypotonia and a characteristic facial appearance. It can be caused by either submicroscopic deletions of 9qter or intragenic loss of function mutations in the *EHMT1* gene. Until now, routine DNA diagnostic testing for Kleefstra syndrome comprised direct sequencing and MLPA (Multiplex Ligation-dependent Probe Amplification) analysis of the coding region of transcript NM_024757.3. Remarkably, in three patients with a clinical suspicion of Kleefstra syndrome, molecular cytogenetic analysis revealed a submicroscopic interstitial 9q deletion proximal to this transcript. Furthermore, by RT-PCR of the transcript in two of these patients, we found mono-allelic expression of *EHMT1*. in agreement with haploinsuffciency of the gene. We therefore hypothesized that a deletion of regulatory elements or so far unknown coding sequences in the 5' region of the *EHMT1* gene might result in a phenotype compatible with Kleefstra syndrome. Based on *in silico* data, it appeared that the N-terminus of the *EHMT1* gene was recently updated with an extra exon, and that the first untranslated exon of the old transcript is now coding exon 2 (NM_024757.4). MLPA analysis confirmed that in all 3 cases, this novel 5' part of *EHMT1* was deleted. Subsequently, in a panel of 75 individuals without previously identified *EHMT1* mutations, we detected one additional case with a deletion comprising only this 5' part of the *EHMT1* gene and the proximal flanking *C9orf37*.
These results have important implications for the genetic screening of patients with Kleefstra syndrome and further studies of the functional significance of *EHMT1*.

P11.088
Potential use of quantitative expression profiles of mutated Lamin A/C gene as part of the diagnostic work-up of patients with dilated cardiolaminopathies

N. Narula[1], *V. Favalli*[1], *P. Tarantino*[1], *A. Pilotto*[1], *M. Grasso*[1], *A. Serio*[1], *F. Gambarin*[1], *R. Bellazzi*[2], *M. Bollati*[3], *E. Arbustini*[1];
[1]*Centre for Inherited Cardiovascular Diseases, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy,* [2]*Department of Computer Engineering and Systems Science, University of Pavia, Pavia, Italy,* [3]*Department of Biomolecular Sciences and Biotechnology, University of Milan, Milan, Italy.*

Introduction: Diagnosis of dilated cardiolaminopathy, characterized by dilated cardiomyopathy (DCM) and increased risk of arrhythmias, is made after sequencing the *Lamin A/C* (*LMNA*) gene. Current knowledge regarding myocardial expression of Lamin A/C protein and quantitative expression of mutated *LMNA* in myocardium and peripheral blood is very limited. If significant differences in quantitative expression profile exist amongst DCM patients with mutated *LMNA* (DCM-*LMNA*-Mut), DCM patients with wild type *LMNA* (DCM-*LMNA*-WT), and normal control individuals (CTRL), this could be important in diagnostic work-up of cardiolaminopathies.
Methods: We performed immunohistochemistry on myocardial samples from 25 DCM-*LMNA*-Mut patients and on endomyocardial biopsies from 20 normal donor hearts, with anti-Lamin A/C antibodies. Mutated *LMNA* mRNA levels in 20 myocardial and 67 blood samples from DCM-*LMNA*-Mut patients were determined. We examined wild-type *LMNA* mRNA levels in 20 myocardial and 96 blood samples from DCM-*LMNA*-WT patients, and 115 blood samples from CTRL individuals.
Results: Myocardial samples from DCM-*LMNA*-Mut patients have variable loss of protein expression at the nuclear membrane of cardiac myocytes versus DCM-*LMNA*-WT and CTRL samples. *LMNA* was significantly under-expressed in myocardial samples from DCM-*LMNA*-Mut versus DCM-*LMNA*-WT patients. In mRNA from peripheral blood, *LMNA* was significantly under-expressed in DCM-*LMNA*-Mut versus DCM-*LMNA*-WT and CTRL individuals, with most under-expression in splice site, out-of-frame and premature termination codon mutations, followed by missense and in-frame insertion/deletion mutations.
Conclusions: Loss of protein expression of myocyte nuclei, and decreased gene expression in myocardial and peripheral blood mRNA of DCM-*LMNA*-Mut patients, reveal that immunohistochemistry and gene expression could supplement diagnostic work-up for cardiolaminopathies.

P11.089
Genotype instability observed in the long term subculture of LCL samples

J. OH, *Y. Kim, J. Lee, Y. Cho;*
Korea National Institute of Health, KCDC, Cheongwon-gun, Korea, Republic of.

The high-throughput microarray based method for single nucleotide polymorphism (SNP) genotyping has a great advantage in genome wide association studies (GWAS) for identifying human disease susceptibility loci. Although peripheral blood mononuclear (PBMC) is a major resource to collect genomic DNA for genotyping, the Epstein-Barr Virus (EBV)-transformed lymphoblastoid cell line (LCL) is a promising alternative choice to overcome the insufficiency of PBMC. To gain insight into the fidelity of SNP array genotyping in using DNA extracted from LCL, we tested genotype stability of LCL at different propagation stages in terms of cell passages. We genotyped PBMC and LCLs of 20 different individuals using Affymetrix SNP 500k genotyping chips. Six LCL samples for each individual were generated from long-term subcultures up to a passage number of 160. We extensively monitored the genotype concordance for overall SNPs by comparing identity-by-state (IBS) between PMBC and LCL at each propagation stage, by which we were able to profile mismatch rate by chromosome at different propagation stages. Although little difference in genotypes

between PBMC and LCL samples has been reported previously, this study detects slightly decreased concordance between PBMC and LCL samples in old passages. These results suggest that DNA isolated from old passage LCL samples (older than passage number 41) should be avoided for microarray based genotyping.

P11.090
Evaluation of multiple High Resolution Melting (HRM) techniques conducted on three commercially available HRM platforms.

***M. D. Poulson**, R. Lems, M. Wall, C. Gundry, R. Crisp;*
Idaho Technology, Inc., Salt Lake City, UT, United States.

Introduction: HRM is a genetic screening tool that allows investigators to rapidly detect, identify and focus on samples with relevant mutations before they proceed to expensive and time consuming traditional or next generation sequencing. This study used diverse HRM methods to compare three HRM capable platforms.

Methods: A suite of assays highlighting different HRM techniques, mutation scanning, small amplicon genotyping (SAG) and unlabeled probe genotyping, were optimized on three HRM platforms: the LightScanner® (Idaho Technology, Inc.) / Eppendorf MasterCycler Realplex^2 (Eppendorf), the LightCycler® 480 (Roche), and the 7500 Fast DX (ABI). The assays used LightScanner mastermix and High Sensitivity mastermix that include the double stranded DNA dye LCGreen®Plus (Idaho Technology, Inc.).

Results: All platforms were able to differentiate the mutations in the LIPC (Scanning) and Human THO1 (SAG) assays and detected down to 10% allele fractions in the ADH4 (LunaProbe) assay. All three platforms were able to distinguish between heterozygous and homozygous samples in the CPS1 (SAG) class 4 SNP assay. The LightScanner was also able to differentiate the two homozygous samples. The LightScanner correctly grouped all three genotypes of the OTC class 4 SNP (LunaProbe) assay while the other instruments could not group the heterozygous samples. With the HFE (Multiplex LunaProbe) assay, the LightScanner correctly separated each group of samples while the other platforms could not.

Conclusions: All three systems performed HRM well. The Lightscanner/Realplex platform provided more precise mutation discovery, differentiation and genotyping of difficult target regions including class 4 SNPs.

Gaslini Institute, Genoa, GENOA, Italy, [3]Department of Pediatrics and CEBR, University of Genoa, Genoa, Italy, [4]Charite, University of Berlin,, Berlin, Germany, [5]Laboratory of Developmental Biology, University of Oulu, Oulu, Finland, [6]Fondazione IRCCS Ospedale Maggiore Policlinico and Fondazione D'Amico per la Ricerca sulle Malattie Renali,, Milan, Italy.

LMX1B protein is a member of the LIM-homeodomain family of transcription factors, containing two zinc-finger LIM domains and a homeodomain. It is encoded by LMX1B gene (MIM 602575), responsible for Nail-patella syndrome (NPS, MIM#161200), a rare autosomal dominant disorder characterized by a classic clinical tetrad of changes in the nails, knees, elbows, iliac horns and in 40% of cases renal involvement.

A major problem in studying the human LMX1B gene is its scarce or null expression in adult tissues. We were able to detect expression of LMX1B in the cells of hair follicle and urine cells pelleted.

Our previous work demonstrated the presence of two isoforms of LMX1B, differing for seven aminoacids, due to alternative splicing in exon 7. Here we present analysis of different cell types in human and mouse, showing difference of expression of the two isoforms, that could be due to cell specific difference in the mecchanism of splicing and could reflect their differential functional roles.

In order to investigate on the biological role of isoforms, we have investigated difference in cellular localization and evaluated their effect on regulation of trasciptional activity by measure of the luciferase reporter gene, controlled by regulatory sequences of different LMX1B putative target genes, like Podocin, WNT4, PXO2A, PHOX2B, and ACVR1 that we have chosen considering the role of LMX1B in development of kidney, some districts of the central nervous system, and limb.

Analysis of worldwide tandem repeat copy number variation of eight macrosatellite repeats

***M. Schaap**, R. Maassen, P. J. van der Vliet, P. de Knijff, R. J. L. F. Lemmers, S. M. van der Maarel;*
Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

Macrosatellite repeats (MSR) comprise a significant proportion of the human genome, usually spanning hundreds of kilobases of genomic DNA. Because of their highly polymorphic nature, MSR represent an extreme example of copy number variation, but their structure and function is largely understudied. This study comprises the genetic analysis of six autosomal and two X chromosomal MSR of HapMap individuals representing Caucasian, Asian and African populations. Tandem repeat copy number variation and stability of the autosomal macrosatellite repeats RS447 (chromosome 4p), MSR5p (5p), FLJ40296 (13q), RNU2 (17q) and D4Z4 (4q and 10q) and X chromosomal CT47 and DXZ4 were investigated. Repeat array size distributions show that these MSR are highly polymorphic with the highest genetic variation among Africans and the least genetic variation among Asians. A mitotic mutation rate of 0.4-1.5% was observed, explaining the high size variability found for MSR. Multimodal distribution patterns show that MSR are organized in a higher order structure. This study extends our knowledge about MSR regarding array size variation and behavior at the population level. Considering that MSR are large repeat arrays, highly polymorphic and can cover large regions of the genome, it is imperative to get a better understanding of their structure and function. Indeed, this extreme form of copy number variation may well explain some of the missing heritability observed in genome-wide association studies.

P11.093
FBN1 gene expression in Marfan Syndrome: a RT-qPCR study.

***V. Favalli**, B. De Giorgio, M. Grasso, N. Narula, L. Gesa, C. Canclini, E. Disabella, F. I. Gambarin, A. Serio, E. Arbustini;*
IRCCS Policlinico, Pavia, Italy.

Background

Marfan Syndrome (MFS) is caused by defects of the *Fibrillin 1* gene (*FBN1*). We investigated the quantitative expression of *FBN1* mRNA in total RNA isolated from blood samples of MFS patients with *FBN1* mutations.

Methods

Quantitative real-time reverse transcription-PCR was performed in 203 mutated vs. 80 wild type subjects. First-strand cDNA was synthesized from RNA according to the cDNA Reverse Transcription Kit protocol (Applied Biosystems, FosterCity, CA, USA) with three replicas for each sample. Analysis was performed using Applied Biosystems 7900HT Real-Time PCR on *FBN1* cDNA using Hs00153462_m1 probe. Beta actin (*ACTb*, Hs99999903_m1) was selected as the housekeeping gene (HGK). Difference in gene expression was calculated by fold change ratio dividing mean 2^-DeltaCt value in mutated/control individuals. Subgroups were generated based on age and mutation type. Statistical significance was assessed by the Mann Whitney test for unpaired data (alpha=0.05, STATA 10).

Results

FBN1 gene expression declined with age in both cases (31% less in MFS adults than children, p=0.03) and controls (65% less in adults than children, p<0.01). *FBN1* gene showed 53% (p<0.01) and 76% (p<0.01) underexpression in MFS adults and children, respectively vs. age-matched controls, irrespective by mutations type.

	Missense	in-frame Insertion/Deletion	premature termination codon	Splice site
Children (N=95)	55% (p<0.01)	56% (p=0.05)	57% (p<0.01)	61% (p=0.02)
Adults (N=108)	75% (p<0.01)	74% (p=0.03)	77% (p<0.01)	76% p<0.01)

Table 1: *FBN1* underexpression group by mutaton type

Conclusions
Defects of *FBN1* are associated with significantly lower *FBN1* mRNA levels in peripheral blood, irrespective of the type of the mutation in both children and adults.

Despite improvements in terms of sequence quality and price per basepair, Sanger sequencing remains restricted to screening of individual disease genes. The development of massively parallel sequencing (MPS) technologies heralded an era in which molecular diagnostics for multigenic disorders becomes reality. Here, we outline different PCR amplification based strategies for the screening of a multitude of genes in a patient cohort. We performed a thorough evaluation in terms of set-up, coverage and sequencing variants on the data of 10 GS-FLX experiments (over 200 patients). Crucially, we determined the actual coverage that is required for reliable diagnostic results using MPS, and provide a tool to calculate the number of patients that can be screened in a single run. Finally, we provide an overview of factors contributing to false negative or false positive mutation calls and suggest ways to maximize sensitivity and specificity, both important in a routine setting.
By describing practical strategies for screening of multigenic disorders in a multitude of samples and providing answers to questions about minimum required coverage, the number of patients that can be screened in a single run and the factors that may affect sensitivity and specificity we hope to facilitate the implementation of MPS technology in molecular diagnostics.

P11.095
Chromothripsis as a mechanism driving complex de novo structural rearrangements in the germline

W. Kloosterman[1], *V. Guryev*[2], *E. van Binsbergen*[1], *M. Tavakoli*[1], *M. van Roosmalen*[1], *K. Duran*[1], *E. de Bruijn*[1], *S. Bakker*[3], *T. Letteboer*[1], *B. van Nesselrooij*[1], *R. Hochstenbach*[1], *M. Poot*[1], *E. Cuppen*[1];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Hubrecht Institute, Utrecht, Netherlands,* [3]*Gelre Hospital, Apeldoorn, Netherlands.*

A variety of mutational mechanisms shape the dynamic architecture of human genomes and occasionally result in congenital defects and disease. We have developed an efficient experimental and bioinformatics platform to systematically analyze de novo and inherited structural variation by using genome-wide long mate-pair sequencing in families, which include offspring with severe congenital abnormalities. The resolution for detection of structural variation allows reconstruction of chromosomal rearrangements at nucleotide precision. We identified and characterized simple de novo structural changes as well as complex series of inter- and intra-chromosomal rearrangements consisting of multiple breakpoints involving different chromosomes. Detailed inspection of breakpoint regions for complex rearrangements indicated that in some cases series of simultaneous double-stranded DNA breaks caused local shattering of chromosomes. Fusion of the resulting chromosomal fragments involved non-homologous end-joining since junctions displayed limited or no sequence homology and small insertions and deletions. The pattern of random joining of shattered chromosomal fragments that we observed for some de novo rearrangements, strongly resembles the somatic rearrangement patterns - termed chromothripsis - that have recently been described in deranged cancer cells. We conclude that a similar mechanism may also drive the formation of de novo structural variation in the germline.

We report four patients with overlapping microdeletions identified by molecular karyotyping using various array platforms. Their common clinical features include developmental delay with delayed or absent speech and micro- and/or brachycephaly.
In patients 1 through 3, de novo deletions of 1.76 Mb, 1.3 Mb, and 2.8 Mb, respectively, in 9q33.3-q34.11 have been detected. Patient 4 has a maternally inherited deletion of ~432 kb spanning 9q33.3. Her mother is reported to have mild intellectual disability.
The smallest region of overlap of the deletions is defined by the deletion of patient 4 and her mother and includes only three RefSeq genes. Interestingly, the three larger deletions in patients 1, 2, and 3 have 27 genes in common including STXBP1, which is predominantly expressed in brain and plays a role in synaptic transmission. STXBP1 loss-of-function mutations and deletions have been associated with early infantile epileptic encephalopathy (EIEE, or Ohtahara syndrome), and were identified in patients with intellectual disability and non-syndromic epilepsy. Neither patient 1 nor 2 presented with seizures, although an EEG of patient 2 gave pathological results. Thus, the seizure phenotype appears to be incompletely penetrant. Notably, patient 4 presented with epilepsy, although her deletion excludes STXBP1. Thus, the involvement of STXBP1 and/or possibly other genes due to deletion of long range regulatory elements cannot be ruled out.
We suggest that deletions of this region on chromosome 9q may cause epilepsy of incomplete penetrance and a clinical spectrum including developmental delay concerning especially speech, micro- and / or brachycephaly, and mild dysmorphisms.

Clinical routine implementation of custom a-CGH in the diagnosis of patients with psychomotor development delay and/or mild-severe mental retardation

E. Vallespin[1,2], *M. Palomares*[1,2], *S. Garcia-Miñaur*[1,2], *F. Santos*[1,2], *M. A. Mori*[1,2], *A. Delicado*[1,2], *M. L. De Torres*[1,2], *L. Fernandez*[1,2], *E. Mansilla*[1,2], *F. A. Garcia-Santiago*[1,2], *M. C. Crespo*[1], *P. D. Lapunzina*[1,2], ***J. Nevado***[1,2];
[1]*INGEMM-IdiPaz (HULP), MADRID, Spain,* [2]*CIBERER, Madrid, Spain.*

Introduction: The use of array-CGH (comparative genomic hybridization) in clinical routine is already a common practice in many countries. We report the implementation in clinical routine of a custom genome-wide high resolution oligonucleotide aCGH-platform, previously validated (KaryoArray® v3.0), for the study of patients with psychomotor development delay and/or mild to severe mental retardation.
Methods: A prospective study of 100 strictly selected patients with psychomotor development delay and/or deficit cognitive were carried out. Patients with one or more of the following associated findings: structural defects (heart, kidney); facial dysmorphic features; hypo/over-growth disorders; macro/microcephaly; family history of mental retardation. In addition these patients had: karyotype, molecular study of FRAXA and MLPA of subtelomere regions and recurrent-genomic-disorders done previously, with normal results. To end this, we selected 60-mer oligonucleotide features from Agilent's eArray_v4.0 probe library in a custom format of 8x60K (KaryoArray®), covering more than 350 microdeleción/microduplicación syndromes, as well as telomeric/centromeric regions with a resolution from 1 kb in the regions

of interest, with an average density of 7 Kb. The average density of the probe coverage is 43Kb.
Results: we identified in ~30% of these patients at least one genomic imbalance responsible for its phenotype.
Discussion: The implementation of use of KaryoArray® in patients with unexplained development delay/intellectual disability and MCAs offers a much higher diagnostic yield than karyotype and/or currently available platforms for this selected cohort of patients. We highly recommend such kind of aCGH-platform as the first-tier test for individuals with development disabilities or congenital anomalies.

DNA methylation constitutes an epigenetic DNA modification and plays important cell function through changes in gene expression. In mammalian cells methylation is catalysed by DNA methyltransferase and covalent binding of the methyl group to cytidine is most common. Usually it is the cytosine residue situated 5' in relation to guanosine in CpG dinucleotides that undergoes methylation. Methylation appears also in mitochondrial genome. Due to unique twin genetics, group of twins has been studied as an ideal subject for observations of epigenetic changes. Still, so far no wide range analysis of mtDNA in twins has been reported. In this study the analysis of mitochondrial DNA D-loop in group of newborn twins was performed. Level of DNA methylation in collected samples was estimated using sodium bisulphite assay which leads to a change of 5mC>C and C>U, followed by a PCR reaction and pyrosequencing using PyroQ-CpGT software. Using this approach quantitative analysis was possible and revealed differences in DNA methylation of CpG in mtDNA D-loop. Different levels of methylation were observed within dizygotic and also monozygotic twins pairs and seems to be related to heteroplasmy of mitochondrial genome. In most cases methylation was not observed.
This work was supported by the grant N N303 457238 from the Ministry of Science and Higher Education

P11.099
MS-SNuPE as a diagnostic tool for the detection of aberrant methylation patterns in growth retarded patients

M. Begemann, *I. Leisten, T. Eggermann, S. Spengler;*
Institute of Human Genetics, RWTH University Hospital Aachen, Aachen, Germany.
In the last decade the crucial role of imprinted genes in human growth and development has become evident. A number of diseases have been found to be directly linked to aberrant methylation of specific loci including Silver-Russell syndrome (SRS), Beckwith-Wiedemann syndrome (BWS) and Transient Neonatal Diabetes Mellitus (TNDM). A considerable fraction of SRS, BWS and TNDM patients shows aberrant methylation at other than the disease specific loci (multilocus methylation defects - MLMD). To identify epigenetic changes a number of methods have been described. MS-MLPA and MS-PCR as well as MS-pyrosequencing and bisulfite sequencing are meanwhile well established methods. However, they are either time-consuming and/or labor intensive or complex to establish. It is therefore necessary to have simply adjustable assays to analyze different loci with the possibility of direct quantification in single-tube reaction formats available. Based on the AB Prism® SNaPhot technology we established MS-SNuPE (methylation-specific single nucleotide primer extension) approaches to analyze the methylation status of several imprinted loci and to elucidate applicability of MS-SNuPE in research and routine diagnostic. We chose the loci of GRB10, MEST, IGF2R, H19, LIT1, DLK1/GTL2 (chromosomes 6, 7, 11, 14) because methylation of these differentially methylated regions is frequently disturbed in MLMD. The method was validated by screening a cohort of probands with (epi)genetic disturbances identified in previous analyses by other techniques. In all cases, the aberrant methylation was confirmed by the newly developed MS-SNuPE approaches.

MicroRNA expression profiling and bioinformatic analysis in human myocardial infarction with focus on innate immunity and ventricular rupture

E. Boštjančič[1], *N. Zidar*[2], *D. Štajer*[3], *D. Glavač*[1];
[1]*Department of Molecular Genetics, Institute of Pathology, Ljubljana, Slovenia,* [2]*Institute of Pathology, Ljubljana, Slovenia,* [3]*Centre for Intensive Internal Medicine, University Medical Centre, Ljubljana, Slovenia.*
Recent studies have indicated the role of microRNAs in various forms of cardiovascular disease, but little is known about the genome-wide microRNAs expression profile in human myocardial infarction (MI). After MI, innate immunity is activated leading to an acute inflammatory reaction. An intensive inflammatory reaction might contribute to the development of ventricular rupture (VR), as well as some microRNAs have influence on the innate immune response. Based on this knowledge, we further analyzed microRNAs in MI patients with and without VR. There were 60 patients with MI and 10 healthy adults. Using microarrays, microRNAs expression was analyzed on human MI compared to healthy adult hearts. Results were validated using qPCR. MicroRNAs target prediction was performed *in silico* (TargetScan, miRanda), and further subjected to functional classification (DAVID). Of 719 microRNAs analyzed, 57 were confidently dysregulated; many of them were not previously related to cardiovascular disease. For 5 microRNAs 37 target genes were predicted, some of them have been already shown to be involved in microRNAs network. qPCR analysis confirmed dysregulation of *miR-150, miR-186, miR-210, miR-451, miR-34a, miR-146a, miR-155, miR-1, miR-133a/b,* and *miR-208*. Comparison of MI patients with VR to those without VR revealed *miR-146a* up-regulation, and *miR-150*/*miR-155* down-regulation. *miR-146a*, *miR-150*, and *miR-155* have been described to play a role in the regulation of the innate immunity. Their differential expression in MI patients with VR compared to those without VR provides further evidence that innate immunity and intense inflammatory reaction play an important role in the VR pathogenesis after MI in humans.

P11.101
Differential expression profile of miRNA in human bloods from preterm infants and adults

C. Y. Lai[1,2], *S. L. Yu*[2,3], *C. M. Liu*[4], *W. S. Hsieh*[5], *Y. T. Wu*[6], *H. G. Hwu*[1,4], *S. F. Jeng*[6,7], *W. J. Chen*[1,2,4];

Accumulating evidence suggests a role for microRNAs (miRNAs) in regulating various age-related diseases and human aging. However, little is known about the changes of miRNA expression before and after adulthood. The aim of the study is to investigate whether there are differential expression in miRNAs between infants and adults, and then explore the possible biological functions of these miRNAs. We profiled the expression of 365 miRNAs in peripheral blood mononuclear cells from preterm infants (n=30) and adults (n=60, age ranging from 21 to 60) using real-time RT-PCR analysis. This genome-wide assessment of miRNA expression revealed that the majority of differentially expressed miRNAs increased in adults. Among 365 miRNAs, 228 (62.5%) were detectable in the more than half of the peripheral mononuclear cells in the samples of either adults or preterm-infants. Among these miRNAs, there were 22 miRNAs expressed in the adults' group only, and one (has-miR-325) is specific to the preterm-infants. For the remaining 205 miRNAs, 101 differentially expressed

between the two groups (p<0.00024 with bonferroni correction), in which 81 miRNAs were up-regulated in adults and 20 were down-regulated in preterm-infants samples. Finally, these differentially expressed miRNAs were subjected to the knowledge-base software of ingenuity pathway analyses (IPA, version 8.8) and found that the most significantly associated biological networks were reproductive system disease, cellular assembly and organization, and nervous system development. The results indicated that approximately one third of the miRNAs was modulated from infant to adulthood, and the implication in human development warrants further investigation.

P11.102**

Identification of trait- and disease-relevant genetic polymorphisms in miRNA target sites

S. Busche[1], *M. Georges*[2], *T. M. Pastinen*[1];
[1]*McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada,* [2]*University of Liege, Liege, Belgium.*

MicroRNAs (miRNAs) are ~22 nucleotide long noncoding RNAs that regulate the expression and function of eukaryotic genomes by acting as adaptors to specifically recognize and degrade targeted mRNAs. Candidate studies suggest that genetic polymorphisms in miRNA target sites (poly-miRTS) are associated with various disorders like Tourette's syndrome, hypertension, or the risk to develop breast cancer. We aim to create a genome-wide catalogue of poly-miRTS to provide the fundamental basis for the characterization of miRNA-related genetic alterations with an impact on human traits and disease, and to unravel the mechanisms of action of some causal poly-miRTS. To identify poly-miRTS in a genome-wide scale, we will monitor RNA levels and differences in allelic expression (AE) with and without active miRNA gene regulation. To shutdown miRNA-mediated gene regulation we interfere with the miRNA processing machinery by silencing Drosha, DGCR8, and/or Exportin-5. Importantly, interference with any of these genes is not expected to prevent siRNA processing. Our present results show that silencing any single gene within the miRNA machinery does not substantially inhibit the level of mature miRNAs. However, successful silencing of Drosha and Exportin-5 leads to a 50% reduction of mature miRNAs. Initial RNA-sequencing and SNP genotyping experiments are underway. To circumvent off-target effects in assessing the global impact of silencing miRNA expression we will monitor genome-wide differences in allelic rather than total gene expression. We anticipate that this effectively eliminates non-specific effects and allows focusing on interaction of miRNA binding and genetic variants at binding sites.

Profiling miRNA using semicondutor sequencing technology on the Personal Genome Machine

K. Bramlett*, J. Schageman, L. Qu, S. Heater, J. Myers, B. Setterquist;*
Life Technologies, Austin, TX, United States.

RNA-Seq technology has become widely utilized as a tool to understand the transcriptome of a given experimental system. This method utilizes next generation sequencing platforms to sequence a cDNA library in order to gain information about the RNA content and transcriptional status of an experimental system. Profiling the transcriptome of a system in this way has become an invaluable tool in many genomic studies.

The Ion Torrent Personal Genome Machine (PGM™) utilizes revolutionary technology, simplifying next generation sequencing instrumentation in order to make this technique available to a wider group of individuals beyond the basic researcher. The PGM™ instrument combines semiconductor technology with simplified chemistry including natural nucleotides and no enzymatic cascades to create a simple and scalable sequencing platform devoid of the need for expensive and complicated optics and imaging capabilities. This new sequencing platform has successfully provided genomic information for multiple DNA based applications, such as amplicon sequencing, in record time.

Here we report the first RNA-Seq libraries analyzed on the Ion Torrent PGM™ instrument. The miRNA content of multiple RNA types was profiled using novel RNA library preparation reagents. Resulting cDNA libraries were sequenced on the PGM™ in record time providing valuable information on the transcriptome of the interrogated RNAs. This is the first demonstration of the Ion Torrent PGM™ as a simple, fast, and scalable technology for transcriptome analysis using established RNA-Seq library methodology.

Plasma mir-155, mir-21 and mir-126 expression profiling in patients with cerebrovascular accident (CVA)

I. V. Iancu[1], *A. Botezatu*[1], *M. Anton*[2], *I. Huica*[1], *E. Lupeanu*[3], *G. Anton*[1];
[1] *"Stefan S Nicolau" Institute of Virology, Bucharest, Romania,* [2]*"Coltea" Clinical Hospital, University of Medicine and Pharmacy, Bucharest, Romania,* [3] *"Ana Aslan" Institute of Geriatric and Gerontology, Bucharest, Romania.*

MicroRNAs (miRNAs) are endogenous 21-25 nucleotides in length RNAs involved in the ethiopathology of various diseases. Recently, plasma miRNAs have been reported to be sensitive and specific biomarkers of various tissue injuries and pathological conditions. miRNAs have distinct expression patterns in stroke etiology, that modulate pathogenic processes including atherosclerosis (*miR-21, miR-126*), hyperlipidemia (*miR-33, miR-125a-5p*), hypertension (*miR-155*), and plaque rupture (*miR-222, miR-210*). The aim of this study was to evaluate some circulating miRNAs expression in plasma patients with cerebrovascular accident (CVA). Blood samples were collected from patients with cardio-vascular disease (CVD) (n=30, aged 57-86 years old, mean = 71.5) who presented hypertension and hyperlipidemia, and from healthy subjects (n=10, aged 20-53 years old, mean = 35.96). 12/30 of the CVD patients presented stroke. Total RNA was extracted from plasma using Trizol reagent. Plasma expression of target miRNAs (*miR-126, 21* and *155*) were assessed by a Real-Time RT-PCR using TaqMan MicroRNA Assays (ABI). Statistical analysis was performed using Mann-Whitney test. qPCR assessment revealed lower plasma levels of *miR-21*, and *miR-126* in CVA group of patients as compared to non-CVA and to the controls. Further evaluation of the miRNA levels in plasma from CVA patients (n =12) demonstrated that *miR-155* levels were substantially lower than those from patients with non-CVA (n = 18, P < 0.03) or healthy people (n = 10, P < 0.01). The results revealed a significantly reduced plasma concentration of *miR-155* in CVA patients indicating it as a potential biomarker for CVA.

P11.105

SM2PH-kb: a novel tool for the integrated study of human missense variants to phenotypes relationships

T. Luu[1], *N. Nguyen*[1], *A. Friedrich*[2], ***J. Muller***[1], *L. Moulinier*[1], *J. Mandel*[1], *O. Poch*[1];
[1]*IGBMC, Illkirch Graffenstaden, France,* [2]*Department of Genetics, Genomics and Microbiology, Strasbourg, France.*

Understanding how genetic alterations affect gene products at the molecular level represents a first step in the elucidation of the complex relationships between genotypic and phenotypic variations, and is thus a major challenge in the postgenomic era. SM2PH-kb (http://decrypthon.igbmc.fr/sm2ph) is the second generation of our tool designed to investigate structural and functional impacts of missense variants and their phenotypic effects in the context of human genetic diseases (Friedrich et al Hum Mutat. 2010). We present our recent and future developments together with a practical example (Audo et al Arch Ophthalmol. 2010) on how SM2PH-kb can be used to analyse genotype to phenotype relations.

Up-to-date interconnected information is provided for each of the 2,375 disease-related entries including data retrieved from biological databases (e.g. STRING networks, KEGG pathways, BioGPS tissue gene expression) and data generated from evolutionary inference in biological networks (e.g. multiple alignments, 3D structural models). The 18,700 recorded disease causing mutations have now been complemented by the 143,000 missense SNPs from dbSNP (release 132). The introduction of the Inductive Logic Programming allowed us to automatically, extract knowledge from these data and generate classification rules. This will guide human experts to improve our understanding of the relationships between physico-chemical and evolutionary features and deleterious mutations. This leads to improved prediction of functional effect and pathogenicity of submitted missense variations.

SM2PH-kb provides a robust infrastructure, interactive analysis tools supporting in-depth study and interpretation of the molecular consequences of mutations, with the more long-term goal of elucidating variants pathogenicity.

P11.106
Potentials and pitfalls of Mitochip v.2.0 in the diagnostic of mitochondrial encephalomyopathies

V. Remenyi[1], *G. Inczedy-Farkas*[1], *T. Kalmar*[2], *S. Spisak*[3], *B. Bereznai*[1], *A. Gal*[1], *I. Rasko*[2], *M. J. Molnar*[1];
[1]*Clinical and Research Centre for Molecular Neurology Semmelweis University, Budapest, Hungary,* [2]*Developmental Genetics Lab Genetics Institute BRC, Szeged, Hungary,* [3]*2nd Department of Medicine, Semmelweis University of Medicine, Budapest, Hungary.*

Background: The identification of mitochondrial disorders due to mutations mtDNA is difficult because the lack of phenotype-genotype correlation and mutation hot spots in the mitochondrial genome. To verify an mtDNA disease the whole mtDNA should have been analyzed.
Methods: Ten patients with neurological and psychiatric symptoms have been investigated. The whole mtDNA was resequenced by MitoChip 2.0 (Affymetrix) according to the manufacturer's instruction. The doubtful SNPs detected by the MitoChip were controlled by bidirectional sequencing with ABI Prism 3100 sequencing machine.
Result: In 1 case a pathogenic heteroplasmic mtDNA substitution A12770G (Glu145Gly) was detected in the ND5 gene. In the other 9 cases many synonym and non-synonym mutations were present .We found 7 unclassified variants in 5 cases. In 2 patients with psychiatric symptoms, axonal neuropathy a unique SNP combination was found which was described previously predisposing for breast cancer and AMD. The haplotype of these patients were: T2, J1c2. These haplogroups harbor substitutions capable of modifying the phenotype of LHON. One of our patients with epilepsy and schizophrenia had haplogroup D4j containing SNPs previously associated with hypoacusis, schizophrenia, LHON. Six of our patients had the typical Hungarian haplogroups (H5, H4, H1, R0, U4). On the base of the MitoChip sequenogram about 22% of the presumed heteroplasmic mtDNA mutations couldn't verified with bidirectional sequencing.
Discussion: We conclude that MitoChip v2.0. is a quick method determining the mtDNA haplotypes and disease modifying homoplasmic SNPs and SNP combinations. To justify the pathogenic heteroplasmic mutations in the mtDNA the bidirectional sequencing is crucial.

P11.107
MUTALYZER 2: Improved Sequence Variant Descriptions from next generation sequencing data and locus-specific mutation databases

J. Laros, M. Vermaat, G. Stouten, J. den Dunnen, ***P. Taschner****;*
Center for Human and Clinical Genetics, Leiden, Netherlands.

Unambiguous and correct sequence variation descriptions are of utmost importance, not in the least since mistakes and uncertainties may lead to undesired errors in clinical diagnosis. The free Mutalyzer sequence variation nomenclature checker (www.mutalyzer.nl/) names all sequence variants following the Human Genome Variation Society sequence variant nomenclature recommendations (www.hgvs.org/mutnomen), using a GenBank or Locus Region Genomic (LRG) accession number, a HGCN gene symbol and the sequence variant as input. Mutalyzer 2 has new functionality lacking in the commercial Alamut tool used by many DNA diagnostic labs. Mutalyzer generates an output containing a description of the sequence variant at DNA level, the effect on all annotated transcripts, its deduced outcome at protein level and gains or losses of restriction enzyme recognition sites. Mutalyzer facilitates batch-wise conversion from dbSNP rsIDs or chromosomal position numbering used in next generation sequencing data to transcript position numbering, as well as checking of sequence variant descriptions in locus-specific mutation databases (LSDBs). Mutalyzer is also used to quickly check new variant submissions in LSDBs based on LOVD software (www.LOVD.nl/). The new Name Generator can be used to train your self to generate correct HGVS descriptions. New webservices also support the use of Mutalyzer's functionality from other computer programs.
Funded in part by the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement nº 200754 - the GEN2PHEN project.

P11.108
Mutation Hotspot - a web application for mutation mining in publicly available exome sequences

S. Rudd*, R. Hercus, T. Liang Chung, L. Chiew Mui, H. Kim Fong, C. Soo Meng, M. Kumar, I. Maarif;*
Malaysia Genomics Resource Centre Berhad, Kuala Lumpur, Malaysia.

Genome and exome sequencing has become affordable and, within clinical research projects, it is now reasonable to perform whole genome or exome sequencing for moderately sized cohorts of individuals. Sequence reads from a variety of sequencing technologies are mapped to a reference genome and the analysis of the systematic differences relative to the reference and those shared by different project subjects may be used to identify rare novel gene variants, genes associated with disease or to characterise finer patterns of genomic context.
The assignment of meaning and the identification of patterns within the data are complicated by the large volumes of complex data. To simplify the process of identifying different classes of variation, we have implemented a web-accessible database system for the mining of sequence variation. Starting with primary sequence read data from publicly available exomes, we mapped the reads to a reference human genome. By applying scoring algorithms to the sequence variations characterised within individual exomes, mutations can be filtered on the basis of confidence scores. The total variation has been loaded into a relational database.
Simple user interfaces provide functionality to identify the patterns of variation, namely, those that are common to groups of individuals, those that contrast groups of individuals, and can be used further to identify the polymorphisms that appear unique within individuals. Genes containing variations, genes enriched for multiple variations and genes belonging to functionally related gene sets are linked to external databases so that the meaning and relevance of specific variations can be assessed.

P11.109
Mitochondrial proteins are responsible for Neurodegeneration with Brain Iron Accumulation (NBIA).

S. Dusi[1], *C. Giorgi*[2], *D. Brunetti*[1], *H. Hama*[3], *P. Pinton*[2], ***V. Tiranti***[1];
[1]*IRCCS Foundation Neurological Institute C. Besta, MIlan, Italy,* [2]*Department of Experimental and Diagnostic Medicine, Section of General Pathology, Interdisciplinary Center for the Study of Inflammation (ICSI) and LTTA center, Ferrara, Italy,* [3]*Department of Biochemistry and Molecular Biology, Medical University of South Carolina, Charleston, SC, United States.*

Neurodegeneration with Brain Iron Accumulation (NBIA) comprises a group of neurodegenerative disorders characterized by brain iron deposition and presence of axonal spheroids. Pantothenate Kinase Associated Neurodegeneration (PKAN) and Infantile Neuroaxonal Dystrophy (INAD) are the most frequent forms of the disease and are due to mutations in PANK2, coding for Pantothenate Kinase 2, and PLA2G6, coding for a calcium independent phospholipase. Recently, mutations in an additional gene dubbed FA2H and coding for a Fatty Acid 2-Hydroxylase were found in two families with symptoms resembling NBIA.
Several findings indicate that PANK2 and PLA2G6 are localized into mitochondria, although it is not completely clear in which compartment. In addition, although the putative localization of FA2H was reported to be into the Endoplasmic Reticulum (ER), software prediction for this protein scores high for mitochondrial localization.
Objective of this work is to establish the PANK2 and PLA2G6 sub-mitochondrial localization and to test the hypothesis that the FA2H protein could also be located in this organelle.
We here demonstrated that the three known proteins involved in NBIA are indeed located into mitochondria with the FA2H being present also in the ER. These data indicate that communication between mitochondria and ER is crucial during the transfer of essential lipids and underline the important role of these organelles and lipids metabolism in causing the disease.

P11.110
Parallel copy number variation and sequence variation detection with next generation sequencing (NGS)

C. Haag[1], *E. Schulze*[1], *M. Schanz*[1], *J. Strub*[2], *F. Raue*[1];
[1]*Endocrine Practice, Heidelberg, Germany,* [2]*JSI Medical Systems GmbH, Kippenheim, Germany.*

Large genomic duplications and deletions have been recognized as pathogenic mutations for many years. Therefore the determination of gene dosage in combination with the sequence variation detection becomes very important in clinical medicine.
We describe a method for the simultaneous mutation and copy number variation (CNV) detection with next generation sequencing (GS Junior, Roche).
We developed a two-step multiplex PCR for the amplification of all coding exons of 4 candidate genes (RET protooncogen, MEN1, CASR and SHOX) in comparison with 10 control fragments. For validation of the multiplex PCR based method we compared these results with traditional Sanger sequencing and MLPA analysis. One big challange with the multiplex PCR approach is the formation of spurious PCR products due to primer dimerization. For removal of primer dimers or short failed PCR products we used the size-selective solid phase reversible immobilization (SPRI) purification technology. After primer dimer removal, about 95% of all reads are within the specific 300 - 400bp range.
The evaluation of the NGS data as well as the Sanger sequence and MLPA analysis was performed with the Sequence Pilot software (JSI medical systems). For the detection of CNVs, dosage quotients were calculated using control fragments and target fragments for patient and control samples.
All deletions or duplications in the 4 candidate genes, which were known from MLPA analysis, could be detected by NGS. Therefore, the multiplex PCR based method for next generation sequencing is an efficient technique to detect copy number variations and sequence variation simultaneously.

P11.111
Next Generation Sequencing on small amounts of DNA and RNA from FFPE-fixed tissues using NuGEN's Ovation® amplification products

L. Vahlkamp*, M. Stapleton, L. Turner, V. Sementchenko, D. Amorese;*
NuGEN Technologies, Inc., San Carlos, CA, United States.

The analysis of clinical samples has long presented challenges to researchers based on sample availability, amount, and integrity. These challenges are most significant for small and typically degraded formalin-fixed, paraffin embedded (FFPE) samples widely used in cancer research and clinical diagnostics.
We have developed highly sensitive and robust amplification systems for the amplification of DNA and RNA from FFPE tumor samples that take advantage of the proprietary Single Primer Isothermal Amplification (SPIA®) technology developed at NuGEN®.
The whole genome amplification system uses 100 ng of routinely isolated FFPE DNA and produces DNA suitable for multiple downstream applications such as aCGH and next generation sequencing (NGS). Data will be presented that illustrates the performance of the SPIA amplified material benchmarked against microgram quantities of its unamplified counterpart. These studies reveal a preservation of copy number changes and breakpoints.
The whole transcriptome approach used in NuGEN's Ovation RNA-Seq FFPE System, enables amplification and sample preparation of as little as 100 ng of FFPE total RNA for accurate and robust analysis on next generation sequencing (NGS) platforms. RNA isolated from FFPE and Fresh Frozen (FF) matched Colon Tumor and Normal Adjacent Tissue (NAT) pairs was amplified and the products were used to prepare libraries with the NuGEN Encore NGS Multiplex System I and sequenced using the Illumina GAIIx platform.

P11.112
A bioinformatic framework to build junction databases for the detection of alternative splicing isoforms from Next Generation Sequencing data

L. Xumerle[1], *A. Ferrarini*[2], *V. Mijatovic*[1], *M. Delledonne*[2], *P. F. Pignatti*[1], *G. Malerba*[1];
[1]*University of Verona, DLRS - Section of Biology and Genetics, Verona, Italy,* [2]*University of Verona, Department of Biotechnology, Verona, Italy.*

The millions of short sequences (reads) generated by next-generation sequencing (NGS) platfroms can be used for a wide range applications including genomewide measurement of gene expression levels (RNAseq), detection of RNA or DNA sequence variations and DNA rearragments.
We were interested in detecting non annotated junctions sequences (JS) at DNA or RNA level. There are several bioinformatic tools (tophat; MMES; gmap; GSNAP) that can do that. However they generally suggest a huge amount JSs that have to be verified. A first validation step can be conducted in silico generating all the sequences corresponding to a JS. If several reads map on a JS, then we have a first indication that the JS suggested by the bioinformatic tools is likely to be a true JS. Therefore we developed a computer program able to generate all possible JSs using genomic coordinates (chromosome name, start and stop positions) of a reference sequence. This tool has now been used to create in silico all possible annotated isoforms for a given gene to check if some unmapped short reads might map on JSs of a specific isoform. This tool can be also used to get an individual sequence from a genome reference sequence by indicating the genomic coordinates of the multiple fragments of interest. The program is included in the Short Reads ToolKit (http://ddlab.sci.univr.it/srtk/), a Python library of functions and programs dedicated to NGS data computation.

P11.113
Highly multiplexed barcoded enrichment of up to 96 samples for next-generation sequencing

M. Harakalova[1], *I. J. Nijman*[2], *S. van Lieshout*[1], *K. Duran*[1], *M. van Roosmalen*[1], *I. Renkens*[1], *B. Hrdlickova*[1,3], *M. Mokry*[2], *R. Houwen*[4], *P. van Hasselt*[4], *T. de Koning*[4], *M. van den Boogaard*[1], *E. Brilstra*[1], *B. Koeleman*[1], *H. Y. Kroes*[1], *M. van Haelst*[1], *H. Ploos van Amstel*[1], *W. Kloosterman*[1], *E. Cuppen*[1,2];
[1]*Department of Medical Genetics, UMCU, Utrecht, Netherlands,* [2]*Hubrecht Institute, UMCU, Utrecht, Netherlands,* [3]*Department of Genetics, UMCG, Groningen, Netherlands,* [4]*Department of Pediatrics, UMCU, Utrecht, Netherlands.*

The unprecedented increase in throughput of next-generation sequencing (NGS) technologies allows for efficient sequencing of multiple exon-centric samples in a single sequencing run. However, library preparation and enrichment of multiple samples has now become a limiting step for high-throughput genomic analysis. To address this, we developed an efficient strategy for enriching pools of pre-barcoded samples using both microarray-based as well as solution-based approaches. We have optimized custom protocols and pipelines for probe design, library preparation, enrichment and variant analysis and prioritization. The multiplexed enrichment protocol is highly efficient and provides the experimental flexibility that meets the needs of various types of variant discovery projects, ranging from small families to population studies, while screening small sets of candidate genes or large genomic intervals. We found that performance for pools between 3 and up to 96 samples is similar in comparison to non-multiplexed samples.
Here, we focus on detection of causal variants using X-chromosome exome sequencing in families with an X-linked inheritance pattern. We designed a custom enrichment array for all protein and RNA coding genes on human chromosome X with a densely tiled probe overlap, which resulted in a very even coverage distribution (>99% of all positions covered by at least 1 read). Using this array, it is possible to enrich approximately 30 individuals from different families in a single assay, which fits the capacity of a single SOLiD sequencing run and provides a flexible strategy for high-throughput variant detection with significantly lowered costs and efforts.

P11.114
Development of an exome sequencing workflow in a diagnostic setting

M. Nelen*, L. Visser, K. Neveling, C. Gilissen, H. Yntema, D. Bodmer, M. Buckley, H. Brunner, J. Veltman, H. Scheffer;*
UMC Nijmegen, Nijmegen, Netherlands.

For many years Sanger sequencing has been the golden standard and workhorse in DNA diagnostic laboratories. However, implementing gene tests for all known monogenic diseases is impossible in single laboratories. Moreover, the cause of many genetic diseases is still

unknown. Together with genetic heterogeneity adding another level of complexity to clinical diagnosis, diagnostic yield remains overall relatively low. Targeted Next Generation Sequencing approaches allows rapid and affordable analysis of genetic variation in multiple loci in parallel. This has been of enormous value in recent disease gene identification studies, especially when expanded to the exome. In a recent family-based exome sequencing study we showed that rare *de novo* mutations can be reliably identified and may explain the majority of cases with mental retardation (Vissers et al, 2010). These results demonstrate that exome sequencing is becoming a robust approach for identification of genetic variation and can be implemented in a diagnostic setting, even for genetically heterogeneous and largely unexplained common disorders like mental retardation.
In this presentation we will describe the development and validation of a diagnostic workflow for exome sequencing in genetically heterogeneous disorders such as hereditary blindness, hereditary deafness, mitochondrial diseases, movement disorders and mental retardation. Important aspects of the implementation of NGS as a diagnostic tool will be addressed; the informed consent procedure, description into our quality system, the laboratory and data-analysis workflow, as well as the reporting to referring clinicians. This will be followed by a discussion on the results of our first diagnostic exome sequencing analyses.

P11.115
Exome sequencing of an italian patient with dHMN

L. Citrigno[1], *S. Züchner*[2], *A. Magariello*[1], *J. Huang*[2], *A. Gabriele*[1], *G. Montenegro*[2], *F. Conforti*[1], *E. Powell*[2], *R. Mazzei*[1], *C. Ungaro*[1], *W. Sproviero*[1], *A. Gambardella*[1], *A. Patitucci*[1], *A. Quattrone*[3], *M. Muglia*[1];
[1]*CNR - Institute of Neurological Sciences, Mangone (CS), Italy,* [2]*Hussman Institute for Human Gemonics - University of Miami - Miller School of Medicine, Miami, FL, United States,* [3]*Institute of Neurology - University "Magna Graecia", Catanzaro, Italy.*

Distal hereditary motor neuronopathy (dHMN) is heterogeneous group of disorders characterized by an exclusive involvement of the motor part of the peripheral nervous system. Often, unusual or additional features are present in 'complicated' distal HMN, including predominance in the hands, vocal cord paralysis, diaphragm paralysis and pyramidal tract signs. To date 16 loci and height genes have been identified. We have previously mapped a novel locus in an Italian family with dHMN complicated by pyramidal signs on chromosome 4q35, in a 26cM region between markers D4S1552 and D4S2930.
The full exome of the proband from the family was submitted to a capturing/enrichment process with SureSelect target Enrichment system (Illumina/Solexa) technology. The captured DNA was submitted to a high throughput sequencing using the Genome Analyzer II (Illumina). We were able to obtain 0.9 Gb of genomics sequences from two runs. The raw data was trimmed and aligned with the human genome reference (hg19) using MAQ software. We identified 65508 high-confidence single nucleotide variants and 87 deletion/insertion polymorphisms (DIPs). After the reads stringencies and based on linkage evidences, the results showed 80 unique variants that are not present in dbSNP (v.131) and 2 novel synonymous DIPs in heterozygous state. The identified variation was confirmed by Sanger sequencing and will be assessed in all members of the family and in a normal control population.
Exome sequencing of a proband from the families with linkage evidence is a powerful and efficient strategy for identifying the genes underlying rare mendelian disorders.

P11.116
Novel sequencing primer and simplified PCR-Sanger sequencing workflow increase 5' resolution and throughput

S. Hung*, P. Ma, S. Berosik, M. Wenz, S. Schneider, S. Lim;*
Life Technologies, Foster City, CA, United States.

High quality and high accuracy are the hallmarks of Sanger re-sequencing projects. We have developed new sequencing primers and workflow that improve 5' sequence resolution, increase throughput, and reduce hands-on time. The novel sequencing primer chemistry and workflow produces high quality sequence data from base 1 on POP-7™ polymer that previously only could be resolved with longer run time on POP-6™ polymer.
The new primer chemistry and workflow, BigDye® Direct Cycle Sequencing, eliminates the need for a separate PCR clean-up step, thereby saving time and cost and reducing possible pipetting errors. These improvements reduce the entire workflow time for PCR to finished sequence data to less than 5 hours, compared to 8 hours for the standard workflow.
We have sequenced many exon sequences, including challenging templates, using our enhanced sequencing primers and workflow on an Applied Biosystems 3500*xl* Genetic Analyzer. We compared 5' resolution, basecalling accuracy and quality of electropherograms generated with traditional sequencing primers and workflows versus BigDye® Direct novel primers and workflow.
On average, the new primers produced high quality bases by base 5, and by base 1 in many cases, compared with base 25 with traditional primers on POP-7™ polymer. The superior resolution increased basecalling accuracy, both in the 5' end and in mixed base positions. In conclusion, the simplified BigDye® Direct Cycle Sequencing workflow generates data superior in quality relative to other currently used reagents and offers significant time savings up to 40%. The product is for research use only. Not for use in diagnostic procedures.

P11.117
Comparison of solution based exome capture methods for next generation sequencing

A. Sulonen[1,2], *P. Ellonen*[1], *H. Almusa*[1], *M. Lepistö*[1], *S. Eldfors*[1], *S. Hannula*[1], *P. Mattila*[1], *P. Salo*[1,2], *A. Suomalainen-Wartiovaara*[3,4], *C. Heckman*[1], *S. Mustjoki*[5], *T. Raivio*[6,7], *A. Lehesjoki*[8], *J. Saarela*[1];
[1]*Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland,* [2]*Unit of Public Health Genomics, National Institute for Health and Welfare, Helsinki, Finland,* [3]*Research programme of Molecular Neurology, University of Helsinki, Helsinki, Finland,* [4]*Department of Neurology, Helsinki University Central Hospital, Helsinki, Finland,* [5]*Hematology Research Unit, Biomedicum Helsinki, Department of Medicine, Division of Hematology, Helsinki University Central Hospital, Helsinki, Finland,* [6]*Institute of Biomedicine, Department of Physiology, University of Helsinki, Helsinki, Finland,* [7]*Children's Hospital, Helsinki University Central Hospital, Helsinki, Finland,* [8]*Folkhälsan Institute of Genetics, Department of Medical Genetics and Neuroscience Center, University of Helsinki, Helsinki, Finland.*

Techniques enabling targeted re-sequencing of the best-understood regions - the protein coding sequences - of the human genome on next generation sequencing instruments are of great interest. We conducted a systematic comparison of the solution based exome capture kits provided by Agilent (SureSelect and SureSelect 50Mb) and Roche NimbleGen (SeqCap and SeqCap v2.0), to weigh their advantages and disadvantages.
A control DNA sample was captured with all four capture methods and prepared for Illumina GAII sequencing. Protocols provided by the manufacturers were slightly modified for equalization. Read counts were normalized to comparable amounts of high quality, non-duplicated reads. Sequence data from additional samples (n 28) prepared with the same protocols in our laboratory for other projects were used in the analyses. For the data analysis a bioinformatics pipeline for QC, variant identification and annotation (VCP) was also developed. The performance of the capture methods was evaluated for sensitivity and specificity of the enrichment of the target regions, ability to identify known and novel variants, and correlation of sequenced variants and genotypes from Illumina 660K Chip.
Both the target designs and the actual captured regions varied between the capture methods. While Agilent kits targeted more regions, sequences from the NimbleGen capture covered more CCDS exons and genes with a minimum of 20x coverage. There was virtually no difference in the concordance compared to chip genotypes, and a minimum of 11x coverage was required to make a heterozygote genotype call with 99% accuracy when compared to common SNPs on GWA arrays.

P11.118
Exact Call Chemistry enables superior accuracy in next-generation sequencing

H. E. Peckham[1], *V. R. Tadigotla*[1], *E. F. Tsung*[1], *F. C. Hyland*[2], *A. Siddiqui*[2], *M. Sikora*[2], *S. Datta*[2], *C. Yang*[2], *H. Breu*[2], *D. Brinza*[2], *A. P. Blanchard*[1], *E. M. Beasley*[2];
[1]*Life Technologies, Beverly, MA, United States,* [2]*Life Technologies, Foster City,*

CA, United States.

Exact Call Chemistry (ECC) is a unique ligation-based sequencing methodology that builds on the SOLiD™ system chemistry. While every base of the DNA template is interrogated twice using two-base encoded probes, ECC performs an additional inspection of the template using a new, four-base encoded probe set that is carefully designed to complement two-base encoding and jointly form a redundant error-correction code. This strategy allows for error detection and correction without the use of a reference sequence. We demonstrate the performance of ECC in the sequencing of human genomes and compare the performance to that of two-base encoding in the absence of ECC. ECC increases overall throughput including over 60% more reads with zero mismatches compared to the reference sequence. We use ECC to detect SNPs and structural variations in these human genomes and demonstrate that the more accurate reads translate to improved variant detection. Using human genomes with 10-14x coverage, we detect 5% more SNPs with ECC and 30% to 100% more small indels (deletions up to size 11 and insertions up to size 3) without loss of specificity using a split-read approach. ECC chemistry also enables the optimization of sample preparation techniques to reduce errors in these steps. Additionally, we introduce reference-assisted ECC sequencing which further increases accuracy. The multi-base encoding functionality of ECC contributes to a lower error rate and reduced systematic noise, resulting in unsurpassed sequencing accuracy and variant discovery.

For Research Use Only. Not intended for any animal or human therapeutic or diagnostic use.

A New Sequencing Workflow Increases Accuracy and 5' Resolution for Capillary Electrophoresis Resequencing Applications

C. Davidson[1], *P. Ma*[1], *S. Hung*[1], *S. Berosik*[1], *S. Schneider*[1], *V. Bourdon*[2], *T. Noguchi*[2], *H. Sobol*[2], *B. Terrill*[3], *S. Vemula*[3], *M. Wenz*[1];

[1]*Applied Biosystems, Foster City, CA, United States,* [2]*Institute Paoli Calmette, Marseille, France,* [3]*University of California San Francisco Dermatopathology, San Francisco, CA, United States.*

Applied Biosystems™ introduces the BigDye® Direct Cycle Sequencing Kit: BigDye® terminator chemistry that combines post PCR clean up with cycle sequencing steps for increased throughput. BigDye® Direct (BDD) uses M13 universal primers and is ideal for resequencing applications. BigDye® Direct improves 5' sequence resolution through novel sequencing primer chemistry producing high quality bases from base 1 on POP-7™ polymer that previously only could be resolved with longer run time POP-6™. Some of the benefits that BigDye® Direct Cycle Sequencing Kit provides include no sample transfer between PCR and sequencing reactions, the complete workflow is performed in the same well of a plate, thus saving time and labor and reducing human error. In conjunction with the BigDye® Direct Cycle Sequencing Kit are new mobility files for improved basecalling accuracy. Here we describe BigDye® Direct sequence reads that are equal to or better than BigDye® Terminator v3.1 reads when the reactions are analyzed using POP-7™. Further, BigDye® Direct is able to achieve readable bases after the sequencing primers and high quality bases after the gene-specific primer sequences. Nearly 40% of BigDye® Direct reads have ≥25 bases with QV20+ scores when compared to the same amplicons sequenced using BigDye® Terminator v3.1. BigDye® Direct can resolve peak compression problems that occur when certain amplicons are sequenced with BigDye® Terminator v1.1 chemistry. In conclusion, the novel primer chemistry and workflow generates data superior in quality when compared to current chemistry solutions and obtains readable sequence within 5 bases of the primer offering improved polymorphism detection.

P11.120***

Variant calling experience from 150 human exome sequences

F. Lescai*, E. Stupka;*

UCL Genomics, University College London, London, United Kingdom.

Exome sequencing provides an approach to detect causative mutations, especially in a clinical context where clinical and familiar information can assist an informed choice of candidate SNPs. We first analyzed 11 exomes to compare:

a) Alignment algorithms: Maq, BWA and Novoalign,

b) SNP and Indel identification: Maq, Samtools and Dindel

This allowed us to compare the results obtained using different combinations of aligners/variant callers. 11,596±631 described and 280±88 novel SNPs and 59±3 described and 10±4 novel Indels were called by all the methods. The comparison lead us to Novoalign as our aligner of choice, Samtools to call the SNPs and Dindel for Indel calling.

With those, we processed 140 exomes, analyzing effects, frequency and distribution of the variants identified and comparing them with the characteristics of the variants in ENSEMBL and the 1000 genomes consortium. This analysis allowed us to characterize Indels across a sizeable dataset. None of our calls exceeds 15bp length, most of them being smaller than 6bp. The correlation of the size of the Indel identified with its described counterpart in Ensembl is 0.7642 for insertions and 0.6118 for deletions. Most of the described variations fall within 10bp from the starting point of the Indel called in our dataset. Frameshift coding consequences represent 49.56% of all the indels annotated by ENSEMBL, while being 5.97% of the known Indels and 27.89% of the novel ones in our data. Non synonymous-coding indels represent 2.59% in ENSEMBL Indels, 9.13% of our described calls and 5.47% of our novel ones.

P11.121

Simultaneous Evaluation of Small RNA, Whole Transcriptome, Whole Genome and Targeted Resequencing on Next Generation Sequencing Platforms

C. Patel*, S. Boege, J. Briggs, D. Cox, E. Foster, N. Fong, N. Hoag, D. Hom, C. Inman, P. Kinney, A. Kivett, R. Padilla, M. Shariati, J. Yang, T. Burcham, H. Shepherd, L. Joe;*

Life Technologies, Foster City, CA, United States.

Researchers are using Next Generation Sequencing platforms to support more and more applications. It is critical for such platforms to be flexible enough to support many applications at the same time while maintaining low cost, high quality and throughput. In this study we describe the development of a next generation sequencing process that facilitates the interrogation of up to twelve independent samples or applications run simultaneously. In a single run we sequenced a single-plex human whole transcriptome sample, a multi-plex of universal human reference, human placenta, human brain reference and HeLa whole transcriptome sample, a microbial whole genome sample, and a human placenta smRNA sample. Each sample type used required a different sequencing run, yet with this new process they all were run together saving time, reagents, and freeing the researcher from having to wait to collect sample of the same type to run together.

P11.122

An Easy to Use Workflow for Next Generation Sequencing

L. K. Joe*, S. Boege, J. Briggs, S. Chang, J. Fayet-Faber, D. Hom, J. Ichikawa, P. Kinney, T. Makuta, K. Perry, H. Shepherd, M. Simon, L. Xu, J. Yang, T. Burcham;*

Life Technologies, Foster City, CA, United States.

A flexible and easy to use workflow is critical for any next generation sequencing platform. As part of such workflow the 5500 and 5500xl SOLiD™ Sequencers are the latest next generation sequencing systems to be introduced by Life Technologies. Both systems fit on a bench top and are designed to be user-friendly from a hardware, consumable and software point of view. Improvements to the system are designed to support the list of ever expanding applications on next generation sequencing platforms with fast time to result, scalable throughput, low run and acquisition cost, and accurate data. Here we describe fluidic, optic, stage, and electronic innovations to reduce cycling, imaging, and processing times. New reagent configurations allow for more flexibility in desired read length and high accuracy output. Other novel features include an internal control that provides real time feedback on the quality of the run and microfluidic chambers that allow interrogation of up to twelve independent samples or applications at a time, such as whole genome, targeted resequencing, small RNA and whole transcriptome. New software concepts include an intuitive user interface for run setup, sequence quality monitoring, primary analysis, and troubleshooting. For Research Use Only. Not intended for any animal or human therapeutic or diagnostic use.

Semiconductor Sequencing for Life

J. W. Myers, *J. M. Rothberg;*
Ion Torrent by Life Technologies, South San Francisco, CA, United States.

Ion Torrent has invented the first device_a new semiconductor chip_ capable of directly translating chemical signals into digital information. The first application of this technology is sequencing DNA. The device leverages decades of semiconductor technology advances, and in just a few years has brought the entire design, fabrication and supply chain infrastructure of that industry_a trillion dollar investment_to bear on the challenge of sequencing. All of these benefits are a result of applying a technology that is massively scalable, as proven by Moore's Law, to a task that has traditionally used optics-based solutions, which work in a linear fashion: increasing capacity requires increasing the number of signals that must be read resulting in longer run times, higher capital costs and ever more sophisticated optics. By contrast, Ion Torrent semiconductor technology can provide increases in chip capacity without impacting capital costs or runtime. Ion Torrent sequencing uses only natural (label-free) reagents and takes place in Ion semiconductor microchips that contain sensors which have been fabricated as individual electronic detectors, allowing one sequence read per sensor. We will show how the technology has scaled in just a few months from ~1 million sensors in the first-generation Ion 314 chips to ~7 million sensors in the second-generation Ion 316 chips_all while maintaining the same 1- to 2-hour runtime. We will also demonstrate that Ion semiconductor sequencing provides exceptional accuracy, long read length and scalability on a single, affordable bench-top sequencing platform.

P11.124
Whole Genome sequencing in patients with the Hallermann-Streiff Syndrome

G. Froyen[1], *H. Van Esch*[1], *K. Devriendt*[1], *T. De Ravel*[1], *S. Belet*[1], *P. Marynen*[1], *M. Veugelers*[2], *S. Plaisance*[2];
[1]*Dept. Human Genetics, Leuven, Belgium,* [2]*VIB Bioinformatics Training and Service Facility, Ghent, Belgium.*

The recent introduction of next-generation sequencing has shifted the focus of gene identification in human diseases from Sanger sequencing and copy number analysis to deep sequencing of linkage intervals, targeted regions and exomes. Although the sequencing technologies provide solid data the main bottleneck remains the isolation and enrichment of these specific regions. Sequence capture on arrays or in solution has significantly improved over the last years but introduces a bias in sequence recovery and still misses a significant proportion of the targeted regions. Deep sequencing of whole human genomes has now become available through the company Complete Genomics. The coverage exceeds 40X for 95% of the exome while repeat-free intra- and intergenic regions are well covered too. The overall error rate is estimated at 1 in 100,000 nucleotides. Through their service, we have sequenced the genomes of three patients with the Hallermann-Streiff syndrome (HSS) as well as the parents of one of these patients. Since the inheritance pattern of HSS strongly points to an autosomal dominant disorder, we aimed to search for de novo variants in genes based on the trios samples, and then look for unknown variants in overlapping genes in the other two patients. For the five samples we obtained 160 to 250 Gb of mapped data, which contained about 3.2 million SNPs each. We are currently validating a set of candidate variations in our patients. We will present data and discuss the experimental set-up in order to maximize the screening efficiency.

P11.125
The immense genomic variability of human olfactory receptor genes

T. Olender[1], *Y. Hasin*[1], *I. Keydar*[1], *M. Khen*[1], *Y. Gilad*[2], *E. Ben-Asher*[1], *D. Lancet*[1];
[1]*The Weizmann Instiute of Science, Rehovot, Israel,* [2]*University of Chicago, Chicago, IL, United States.*

Humans are highly variable in their olfactory sensitivity and odor quality perception. This is partially attributed to genetic variations in the olfactory receptor (OR) coding regions. Specifically deleterious variations, such as frame-disrupting single nucleotide polymorphism (SNP) or copy number variation (CNV) with deletion alleles, are excellent candidates to underlie this phenomenon. One example is a significant association which we have discovered between nonsense SNP in OR11H7P and sensitivity for isovaleric acid. To provide a genomic infrastructure for associating OR genotypes to olfactory phenotypes we applied in-silico data mining, combined with Next Generation Sequencing (NGS) to the OR sub-genome and transcriptome sequences. Scrutinizing dbSNP, the 1000 Genomes Project (1000GP), and several published individual genomes, we identified 285 deleterious variations in 210 ORs. Using the recently published CopySeq algorithm, applied to the low-coverage 1000GP data we obtained 72 OR genes with deletion allele. Altogether, we find that ~60% of the OR genes segregate in the human population between an intact and disrupted allele, indicating huge functional variability and suggesting that each human on the planet has a different nose. NGS transcriptome analysis of human olfactory epithelium unravels novel mutation targets, including 412 genes that are X10 overexpressed compared to control tissues. In addition, we successfully assembled from the data 452 novel transcripts that are in the OR gene territories uncovering yet uncharacterized untranslated exons in ORs and in olfactory transduction genes (targets for general olfactory sensitivity phenotypes). Many of these variations are presently tested for genetic association with odorant threshold phenotypes.

P11.126
Characterization of CD4+ NKG2D+ T lymphocytes based on whole genome expression analysis

K. Schlangen[1], *B. Suarez-Alvarez*[2], *A. Fernandez-Sanchez*[2], *C. Lopez-Larrea*[2], *A. M. Aransay*[1];
[1]*Genome Analysis Platform, CIC bioGUNE, Derio, Spain,* [2]*Unidad de Histocompatibilidad y Trasplante. Servicio de Inmunologia. Hospital Universitario Central de Asturias, Oviedo, Spain.*

The NKG2D activating receptor is expressed on γδ T, αβ CD8+ T, NKT and all NK cells but not on CD4+ T cells. However, under certain circumstances, such as infections, autoimmune diseases or tumors, an anomalous expression of NKG2D on CD4+ T cells can be detected. Flow cytometric analysis of NKG2D expression on CD4+ T lymphocytes from several transplanted patients (kidney, heart, liver) and healthy donors revealed that kidney and liver transplanted patients presented an unusual subset of CD4+ NKG2D+ T lymphocytes (41.0% and 27.6% respectively) whereas only in a negligible number of heart transplanted and control donors this cell type could be detected.
Whole genome microarray expression studies were performed with this CD4+ NKG2D+ T cell population compared to CD4+ NKG2D- T cells in order to determinate its phenotypic and functional characteristics. Furthermore, functional analyses using Gene Ontology annotations were conducted in order to identify molecular pathways that exhibit activation or repression in this cell type.
Functional analysis showed that several pathways associated with immune response, apoptosis, inflammatory response and cellular catabolic processes were significantly affected. Examination of costimulatory molecules and specific cytotoxic cell markers as well as apoptosis-related molecules showed that the CD4+ NKG2D+ T cells in the kidney and liver transplanted patients represented a highly differentiated T cell subset with cytotoxicity ability and apoptosis resistance. The identification of biomarkers to predict the allograft outcome and immune response in transplanted patients is decisive to decrease the current transplantation failure.

P11.127
Non-coding elements of disease-causing genes

M. Naville[1], *C. Mugnier*[2], *M. Girard*[3], *S. Bandiera*[3], *A. Munnich*[3], *S. Lyonnet*[3], *H. Roest Crollius*[4], ***A. HENRION-CAUDE***[3];
[1]*Ecole Normale Superieure, CNRS UMR8541, Paris, France,* [2]*Université René Descartes, Service Informatique, Paris, France,* [3]*INSERM U781, Paris, France,* [4]*Ecole Normale Supérieure, CNRS UMR 8541, Paris, France.*

Three percent of the human genome consists of conserved non-coding elements (CNEs). Those elements are non-transcribed or transcribed such as microRNAs. In the present work, we considered three groups of genetic diseases: diseases with mapped loci but no known genes (group I), diseases with cloned genes (group II), and diseases with recurrent chromosomal rearrangement (group III). To address the interest of studying non-coding elements in disease-causing genes for which mutations are already known and characterized, we plotted group II together with the location of microRNAs. Interestingly, we

could identify 274 diseases with cloned genes that may still involve microRNAs. In particular, we were able to identify a notable enrichment in monogenic diseases with clinical heterogeneity in this category. By comparative genomics alignments across multiple vertebrate species we then selected possibly functional CNEs. We further aimed at establishing functional linkages between these CNEs and their likely target gene by replacing them in an ancestral mammalian genome, and postulating the maintenance of CNE/target gene physical proximity in ancestral and modern genomes. This approach led us to the identification of 72 disease-causing genes putatively controlled by CNEs and involved in diseases that are listed herein. Our results provide a source of non-coding elements associated with disease-causing genes to be sequenced in those patients with no mutation previously identified. It also paves the way to unravel sets of CNEs aiming to the concerted phenotypic-specific regulation of a disease-causing gene, otherwise involved in numerous developmental fields.

P11.128

Disruption of the histone acetyltransferase MYST4 leads to a Noonan syndrome-like phenotype and hyperactivated MAPK signaling

M. Kraft[1], *A. Voss*[2,3], *T. Thomas*[2,3], *I. C. Cirstea*[4], *I. Goehring*[5], *B. Sheikh*[2,6], *L. Gordon*[2], *H. Scott*[2,3], *G. Smyth*[7,3], *M. Ahmadian*[4], *U. Trautman*[1], *M. Zenker*[5], *M. Tartaglia*[8], *A. B. Ekici*[1], *A. Reis*[1], *H. Doerr*[9], *A. Rauch*[10], *C. T. Thiel*[1];
[1]*Institute of Human Genetics, Erlangen, Germany,* [2]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [3]*Department of Medical Biology, Parkville, Australia,* [4]*Institute of Biochemistry and Molecular Biology II, Dusseldorf, Germany,* [5]*Institute of Human Genetics, Magdeburg, Germany,* [6]*Department of Medical Biology, Pakrville, Australia,* [7]*Walter and Eliza Hall Institute of Medical Research, Meölbourne, Australia,* [8]*Dipartimento di Ematologia, Rome, Italy,* [9]*Division of Paediatric Endocrinology, Erlangen, Germany,* [10]*Institute of MedicalGenetics, Schwerzenbach-Zurich, Switzerland.*

Epigenetic regulation of gene expression through covalent modification of histones is a key process controlling growth and development. Breakpoint mapping of a balanced *de novo* chromosomal translocation t(10;13)(q22.3;q34) in an individual with a Noonan syndrome-like phenotype encompassing short stature, blepharoptosis and attention deficit/hyperactivity disorder, identified haploinsufficiency of the MYST4 gene. MYST4 belongs to the family of MYST histone acetyltransferases (HAT) and specifically acetylates H3k14. We observed a correlation of MYST4 levels with H3 acetylation in two cell lines after siRNA knock down (Rank Correlation coefficient p < 0.02793). In Mice homozygous for a hypomorphic gene trap allele of *Myst4* [*Querkopf* (*Qkf*$^{gt/gt}$)] we found a failure to thrive phenotype and high expression in the primordial of the cartilage and the neuronal stem cells. Genome wide transcriptome profiles in three human and two mice cell lines uncovered an enrichment of significantly differentially expressed genes in 10 KEGG pathways. To distinguish between primary and secondary targets we performed ChIP-CHIP and found enrichment only for the MAPK signaling pathway. As hyperactivation of the RAS-MAPK transduction pathway is the main underlying pathomechanism in Noonan syndrome we confirmed a hyperactivation of the MAPK pathway by hyperphosphorylation of key proteins by MYST4. In addition, we were able to reverse this effect by MYST4 overexpression in MYST4 deficient cell lines.
This further elucidates the complex role of histone modifications in mammalian development and adds a new pathomechanism to the phenotypes resulting from misregulation of the RAS signaling pathway.

P11.129

Methylation markers of early-stage non-small cell lung cancer

K. Kirotar[1], *T. Vooder*[1,2], *R. Kolde*[3], *K. Välk*[1], *M. Solovjova*[1], *R. Roosipuu*[2], *T. Annilo*[1], *A. Metspalu*[1,4], *N. Tõnisson*[1,2];
[1]*Institute of Molecular and Cell Biology, University of Tartu / Estonian Biocentre, Tartu, Estonia,* [2]*Tartu University Hospital, Tartu, Estonia,* [3]*Institute of Computer Sciences, University of Tartu, Tartu, Estonia,* [4]*Estonian Genome Center, Tartu, Estonia.*

DNA methylation changes are common and relatively stable in various types of cancer and may be used as diagnostic or prognostic biomarkers. To gain an insight into the epigenetic dysregulation in NSCLC, we've analysed stage I NSCLC samples from 48 patients together with 18 matching macroscopically cancer-free control samples with Infinium™ HumanMethylation27 BeadChips (Illumina Inc., San Diego, CA, USA) that cover the predicted promoter regions of over 14 500 genes.
Cluster analysis was performed with Limma program of Bioconductor package in R statistical computing software. We've detected 496 CpG-s in 379 genes hyper- and 373 CpG-s in 335 genes and pseudogenes hypomethylated in NSCLC. All the methylation differences were identified with FDR corrected p<0.05 and ≥0.136 mean difference in methylation level. Analysis with Ingenuity Pathway Analysis (IPA) software (Ingenuity Systems, Redwood City, CA, USA) showed that the top functions of these genes were cell-to-cell signaling and interaction, hematological system development and function, immune cell trafficking, cellular growth and proliferation, cell death, cancer, inflammatory response etc. The most prominently represented gene network was related to tumor necrosis factor (TNF). Comparing methylation data with gene expression data, we found form the hypermethylated genes 41 downregulated and from the hypomethylated genes 12 upregulated. Many of these hypermethylated and downregulated genes haven't been reported yet to be involved with lung cancer but some of them (RASSF1, AXUD1) are known or proposed to be tumor suppressors in lung cancer progression. From the hypomethylated and upregulated genes the most interesting finding was SERPINB5 (Maspin).

P11.130

Distal gene regulatory elements have an average size of a nucleosome

O. Wallerman, *M. Bysani, M. Wadelius, C. Wadelius;*
IGP, Uppsala, Sweden.

Nucleosomes consists of 147 bp of DNA wrapped around eight histone proteins, with a normal distance of 20-30 bp between the nucleosome ends. Transcription factors (TFs) bind to promoters and distal regulatory elements and regulate the activity of nearby genes. Promoters located upstream of genes are well known but distal regulatory elements are poorly defined as to location and size. Using 200 million aligned reads from MNase I digested HepG2 chromatin, we created genome-wide nucleosome profiles. These were correlated to ChIP-seq results for the TFs HNF4a and FOXA2, which bind to distal regulatory elements. The patterns suggest that one nucleosome is displaced at the regulatory elements. Footprints of nucleosomes around public ENCODE data of DNase I hypersensitivity sites at distal locations also suggests that in general, a single nucleosome is removed by the TF complexes.
To apply the strategy to a gene of medical interest, we studied SNPs identified in GWAS studies for dose requirement of the drug warfarin, which is commonly used to prevent thrombosis. These studies have identified several SNPs in high linkage disequilibrium in and around the *VKORC1* gene, but the functional one has not been identified. We used several chromatin signals and FAIRE DNA as a measure of open chromatin to prioritize among *VKORC1* SNPs and found that most of them are located in chromatin without regulatory potential. Out of 22 tested *VKORC1* SNPs, 7 are located in nucleosome-free regions as determined by MNase-seq and qPCR of FAIRE DNA, which indicates that they may be functional.

P11.131

Distillation of potential drug targets for type 2 diabetes by overlaying TCF7L2 ChIP-seq and pancreatic islet open chromatin maps

J. Zhao[1], *J. Schug*[2], *J. Sainz*[3,4], *K. H. Kaestner*[2], *S. F. A. Grant*[1,2];
[1]*Children's Hospital of Philadelphia, Philadelphia, PA, United States,* [2]*University of Pennsylvania School of Medicine, Philadelphia, PA, United States,* [3]*Institute of Biomedicine and Biotechnology of Cantabria (IBBTEC), University of Cantabria, Santander, Spain,* [4]*Spanish National Research Council (CSIC), Santander, Spain.*

Variation in TCF7L2 is strongly associated with type 2 diabetes (T2D). We previously mapped the genomic regions bound by TCF7L2 using ChIP-seq. The list of genes bound by TCF7L2 harbor a highly significant over-representation of loci uncovered in GWAS of T2D. Further support for our conclusions came from a subsequent VDR ChIP-seq study that gave a similar enrichment of GWAS-discovered genes. Therefore, it is our hypothesis that a substantial portion of the reminder of genes bound by TCF7L2 on our list, not previously implicated in disease, also harbor genetic variants associated with T2D. We aimed at distilling down genes bound by TCF7L2 that encode

proteins that would be considered attractive drug targets. We analyzed the overlap of loci between our TCF7L2 ChiP-seq gene list and the published open chromatin map for pancreatic islets in order to get an indirect measure of relevant sites in this key tissue. We found that 94 genes overlapped, and interestingly, 36% of the gene products fall in to drug target classes. Attempting to distill this gene list further, we also carried out ChIP-seq in HepG2 cells where TCF7L2 is abundantly expressed. 24 genes remained of which 7 encode what would be considered druggable targets. In summary, we have distilled down loci that are both bound by TCF7L2 across two cell lines and coincide with open chromatin in human pancreatic islets, of which a number encode potentially attractive drug targets that are also likely candidates to be genetically validated when sequenced in a T2D cohort.

P11.132
Identifying Candidate Genes for Phenotypes in CNV Diseases by Computational Model Organism Comparisons

S. C. Doelken[1], *C. Mungall*[2], *S. Köhler*[1], *G. V. Gkoutos*[3], *B. J. Ruef*[4], *P. Schofield*[5], *M. Westerfield*[4], *P. N. Robinson*[1], *S. E. Lewis*[2];
[1]*Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*Berkeley Bioinformatics and Ontologies Project, Lawrence Berkeley National Labs, Berkeley, CA, United States,* [3]*Department of Genetics, University of Cambridge, Cambridge, United Kingdom,* [4]*ZFIN University of Oregon, Eugene, OR, United States,* [5]*Department of Physiology, Development and Neuroscience, University of Cambridge, United Kingdom.*

An accurate description of phenotypic abnormalities is the foundation of clinical diagnostics and the basis of our understanding of diseases. The Human Phenotype Ontology (HPO) was developed by our group as a hierarchical, standardized vocabulary for human phenotypes in human monogenic and other diseases (http://www.human-phenotype-ontology.org).

Applying standardized vocabularies is the basis of a computational interspecies comparison of phenotypic features and disease models. Using phenotypic data for human CNV diseases (HPO), as well as zebrafish (ZFIN, Oregon) and mouse phenotypes (MGI, Jackson Laboratory, Cambridge and Bar Harbor), we have developed novel strategies for computational interspecies comparisons and applied these phenotypic similarity algorithms to identify the disease causing genes in recurrent human copy number variation disorders (CNV disorders). We examined the relationships between phenotypes associated with CNV disorders and phenotypes associated with humans or model organisms with single-gene diseases whose genes are located within the CNVs in order to identify previously unrecognized genotype-phenotype associations by using interspecies phenotypic comparisons to uncover the pathogenesis of CNV disorders.

Our method reliably detected known associations such as the relationship between elastin haploinsufficiency and supravalvular aortic stenosis in Williams syndrome as well as a host of novel explanations for phenotypic features of CNV disorders including candidate genes for cancer risk in CNV-related Sotos syndrome and for diabetes mellitus in Williams syndrome. Our methods for interspecies comparison will provide a basis for integrating the large amounts of model organism phenotype data expected to come from the international knockout mouse consortium and other projects.

P11.133
EnSpm-N6_DR DNA transposons shape the repertoire of p53 target genes in zebrafish

M. N. Loviglio, *L. Micale, C. Fusco, A. Calcagnì, B. Augello, E. V. D'Addetta, G. Merla;*
Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy.

Transposable elements (TEs) represent a considerable fraction of the genome of eukaryotes. With their high turnover, TEs play a strong role in genomes evolution and adaptation. They directly regulate the expression of nearby genes both transcriptionally and post-transcriptionally. For instance, TEs are known to donate a wide variety of gene regulatory sequences to the human genome, which exert diversifying effects on the expression patterns of adjacent genes. Here we report their role in shaping the repertoire of a transcription factor, the pleiotropic master regulator p53. The multiple copies of En-SpmN6_DR non-autonomous DNA transposon are mapping throughout the genome of zebrafish (*Danio rerio*), mainly upstream or in the introns (less frequently just downstream) of genes, like *trim8.1*, whose human orthologs are annotated as putative p53 targets. We thus assessed if the p53 transcription regulator was able to bind members of this family of TEs, through a putative p53 responsive elements (RE) mapping within the EnSpm-N6_DR transposons. By luciferase assay, we showed that this well conserved p53 binding site can be directly associated with p53-dependent transcriptional activation of multiple zebrafish orthologs, including *trim8.1* and *spred2*. Our data strongly support the hypothesis that the EnSpm-N6_DR class of mobile genetic element promoted the spreading of p53RE within *Danio rerio*'s genome, potentially illustrating a remarkable case of convergent evolution.

P11.134
A new missense mutation (p.L481R) of the ABCB4 gene segregates in three affected members belonging to one large family with more siblings affected by recurrent cholelithiasis and/or cholestatic diseases

D. Degiorgio[1], *G. Castaldo*[2,3], *R. Tomaiuolo*[2,3], *M. Seia*[1], *L. Costantino*[1], *L. Porcaro*[1], *M. Castagni*[1], *L. Castellano*[4], *A. Ragozzino*[5], *M. P. Rastaldi*[6,7], *D. A. Coviello*[1,8], *C. Colombo*[9];

Ospedali Galliera, Laboratory of Human Genetics, Genoa, Italy,* [9]*Department of Pediatrics, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy.*

Progressive intrahepatic cholestasis type 3 associated with complete absence of biliary phosphatidylcholine (PC) results in liver failure at pediatric age.

This phenotype is caused by 2 ABCB4 alleles which encode a protein without floppase activity across the canalicular membrane of the hepatocyte.

Liver failure associated with absence of biliary PC was originally described in mice knockout for the orthologous ABCB4 gene whereas no detectable pathology was then reported in mice with a single mutant allele.

Molecular analysis of the ABCB4 by sequencing the 27 coding exons was carried out in three siblings, a 45 year old man and two women, 41 and 47 years old.

All had experienced recurring symptomatic cholelithiasis, the younger sister has also presented an episode of cholangitis and pruritus in pregnancy.

In these siblings we identified the new mutation c.1442T>G (absent in 110 controls), in the heterozygous state, which leads to an amino acid change (p.L481R) in the Nucleotide Binding Domain; the family history suggests paternal lineage of the mutation: their father with a history of cholelithiasis died at the age of 56 years with biliary cirrhosis.

This family includes others 12 siblings, 4 with symptomatic cholelithiasis (their DNA is not currently available). Although it is plausible that additional genetic loci (and environmental factors) with modifier effect may be involved, the analysis of segregation in 3 siblings suggests that a single mutant allele of the ABCB4 can be a critical factor for susceptibility to the manifestation of cholelithiasis or progressive liver disease in adulthood.

P11.135
Multi-omics Landscape of Clear Cell Renal Carcinoma

L. Wang, *X. Wang;*
BGI, Shenzhen, China.

Tumor is considered to be a systematic disorder of molecular network in tissue cells, while the incidence of renal cell carcinoma (RCC) has a significant and continually increasing trend. In our study, we present a comprehensive (more than 250 Gbp) data set from whole genome, DNA methylome and transcriptome sequencing of RCC. By comparison between RCC and corresponding para-carcinoma (PARA) tissues, we identified 43428 single nucleotide variations (SNVs), with 168 in coding region, 5448 insertions and deletions (indels, 1-10 bp)

and 9095 segmental rearrangements or copy number changes (SVs/CNVs, 1k-50k bp). We discovered 24187 differentially methylated regions and 8416 differentially expressed protein-coding genes as well as non-coding RNAs between RCC and PARA. We attempted to integrate all information from these omics levels to detect the inter-correlations in-between, and the discovered patterns are associated with Focal adhesion, MAPK signaling and other pathways related to cell metabolism, proliferation and development. The methylation pattern and expression level indicates IFI16 gene, which encoding interferon, gamma-inducible protein 16, not only modulates p53 function, but also plays an important role, as a hub gene, in apoptosis pathway. Our results demonstrate an initial investigation of whole omics landscape of tumor tissues and pave a new way to understanding the important disease by multi-omics sequencing approaches.

Retinitis Pigmentosa (RP) is a heterogeneous group of inherited retinal dystrophies characterised by the loss of photoreceptors cells and retinal pigment deposits. Autosomal-recessive Retinitis Pigmentosa (arRP) has recently been associated with mutations in a novel gene, EYS, which is a major gene for this disease. All published mutations so far are based upon conventional PCR and are not adequate to identify mid-sized DNA rearrangements. The purpose of this study was to establish the prevalence of Copy-Number Variations (CNVs) in the EYS gene, using a novel EYS specific MLPA kit, in a cohort of arRP patients, including individuals in whom only one pathogenic change was detected by PCR-based sequencing. Here we report the identification of 6 pathogenic CNVs and confirm the presence of mid-sized rearrangements as the second mutated allele in a ~15% of families that were carriers of another EYS mutation. Our results also suggest that mid-sized genomic rearrangements in EYS gene would be a common event in the appearance of RP phenotype with an estimated frequency of ~4% (3/71) of total arRP cases with unknown mutation. We have demonstrated an efficient and cost-effective strategy validating a novel MLPA Kit as a complementary diagnostic method for EYS pathogenic evaluation.

P11.137

Haplotype analysis of *EYS* mutations identified in different European populations

I. Barragán[1,2], ***N. Matamala***[1], *M. González-Del Pozo*[1,2], *J. Pieras*[1,2], *K. Littink*[3,4], *F. Cremers*[3,5], *S. Borrego*[1,2], *G. Antiñolo*[1,2];

[1]*Unidad de Gestión Clínica de Genética, Reproducción y Medicina Fetal. Box 9101, 6500 HB, Nijmegen, Netherlands,* [4]*The Rotterdam Eye Hospital, P.O. Box 70030, 3000 LM, Rotterdam, Netherlands,* [5]*Nijmegen Centre for Molecular Life Sciences, Radboud University Nijmegen, Nijmegen, Netherlands.*

Retinitis Pigmentosa (RP) is a heterogeneous group of inherited disorders primarily affecting rods with secondary cone degeneration. It is the most common inherited form of potentially severe retinal degeneration and blindness, with a frequency of about 1 in 4000 births. Inheritance of RP can be either autosomal recessive, autosomal dominant or X chromosomal with also rare cases of mitochondrial transmission. Recessive and isolated cases account for 50-60% of all forms of RP. Recently, we have identified a new gene, *EYS,* corresponding to the *RP25* locus, as a commonly mutated gene in arRP. Spanning over 2 Mb within *RP25*, *EYS* is the largest eye-specific gene identified so far. Population studies in cohorts of different origins have been performed, resulting in the identification of more than 70 mutations so far. Among them, 3 pathogenic variants have been recurrently reported in Spanish and Dutch populations: p.I2239SfsX17, p.W2640X and p.Y3135X. In this study, we performed the haplotype analysis in the non related families bearing those mutations with the aim of elucidating their recurrent or founder origin. For that purpose, we used both microsatellite and SNPs genotyping covering *EYS* and the specific mutations regions, respectively. *EYS* flanking microsatellite haplotypes were different among families in all the mutation groups, suggesting a recurrent origin of the variants. However, SNPs genotyping of the mutation intervals allowed a higher resolution haplotyping. According to these data, we can confirm that mutations p.W2640X and p.Y3135X have an ancestral origin, each of them transmitted by a common founder, whereas p.I2239SfsX17 is recurrent.

Next generation sequencing (NGS) opens the way to high throughput analysis of targeted genomic regions or even the whole exome/genome. Recent publications show the advantages of NGS in genetic research, e.g. in gene discovery in rare inherited syndromes. However, for the usage of NGS in diagnostics several additional performance parameters have to be met: high quality, high throughput, low costs. Here we describe the design and validation of an NGS approach for the diagnostics of inherited retinal dystrophy. We developed a 12-plex Nimblegen sequence-capture array to enrich exons, splice junctions and UTRs of 111 known retinal dystrophy genes. This array was used to enrich the determined gene package in 100 previously unsolved patients with isolated or autosomal-recessive RP. DNAs of 12 RP patients carrying 24 known disease-causing variants served as controls. All 112 samples were sequenced on a Roche454 GS-FLX Titanium. Stringent bioinformatic data-analysis and variant detection on average resulted in 4 variants per sample which were validated using conventional Sanger sequencing and subsequently tested for segregation within the family. Preliminary data on the confirmation and segregation analysis revealed the likely pathogenic mutations in at least 35 probands. These results show that our approach is operational, e.g. that the coverage obtained allows for reliable identification of the disease-causing variations. Targeted NGS combined with stringent bioinformatic data-analysis holds the promise to optimize cost-effectiveness in molecular diagnostics for genetically heterogeneous disorders like RP, and we are convinced that this approach is an important step towards the successful implementation of NGS in diagnostics.

Biomédica en Red de Enfermedades Raras (CIBERER), Seville, Spain.

Retinitis Pigmentosa (RP) is a heterogeneous group of inherited retinal dystrophies characterised ultimately by the loss of photoreceptor cells. RP is the leading cause of visual loss in individuals younger than 60 years, with a prevalence of about 1 in 4000. The molecular genetic diagnosis of autosomal recessive RP (arRP) is challenging due to the large genetic and clinical heterogeneity. Traditional methods for sequencing arRP genes are often laborious and not easily available and a screening technique that enables the rapid detection of the genetic cause would be very helpful in the clinical practice. The goal of this study was to develop and apply microarray-based resequencing technology capable of detecting both known and novel mutations on a single high-throughput platform. Hence, the coding regions and exon/intron boundaries of 16 arRP genes were resequenced using Affymetrix microarrays in 103 Spanish patients with clinical diagnosis of arRP. All the detected variations were confirmed by direct sequencing and potential pathogenicity was assessed by functional predictions and frequency in controls. For validation purposes 7 positive controls for variants consisting of previously identified changes were hybridized on the array. As a result of the resequencing screening, we detected 36 variants, of which 17 are very likely pathogenic. They consist of 1 nonsense mutation, 3 splicing mutations, 1 5' UTR variant and 12 missense mutations. The 19 remaining identified variants included 3 non synonymous, 4 synonymous and 12 intronic polymorphic changes. The accurate detection of the positive controls allowed the validation of the technique.

Rheumatoid arthritis (RA) associated-gene, *CD244* expressed in RA synovial tissue

A. Suzuki[1], *R. Yamada*[1,2], *Y. Kochi*[1], *Y. Okada*[1], *M. Yamanaka*[1], *T. Sawada*[3], *K. Yamamoto*[1,4];

[1]*RIKEN, Yokohama, Japan,* [2]*Kyoto University, Kyoto, Japan,* [3]*Tokyo Medical University, Tokyo, Japan,* [4]*University of Tokyo, Tokyo, Japan.*

RA is well-known as an autoimmune disease and is a chronic inflammatory disorder characterized by the destruction of multiple joints. Many genome wide association studies were performed and multiple RA-susceptibility loci and autoimmune-susceptibility loci have been identified. These studies suggested that multiple genes and its functions were related with disease causing and development. These studies also indicated an important factor regarding genetic factors of RA and autoimmune diseases; some of the RA-susceptible polymorphisms also increase the risks of other autoimmune diseases. One of the mechanisms of the inflammation in autoimmune diseases associated with signal transduction via signaling lymphocytic activation molecule (SLAM). It was reported that SLAM family gene, e.g., Ly108 is also associated with systemic lupus erythematosus (SLE). We identified CD244 gene as susceptibility gene to RA. The association peak in the block was observed at two functional SNPs (rs3766379 and rs6682654) in CD244 in two independent RA cohorts from Japan ($P= 3.23 \times 10^{-8}$ and $P=7.45 \times 10^{-8}$) and a SLE cohort. These RA-susceptible variants of rs3766379 and rs6682654 upregulate expression of CD244, their causative role to increase the risk of autoimmunity has to be further investigated for its validity and its precise molecular mechanism. Furthermore, we indicated that CD244 also expresses in synovial tissues of CIA mice and RA patients. We supposed that up-regulation of CD244 affect on RA and other autoimmune diseases, including SLE. Thus, CD244 is a novel genetic risk factor for RA and may have a role for autoimmunity in RA.

P11.141

Functional characterization of OA risk polymorphism rs225014 at DIO2 in human OA cartilage

S. D. Bos[1], *J. Loughlin*[2], *R. G. H. H. Nelissen*[3], *P. E. Slagboom*[1], *I. Meulenbelt*[1];

[1]*Department of Molecular Epidemiology, LUMC, Leiden, Netherlands & Netherlands Consortium for Healthy Aging, Leiden, Netherlands, Leiden, Netherlands,* [2]*Newcastle University, Institute of Cellular Medicine, Musculoskeletal Research Group, Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom,* [3]*Department of Orthopedics, LUMC, Leiden, Netherlands, Leiden, Netherlands.*

Previously, the deiodinase iodothyronine type-2 gene (*DIO2*) was identified as an osteoarthritis (OA) risk gene, and SNP rs225014 located within the DIO2 gene was found to be associated with OA. To date, the underlying mechanism of this association is unknown and functional characterization of alleles discriminated by this SNP using an allelic imbalance assay may give more insight in putative genetic regulatory elements underlying the association.

Cartilage RNA obtained from heterozygous individuals (N=13) was subjected to an allele discriminating Taqman assay and the relative peak heights of allele C and T fluorescence signals were assessed at both genomic DNA (1:1 reference) and RNA level. Deviations from allelic balance in the normalized log transformed RNA samples were tested against the normalized log transformed DNA samples for significance using a Mann-Whitney non-parametric test.

We show a highly significant allelic imbalance, where the OA risk allele (C) is present at higher levels in OA cartilage RNA of 13 subjects than allele T (Table 1). None of the genomic DNA's showed signs of deviations from allelic balance when tested against all remaining genomic DNA's. To further investigate the *DIO2* gene activity in OA we aim to assess absolute expression levels of *DIO2* in both healthy and OA affected cartilage samples and investigate the protein presence of DIO2 in OA and healthy cartilage.

Table 1. Allelic imbalance measurements.

Multiplexed and Targeted next-generation sequencing for the molecular genetic diagnostics of Osteogenesis Imperfecta

F. S. van Dijk*, N. Ameziane, E. Setijowati, S. Dentro, D. Sie, T. Uithuisje, Y. Moutaouakil, H. Meijers-Heijboer, E. Sistermans, G. Pals;*

VU University Medical Center, Amsterdam, Netherlands.

Background: Osteogenesis Imperfecta(OI) is characterized by susceptibility to bone fractures and defects in collagen type I biosynthesis. OI is caused in 90% of cases by dominant variants in 2 genes(*COL1A1*, *COL1A2*) and in ≤10% of cases by recessive variants in 7 genes (*CRTAP*, *LEPRE1*, *PPIB*, *SERPINH1*, *FKBP10*, *PLOD2, SP7*). In some cases no mutation can be found in these genes. or in other unidentified genes. Sequencing occurs stage wise, which is time consuming, and expensive.

Methods: OI patients were selected for abnormal collagen type I production without sequencing results or because of negative sequencing results with clinical/radiological information and/or protein analysis suggestive of OI types II-IV. Samples were analysed by targeted enrichment for known and candidate genes, followed by next-generation sequencing on the Illumina GAIIx platform. DNA libraries from 20 individuals were multiplexed and sequenced on a single Illumina flowcell lane using a 75 cycles paired-end protocol. An in-house variation detection pipeline was used to score for relevant mutations.

Results: An average of 2.9 million reads per sample was obtained of which 2.1 million reads (71%) mapped to the targeted regions. This resulted in an average depth of coverage exceeding 180 fold. Analyzing 12 out of 20 samples, 2 causative *COL1A1* variants and 2 causative *COL1A2* variants were discovered. Furthermore, 12 non-synonymous amino acid changes were detected, which are predicted to be harmful and may represent causative variants.

Conclusion: Multiplexed and Targeted next-generation sequencing

allows for comprehensive genetic screening of OI patients in a fast and cost-effective manner.

P11.143
Identification of genes expressed in human inner ear tissue using next generation RNA sequencing

J. J. Corneveaux[1], *J. Ohmen*[2], *C. White*[2], *A. N. Allen*[1], *G. Van Camp*[3], *R. Friedman*[2], *M. J. Huentelman*[1];
[1]*Translational Genomics Research Institute, Arizona, AZ, United States,* [2]*House Ear Institute, Los Angeles, CA, United States,* [3]*University of Antwerp, Antwerp, Belgium.*

Characterization of the human inner ear transcriptome is important for the study of the basic biology of hearing and diseases of the inner ear. We present RNA-Seq data of the cochlea, ampulla, saccule, utricle, and total vestibular regions of the human inner ear derived from fresh surgically resected tissue from four donor patients. Tissue was collected from non-diseased regions during an operation to remove a tumor located near the inner ear. Libraries were sequenced on the Illumina HiSeq 2000 instrument with an average of 127 million quality-filtered, 104bp paired-end reads per sample. We performed mapping with TopHat to human GRCh37 and quantitation with Cufflinks. In the three sequenced cochleas, we measured expression from 20655 genes that produce 89066 total transcripts. In vestibular regions we find 21501 expressed genes with 92377 unique transcripts. Comparisons between cochlea and vestibular regions showed 1567 genes unique to the cochlea and 2413 genes unique to vestibular tissue. In total we find 23068 genes expressed in the inner ear along with 98837 total transcripts, an average ratio of >4 transcript variants per gene. Of note, Aquaporin-1 is expressed 25-times higher, FOS is 18.5-times higher, and Otospiralin is expressed 40-times higher in cochlea versus vestibular samples. Otogelin is expressed 65-fold higher in vestibular tissue over cochlea replicating previous expression studies in the mouse. These data represent one of the first high-resolution transcriptome maps of the human inner ear and may prove useful as a resource for prioritization of candidate genes for the study of hearing loss.

P11.144
RNA-seq uncovers the influence of structural variants on transcriptome diversity

E. Ait Yahya Graison*, A. Reymond;*
Center for Integrative Genomics, Lausanne, Switzerland.

Structural variation (SV) of DNA segments has been identified as a major source of genetic diversity, but a comprehensive understanding of the phenotypic effect of these variants is only beginning to emerge. Our group and others established extensive maps of SVs in wild mice and inbred strains, covering ~11% of their autosomal genomes. SVs shape tissue transcriptomes on a global scale and thus represent a substantial source for within-species phenotypic variation. The recently described RNA-seq method has brought transcriptome analysis to a new level, as it addresses gene expression at nucleotide resolution and alternative splicing events simultaneously. We used these advantages to unravel the effects of SVs on expression. We generated by ultra high-throughput sequencing on Illumina Genome Analyzer II >450 millions RNA-seq reads from brain and liver of three mouse inbred strains (129S2, DBA/2J and C57BL/6J) to monitor expression changes of transcripts that map within and outside SVs. We used TopHat and Cufflinks to map, assemble and estimate the abundance of the different isoforms. Results show that SVs impact gene expression and splicing diversity of genes lying within, but also that of genes which present structural variation in their 5' and/or 3' regions. SV related genes are enriched among isoforms differentially expressed between strains (p-val = 5e-08 and 8e-04 in 129S2 and DBA/2J respectively).
This study provides a unique opportunity to extensively gauge the influence of structural variants on the transcriptome complexity and regulation.

P11.145
Contrasting features of the close homologues SERPINA2 and SERPINA1

P. Marques[1,2], *Z. Ferreira*[1,3], *M. Martins*[1], *J. Figueiredo*[1], *J. Correia*[1], *S. Seixas*[1];
[1]*Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal,* [2]*Instituto de Ciências Biomédicas Abel Salazar, Porto, Portugal,* [3]*Faculdade de Ciências da Universidade do Porto, Porto, Portugal.*

Serine protease inhibitors (SERPINs) are a superfamily of highly conserved proteins that play a key role in controlling the activity of proteases in diverse biological processes. In humans, the largest SERPIN cluster is located at 14q32.1 region and includes the gene coding for the archetypical SERPIN, SERPINA1, and a highly homologous sequence, SERPINA2, which was originally thought to be a pseudogene. However, several lines of evidence collected in our work have identified SERPINA2 as a polymorphic gene, probably encoding a functional protein with unknown inhibitory activity. Previously, we have found that SERPINA2 could carry a 2kb deletion leading to an inactive SERPINA2 that is likely to be associated with a signature of positive selection in Africa. To further evaluate SERPINA2 functionality we performed several molecular assays in cell lines stably expressing different SERPINA2 and SERPINA1 variants. In contrast to SERPINA1 recombinants, which were found at both intra- and extra-cellular levels, SERPINA2 was detected only inside the cells. These results differ from the expected patterns of Clade-A SERPINs, which are normally secreted and retained in the cells, within the endoplasmatic reticulum (ER), in case of abnormal folding. Still, assays of proteosome and fagosome inhibition resulted in similar patterns for SERPINA2 and SERPINA1, suggesting that both recombinants expression is down-regulated by post-translation mechanisms mainly involving ER-associated degradation. Although enzymatic assays are still needed to determine the inhibitory properties of SERPINA2, our findings provide the first in vitro evidence for SERPINA2 expression and suggest an activity distinct from its closest homologue, SERPINA1.

P11.146
Effects of a dietary intervention with red wine, dealcoholized red wine and gin on the expression of *SIRT1* in human peripheral blood mononuclear cells

D. Corella[1], *C. Andres-Lacueva*[2], *G. Chiva-Blanch*[3], *R. Estruch*[3], *O. Portoles*[1], *E. Serna*[4], *M. Urpi-Sarda*[2], ***M. Guillen***[1];
[1]*University of Valencia and CIBER OBN, Valencia, Spain,* [2]*University of Barcelona, Barcelona, Spain,* [3]*Hospital Clinic, Barcelona, Spain,* [4]*Faculty of Medicine. University of Valencia, Valencia, Spain.*

Sirtuins are becoming increasingly recognized as important epigenetic drug targets in aging and several metabolic diseases. The first sirtuin identified was silent mating type information regulation-2 homolog (SIRT1), considered a longevity gene. Resveratrol, a polyphenol found in red wine, is known to activate *SIRT1*. Various studies have demonstrated that resveratrol extends the life span of diverse species through activation of *SIRT1*. On the other hand, some studies have reported that alcohol intake can also increase *SIRT1* expression. Our aim was to investigate the effects of a dietary intervention with red wine (resveratrol+alcohol), dealcoholized red wine (resveratrol) and gin (alcohol) on the expression of *SIRT1* in humans. 73 men (60+/-8 years) were enrolled in a crossover study in which three dietary interventions (28 days each) were randomized. During these interventions the same subjects must take 100 ml of gin (or 272 ml of red wine or 272 ml of dealcoholized red wine per day. We analyzed *SIRT1* expression in 66 subjects who completed the trial. Total RNA was extracted from peripheral blood mononuclear cells (PBMC). RNA levels were measured with real-time PCR and normalized using the Ct method of relative quantification. We checked 31 housekeeping genes, and *GADPH* was used. We observed that the dietary intervention with red wine, dealcoholized red wine and gin statistically increased *SIRT1* gene expression (about a 11%) compared to baseline levels (1.14+/-0.5 vs 1.03+/-0.03; P=0.008). In conclusion, our results suggest that both resveratrol and ethanol contribute to increase *SIRT1* gene expression in human PBMC.

P11.147

Architecture and patterns of population differentiation of SNPs in drug response pathways

C. G. Lee[1,2,3], *M. Bachtiar*[2], *J. Wang*[2], *S. S. Chong*[2];
[1]*National Cancer Centre, Singapore, Singapore,* [2]*National University of Singapore, Singapore, Singapore,* [3]*DUKE-NUS Graduate Medical School, Singapore, Singapore.*

Response to drugs varies amongst different populations. We hypothesized that these differences in drug response are influenced by Single-Nucleotide-Polymorphisms (SNPs) that are highly differentiated amongst the different populations. We thus examined the SNP architecture and patterns of population-differentiation (F_{ST}) of SNPs in genes of drug-response-pathways (DRP) in the human genome using a gene-based 'functional region-directed approach. A total of 500,000 SNPs were found to localize to 715 genes of 66 DRPs. The 5'/3'UTRs of genes in most DRPs exhibit significantly higher SNP density than the average genome SNP density while the coding region showed the reverse trend suggesting that the UTRs of DRP genes are more polymorphic while the coding regions are more constrained and highlighting that differences in drug response may be more likely due to differences in the expression of these genes and not to differences in the protein structure/function. Significantly, non-synonymous coding-SNPs of 2 DRPs of drugs involved in vasoconstriction and ischemic heart diseases were found to be significantly population differentiated suggesting that population differences in response to these drugs may be due to population differences in SNPs of these pathways. Notably, SNPs in most regions, except promoter and 3'UTR, of the genes involved in drugs affecting the Sympathetic Nerve Pathway (SNPy) exhibit significant population differentiation suggesting that there may be population differences in response to drugs targeting this SNPy pathway. Hence this study highlights potential population differences in the response to drugs that target specific pathways with high F_{ST}.

P11.148

A SNP array evaluation tool to identify autosomal recessive conditions in the offspring of consanguineous unions.

K. J. Wierenga[1], *Z. Jiang*[2], *A. M. Alazami*[3], *F. S. Alkuraya*[3], *N. F. Tsinoremas*[2];
[1]*OUHSC, Oklahoma City, OK, United States,* [2]*University of Miami, Miami, FL, United States,* [3]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.*

Introduction.
Mendelian disorders for which the genetic basis has been identified is increasing rapidly. These disorders pose a challenge to the clinician to diagnose. In a consanguineous union, the offspring has various runs of homozygosity (ROHs), identifiable by single nucleotide polymorphism (SNP) array technology. We hypothesized that an evaluation tool that identifies all genes associated with OMIM-annotated AR conditions in ROHs of a patient will allow the clinician to compare the patient's clinical features with the phenotypes of these autosomal recessive (AR) conditions, making a SNP-array the preferred diagnostic approach.
Approach/Results.
We developed a Perl-CGI online evaluation tool that allows the clinician to identify genes associated with OMIM-annotated AR conditions in ROHs obtained from SNP-array. It incorporates the OMIM database and other genetic databases, providing the user with a summary of genes and pertinent genetic information mapping to the query ROHs. The scale of gene search on the query ROHs can be adjusted. We have tested this tool using cases from our clinical practice. In this manner we diagnosed known AR conditions that had remained unrecognized until employment of this tool.
Conclusions.
SNP-array can be employed to determine the ROHs in the setting of consanguinity. These ROHs can be evaluated for OMIM-annotated AR conditions. We have developed a genomic SNP-array evaluation tool allowing the clinician to evaluate for these AR conditions. We have demonstrated its usefulness in clinical practice, and believe that the SNP-array, together with this Perl-CGI evaluation tool, will change the diagnostic approach in the setting of consanguinity.

P11.149

An integrative bioinformatics pipeline for structural variation analysis of whole-genome sequencing data

G. Escaramís, *C. Tornador, L. Bassaganyas, J. M. C. Tubio, S. Ossowski, R. Rabionet, X. Estivill;*
Center Genomic Regulation (CRG-UPF), Barcelona, Spain.

Recent introduction of high-throughput sequencing technologies has increased research activities in efficient computational tools for the identification of structural variants (SV) and their association with human diseases. We have designed a pipeline (PeSV-Fisher) for the analysis of paired-end and mate-paired sequencing data, using a combination of geometrical paired-end mapping strategies (PEM) and depth-of-coverage analysis(DOC), and focused on the identification of somatic variation. It is capable of analyzing several samples simultaneously and provide a list of variants and their carriers.
PEM is used for the identification of four types of SV: insertions, deletions, inversions and translocations. Read-pairs with a phred-based quality score over 35 are classified into four categories: (1) correct order and orientation (insertions, deletions and normal); (2) wrong orientation (inversions); (3) mapping to different chromosomes (translocations); and (4) unpaired or unmapped. The empirical distribution of the insert size is calculated from the first category, and used to define cut-off sizes to discriminate read-pairs supporting insertions or deletions. Then, a clustering procedure to group read-pairs pointing to the same SV is performed. Breakpoints of presumed SV are predicted from each cluster containing at least two read-pairs.
Further support for identified variants is obtained by DOC analysis. The genome is fragmented into non-overlapping 100 nt intervals. The number of sequences mapping to each fragment is counted and normalized based on GC-content. This values are fed into a segmentation algorithm. In addition, sequences from the 4th category mapping around the breakpoints of the predicted SV are checked for split reads using GEM.

P11.150

The new method for quantitative tracking of T cell clones.

I. Z. Mamedov, *I. V. Zvyagin, S. V. Ustyugova, V. Y. Dorodnykh, O. V. Britanova, D. A. Bolotin, D. M. Chudakov, Y. B. Lebedev;*
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russ. Acad. Sci., Moscow, Russian Federation.

The individual repertoire of T Cell Receptors (TCRs) is a mirror of functioning of an immune system that keeps detailed information concerning infectious and autoimmune conditions. Here we have developed a new approach that enables unbiased quantitative analysis of the human TCR V beta repertoire by mass sequencing. The method based on direct amplification of TCR cDNA with universal primers with subsequent next generation sequencing. Two next generation sequencing platforms were compared showing good correspondence of obtained results. We employed the new method to perform detailed long-term tracking of the fate of T cell clones after high-dose chemotherapy and autologous hematopoietic stem cell transplantation (HSCT). We show that multiple clones survived the transplantation procedure, some of them being essentially suppressed, but some of them expanding and fighting infections early after HSCT. We believe that wide application of the proposed approach will lead to better understanding of infectious and autoimmune conditions, and development of the individual sequence-based diagnostics of immune status.

P11.151

Epimutations in teratocarcinoma development

N. Sincic[1], *M. Vlahovic*[1], *F. Bulic-Jakus*[1], *Z. Herceg*[2];
[1]*School of Medicine, Zagreb, Croatia,* [2]*International Agency for Research on Cancer, Lyon, France.*

Testicular germ cell tumors (TGCTs) are the most frequent cancers in young men. Present study takes advantage of the experimental mouse teratocarcinoma (TCa) model, a powerful tool for detecting /monitoring alterations, including epigenetic disruptions, during a timeframe of cancer development in vivo.
TCas were obtained by transplanting 7,5-days-old C3H embryos under the kidney capsule of syngeneic adults. Animals were killed after 2, 4, 6 or 8 weeks. Bisulfite modification of gDNA was performed and DNA methylation status was analyzed by pyrosequencing assay.

TCas exhibited two time points of intensive growth; in the 4th and 8th week. Significant changes in Oct3/4 DNA methylation were found during 8 weeks TCa development. From the 4th week, TCas showed significant Oct3/4 hypermethylation when compared to testicular tissue. Only 8 weeks old TCas showed strong negative correlation between Oct3/4 DNA methylation and TCa growth. Significant changes in DNA methylation of Nanog promoter were found during 8 weeks TCa development. All TCas showed significant Nanog hypomethylation when compared to testicular tissue. We noticed negative correlation between TCa weight and Nanog DNA methylation in 4 weeks old TCas. Scgb3a1 and Prss21 showed constant hypermethylation in TCas when compared to normal testicular tissue.We suggest that Nanog DNA hypomethylation represents an early cancerogenic force pushing cells into TGCT/teratocarcinoma development while Oct3/4 DNA hypermethylation seems to compensate cancer initiation and inhibit cancer progression. If Oct3/4 is not methylated, intense cancer progression can take place. Genes involved in testicular differentiation seems to remain suppressed during TCa cancerogenesis.

P11.152
Genetic variation in monozygotic twins

S. White[1], *E. Turbitt*[2], *R. Chavez*[2], *J. Ellis*[2], *E. Joo*[2], *B. Novakovic*[2], *R. Andronikos*[2], *R. Saffery*[2], *J. Craig*[2];
[1]*Monash Institute of Medical Research, Melbourne, Australia,* [2]*Murdoch Childrens Research Institute, Melbourne, Australia.*

Twins are defined as two births from a single pregnancy. Fraternal, or dizygotic twins, are derived from separate fertilization events and share on average 50% of their DNA, as do any other siblings. However, approximately one third of twins are derived from a single egg that splits post-zygotically. These are referred to as identical or monozygotic twins, and are considered to be genetically the same. Based on this assumption, twin studies have been considered a powerful tool for determining the contribution of genetic versus environmental factors to specific phenotypes.

In recent years there have been reports suggesting that genetic differences within twin pairs due to somatic mosaicism may have been underestimated. To explore this further we have performed copy number variation (CNV) analysis on DNA from four different sources - placenta, buccal swabs, umbilical vein vascular endothelial cells and cord blood mononuclear cells - from four different monozygotic twin pairs (32 samples in total) using the Illumina HumanOmni1-Quad beadchip.

To date we have identified a number of potential mosaic CNVs, either between tissues within an individual or between individuals of a twin pair. We are currently confirming these findings using different molecular techniques such as high resolution melting curve analysis, and are looking at single nucleotide variant differences using next-generation sequencing.

P11.153
SNP array study of uniparental disomy in Estonian mental retardation patients and general population

M. Nõukas[1], *K. Männik*[1], *S. Parkel*[1], *R. Mägi*[1,2,3], *M. Remm*[1,2], *A. Metspalu*[1,2,4], *A. Kurg*[1];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Estonian Biocentre, Tartu, Estonia,* [3]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [4]*Estonian Genome Centre, University of Tartu, Tartu, Estonia.*

Detecting loss of heterozygosity or uniparental disomy (UPD) with whole-genome SNP arrays might be as informative as copy-number data in unexplained cases of genomic disorders. Although these copy-neutral rearrangements have not been extensively studied at whole-genome level so far, it has been shown that SNP microarrays are reliable in detecting known UPD regions.

We report a cohort of Estonian patients with idiopathic mental retardation (MR) and their unaffected family members screened by Illumina Infinium HD whole-genome genotyping arrays. To detect possible inconsistencies in Mendelian inheritance as indicative in UPD, we compared genotype data for 36 parent-offspring trios. As a reference we used 48 parent-offspring trios provided by the Estonian Genome Centre at the University of Tartu to investigate possible UPD regions in general population by applying the same genotyping platform and UPD detection approach. A patient diagnosed with Prader-Will syndrome, confirmed by microsatellite analysis to have maternal UPD 15, was used as a positive control.

To evaluate the UPD detection approach, we confirmed heterodisomy along the long arm of chromosome 15 in case of the control patient, but also revealed a maternally inherited isodisomic segment encomapssing the region. Using genome-wide high-density SNP markers gives an advantage over locus-specific analyses for detecting UPD events and describing the mechanisms of formation. So far our results in general population and MR trios suggest that UPD is not extensively present in the human genome. A similar outcome has previously been reported in other cohorts of patients with idiopathic MR by SNP arrays.

P11.154
Haploinsufficiency of the CLIP2 gene is not the cause of visuospatial impairment in Williams-Beuren syndrome

F. Kooy[1], *G. Vandeweyer*[1], *N. Van der Aa*[2];
[1]*University of Antwerp, Edegem, Belgium,* [2]*University and University Hospital Antwerp, Edegem, Belgium.*

Williams-Beuren syndrome (WBS) is a contiguous gene deletion syndrome, associated with a recognizable facial appearance and an unusual cognitive profile. In total 26-28 genes are located in the commonly deleted region on chromosome 7q11.23 that is 1.5 Mb in size. The study of atypical deletions and mouse models with deletions of individual genes has enabled limited unravelling of the relationship of the individual genes to each of the clinical features. Three genes are believed responsible for the Williams-Beuren syndrome cognitive profile, including LIMK1, CLIP2 and GTF2I(RD1/2) , yet no specific deletions or mutations in any of these 3 individual genes have been described. A major role for the CLIP2 gene in the cognitive characteristics of WBS has been suggested in reports of patients with partial deletions of the WBS region not including CLIP2 , that displayed only mild or no visual-spatial impairment.

We describe here two patients with deletions taking away exon 3-15 of the CLIP2 gene in two sibs. Specific deletions of the CLIP2 gene have not been reported before. Cognitive testing of both sibs revealed an intelligence in the normal range and showed no evidence for deficits in visual-spatial construction. These data make it highly unlikely that haploinsufficiency of CLIP2 on its own causes the cognitive disabilities associated with this syndrome. The cognitive profile in the Williams Beuren syndrome can therefore not be explained by dissecting the contribution of individual genes but has to be considered the consequence of the interaction between several genes within the deleted region.

P11.155
New clinical delineation of the 14q11.2 duplication syndrome based on a new case and the contribution of maternal UPD14 in the previous patient

F. Martinez[1], *S. Mayo*[1], *F. Galan*[2], *S. Monfort*[1], *J. Jover*[3], *M. Rosello*[1], *S. Oltra*[1], *C. Orellana*[1];
[1]*Hospital Universitario La Fe, Valencia, Spain,* [2]*Centro de Genética Humana, Alicante, Spain,* [3]*Hospital General Universitario de Alicante, Alicante, Spain.*

In 2007 we reported a de novo duplication of 14q11.2
(5.38 Mb) associated to short stature, mild mental retardation, hypotonia and minor dysmorphic features. Later the complementary microdeletion syndrome was characterized and narrow down to ~35 kb, with SUPT16H and CHD8 as the best candidate genes. Here we present the new clinical delineation of the 14q11.2 duplication syndrome based on a new case, as well as on the recent finding that the previous patient also showed maternal uniparental disomy 14 (UPD14). In consequence, many of the clinical features previously associated to 14q11.2 duplication, were indeed due to maternal UPD14. These features include prenatal and postnatal growth retardation, hypotonia, orthopedic problems, motor delay, early onset of puberty and minor dysmorphic features of the face.On the other hand, array-CGH analysis of a new patient identified a *de novo* duplication of 4.62 Mb in 14q11.2 (18679179-23294903; hg18). She presented expressive language delay, no motor delay, behavioral problems and minor dysmorphic features: hypothelorism, bushy eyebrows, flat nasal root, highly arched palate, bilateral genu recurvatum and dorso-lumbar kyphosis. Other clinical features, such as growth parameters or IMR, were normal at examination. Based on the common clinical signs between both patients, we can conclude that 14q11.2 duplication only associates a

mild developmental delay and minor dysmorphic features, but no or very mild cognitive impairment.

P11.156
The Efficiency of Double-Stranded DNA Formation in cDNA synthesis can be Crucial for Precision of Microarray Expression Analysis

H. G. Thormar[1,2], *B. Gudmundsson*[1,2], *F. S. Eiriksdottir*[2], *G. H. Gunnarsson*[1,2], *M. K. Magnusson*[1], *S. Kil*[3], *J. Hsu*[3], *J. J. Jonsson*[1,4];
[1]*Univ. of Iceland, Reykjavik, Iceland,* [2]*Lifeind ehf., Reykjavik, Iceland,* [3]*Ohio State University, Columbus, OH, United States,* [4]*Landspitali - University Hospital, Reykjavik, Iceland.*

Introduction. The quality and reproducibility of microarray expression experiments within and between laboratories are compromised by the complexity of the samples and procedures. We used Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE) to investigate the quality and reproducibility of the cDNA synthesis. 2D-SDE can measure double-stranded cDNA the essential template for T7 RNA polymerase.

Material and Methods. SuperScript III reverse-transcriptase was used to synthesize cDNA from Universal Human Reference RNA (Stratagene) using T7(dt) primer. The samples were synthesized both according to kit protocol and according to our improved methodology. The amount of dsDNA was mesured with 2D-SDE. The cDNA was transcribed with T7 RNA Polymerase and the labeled aRNA hybridized to Agilent microarray containing probes from 230 genes. Each gene was represented by 10 probes and each probe was replicated six times to estimate the variability of the experiments. Results were analyzed using the R software.

Results. The amount of double-stranded cDNA after synthesizing the same RNA samples six times was very variable ranging between 0 and 73%. Microarray experiments showed that the higher the dsDNA percentage the fewer probes had significant variability between samples. Approximately 15% of probes showed variability (p = 0,05) between samples when the dsDNA percentage was between 12% and 35%. In contrast, only 3% of probes showed variability between samples when the dsDNA percentage was 69% and 73%.

Conclusions. Our results indicate that an important component in imprecision in T7 RNA polymerase-based microarray expression analysis can be explained by the amount of double-stranded cDNA synthesized.

P11.157
Array-DASH: Dynamic microarrays for broad utility in DNA fingerprinting, genotyping, and re-sequencing in diagnostics

S. Gibson[1], *N. Zahra*[1], *J. Avarre*[2], *J. van Helvoort*[3], *S. Matysiak*[3], *C. Schäfauer*[2], *A. J. Brookes*[1];
[1]*University of Leicester, Leicester, United Kingdom,* [2]*Genewave, Paris, France,* [3]*FlexGen B.V., AL Leiden, Netherlands.*

Despite the emergence of ultra-high-throughput DNA analysis platforms, it is probable that the need for low cost and simple/automated methods that robustly assay specific fragments of DNA will remain. Examples include DNA diagnostics of infectious disease, Mendelian disease, certain cancer situations, environmental monitoring, and forensics. In such cases, microarrays offer a convenient and flexible way of analysing DNA, but suffer from imperfect fidelity if hybridisations are conducted at a single stringency. Arrays can, however, fully resolve all short DNA sequence variations in all sequence contexts if hybridisation and/or washing entails a dynamically changing temperature range with real time signal monitoring.

This 'Dynamic Allele Specific Hybridisation' (DASH) principal requires interpretation of surface-phase melt-curves, enabling DNA fragments to be re-sequenced with high precision compared to standard arrays, in both a quantitative and sensitive manner (alleles detectable at a few percent of the input DNA).

Current work fuses the original plate-based DASH approach, with the semi-automated HybLive microarray platform (Genewave) and on-slide oligo synthesis using the FlexArrayer (FlexGen). Single base variants, small indels, and microsatellites are resolved with melting temperature differences of up to ~10°C. 'Array-DASH' is now being assessed for real world diagnostics applications involving re-sequencing, multiplexed mutation scoring, regional scanning for mutations, and combinations of the above - providing a single, generic platform for convenient analysis of clinical and other DNA samples in a multitude of scenarios.

This research received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement 201418, entitled READNA.

P11.158
Transcriptome analysis in haematopoiesis in development and disease

M. A. Kostadima[1], *S. Nuernberg*[2,3], *W. H. Ouwehand*[2,3,4], *P. Bertone*[1];
[1]*EMBL - European Bioinformatics Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, United Kingdom,* [2]*Department of Haematology, University of Cambridge, Cambridge, United Kingdom,* [3]*NHS Blood and Transplant, Cambridge, United Kingdom,* [4]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.*

Platelets are the second most abundant cell in the blood and are derived from haematopoietic stem cells (HSCs) through a process named megakaryopoiesis. The process of platelet formation by polyploid megakaryocytes (MKs) in the bone marrow is tightly regulated and each MK produces about 3000-6000 platelets. The anucleated platelet plays an important role in maintaining haemostasis by surveying the vessel wall for damage and if identified initiate repair. Rare inherited Mendelian disorders of platelets may be associated with impaired platelet function, abnormal platelet numbers and/or volume and some of these disorders are associated with a propensity of bleeding.

Studying the transcriptome of platelets is challenging given that platelets survive only nine days on average and their mRNA degrades rapidly. We have therefore used high-throughput technologies (microarrays and next generation sequencing platforms) to gain a comprehensive insight in the repertoire of actively expressed RNA transcripts in megakaryocytes, the precursors of platelets.

In this study we have applied high-throughput sequencing of RNA from human MKs that have been obtained by *in vitro* culture of purified CD34+ HSCs in the presence of thrombopoietin and interleukin 1β. We integrate these data with ChIP-seq data of two key transcription factors in megakaryopoiesis and platelet formation (MEIS1 and NFE2) in order to study genome-wide regulatory targets and their role in driving lineage-specific transcription in megakaryocytes.

P11.159
Parallel Detection of Copy Number Variation and Loss of Heterozygosity with CGH Microarrays

J. M. Geoghegan, *X. Zhang, E. Rorem, T. A. Richmond, K. O'Moore, D. Raterman, C. J. Shaw, R. R. Selzer;*
Roche NimbleGen, Inc., Madison, WI, United States.

High resolution array CGH has been widely used to investigate DNA copy number variation (CNV) associated with complex disorders. Disease association studies have become increasingly focused on CNVs, and several recent reports show links between CNVs and schizophrenia, autism, and cancer, among others. However, many copy neutral events undetected by conventional array CGH, including copy neutral loss of heterozygosity (LOH) and uniparental disomy (UPD), also contribute to disease phenotypes. Regions of the genome absent of heterozygosity are usually determined through the detection of single nucleotide polymorphisms (SNPs) for which each parent has contributed a different allele.

Until recently, cytogenetic research needing both high resolution, high quality copy number analysis and LOH detection required two separate array platforms. At Roche NimbleGen we have developed a combination array CGH/LOH detection platform by adding probes that respond to SNPs to existing array CGH designs. Two probes detect each SNP location, including a perfect match probe (A allele) and a mismatch probe (B allele) similar to our comparative genomic sequencing platform. Using our patented probe design strategy, the detection of over 600,000 common SNPs (MAF >0.4) was tested to ensure the best responding SNP probes were added to the array CGH designs. We will show data from a new 6X630K platform that allows high resolution and high sensitivity detection of both CNVs and LOH following the standard CGH workflow. Samples with known regions of UPD were used to assess the performance of this new design with a resolution for detecting LOH at approximately 1MB.

J11.01
Investigating the effect of single nucleotide polymorphisms at -7 & -138 positions on MGP gene promoter activity

M. Taghizadeh, *P. Ahmadi, M. Keramatipour;*
Tehran University of Medical Sciences, School of Medicine, Department of Medical Genetics, Tehran, Islamic Republic of Iran.

The matrix Gla protein (MGP) is an important inhibitor of vessel and cartilage calcification that is strongly expressed in human calcified, atherosclerotic plaques. Two single nucleotide polymorphisms (SNPs) at -7 & -138 positions on MGP gene have been suggested to play a role in susceptibility towards Coronary Artery Disease (CAD). Such a role is possibly due to the effect of these SNPs on the level of gene expression. The aim of this study was to investigate the possible effect of -7 and -138 SNPs on MGP gene promoter activity *in vitro*.

To achieve this aim, four appropriate vectors that express GFP under the control of different haplotypes of MGP promoter have been constructed. To assess the effects of haplotypes on promoter activity, vectors were transfected into the Hek293 cells and relative expression of GFP was quantified. Analysis of data using Student's T-test, revealed that G-7A SNP has a significant effect on promoter activity in cultured cells. Presence of nucleotide A in -7 position resulted in 12% increase in promoter activity (p<0.002). T-138C SNP did not show a significant change in promoter activity (p>0.7). The maximum difference in promoter activity is seen between vector containing A-C and G-T haplotypes (p<0.0005). Less significant differences in promoter activity were shown between A-T and G-T haplotypes as well as A-T and G-C haplotypes (p<0.05).

J11.02
Genetic analysis of HTR2A and HTTLPR polymorphisms in Russian population using biochips.

D. Galaktionova[1], *O. Gra*[1], *N. Filimonova*[1], *Y. Lysov*[1], *V. Golimbet*[2], *T. Nasedkina*[1];
[1]*Engelhardt Institute of Molecular Biology, Moscow, Russian Federation,* [2]*Mental Health Research Center, Moscow, Russian Federation.*

Previously it was show that both serotonin 2A receptor (5-HTR2A) and serotonin transporter linked promoter region (HTTLPR) were important for normal functioning of the brain. Molecular genetic studies revealed that HTTLPR and 5-HTR2A polymorphisms were associated with schizophrenia and possibly influenced clinical outcome or response to treatment.

The objective of this study was to develop a biochip to determine serotonergic system genes polymorphisms for further clinical application. A biochip allows to analyze a spectrum of allelic variants in two different genes such as HTR2A (rs6311, rs6313, rs6314 and rs7997012) and HTTLPR (rs28914832). To estimate the accuracy of the method we examined 120 DNA samples of healthy individuals in Russian population. The results of hybridization on biochip showed 100% coincidence with direct sequencing. The genotype distributions were in Hardy-Weinberg equilibrium. The frequencies of serotonergic system gene alleles in healthy individuals are compared with allele frequencies in patients with schizophrenia to find out susceptibility allelic variants of the disease in Russians.

The work was supported by Federal Task Programme for Scientific and Technical Research (grants ## 02.740.11.0869 and 02.527.11.0006).

Exceptional human core promoter nucleotide compositions

H. Darvish[1], *M. Olad-Nabi*[1], *S. Ghasemi Firouzabadi*[1], *M. Karimlou*[2], *A. Heidari*[1], *S. Jamldini ezabady*[1], *M. Ohadi*[1];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Biostatistics, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

The proximal promoter sequences contain basic motifs for the expression of the downstream genes. We present genome-scale computational analyses of the 120-bp immediate upstream sequences to the +1 transcription start sites (TSSs) of 10,117 human protein-coding genes, and unravel exceptional genes in respect with the core promoter nucleotide composition. Our data reveal that while in 99% of the genes the absolute purine/pyrimidine ratio ranges between 0.2 - 2.5, certain genes show exceptional skew in this balance (e.g. ratios of 82.3 in VWA3A, 61.5 in Sox5, and 24.0 in BRWD3), and consist of islands of purines or pyrimidines. Furthermore, while over 95% of the genes lack more than one short tandem repeat (STR) in their core promoters, certain gene promoters are exceptionally rich in multiple STRs (e.g. eight consecutive STRs in UBE2QL1, and six STRs in GRIA2). We found sequence bias for the majority of those promoters across species, supporting functional roles for them in gene expression. Genes downstream to those promoters were also found to be of ontologic importance (i.e. we were able to track the majority of those genes to the lower species such as S. Cerevisiae and C. elegans). The exceptional promoters presented in this study lack the conventional motifs for the TATA, and TATA-less promoters, hence offering novel mechanisms for gene expression. They may also provide potential mechanisms for inter-individual variations in gene expression, and complex traits/disorders.

Screening of three mtDNA mutations using PCR-RFLP technique a province of Iran

F. Azadegan-Dehkordi[1], *M. Montazer-Zohouri*[2], *E. Farrokhi*[1], *A. Shirmardi*[3], *M. Saedi-Marghmaleki*[1], *Z. Ataei*[4], *S. Reisi*[1], *M. Abolhasani*[1], *H. Khazraei*[5], *M. Akbari*[6], *M. Hashmzadeh-Chaleshtori*[7];
[1]*Cellular and Molecular Research Center. Shahrekord Univ. of Med.Sci, Shahrekord, Islamic Republic of Iran,* [2]*Department of Medical Genetics school of Medical Sciences-Tarbiat Modares university, Tehran, Islamic Republic of Iran,* [3]*General Physician, Welfare Organization of Chaharmahal va Bakhtiari province, Shahrekord, Islamic Republic of Iran,* [4]*Human Genetics, Iran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Assistant Professor of ENT, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran,* [6]*Assistant Professor of Medical Genetics, Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [7]*Professor of Human Genetics, Cellular and Molecular Reserch Center, Shahrekord university of Medical Sciences, Shahrekord, Islamic Republic of Iran.*

Non-syndromic hearing loss may be induced by mutations in both nuclear and mitochondrial genes. Mutations in mtDNA are present in less than 1% of the children with pre-lingual deafness but are more prevalent later. Most of the molecular defects responsible for mitochondrial disorder, associated with hearing loss may be induced by mutations in the 12SrRNA and tRNA genes. This aim of this study was to investigate the frequency of three common mtDNA mutations including A1555G, A3243G and A7445G in a cohort of autosomal recessive non-syndromic hearing loss (ARNSHL) subjects in Sistan va Baluchestan province.

Material and Methods: In this descriptive- experimental based study, a total of 110 **Methods:** ARNSHL subjects from Sistan va Baluchestan province were investigated for three common mtDNA mutations using PCR-RFLP procedure. The possible mutations were confirmed by direct sequencing.

Results: None of the A1555G and A7445G mutations were detected in this study. However, we found one sample to carry A3243G mutation (0.9%). Moreover abolishing a MTTL1 restriction site close to A3243G mutation revealed a G3316A allelic variant in 0.9% of patients studied.

Discussion: This study showed that mtDNA mutations are responsible for less than 1% of pre-lingual ARNSHL associated subjects. The present study will improve the genetic counseling of hearing impaired patients in Sistan va Baluchestan province, Iran.

J11.05
Study of genetically determined production of interleukin-1b

E. M. Vasilyeva, *G. F. Galikeeva, E. V. Vorobieva, V. Y. Gorbunova;*
Bashkir State Pedagogical University of the name M. Akmulla, Ufa, Russian Federation.

Revealed increasing levels of interleukin-1 beta (IL-1b) have "conditional" healthy people in the republic of Bashkortostan.

Investigated 180 "conditionally" healthy individuals. The level of production IL1b sample was divided into groups: Group 1 (n = 96) - product IL1b to 10 pg / ml, group 2 (n = 56) - from 10 to 50 pg / ml, group 3 (n = 28) - above 50 pg / ml.

To identify genetic characteristics of the regulation of production IL-1B, have studied the distribution of genotypes and alleles of the family, interleukin-1 in the three groups studied: IL1b (C3953T), an antagonist of IL-1 receptor - IL1Ra (VNTR-polymorphism), IL-1 receptor - IL1RI (T976C).

Results. In group 1, revealed a high frequency of combinations of

genotypes E1E1 / / I / I / / CC (p = 0,05, χ2 = 3,7), it provides a low production and reception of IL-1b, high competition for the cytokine receptors with anatagonistom. Balance between the production, expression and inhibition of synthesis of IL-1 plays a key role in the course of the inflammatory process.
In group 2, and 3 revealed a high frequency of combinations of genotypes E1E2 / / I / II / / TC (p <0.05), whereas in group 1 is the combination does not occur. This interaction between genotype causes high production and reception of IL-1b, and also promotes the launch of a cascade of reactions involving other cytokines.

J11.06
Establishment of stable CHO cell line, expressing recombinant HO-1 and study of its cytoprotective property'

S. Ebrahimian Motlagh[1], *R. Halabian*[2], *M. Jalili*[2], *M. Habibi Roudkenar*[2];
[1]*Islamic azad university, Science and Research Campus, Tehran, Islamic Republic of Iran,* [2]*Iranian blood transfusion organization,research center, Tehran, Islamic Republic of Iran.*

Exposure of mammalian cells to oxidative stress conditions induces Heme Oxygenase-1(HO-1) as well as 32-KD a heat shock protein. Heme oxygenases are rate- limiting enzymes in Heme degradation. Three distinct isoforms of Heme oxygenase have been described: HO-1, HO-2 and HO-3.Application of pharmacological agents and genetic probes to manipulate HO has brought about to new insight into the complex relationship of the Heme-HO system with the biological and pathological system under investigation. The strategies used to target HO-1 offer promising therapeutic opportunities for the effective treatment of many diseases, including diabetes, obesity, hypertension, heart disease, cancer, autoimmune disease and even allograft rejection.
In our study ho-1 gene was cloned to pcDNA3.1 plasmid by using genetic engineering method. The recombinant vector was transfected to CHO(Chinese Hamster Ovarian) cell line in order to establish stable cells expressing ho-1 gene and the expression of HO-1 confirmed by RT-PCR .Then CHO-HO-1 cell lines were treated by variety of H_2o_2 concentrations in different times compared with CHO-pcDNA3.1 and the cell viability was measured by MTT assay.
The results indicated that the expression of ho-1 lead to cytoprotective effect since the CHO-ho-1 cells showed higher viability rate compared with the control cells. On the other hand the Flow-Cytometric test revealed that the ho-1 has anti-apoptotic effect as the CHO-ho-1 cells had delay in promoting apoptosis after H_2o_2 treatment in comparison with CHO-pcDNA3.1 cells.

SCN1A gene polymorphism in Iranian patients with migraine

M. Ansari[1], *A. Ebrahimi*[2], *M. Moghadasi*[3], *N. Hatamnejadian*[1], *B. Sedaqati Khayat*[1], *F. Abbasi*[1], *F. Rezaei*[2], ***M. S. Fallah***[2];
[1]*Department of Clinical Biochemistry, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [3]*4Department of Neurology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Migraine is a prevalent and debilitating disease affecting a large proportion of the population. Mutations in three genes (CACNA1A, ATP1A2 and SCN1A) have been detected in familial and, more rarely, in sporadic cases with migraine. Here we report the molecular analysis for 2 SNPs in SCN1A gene in affected Iranian patients with migraine.
Material and Methods: Patients with clinical diagnosis of migraine according to the international headache society criteria entered in the study. SCN1A gene polymorphisms (rs7601520 and rs2298771) were investigated using direct sequencing method.
Results: Genotypes for rs7601520 were AG, AA and GG in 23 (56.1%), 14 (34.15%) and 4 (9.76%) respectively. Allele frequency were A and G in 51 (62.2%) and 31 (37.8%) respectively. Genotypes for rs2298771 were AG, AA and GG in 26 (57.8%), 15 (33.3 %) and 4 (8.9%) respectively. Allele frequency were A and G in 56 (62.2%) and 34 (37.8%) respectively.
Conclusion: Genotype and allele frequency were in the range of other studies. Further analysis f other common SNPs in this gene and in comparison with healthy controls could be helpful to study association with the risk of migraine.

In silico and ex vivo analysis of two chimeric polytope constructs for applications in dendritic cell-based cancer immuno-genetherapy

M. M. Forghanifard[1], *M. Gholamin*[2], *M. R. Abbaszadegan*[2];
[1]*Islamic Azad University, Damghan Branch, Damghan, Islamic Republic of Iran,* [2]*Division of Human Genetics, Immunology Research Center, Bu-Ali Research Institute, Mashhad University of Medical Sciences (MUMS), Mashhad, Islamic Republic of Iran.*

In silico techniques are suited for discovery of new and development of existing vaccines. Cancer immunization using the epitopes derived from the processing of proteins that are preferentially expressed on tumor cells appears to be a reasonable approach to induce antitumor immunity aimed at achieving therapeutic advantage. It would be beneficial to use T cell epitopes from more than one tumor Ag to increase disease coverage and prevent the emergence of tumor-escape variants. In current study, the related sequences of HLA-restricted immunogenic epitopes for some cancer/testis antigens which are highly overexpressed in cancers were obtained from Genbank. Two chimeric sequences were constructed by fusing the selected epitopes using hydrophobic amino acid linkers. The *in silico* gene analysis and multi parameter gene optimization of the synthetic chimer genes were performed using Stand-alone softwares. The mRNA and recombinant protein secondary-structures were predicted and 3D structural stability of the synthetic proteins were analyzed. The VaxiJen server was used to predict the immunogenecity of the whole antigens. Finally the desired properties were verified by Gen-Script (NJ, USA) and the multimeric genes were synthesized. Monocytes-derived dendritic cells (DCs) of a healthy donor were electroporated with synthesized chimeric genes. T cells were primed with transfected DCs and lytic effects of the generated CTL were measured with Cytotoxicity assay. Based on *in silico* and primary *ex vivo* results, this is promising that the structural models for chimeric genes from antigenic epitopes of CTAs which are presented may define accessibility, solubility and immunogenicity for applications in cancer immuno-genetherapy.

Targeted re-sequencing of the 22q11 region in atypical DiGeorge patients.

B. A. Nowakowska[1,2], *J. K. J. Van Houdt*[1], *A. Swillen*[1], *K. DeVriendt*[1], *J. R. Vermeesch*[1];
[1]*Center for Human Genetics, K.U.Leuven, UZ Gasthuisberg, Leuven, Belgium,* [2]*Foundation for Polish Science (FNP), Warsaw, Poland.*

The 22q11 deletion syndrome, also called the DiGeorge syndrome (OMIM 188400) is the most common chromosomal deletion syndrome in humans with an incidence of 1 in 2-4000 live births. Although the clinical presentation of 22q11 syndrome is variable, the major clinical characteristics of the syndrome are the intellectual disability, congenital heart anomalies, velopharyngeal abnormalities and characteristic facial appearance. Also these patients are at significant risk for psychiatric disorders. In addition, to the variability amongst patients with the “typical” phenotypic features, occasionally (about 1/100) 22q11 deletion carriers present atypical malformations. Despite intensive studies it remains unclear what causes this phenotypic variability of patients with the same deletion. We hypothesize that the distinct rare features are caused by unmasking a recessive allele which occurs at low frequency in the general population. In our study we focused on 24 patients with 22q11 deletion and one of the phenotypic features outside the traditional 22q11 spectrum, like anorectal malformation, arthrogryposis, polymicrogyria, eye anomalies, inner ear malformations and laryngeal web. For identification of the functional role of genes within the common deletion we captured coding parts of the remaining 22q11 region using custom designed Nimblegen capture arrays, and re-sequenced the enriched samples with 454 GS FLX Titanium chemistry. Analysis was performed based on comparison of variants present in patients with the same phenotypic feature against variants found in patients without that characteristic. The candidate genes responsible for particular features will be presented.

A 14kb homologous deletion in intron2 of DMRT1 in two sisters with 46,XY karyotype

B. Xiao, *X. Ji, F. Long, W. Jiang, Y. Xing, J. Tao;*
Xinhua Hospital Affiliated to Shanghai Jiao Tong University,Shanghai Institute for Pediatric research, Shanghai, China.

We describe two sisters with 46,XY karyotype in a consanguineous family manifested primary amenorrhea, no onset of puberty, no secondary sexual characteristics, small immature uterus and gonadal dysgenesis. Mutations in known candidate genes including SRY, SOX9, DAX1, DMRT1, SF1, WT1, CBX2, DHH, SOX8 had been excluded. Genome wide copy number changes were analyzed by running on SNP 6.0 arrays and a about 14kb homologous deletion in intron 2 of DMRT1 was identified, PCR spanned the junction and gap revealed healthy parents were heterozygous carriers. Using comparative genomics in vertebrate organisms, generated by PhastCons on sequence alignments created by MULTIZ, we found several evolutionarily conserved segments in this 14kb region. Further study on the potential effect of this noncoding sequence on DMRT1 expression is undergoing.

P12.003
Aarskog-Scott syndrome : Report of the first duplication in the *FGD1* gene.

I. Maystadt[1,2], *N. Ronce*[3,4], *C. Hubert*[3], *S. Vonwill*[3,4], *K. Devriendt*[5], *M. P. Moizard*[3,4], *M. Raynaud*[3,4];
[1]*Institut de Pathologie et de Génétique (IPG), Charleroi (Gosselies), Belgium,* [2]*Facultés Universitaires Notre-Dame de la Paix (FUNDP), Namur, Belgium,* [3]*CHRU de Tours - Hôpital Bretonneau, Tours, France,* [4]*INSERM U930 - CHRU de Tours, Tours, France,* [5]*University Hospitals Leuven (KUL), Leuven, Belgium.*

Aarskog-Scott syndrome (AAS), a rare X-linked condition characterized by skeletal and genital anomalies, is caused by mutations in the faciogenital dysplasia 1 (*FGD1*) gene. To date 27 distinct point mutations and 2 deletions have been described. Here, we report on a male patient presenting with highly suggestive clinical features of AAS (postnatal growth retardation, widow's peak, hypertelorism, short nose, short broad hands, camptodactyly, cryptorchidism and shawl scrotum). No mutation was found by sequencing of the entire coding sequence of the *FGD1* gene. Quantitative PCR and cDNA sequencing analyses revealed a large out-of-frame tandem duplication of exons 2-12 which probably occurred by unequal recombination between two *Alu* sequences. This maternally inherited duplication implicates the RhoGEF (DH or Dbl homology) and the first plekstrin homology (pH) domains and is predicted to be a loss-of-function mutation. This is the first duplication described in the *FGD1* gene and systematic screening of large rearrangements should be included in the diagnostic strategy of AAS.

ADRB2 gene polymorphisms and the ocular hypotensive response to topical betaxolol in Mexican patients with open angle glaucoma.

L. Gonzalez-Huerta[1], *O. Messina*[1], *I. Babayan*[1], *F. Lara*[1], *G. Pacheco*[1], *S. Cuevas*[2];
[1]*HOSPITAL GENERAL DE MEXICO, MEXICO D.F., Mexico,* [2]*HOSPITAL GENERAL DE MEXICO, UNIVERSIDAD NACIONAL AUTONOMA DE MEXICO, MEXICO D.F., Mexico.*

Glaucoma is defined as a disease characterized by loss of retinal ganglion cells, excavation of the optic nerve head, visual field defects and eventually blindness, being the second leading cause of blindness worldwide. The main risk factors include elevated intraocular pressure, age, ethnicity, family history and myopia. camenteiccionario - Ver diccionario detallaB-adrenergic receptors. ADRB2 (B-2 adrenergic receptor) is expressed in the ciliary body, trabecular meshwork and wall of the vasculature of the optic nerve. Betaxolol is a beta adrenergic blocker that acts selectively on beta 1 receptors, at eye level, it is assumed that betaxolol inhibits the adrenergic tone and therefore the formation of aqueous humor in the ciliary body. The present study aimed to determine the association between the Arg16Gly and Gln27Glu polymorphisms of the *ADRB2* gene and the ocular hypotensive response to topical betaxolol in Mexican patients with open angle glaucoma. Thirty-three patients were genotyped at the Arg16Gly and Gln27Glu polymorphisms. Demographic data, disease severity, ocular pressure tests and betaxolol medication usages were recorded for each patient. The frequencies of the Arg16 and Gln27 alleles were found to be 48.8% and 72.07.%, respectively. Two haplotypes were estimated, i.e. Arg-Gln, Gly-Gln with frequencies of 5 (15.2%), 10 (30.3%). We found no statistical differences in the outcome of betaxolol treatment between the different haplotypes. We consider that other genetic factors, apart from ADRB2 polymorphisms, are involved in the outcome to the hypotensive response to topical betaxolol .

P12.005
Patients with Alagille syndrome and large deletions in JAG1 gene.

A. Skórka[1,2], *D. Jurkiewicz*[2], *D. Gliwicz*[3], *N. B. Spinner*[4], *J. Gerfen*[4], *E. Ciara*[2], *D. Piekutowska-Abramczuk*[2], *D. Gieruszczak-Białek*[1,2], *M. Kugaudo*[2], *M. Krajewska-Walasek*[2];

Alagille syndrome (AGS) is a complex autosomal-dominant multisystem disorder with a highly variable expressivity. The main phenotypic features include chronic cholestasis caused by paucity of intrahepatic bile ducts, cardiac disease (mainly peripheral pulmonary stenosis), posterior embryotoxon in the anterior chamber of the eyes, vertebral defects and a typical face characterized by a triangular shape with prominent forehead, broad nasal bridge and a pointed chin. Current screening methods allow for identification of mutations in 70-90% of individuals with AGS. Most of cases are caused by intragenic point mutations in the JAG1 (Jagged1) gene localized on chromosome 20p12. A minority of AGS patients (3-6%) have microdeletions of chromosome 20p12.

Here we present 6 Polish cases of Alagille syndrome with deletions comprising a number of JAG1 exons or the entire JAG1 gene. Analysis was performed by multiplex ligation dependent probe amplification using SALSA MLPA KIT JAG1 (MRC-Holland). In two cases deletions were inherited from one of the parents who presented with minimal symptoms. All 6 cases presented with classical symptoms: cholestasis due to paucity of bile ducts, cardiac defects, eye and vertebral anomalies and typical facies. One patient was also diagnosed with hearing impairments, one with renal tubular acidosis and one with bilateral ureterovesical refluxes.

The study was supported by Children's Memorial Health Institute Grant no. 212/10.

P12.006
X-linked Alport syndrome investigation in Hellenic families. G624D mutation in *COL4A5* may explain many familial hematuria cases in Greek mainland that hardly can be diagnosed as Alport syndrome

P. Demosthenous[1], *K. Voskarides*[1], *M. Hadjigavriel*[2], *M. Arsali*[3], *C. Patsias*[3], *P. Zirogiannis*[4], *P. Goudas*[5], *A. Diamantopoulos*[5], *K. Sombolos*[6], *C. Stavrou*[7], *E. Alexopoulos*[8], *A. Pierides*[9], *C. Deltas*[1];
[1]*University of Cyprus, Nicosia, Cyprus,* [2]*Department of Nephrology, Larnaca General Hospital, Larnaca, Cyprus,* [3]*Department of Nephrology, Nicosia General Hospital, Nicosia, Cyprus,* [4]*Lamia Hospital, Lamia, Greece,* [5]*Renal Department, St Andrews General State Hospital, Patra, Greece,* [6]*Department of Nephrology, General Hospital G. Papanikolaou, Thessaloniki, Greece,* [7]*Evangelismos Hospital, Paphos, Cyprus,* [8]*Department of Nephrology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [9]*Department of Nephrology, Hippocrateon Hospital, Nicosia, Cyprus.*

The X-linked Alport syndrome (ATS) is caused by mutations in *COL4A5*. ATS is heralded with continuous micro-hematuria which rapidly progresses to proteinuria, hypertension and chronic or end-stage renal disease (ESRD) by adolescence, frequently accompanied by sensorineural deafness and ocular complications. Milder forms of ATS also exist. We initially studied nine Hellenic families suspected clinically of X-linked ATS who presented with marked phenotypic heterogeneity. We identified four mutations in *COL4A5* in six families.

Males currying E228X or c.2946delT mutation had the classical ATS symptoms with early onset of renal failure and deafness. However four males with the milder mutation G624D, belonging in two families originating from Greek mainland, reached ESRD after 39-yo and one patient showed Thin Basement Membrane Nephropathy (TBMN: a milder phenotype than ATS, classically attributed to *COL4A3/COL4A4* genes). Another 5/8 affected males with mutation P628L also developed ESRD between 30-57-yo, while three exhibit only mild chronic renal failure (CRF). Surprisingly, screening three more hematuric families from Greek mainland for G624D, were found positive for this mutation. The data support previous findings that certain mutations are associated with milder phenotypes, such as TBMN and familial microscopic hematuria. G624D may explain a lot of familial hematuria cases in Greece. We are designing a Greek genetic epidemiological study in order to find the exact frequency of the mutation in hematuric patients. Similar conclusions apply for missense mutation P628L. Interestingly, mutations G624D and P628L are near the 12th natural interruption of *COL4A5* triple-helical domain, which may explain the milder phenotype.

P12.007
Three novel mutations in Turkish patients with Alstrom Syndrome

A. Güzel[1], *J. Marshall*[2], *R. Özgül*[3];
[1]*Hacettepe University, Biology Department, Ankara, Turkey,* [2]*Jackson Laboratory, Bar Harbor, ME, United States,* [3]*Hacettepe University, Institute of Child Health, Ankara, Turkey.*

Alström syndrome (AS) is a rare multisystemic disorder. Major clinical symptoms of the disease are congenital retinal dystrophy leading to blindness, neurosensorial hearing lost, childhood obesity, insulin resistance, and type 2 diabetes, dilated cardiomyopathy. Mutant form of *ALMS1* gene causes AS. *ALMS1* is a novel gene which is comprised of 23 exons encoding a protein of 4169 amino acids that does not share significant sequence homology with any other known genes. The ALMS1 protein is ubiquitously expressed and localizes to centrosomes and basal bodies of ciliated cells, perhaps playing an important role in cilia function and intraflagellar transport. RNA interference knockdown experiments indicate that a total lack of ALMS1 impairs cilia formation. To date, more than 100 mutations, mostly nonsense and frameshift type, in *ALMS1* have been reported in Alström syndrome. The reported mutations are primarily clustered in exons 16, 10, and 8, but less common mutations also occur in exons 12, 18 and 11. In present study, four Turkish AS patients were analysed. Mutation screening of the whole coding region and all intron/exon boundaries were performed by PCR and direct sequencing. As a result of sequence analysis, three novel mutations; c.4155insA; T1386NfsX15, c.5311C>T; p.Q1771X, c.9749C>A; p.S3250X and several polymorphism; IVS4+20T>A, F731F, V673G, D2674H, R4031K, IVS18-12T>C were detected in patients. This study was supported by State Planning Organization of Turkey (Project No: DPT 2006 K120640)

P12.008
APP gene mutation (D678N) in a patient with an Early-Onset Alzheimer‘s Disease

F. Trecroci*, A. La Russa, R. Cittadella, M. Liguori, P. Spadafora, G. Di Palma, M. Caracciolo, V. Andreoli;*
Institute of Neurological Sciences-National Research Council, Pianolago di Mangone (CS), Italy.

Introduction: Notably, the clinical presentation of familial forms of AD (FAD) is more complex, and mutations of APP gene have also been described in these patients. Only about 26 different missense mutations, located in exons 16 and 17 of APP, have been reported. Aims: To better assess the genetic contribution of APP to FAD, we performed a systematic mutation analysis of this gene in a series of Italian patients with FAD. Methods: Ninety-seven patients (age, 66.48 ± 10.1 years; mean ± SD) with FAD were recruited at the Institute of Neurology, University “Magna Graecia” in Catanzaro, and subsequently screened for mutations at the Institute of Neurological Sciences, National Research Council, in Cosenza, Italy. The exonic regions of APP (exons 16 and 17) gene were amplified and a mutational screening was done by DHPLC and direct sequencing. Results: Within our FAD, a non-synonymous change in exon 16, previously described in a Japanese pedigree, was detected (D678N) in a proband with cognitive decline having had commenced at 58 years of age. We found five affected subjects of the same family, who showed cognitive disorders with the age at onset ranging from 50 to 65 years. Conclusion: In this study, we found a D678N mutation in a patient showing a inheritance pattern consistent with EO-autosomal dominant transmission. Our data confirmed that APP is actually an EO-AD gene, in which onset occurs primarily prior to 65 years of age and often much younger; and for a given mutation, onset ages are tightly clustered.

P12.009
Missense mutations in myosin light chain kinase MYLK in familial thoracic aortic aneurysms and dissections (TAAD)

F. Cayami[1,2], *A. Maugeri*[1], *E. Sistermans*[1], *S. M. H. Faradz*[2], *G. Pals*[1];
[1]*VU medical center, Amsterdam, Netherlands,* [2]*Center for Biomedical Research, DiponegoroUniversity, Semarang, Indonesia.*

Background: A recent study showed that mutations in myosin light chain kinase MYLK may cause familial thoracic aortic aneurysms and dissections (TAAD). Five mutations were found in 193 probands.
Two previously identied TAAD genes, MYH11 en ACTA2, encode respectively the SMC-specific isoform of actin and myosin heavy chain, while MYLK encodes the MCLK protein. This kinase phosphorylates regulatory light chain (RLC), a protein that regulates the actin and myosin activities and actin-myosin II cytoskeleton-mediated functions inside the smooth muscle cells of aortic wall. These processes are important in maintaining the aortic wall, which is subject to biomechanical forces throughout life.
Methods: We studied the MYLK gene in 95 probands from TAAD families by high resolution melting curve analysis, followed by sequencing of aberrant fragments. All patients had negative test results for sequencing of the genes FBN1, TGFBR1, TGFBR2, MYH11 and ACTA2.
Results: Two missense mutations were identified in the MYLK gene: c.2183G>A (p.Arg728His) and c.4565C>T (p.Val1522Ala). Both mutations were not detected in 120 ethnically matched healthy controls. The mutations involve highly conserved amino acids, 100% conserved down to Tetraodon, in highly conserved domains. However, there is only a small difference in properties of the variant amino acids.
Conclusion: We identified 2 missense mutations in 95 (2.1%) families with TAAD. This finding is in agreement with the result of the previous study. However, to assess clinical significance of the identified mutations, further studies, such as functional analysis of missense mutations, are needed.

P12.010
Arthrogryposis multiplex congenita associated with a heterozygous mutation and 855 kb microduplication in 17q12 both likely affecting function of the cation channel gene ACCN1 in a male fetus.

P. M. Kroisel[1], *K. M. Roetzer*[1], *M. Mach*[1], *K. Wagner*[1], *M. R. Speicher*[1], *E. F. Karpf*[2], *E. Heitzer*[1], *M. Häusler*[3];
[1]*Institute of Human Genetics, Graz, Austria,* [2]*Institute of Pathology, Graz, Austria,* [3]*Department of Obstetrics & Gynecology, Graz, Austria.*

A very severe form of congenital arthrogryposis multiplex was identified by prenatal sonography in the 22th week in the second pregnancy of a 25 years old healthy woman of Austrian origin. Her 4 years old son is healthy as is her non-consanguineous 28 years old husband, also of Austrian extraction. Because of an elevated risk (1:38) for fetal Down syndrome based on combined test results, an amniocentesis in the 16th week of an otherwise thus far uneventful pregnancy was performed, revealing normal cytogenetic and biochemical (AFP) results. However during midtrimester targeted fetal organ screening in the 22th week a complete absence of fetal movements (akinesia) and further fetal anomalies were recognized, leading to the diagnosis of congenital arthrogryposis multiplex with some similiarities to Pena-Shokeir-syndrome, a heterogeneous autosomal recessive disease. Because of the bad prognosis parents decided to derminate the pregnancy and further genetic analyses as well as fetal autopsy were performed. A 60k Agilent array CGH analysis of fetal DNA showed a 855 kb microduplication of 17q12 in the fetus and his mother. Because one of the chromosomal breakpoints is quite likely to affect the ACCN1 gene, we consecutively performed DNA sequencing of this gene from fetal DNA. The heterozygous missense mutation c.137G>T[p.R46L] was identified, and this rare mutation was found to be of paternal

origin. Although Pena-Shokeir-syndrome and related disorders are heterogeneous and several potential causative gene have been identified so far, we seriously consider the compound heterozygous mutations described here as another potential pathogenetic mechanism in such disorders.

P12.011
LRRK2 haplotype analysis in exon 41 p.G2019S positive patients with Parkinson disease.

F. Sironi[1,2], *T. Brambilla*[1,2], *C. Mariani*[2], *S. Tesei*[2], *G. Pezzoli*[2], *S. Goldwurm*[2], *M. Seia*[1], *P. PRIMIGNANI*[1];
[1]*Medical Genetics Laboratory - Fondazione IRCCS ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [2]*Parkinson Institute - I.C.P., Milan, Italy.*

Mutations in the *LRRK2* gene have been found to be responsible for autosomal dominant forms of Parkinson Disease (PD).
The most common *LRRK2* p.G2019S mutation, laying in exon 41, has been reported to account for 5-6% of familial PD and 1.6% of sporadic PD in Europe. Three different *LRRK2* haplotypes have been associated with this point mutation: haplotype 1, characteristic of North African, Arabs and western European subjects; haplotype 2, typical of American European-descent individuals; haplotype 3, identified in Japanese families. The p.G2019S mutation seems to be occurred independently at least twice in humans: once on the haplotype 1 and once in the phylogenetically related haplotype 2 and 3.
A total of 2261 unrelated consecutive PD patients (Parkinson Institute Biobank of Milan - http://parkinson.it/dnabank.htlm) has been screened and 35 subjects were found to carry exon 41 *LRRK2* variants:
30 p.Gly2019Ser heterozygotes (of which one was also heterozygote carrier of IVS41+30 A>G)
1 p.Gly2019Ser homozygote
1 p.Ile2020Leu heterozygote
1 p.Pro2036Arg heterozygote
1 p.Tyr2018Tyr heterozygote
1 p.Pro2007Pro heterozygote
In addition, 5 subjects were found to be carrier of intronic variants (2 IVS40-39 A>G heterozygotes, 1 IVS40-103 T>C heterozygote; 1 IVS41+30 A>G heterozygote; 1 IVS40-47 A>G heterozygote).
Ten *LRRK2* SNP markers, spanning from exon 8 to 43, have been directly sequenced in the 31 p.G2019S carriers. According to previous studies we found that the haplotype 1 is the most frequent in p.G2019S carriers in our population suggesting that the mutated allele derived from a single common founder probably of North-African origin.

P12.012
Alpha-synuclein gene rearrangements in autosomal dominant form of Parkinson's disease in Russia.

A. Drozdova[1], *A. Yakimovsky*[2], *A. Emelyanov*[1,2], *S. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, RAS, Saint-Petersburg, Russian Federation,* [2]*St.Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation.*

Recent studies have shown that the development of Parkinson's disease (PD) may be affected by the increase in the alpha-synuclein gene (*SNCA*) copy number (duplications and triplications). We have assessed the frequency of *SNCA* rearrangements in 39 patients (average age 58.4±10.4, average age at disease onset 44.4±11.9) with autosomal dominant PD form. Alpha-synuclein gene dosage analysis was carried out using Real-time PCR on an ABI 7000 genetic analyzer (Applied Biosystems) with Taqman probes. Beta-globin gene was amplified in one tube with exon 3 of *SNCA* as an internal control. All samples were tested in triplicates. To assess the *SNCA* gene copy number we compared the values of the threshold cycle of alpha-synuclein with those of beta-globin. Ratios from 0.8 to 1.2 indicated a normal gene dosage; from 1.3 to 1.7 - a heterozygous duplication; and from 1.8 to 2.2 - a triplication or a homozygous duplication. For all samples we obtained values which were in the range 0.8 to 1.2. These results did not reveal multiplications of the *SNCA* gene in the examined patients and allowed to suggest that *SNCA* duplications and triplications are a rare cause of autosomal dominant PD in Russia.

P12.013
Association study between the LINGO1 gene and Parkinson's disease in the Italian population

F. Annesi[1], *E. V. De Marco*[1], *F. E. Rocca*[1], *P. Tarantino*[1], *A. Nicoletti*[2], *P. Pugliese*[3], *G. Nicoletti*[3], *G. Arabia*[3], *M. De Mari*[4], *P. Lamberti*[4], *S. Gallerini*[5], *R. Marconi*[5], *A. Epifanio*[6], *L. Morgante*[6], *A. Cozzolino*[7], *P. Barone*[7], *G. Torchia*[3], *M. Gagliardi*[1], *M. Zappia*[2], *G. Annesi*[1], *A. Quattrone*[3];
[1]*Istituto di Scienze Neurologiche, Consiglio Nazionale delle Ricerche, Mangone (CS), Italy,* [2]*Dipartimento di Neuroscienze, Università di Catania, Catania, Italy,* [3]*Clinica Neurologica, Università Magna Graecia, Catanzaro, Italy,* [4]*Clinica Neurologica, Università di Bari, Bari, Italy,* [5]*Divisione di Neurologia, Ospedale Misericordia, Grosseto, Italy,* [6]*Dip. di Neuroscienze, Scienze Psichiatriche ed Anestesiologiche, Università di Messina, Messina, Italy,* [7]*Dip. di Scienze Neurologiche, Università Federico II, Napoli, Italy.*

A genome wide association study in European and American patients with Essential Tremor(TE)showed a significant association with the rs9652490 SNP of the leucine rich repeat and Ig domain containing 1 (LINGO1) gene. LINGO1 gene codes for a nervous system-specific transmembrane protein. Its expression is increased in the substantia nigra of some PD patients, thus suggesting that LINGO1 may be involved in PD pathophysiology. In this study, we performed a case-control analysis in an Italian population to assess the role of the LINGO1 gene in PD patients.
A total of 567 patients with PD and 468 control subjects were enrolled in Central-Southern Italy. Genotyping of LINGO1 SNPs (rs9652490 and rs11856808) was performed by TaqMan pre-designed assays using an ABI 7900 HT-SDS system.
No significant differences were found in allele or genotype frequency distribution of rs9652490 between patients and controls (P>0.05). Regarding rs11856808, the C allele of this marker was more frequent in patients than in controls, but after Bonferroni correction only a borderline P-value was obtained from the comparison (P=0.024; Padjusted=0.048). Genotype frequencies did not differ between the two groups.
Our study demonstrates that LINGO1 SNPs are not associated with our PD patients, thus showing that this gene does not represent a possible risk factor for PD in our population.

P12.014
A comprehensive mutation analysis of the PINK1 gene in Southern Italian patients with early- and late-onset parkinsonism

E. V. De Marco[1], *V. Scornaienchi*[1], *P. Tarantino*[1], *F. E. Rocca*[1], *V. Greco*[1], *G. Provenzano*[1], *D. Civitelli*[1], *F. Annesi*[1], *G. Nicoletti*[1], *A. Uncini*[2], *A. Quattrone*[3], *G. Annesi*[1];
[1]*Institute of Neurological Science, National Research Council, Mangone (CS), Italy,* [2]*Neuromuscular Diseases Unit, Centre for Excellence on Aging, "G. d'Annunzio" University Foundation, Chieti, Italy,* [3]*Neuroimaging Research Unit, National Research Council, Catanzaro, Italy.*

Mutations in the PINK1 gene are associated with both familial recessive and sporadic early-onset Parkinson's disease (EOPD).
Data on Italian EOPD patients show mutations in a relatively high percentage (8-9%). Heterozygous or compound heterozygous mutations were also reported in a small number of late-onset PD patients (LOPD). In this study, we aimed at assessing the frequency and possibly the pathogenic role of PINK1 mutations in familial and sporadic patients with EOPD and LOPD coming from Southern Italy.
We selected 115 patients, including 102 cases with EOPD, 9 of which had a positive family history, and 13 familial cases with LOPD. All the eight PINK1 exons were analyzed by PCR and sequencing. The MLPA method was used in the heterozygous patients in order to detect exon dosage changes, caused by genomic rearrangements, of the known PD genes. Four already know different mutations (three homozygous: Q126P, W437X , Q456X and one heterozygous: E476K) and one novel heterozygous mutation (R207Q) were found in five patients (4.3%). In particular, 4 out of 103 EOPD patients (3.9%) carried PINK1 mutations. This frequency is lower than previous studies on Italian EOPD have suggested. Furthermore, a frequency of 1 out 13 (7.7%) in familial LOPD patient was found, thus confirming a certain influence of the PINK1 gene also in LOPD as observed in other studies. In conclusion, our study confirms the role played by the PINK1 gene mutations both in heterozygous and homozygous condition in PD development.

P12.015

CAA interrupted SCA2 alleles of 38 repeats jointly several SCA8 expansions segregate from a late onset parkinsonism index case

J. Corral Seijas[1], *H. San Nicolàs Fernàndez*[1], *L. De Jorge López*[1], *M. Calopa Garriga*[2], *V. Volpini Bertrán*[1];
[1]*Institut d'Investigació Biomèdica de Bellvitge, IDIBELL; Centre de Diagnòstic Genètic-Molecular de Malalties Hereditàries, CDGM, L'Hospitalet de Llobregat, Barcelona, Spain,* [2]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain.*

Several Spinocerebellar Ataxia genes (SCAs) *SCAs1-3*, *SCAs6-8, SCA12* and SCA17 have been cloned, generally sharing a CAG (CAG/CTG in SCA8) repeat expansion mutations which usually encodes a polyglutamine tract. In our Spanish casuistic, SCA2 was found in 45 index cases over 408 familial cases with ataxia (25.47 % ± 3.90). No SCA mutation was found in any of 1,089 sporadic and idiopathic cases. Is generally known that SCA2 expanded alleles without CAA interruptions are associated with pathological development of the disease and that the interruptions would prevent elongation of the expanded sequence. In this study we present one pedigree showing SCA2 expanded alleles with CAA interruptions coexisting with SCA8 expanded alleles in several members. The index and founder case shows a SCA2 interrupted expanded allele of 38 CAG repeats coexisting with an SCA8 allele of 89 repeats. He presents late onset essential tremor and cerebellar atrophy. No mutations were found in *LRRK2* and *Parkin* genes associated with Parkinson's disease as his aetiology. One of his sons and two of his grandchild's share the same expanded interrupted SCA2 allele, coexisting with SCA8 expansions from 78 to 84 repeats, and all of them remain asymptomatic. In conclusion, SCA2 expanded alleles in pathological range with CAA interruptions could be associated with late onset Parkinsonism with uncertain penetrance. The role of SCA8 expansion coexisting with SCA2 expanded alleles remains unknown.

P12.016**

Compensatory molecular and functional mechanisms in neurons of the *Grm1*^{crv4} mouse, a murine model for ataxia lacking the mGlu1 receptor.

P. I. A. Rossi[1,2], *I. Musante*[1,2], *M. Summa*[3], *A. Pittaluga*[3], *M. Ikehata*[4,5], *M. P. Rastaldi*[4,5], *R. Ravazzolo*[1,2], *A. Puliti*[1,2];
[1]*Molecular Genetics and Cytogenetics Unit, Gaslini Institute, Genoa, Italy,* [2]*Department of Pediatric Sciences, University of Genoa, Genoa, Italy,* [3]*Department of Experimental Medicine, Section of Pharmacology and Toxicology, University of Genoa, Genoa, Italy,* [4]*Renal Research Laboratory, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy,* [5]*Fondazione D'Amico per la Ricerca sulle Malattie Renali, Milan, Italy.*

The metabotropic glutamate type 1 (mGlu1) and 5 (mGlu5) receptors are the only members of group I mGlu receptors, a subfamily of G protein-coupled receptors implicated in synaptic plasticity, and in mechanisms of feed-back control of glutamate release. mGlu1 and mGlu5 receptors exhibit a complementary distribution throughout the central nervous system, more evident in the cerebellum, where mGlu1 receptor is most intensely expressed while the mGlu5 receptor is not. Despite the different distribution, they show a similar subcellular localization relative to transmitter release sites, and use common transducing pathways.

We recently described the *Grm1*^{crv4} mouse mutant carrying a spontaneous inactivating mutation of the mGlu1 receptor. Homozygous *Grm1*$^{crv4/crv4}$ mice exhibit a complex phenotype with ataxia. To better define the pathophysiological mechanisms of ataxia in these mice, we evaluated expression and function of the other member of group I mGlus, the mGlu5 receptor, in *Grm1*^{crv4} mouse cerebellar and brain cortices. Western blot and immunofluorescence analyses show mGlu5 receptor overexpression in the homozygous *Grm1*$^{crv4/crv4}$ mice. Real-time quantitative RT-PCR results indicate that up-regulation is already evident at RNA level, suggesting a cellular compensatory mechanism due to the absence of active mGlu1 receptor molecules. Finally, functional studies confirm an enhanced glutamate release from cortical cerebellar and brain synaptosomes as respect to wild type, that is abolished by mGlu5 receptor specific inhibitors.

Mechanisms that affect glutamate bioavailability and glutamatergic transmission at the synaptic level may contribute to the development and/or to the rescue of the affected phenotype.

Supported by RFPS-4-631972 grant, Italian Ministry of Health.

P12.017

Prodynorphin (PDYN) mutations are rare in Spanish patients with Spinocerebelar Ataxia

M. Garcia-Murias[1], *M. Villanueva-Millán*[1], *J. Joglar-Santos*[1], *B. Quintáns*[2,3], *A. Carracedo*[1,3,4], *M. Sobrido*[1,3];
[1]*Fundación Pública Galega de Medicina Xenómica-SERGAS, Santiago de Compostela, Spain., Santiago de Compostela, Spain,* [2]*Hospital Clínico de Santiago de Compostela-SERGAS, Spain., Santiago de Compostela, Spain,* [3]*Centro Para Investigación en Red de Enfermedades Raras (CIBERER), ISCIII, Spain., Santiago de Compostela, Spain,* [4]*Grupo de Medicina Xenómica-University of Santiago de Compostela, Spain., Santiago de Compostela, Spain.*

Spinocerebellar ataxias (SCAs) represent a group of dominantly inherited neurological disorders characterized by variable degeneration in the cerebellum, spinocerebellar tracts, and brain stem. The SCAs present with gait ataxia, dysarthria, oculomotor abnormalities and may have additional symptoms. Recently, missense mutations in prodynorphin (PDYN), the precursor protein for several opioid neuropeptides have been reported as the cause of SCA23. In order to investigate the contribution of this new SCA gene in Spanish patients we studied 335 individuals with clinical diagnosis of SCA and negative for SCA 1, 2, 3, 6, 7, 12, 17 and DRPLA. A positive family history was present in 43% of cases, 28% were sporadic and for the reminding cases family history was unclear or unknown. All exons and exon-intron boundaries of PDYN (NM_024411.4) were sequenced on an ABI3730 analyzer and sequence analysis was performed with the Staden package. All identified sequence variations were screened in 186 control individuals without neurological disorders. We identified four sequence changes in non-coding exons 1 and 2 (c.-241 G>C, c.-162 A>G, c.-124 G>T and c.-48 G>C). In addition, a synonymous alteration (c.72 G>A; p.Ser24Ser) was identified in exon 3 and a single nucleotide substitution c.130-46 T>G in intron 3 of PDYN. None of these changes was present in searchable databases of human polymorphisms and they were not detected in healthy controls from our population. SCA 23 appears to be a very infrequent cause of SCA in Spain. Whether these new sequence variations in PDYN have any functional effect needs further investigation.

P12.018

Genetic and epidemiological data of spinocerebellar ataxia type 8 in Spanish population

H. San Nicolàs Fernàndez[1], *L. De Jorge López*[1], *J. Corral Seijas*[1], *D. Genís Batlle*[2], *A. Matilla Dueñas*[3], *V. Volpini Bertrán*[1];
[1]*Institut d'Investigació Biomèdica de Bellvitge, IDIBELL; Centre de Diagnòstic Genètic-Molecular de Malalties Hereditàries, CDGM, L'Hospitalet de Llobregat, Barcelona, Spain,* [2]*Hospital Universitari Josep Trueta, Girona, Spain,* [3]*Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, Spain.*

Autosomal Dominant Cerebellar Ataxias (ADCAs) are a clinically and genetically heterogeneous group of neurodegenerative disorders in which several Spino-Cerebellar Ataxia genes (SCAs) have been cloned: *SCA1-3, SCA5-8, SCA10-11, SCA13-15, SCA27-28* and *SCA31*. We have analyzed 408 unrelated familial and 1,089 sporadic and idiopathic cases of SCA. Over the familial cases 6.25% cases were SCA1; 25.57% SCA2; 34.09% SCA3; 7.39% SCA6; 5.68% SCA7; 14.77% SCA8; 3.41% SCA17; and 2.84% DRPLA. About 55% of our pedigrees remained genetically unclassified and no SCA mutations were detected in the 1,089 isolated and idiopathic cases. In 26 pedigrees with SCA8 expansions the allele size ranges from 85 to 726 repeats (140.94 ± 105.90; Pearson Coefficient= 75.14%). Maternal transmissions presented elongations of the CAG/CTG combined sequence ranging from +3 to +13 repeats. In contrast paternal transmissions presented contractions from -1 to -17 repeats. Giant SCA8 expansions ranges from 270 to 1,126 (N=13), all carried by unaffected adult individuals. These expansions have been originated from homozygous SCA8 females with alleles of moderate size in two unrelated pedigrees. Remarkably, homozygous males have transmitted contracted alleles, as in heterozygous cases occurs. The distribution of SCA8 alleles in a sample of 90 individuals from general population is bimodal, with two groups: 15 to 34 CAG/CTGs with frequency of 98% and 77 to 86 with frequency of 2%. SCA8 alleles with moderate size in general population could be the origin of new expanded alleles.

Prodynorphin mutations cause the neurodegenerative disorder spinocerebellar ataxia type 23

*G. Bakalkin[1], J. Jezierska[2], H. Watanabe[2], C. Verschuuren-Bemelmans[2], K. Artemenko[1], K. Hauser[3], C. Wijmenga[2], B. Kremer[2], R. J. Sinke[2], **D. S. Verbeek**[2];*

[1]Uppsala University, Uppsala, Sweden, [2]UMCG, University of Groningen, Groningen, Netherlands, [3]Virginia Commonwealth University, Richmond, VA, United States.

Spinocerebellar ataxias (SCAs) are dominantly inherited neurodegenerative disorders characterized by progressive cerebellar ataxia and dysarthria. We have identified missense mutations in the prodynorphin (*PDYN*) gene to cause SCA23 in four Dutch ataxia families. PDYN is the precursor protein for the opioid neuropeptides, α-neoendorphin, and dynorphins A and B (Dyn A and B). PDYN peptides regulate pain processing and modulate the rewarding effects of addictive substances. Three mutations are located in Dyn A, a peptide with opioid activities, as well as non-opioid neurodegenerative actions, while a fourth mutation is in the non-opioid PDYN domain. The mutations stabilize Dyn A by restricting its conversion to shorter enkephalins. In addition, two of the mutant Dyn A peptides induced toxicity above that of wild type Dyn A in cultured striatal neurons. The mutation in the non-opioid domain was associated with altered expression of components of the opioid and glutamate system as evident from analysis of SCA23 autopsy tissue. In line with our findings, Dyn A was already found to be upregulated in aging rodent brain contributing to age-related impairment of spatial learning and memory and additionally in the prefrontal cortex of Alzheimer disease patients, elevated Dyn A levels correlated with neuritic plaque density. Thus, alterations in Dyn A activities and/or impairment of secretory pathways by mutant PDYN may lead to glutamate neurotoxicity which underlies Purkinje cell degeneration and ataxia.

Investigation of correlation between triplet repeat numbers in ATXN1, ATXN2, MJD, CACNA1A, ATXN7, ATXN8OS, ATXN10, PPP2R2B, TBP genes and age of onset in SCA suspected patients

***Z. Ghaderi Ardekani**[1,2], M. Houshmand[1,3], O. Aryani[1], N. Chaparzadeh[2];*

[1]Genetic lab,Special Medical Center, Tehran, Islamic Republic of Iran, [2]Department of Biology, Azarbaijan University of Tarbiat Moallem, Tabriz, Islamic Republic of Iran, [3]National Institute of Genetic Engineering and Biotechnology Depatment of Medical Biotechnology, Tehran, Islamic Republic of Iran.

Introduction: Spinocerebellar ataxias (SCAs) are a group of neurogenetic diseases caused by expansion of triplet repeats in various genes on different chromosomes. SCA1, 2, 3, 6, 7, 12 and 17 are produced by CAG repeats and SCA8 and10 by CTG and ATTCT repeats, respectively. Expanded repeats in SCA1, 2, 3, 6, 7 and 17 and the SCA8 coding strand code for polyglutamine tracts. Previous studies have shown variable results concerning the correlation between numbers of triplet repeats in these genes and the age of onset in patients.

Materials and Methods: 52 patients with clinical features resembling SCA were analysed. DNA was extracted and PCR performed for the region of the genes containing the triplet repeat. The PCR products were electrophoresed in polyacrylamide gels. repeat numbers were scored and the data analysed using SPSS software.

Results: There was no significant correlation between triplet repeat numbers in two alleles of all genes analysed and age of onset in all SCA suspected patients. A non-significant correlation was observed between the number of triplet repeats in the *ATXN7* and *ATXN8OS* genes and age at onset. In other genes a non-significant inverse correlation was observed.

Discussion: Our hypothesis was that triplet repeat numbers in some of the analysed genes and age of onset would be significantly correlated, but our results did not support this. We conclude that in the Iranian population, expansion in triplet numbers does not correlate with age of onset. However, the small number of patients studied or errors in the remembered age of onset could also cause this result.

P12.021

Polyglutamine-expanded protein ataxin-3 induces mitochondrial ERK activation and autophagic cell stress

***H. TSAI**, C. Chan;*

CHUNG SHAN MEDICAL UNIVERSITY, Taichung, Taiwan.

Spinocerebellar ataxia type 3 (SCA3), also called Machado-Joseph disease, an autosomal dominant neurodegenerative disease, is caused by an increased number of CAG trinuclear expansion repeats in coding regain of *Ataxin3* and resulted in a disease protein with a higher polyQ domain. Although the detail mechanism of pathogenesis is yet to be defined, neurotoxin, especially reactive oxygen species (ROS), released from aggregated mutant proteins, may play a role in the pathogenic process. Previous studies also suggested that mitochondrial phosphorylated extracellular signal-regulated protein kinase1/2 (p-ERK1/2) was induced oxidative stress and lead to cell death. In this study, two lymphoblastoid cell lines were isolated from SCA3 patients, one contains 31 and 82 CAG repeats in ataxin-3 individual, denoted MJD07; another contains 30 and 78 CAG repeats, denoted MJD08. We investigated the crucial relationship between the expression of p-ERK1/2 and autophagy. Results found the endogenous p-ERK1/2 and autophagy marker protein, Atg8 (LC3 class II) were higher in SCA3 patients. Electron micrographs showed that only the cells expressing expanded ataxin-3 contained aggregated protein and autophagic vacuoles. Based on the above observations we hypothesized that the aggregated mutant Ataxin-3 proteins may generate ROS in mitochondria, which subsequently up-regulate p-ERK1/2 and Atg8 expression levels and ultimately lead to autophagy and cell death.

P12.022

High incidence of DYNC2H1 mutations in a cohort of 51 patients with ATD/SRPIII

***C. HUBER**[1], J. Hokayem[1], G. Baujat[1], L. I. Al-Gazali[2], A. David[3], A. Dieux-Coeslier[4], C. Francannet[5], P. Sarda[6], S. Sigaudy[7], I. Vogel[8], M. Le Merrer[1], K. H. Le Quan Sang[1], A. Munnich[1], V. Cormier-Daire[1];*

[1]Service de Génétique, INSERM U 781, Université Paris Descartes, AP-HP, Hôpital Necker Enfants Malade, PARIS, France, [2]Department of Pediatrics, Faculty of Medicine and Health Sciences, United Arab Emirates University, Al Ain, United Arab Emirates, [3]Service de Génétique Médicale, CHU, Nantes, France, [4]Service de Génétique Clinique, Hôpital Jeanne de Flandre, CHRU, Lille, France, [5]Génétique Médicale, CHU Estaing, Clermont-Ferrand, France, [6]Service de Génétique Médicale, Hôpital Arnaud de Villeneuve, CHU, Montpellier, France, [7]Génétique Médicale, hôpital d'Enfants de la Timone, Marseille, France, [8]of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark.

The short-rib polydactyly (SRP) group includes 4 lethal disorders i.e. type I Saldino-Noonan, type II Majewski, type III Verma-Naumoff, and type IV Beemer-Langer and 2 disorders compatible with life, namely asphyxiating thoracic dysplasia (ATD) and Ellis-van Creveld (EVC) syndrome. They are characterized by autosomal recessive inheritance, short ribs, short long bones, inconstant polydactyly and trident acetabular roof but distinct by variable malformations and metaphyseal changes. Recently, 6 genes encoding primary cilia proteins have been involved in the SRP group (EVC/EVC2, IFT80, DYNC2H1, NEK1 and TTC21B), confirming that this group belongs to the ciliopathy spectrum. We have also demonstrated that SRPIII and ATD belong to the same heterogeneous spectrum of conditions caused either by IFT80 or by DYNC2H1 mutations.

The aim of our study was to screen DYNC2H1 and IFT80 in 51 ATD/SRPIII consanguineous families or with sib recurrence and to identify other disease genes.

We identified no mutation in IFT80 but DYNC2H1 mutations in 16 cases and the screening is still in progress for 13 cases. Among 24 consanguineous families unlinked to DYNC2H1 or IFT80, a genome wide search was performed in 9 and led to the identification of 3 regions of homozygosity respectively for 3 families originating from Algeria, Turkey and Yemen. In each region of interest, candidate genes selected from the cilia database are currently tested.

We conclude that DYNC2H1 is involved in a significant part of ATD-SRPIII spectrum. Ongoing studies will hopefully lead to identify other disease genes presumably also involved in primary cilia function.

P12.023
Deafness due to mutations in *Otoferlin* gene (*OTOF*): additional identification of so far unreported mutations and unclassified variants

X. Pepermans[1], *N. Deggouj*[2], *M. Vast*[1], *K. Dahan*[1], *Y. Sznajer*[1];
[1]*Cliniques Universitaires Saint-Luc, Center for Human Genetic, U.C.L., Brussels, Belgium,* [2]*Cliniques Universitaires Saint-Luc, Deafness Clinic, Audiophonology and ENT Departement, Bruxelles, Belgium.*

Background: Auditory neuropathy spectrum disorders (ANSD) are characterised by preserved outer hair cells function (normal otoacoustic emissions and/or cochlear microphonic potentials) but inner hair cells and/or cochlear nerve disrupted function (abnormal auditory brainstem evoked potentials). ANSD may be caused by OTOF gene mutations (DFNB9)(so far 36 genes cause recessive form). We screened for OTOF gene mutations in belgian patients with ANSD.

Methods: Patients' DNA was studied after family history, clinical evaluation were completed (absence for syndromic form, thyroid dysfunction, heart rhythm, kidney or inner ear malformation; mutations in GJB2, GJB6 genes were excluded). Molecular investigation on DNA double-strand direct sequencing of the 46 coding exons of OTOF gene (NM_194248.2, long isoform, 1997 aa)(Dye Terminator Sequencing v3.1/ABI 3130xl) was performed. Exons 19-46 of the long isoform correspond to exons 1-28 of the short isoform (NM_004802.3, 1230 aa). Unclassified variants (UV) refer to changes absent from Ensembl and Uniprot databases or from publications.

Results: 10 unrelated patients, non consanguineous pedigree were included. None had temperature-sensitive auditory neuropathy. One patient was identified homozygous for the reported c.3269C>A mutations; one for compound heterozygous c.2401G>T and c.2402A>T mutations as well as UV (c.3608A>G). Four patients were identified with UV (one patient: c.2123G>A /c.2406+9G>A) and 1 UV (three patients with UV: p.Asn727Ser, p.Cys1251Gly, p.Arg1853Gln). 4 patients did not show any substitution. Parental screening is pending.

Conclusions

These results underline OTOF gene structure complexity (numerous mRNA isoforms and UV). Once identified, screening in parents/relatives and gene expression studies are needed to better understand their possibly pathogenic role.

P12.024
Mutations in *PYCR1* gene in three families with Autosomal Recessive Cutis Laxa, Type 2

D. Z. Scherrer[1], *M. B. Puzzi*[2], *C. V. Maurer-Morelli*[1], *C. E. Steiner*[1];
[1]*Department of Medical Genetics, University of Campinas (UNICAMP), Campinas, Brazil,* [2]*Department of Internal Medicine, University of Campinas (UNICAMP), Campinas, Brazil.*

Autosomal recessive cutis laxa, type 2 (ARCL2), is a rare disorder of connective tissue in which the skin sags excessively, giving to the individual an aged aspect. It has been suggested that ARCL2 is the same entity described under the denominations of wrinkly skin syndrome and gerodermia osteodysplastica. Such confusion is caused, in part, by overlapping of the histological and clinical findings, thus nosology remains uncertain until the definitive elucidation of the molecular basis of these conditions. In the present study we analyzed three unrelated families who presented clinically with ARCL2 for mutations in three genes implicated in several forms of cutis laxa; *ATP6V0A2*, *SCYL1BP1*, and *PYCR1*. No causative mutations were identified in *ATP6V0A2* and *SCYL1BP1* genes. However, screening for mutations in *PYCR1* revealed two new variant by direct DNA sequencing. Patients 1 and 2 were both homozygous for a missense alteration replacing the triplet CAG of the codon 10 by TAG, creating a stop codon that determined the loss of 298 codons. Patient 3 showed a homozygous missense alteration (c.722C>T; Ala241Val), however it will be necessary confirm if this variant is present or not in a large cohort of control individuals. It is important highlight that *PYCR1* gene performs a critical role in proline biosynthesis. The genetic changes found in this work contribute to the elucidation of the molecular basis of cutis laxa. Further studies should be conducted in individuals with other phenotypic presentation to establish the nosology of this group.

In Search of Oligogenicity in Bardet-Biedl Syndrome

L. Abu Safieh[1], *L. Al-Abdi*[1], *S. Al-Anazi*[1], *M. Hashem*[1], *H. Alkuraya*[1], *M. Alamro*[1], *M. O. Sirelkhatim*[1], *Z. Al-Hassnan*[2], *M. Alrashed*[1], *E. Faqeih*[3], *A. Suftah*[3], *A. Al-Hashem*[4], *J. Y. Mohamed*[1], *B. Alkuraya*[1], *M. Alsayed*[2], *A. O. Khan*[5], *L. Al-Gazali*[6], *S. Al-Hazzaa*[7], *F. S. Alkuraya*[1];
[1]*Department of genetics, King Faisal Specialist hospital, Riyadh, Saudi Arabia,* [2]*Department of medical genetics, King Faisal Specialist hospital, Riyadh, Saudi Arabia,* [3]*Department of Pediatrics, King Fahad Medical City, Riyadh, Saudi Arabia,* [4]*Department of Pediatrics, Riyadh Military Hospital, Riyadh, Saudi Arabia,* [5]*Department of Retina, King Khaled Eye Specialist Hospital, Riyadh, Saudi Arabia,* [6]*Department of Paediatrics, Faculty of Medicine & Health Sciences, Al-Ain, United Arab Emirates,* [7]*Department of surgery, King Faisal Specialist hospital, Riyadh, Saudi Arabia.*

Bardet-Biedl syndrome (BBS) is a model disease for ciliopathy in humans. The remarkable genetic heterogeneity that characterizes this disease is consistent with accumulating data on the interaction between the proteins encoded by the 14 BBS genes identified to date. Previous reports suggested that such interaction may also extend to instances of oligogenic inheritance that defies the long held view of BBS as an autosomal recessive disease. In order to investigate the magnitude of oligogenic inheritance in BBS, we conducted a comprehensive analysis of all 14 BBS genes as well as the *MGC1203* modifier gene in a cohort of 29 BBS families, most of which are multiplex. Two in *trans* mutations in a BBS gene were identified in each of these families for a total of 20 mutations including 12 that are novel. In no instance did we observe two mutations in unaffected members of a given family or observe the presence of a third allele that convincingly acted as a modifier of penetrance or even expressivity. In addition to presenting a comprehensive genotype/phenotype overview of a large set of BBS mutations, including the occurrence of nonsyndromic retinitis pigmentosa in a family with a novel *BBS9* mutation, our study strongly argues against the oligogenic model of BBS in the overwhelming majority of cases.

P12.026
Screening Iranian thalassemia intermedia patients with normal or carrier status of beta-globin gene for mutations in 5'HS3 and 5'HS4 LCR core regions and NF-E2

M. Neishabury[1], *A. Azarkeivan*[2], *S. S. Abedini*[1], *S. Zamani*[1], *H. Najmabadi*[1,3];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, tehran, Islamic Republic of Iran,* [2]*Thalassemia Clinic, Research Center, Iranian Blood Transfusion Organization (IBTO), tehran, Islamic Republic of Iran,* [3]*Kariminejad and Najmabadi Pathology and Genetics Center, Tehran, Islamic Republic of Iran.*

Analysing beta globin gene sequence in 114 Iranian individuals with thalassemia intermedia phenotype revealed homozygous or compound heterozygous beta-globin mutations to be the major primary disease factor in 86.2% of cases. However, 8.2% of these individuals were found to be heterozygous or wild type for beta-globin mutations. In search for determinants outside of the beta-globin gene, which could be responsible for the unexpected thalassemia intermedia phenotype in these subjects, we screened the alpha-globin genes, the 5'HS3 and 5'HS4 regions of the beta-globin LCR and the NF-E2 transcription factor for sequence variations in selected individuals. The -3.7 deletion was the only alpha-globin mutation detected, and no alterations were found in 5'HS3 and NF-E2. Sequence analysis of the 5'HS4 LCR core region identified three known SNPs in a single patient, who required irregular blood transfusions. The A/G polymorphism in the 5'HS4 palindromic region was also observed to be variable. Family studies were carried out on a female G/G homozygous patient , who received irregular blood transfusions. Her father, who had the same heterozygous IVSII-1 beta-globin mutation, but the A/G genotype at the 5'HS4 palindromic site, presented with mild anemia and no requirement for blood transfusions. This suggests an impact of SNPs in the 5'HS4 LCR core region on the thalassemia phenotype, and offers an interesting subject for further investigations in the Iranian population.

P12.027
Notch 1 mutations in patients with aortic aneurysm and bicuspidal valve

T. Nikulina, *O. Freilichman, A. Malashicheva, O. Irtuga, O. Moiseeva, A. Kostareva, E. Shlyakhto;*
Almazov Federal Centre of Heart, Blood and Endocrinology, St. Petersburg, Russian Federation.

NOTCH1 encodes for a transmembrane protein that activates a signaling pathway with an active role in cardiac embryogenesis, including aortic and pulmonary valve development.We, therefore, investigated the potential relationship between mutations in regions of *NOTCH1* recently reported to be associated with bicuspid aortic valve. We performed a sequencing analysis of 9 of coding exons (exons 10, 11, 12, 13, 20, 23, 29, 30, 34) of NOTCH1 gene in 47 patients with sporadic BAV. Our analyses revealed 17 NOTCH1 heterozygous variants in the analyzed patients. Nine are located within exons and 8 within intronic. Seven variants were described previously as polymorphisms. However, five coding substitutions and one silent were neither listed in public SNP databases nor in the literature and were therefore considered novel. Two novel nucleotide changes, one missense mutation c.3679 C > T located in exon 23 and one polymorphism c.7347 C > A located in exon 34, were nonsynonymous leading to amino acid substitutions (p.P1227S, p.S2449R, respectively). Out of five patients, one had bicuspidal valve and aortic aneurysm, two - aortic aneurysm and valve calcification and two bicuspidal valve, aortic aneurysm and valve calcification.

Four unique, nonsynonymous (2 novel) variants were identified in 4 (8,5%) of 47 patients with concomitant bicuspid aortic valves).

The principal finding of this targeted mutation analysis of the *NOTCH1* gene is the identification of one novel missense mutation among patients with BAV phenotype. The studies warrant further investigation into the role of *NOTCH1* missense variants in the pathogenesis of aneurysmal associated valve disease.

P12.028
A novel autosomal recessive cardiac and brain malformation syndrome in a consanguineous Indian family

M. J. DASOUKI[1], *W. G. Sanger*[2], *S. W. Cheung*[3];
[1]*University of Kansas Medical Center. Departments of Pediatrics & Internal Medicine., Kansas City, KS, United States,* [2]*University of Nebraska Medical Center. Munroe-Meyer Inst., Omaha, NE, United States,* [3]*Baylor College of Medicine. Department of Molecular and Human Genetics., Houston, TX, United States.*

Two siblings of healthy consanguineous Indian parents were born with congenital heart and brain malformations including double outlet right ventricular, bilateral frontal polymicrogyria, atrophy and periventricular cysts, agenesis of the corpus callosum, and atypical Dandy-Walker malformation. Both children (a brother and sister) died by 3 months of age. Routine blood chromosome analysis, FISH for DiGeorge syndrome and 1 Mb-BAC chromosomal microarray analysis (CMA) were all normal. However, CMA-SNP analysis identified a 7 Mb region of absence of heterozygosity (AOH) at chromosome 7p14 shared between these two affected siblings. This region contains 46 annotated genes, one of which (COBL) was identified as a strong candidate gene. Cordon-bleu (COBL) is a conserved and novel actin nucleation ciliary gene involved in neural tube formation in mouse and chick embryos. Direct sequencing and expression studies of COBL are pending.

P12.029
Gene expression profiling reveals novel insights into the molecular pathogenesis of brittle cornea syndrome and Ehlers-Danlos syndrome kyphoscoliotic type

P. Vlummens[1], *F. Malfait*[1], *A. Christensen*[2], *E. Rødahl*[2], *A. De Paepe*[1];
[1]*Center for Medical Genetics, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, Haukeland University Hospital, Bergen, Norway.*

Brittle cornea syndrome (BCS) is a rare autosomal recessive connective tissue disorder characterized by thin, fragile cornea leading to corneal rupture upon minor trauma, blue sclerae and joint and skin hyperlaxity. The condition is caused by mutations in *ZNF469*, encoding a Zinc Finger 469 protein of unknown function which belongs to the C_2H_2-zinc finger protein family. Clinical comparison reveals considerable overlap with Ehlers-Danlos syndrome kyphoscoliotic type (EDS VIA), caused by mutations in *PLOD1*. We performed direct sequencing of *ZNF469* in two consanguineous Turkish BCS families and identified novel homozygous *ZNF469* mutations, respectively c.6509_6512dupTCTT (p.Leu2171PhefsX99) in F1 and c.9792dupT (p.Ala3265CysfsX6) in F2. To unravel the molecular pathogenesis of BCS and the relationship with EDS type VIA, we studied gene expression profiles on the Affymetrix Human Gene 1.0 ST platform using patient's fibroblasts with either a homozygous frameshift (n=2) or missense (n=1) mutation in *ZNF469* alongside EDS VIA fibroblasts carrying *PLOD1* mutations (n=3). Comparison with wild type controls (n=6) identified deregulation of *COL8A1*, *PLOD2*, *LOXL2*, *FBN2* and *MMP12*, next to other extracellular matrix related genes, in both BCS and EDS VIA fibroblasts. Deregulation of several players of the Wnt-pathway, important in ocular embryogenesis, was also observed in both BCS and EDS VIA fibroblasts and implicate this developmental pathway in the pathogenesis of these connective tissue diseases. These novel findings suggest a role for the ZNF469 protein in connective tissue homeostasis and ocular development and provide important new insights into molecular pathways involved in EDS and related connective tissue diseases.

P12.030
A novel Brugada syndrome variant shown to be causal based on segregation analysis and familial genotypic-phenotypic correlation.

S. J. Van Dooren[1], *W. Lissens*[1], *S. Seneca*[1], *L. Peirsman*[1], *U. Ullmann*[1], *A. Sarkozy*[2], *P. Brugada*[2], ***M. Bonduelle***[1];
[1]*Centre for Medical Genetics, UZ Brussel and VUB, Brussels, Belgium,* [2]*Heart Rhythm Management Institute, UZ Brussel and VUB, Brussels, Belgium.*

Brugada syndrome is an autosomal dominant inherited disorder characterised by a primary cardiac arrhythmia in a structurally normal heart, with a propensity to sudden cardiac death. Genetic defects have mainly been attributed to mutations in the SCN5A gene, coding for the alpha subunit of the sodium channel, although they account for only 20% of cases.

SCN5A mutation analysis of all 27 translated exons and flanking intron-exon boundaries in our outclinic patient population revealed a novel variant c.4300-2 A>T in intron 24. This variant was discovered in one of our clinically diagnosed Brugada syndrome index patients with a spontaneous typical type I electrocardiogram (ECG) and a positive family history of Brugada syndrome.

In silico splice prediction analysis corroborates the omission of splicing through abolishment of the splice acceptor site at the intron24-exon25 boundary, thereby affecting the formation of the DIII/S5-S6 of alpha-subunit of the sodium channel.

To further investigate whether this variant is causal for Brugada syndrome we tested all available 10 family members for the presence of this variant. The sequencing analysis demonstrated that the mutation segregates within the family according to spontaneous or drug-induced (ajmaline) type I ECG and not within the ajmaline negative and type I ECG negative family members.

Detection of this variant in a control population is ongoing to further prove its pathogenic character.

P12.031
Compound heterozygous mutations D1690N and G1748D in *SCN5A* gene associated with the Brugada Syndrome

L. Núñez[1], *M. I. Rodríguez-García*[2], *I. Mosquera*[2], *X. Fernández*[3], *L. Cazón*[3], *M. Pérez*[3], *E. Álvarez*[3], *E. Maneiro*[3], *M. Ortiz*[3], *R. Barriales-Villa*[3], *D. García*[3], *E. Veira*[3], *A. Castro-Beiras*[2], *L. Monserrat*[2];
[1]*Universida de A Coruña. Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña, Spain,* [2]*CHUAC. Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña, Spain,* [3]*Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña, Spain.*

Purpose: Brugada Syndrome (BS) is an inherited cardiac disorder caused, in 20-25% of the cases, by mutations in *SCN5A* gene, which encodes for the alpha-subunit of the cardiac Na+ channel.

In this study, we identified two novel mutations in *SCN5A* in a BS patient.

Methods: To screen for mutations, the complete *SCN5A* coding region, including the intron/exon boundaries, was amplified by PCR and performed to direct sequencing. For each variant we made a prediction of the effect of mutation based on three online softwares

(Polyphen, PMUT and SIFT).
Results: Genetic analysis revealed that the proband carries two mutations, in exon 28, in two highly conserved amino-acids. The first one was a heterozygous mutation in c5068G>A, that causes the substitution D1690N in the linker between S5-S6 of the DIV of the channel. The second variant found was a G to A substitution at position c5243 that caused the mutation G1748D, which is located in the NH3 *termini* part of the segment S6 of the DIV of the channel.
Both mutations are predicted to affect protein function by the three softwares.
The familial study showed that the proband transmitted the G1748D mutation to a daughter. This result showed that the index case carried the mutations in separate alleles.
Conclusions: In this study, we described compound heterozygous mutations D1690N and G1748D in *SCN5A* associated with BS. The *in silico* analysis predicted that both mutations are pathogenic. Our data suggests an important role of compound heterozygosity in modulating the phenotypic expression of BS.

Analysis of coding sequence of SNTA1 gene in Russian BrugadaSyndrome patients

M. E. Polyak[1], *E. I. Gutovskaya*[1], *H. Abriel*[2], *E. V. Zaklyazminskaya*[1];
[1]*Petrovsky Russian Research Centre of Surgery RAMS, Moscow, Russian Federation,* [2]*University of Bern, Bern, Switzerland.*

Background. Brugada syndrome (BrS) is inherited cardiac arrhythmic disorder characterized by ST-segment elevation in right precordial leads, conduction disorders and high risk of cardiac sudden death. The SCN5A gene was identified as causative in 1998 and has been only one known for BrS for many years, though mutations in this gene account 15%-30% of all cases. Starting from 2007 the list of genetic variants was increased up to 8 but all those genes seems to be much less prevalent and does not explain vast of majority BrS cases.
The aim of our study is to screen the coding sequence of *SNTA1*gene. SNTA1 protein is associated with dystrophin complex and SCN5A sodium channel.
Patients and Methods. We observed a cohort of 16 patients with clinical diagnosis “Brugada syndrome”. We did performed full coding analysis of SCN5A gene and did start screening of SNT1A coding sequence in SCN5A-negative BrS patients.
Results. Three BrS patients were carried SCN5A mutations (19% of cases). In SNT1A gene we did find one rare missence genetic variant c.R106Q in exon 2 in affected person. Two intronic substitutions c.IVS2+112g>a and c.IVS2+82g>t were found in three unrelated patients.
Conclusion. New rare genetic variants had been found in Russian BrS cohort (about 8%).To elucidate possible causative role of c.R106Q change in*SNTA1*gene further investigations are required. Population analysis of ethnically-matched controls and functional analysis of mutant protein will be performed.
This work has been supported by grants: SNSF SCOPES Project 2010-2013- Cardiac Channelopathies; Russian Ministry of Education and Science contract 2010-1.1-203-060.

P12.033
Exploration of microRNAs that mis-target SCN5A as a new mechanism for Brugada Syndrome

R. A. Peat[1,2], *S. Duchatelet*[1,2], *S. Maugenre*[1,2], *M. Berthet*[1,2], *D. Klug*[3], *I. Denjoy*[1,4], *F. Hidden-Lucet*[5], *A. Leenhardt*[4], *P. Guicheney*[1,2];

Brugada syndrome (BrS) is an autosomal dominant cardiac disorder associated with ventricular fibrillation and sudden death. About 20% of patients have mutations in SCN5A resulting in a loss of functional cardiac sodium channels. Rare mutations do exist in other genes, however, the genetic origin of BrS in the majority of patients remains unknown.
We aim to determine if rare variants in the SCN5A 3’UTR region can modulate channel expression by creating novel, (or by enhancing existing), targets of microRNAs. MicroRNAs are short single-stranded RNAs, which, when bound to specific targets in mRNA transcripts, cause post-transcriptional repression of protein expression. We sequenced the SCN5A 3’UTR (2384bp) in a cohort of 97 BrS patients without mutations in the SCN5A coding regions or other tested genes. Thirteen known SNPs and two new heterozygous variants were identified; c.*539A>G and c.*1677G>A, neither of which were detected in more than 150 controls.
In silico analysis of the two variants was performed using on-line programs predicting microRNA targeting to a given nucleotide sequence. Several microRNAs reported to be expressed in the heart were found to target the new variant 539, however we excluded the possibility that variant 1677 creates new target sites for microRNAs. We are pursuing the candidate microRNAs with in vitro studies.
It’s not known if SNPs in the 3’UTR can play a role in the regulation of SCN5A, however, we propose that these, or new variants, could cause or influence disease severity in BrS or other arrhythmias via the action of microRNAs.

Background: Idiopathic dilated cardiomyopathy (DCM) is a clinically highly heterogeneous disorder, characterized by dilation and impaired contraction of the left ventricle. Monogenic inheritance is observed in one-third of the idiopathic cases and mutations in the >40 known genes explain only ~25% of familial cases. In order to identify novel DCM disease genes, we investigated two DCM families by Haplotype Sharing Test (HST) combined with exome sequencing.
Methods: To localise novel DCM genes, 250K SNP genotyping was performed to identify regions shared between patients from a single pedigree. The HST was applied to (I) a family with 4 DCM and 2 peripartum cardiomyopathy patients and (II) a family with 3 DCM patients and 1 patient with reduced left ventricular function. To subsequently identify the corresponding disease genes, DNA of the index-patient and an affected relative from each family were analysed by exome sequencing.
Results: The HST revealed largest shared haplotypes of 71 cM on chromosome 15 containing ~600 genes (family I) and 46 cM on chromosome 9 containing ~475 genes (family II). Exome sequencing revealed potentially pathogenic variants shared by the two affected family members in both families. Confirmation by Sanger sequencing and carriership analysis in affected family members and healthy controls is in progress.
Conclusions: We identified potentially pathogenic variants in the largest shared haplotypes in two DCM families. Our results show that a combination of the HST and exome sequencing is a promising approach to identify novel genes underlying familial cardiomyopathies.

Cardiomyopaties are the most common disorders resulting in heart failure. Dilated cardiomyopathy (DCM), a disorder characterized by cardiac dilatation and reduced systolic function, is the most frequent cause. However, recessive neonatal isolated dilated cardiomyopathy has scarcely been associated with a mutation. We have identified patients with acute DCM in one tribe with consanguineous family of the Bedouin population. Three subfamilies contain five patients and four healthy siblings were investigated. The disease appears to be familial, with an autosomal recessive pattern of inheritance. SNPs array and then linkage analysis was performed using polymorphic microsatellite markers to confirm the linkage region on chromosome 2[2q35-2q36.3] with 10cM and to construct the haplotypes. The highest lod score for this region was 3.5 with two point analysis.

P12.036
Identification of a new chromosomal locus for a mutation causing Left ventricular non-compaction with ventricular tachycardia cardio-pathology.

R. Parvari[1,2], *E. Muhamad*[1], *V. C. Sheffield*[3], *A. Levitas*[4];
[1]*Ben Gurion University of the Negev, Beer Sheva, Israel,* [2]*National Institute of Biotechnology Negev, Beer Sheva, Israel,* [3]*University of Iowa, Iowa City, IA, United States,* [4]*Soroka Medcal Center, Ben Gurion University of the Negev, Beer Sheva, Israel.*
Structural and functional disorders of the heart are important causes of morbidity and mortality. Three Bedouin patients at ages 14-18 years of a single large consanguineous Bedouin family presented with Left ventricular non-compaction and sustained Ventricular Tachycardia. They were evaluated by Echocardiography which showed severe left side enlargement, severely depressed left ventricular (LV) function with focal lacunas in the LV free wall, but normal origin of the coronary artery. The 2 older patients were treated with recurrent electrical cardio version and intravenous administration of amiodarone and on discharge have undergone implantable cardioverter-defibrillator (ICD) implantation. The recessive pattern of inheritance in the consanguineous family suggested homozygosity of the mutation inherited from a common founder. We have performed homozygosity mapping using the affymetrix SNP 5 array on the patients and found a single large chromosomal block of homozygosity on chromosome 11q24 shared by all of them. Verification of this block with VNTR markers in all available family members proved linkage. The Lod score analysis, under the model of a recessive trait with full penetrance, using the PedTool server, was 2.46 for 2 point with marker D11S4958 and 4.59 for the multipoint analysis.
This chromosomal locus does not contain any of the known genes causing this disease; efforts are now being done to identify the mutated gene.

P12.037
New phenotype variance in the background of dynamin2 mutation

A. Gal[1], *L. Geller*[2], *E. Pal*[3], *B. Bereznai*[1], *Z. Szelid*[2], *G. Inczedy-Farkas*[1], *B. Merkely*[2], *M. J. Molnar*[1];
[1]*Clinical and Research Centre for Molecular Neurology, Semmelweis University, Budapest, Hungary,* [2]*Heart Center, Semmelweis University, Budapest, Hungary,* [3]*Department of Neurology, University Pecs, Pecs, Hungary.*
Background: Dynamin-2 (DNM2) gene mutations cause two district human diseases: Charcot-Marie-Tooth disease (CMT) and centronuclear myopathy (CNM)). Here we report a 47 years-old women with severe cardiomypathy and centronuclear myopathy.
Methods: The patient underwent detailed neurological, cardiological, electrophysiological, myopathological and genetic sequence analysis.
Result: Left bundle branch block was first detected at age 40. The echocardiogram showed diffuse hypokinesis, with severe left ventricular dysfunction and dysyncrony. No coronary artery disease was detected and cardiac resyncronization device therapy was performed. The neurological symptoms started at age 42. Neurological investigation detected ptosis on the left side, strabismus convergent, myopatic face, atrophy and weakness in the small hand muscles, decreased tendon reflexes. The EMG found a myopathy and complex repetitive discharges. The exercise lactate test showed aerobe metabolic dysfunction. Muscle biopsy detected centronuclear myopathy. The DNM2 mutation analysis found a pathogenic heterozygous c. 1105 C>T (p. R369W) mutation in the exon 8 and 3 other polymorphisms.
Conclusion: It is the first case which reports about severe cardiomyopathy related to DNM2 gene mutations resulting in centronuclear myopathy. Our data broaden the phenotypic spectrum of the symptoms due to DNM2 mutations.

P12.038
MYBPC3-Glu258Lys related Hypertrophic Cardiomyopathy: a founder effect in Tuscany

S. Bardi[1], *F. Girolami*[1], *I. Olivotto*[1], *L. Berti*[1], *T. Pippucci*[2], *F. Cecchi*[1], *F. Torricelli*[1];
[1]*Referral Center for Myocardial Diseases, Genetic Diagnostic Unit, Careggi University Hospital, Flore, Florence, Italy,* [2]*Medical Genetic Laboratory, Policlinico S. Orsola-Malpighi ,University of Bologna, Italy., Bologna, Italy.*
Background: MYBPC3 is the most common gene involved in HCM. Even if the majority of mutations identified are novel, it is possible to find some recurrent pathogenic mutation. A few founder mutations have been reported, and most of them are in the MYBPC3 gene. Interestingly, the occurrence of a founder effect has never been reported in Italy.
Objectives: The aim of the present study was to describe a founder effect in Tuscany caused by MYBPC3-Glu258Lys mutation.
Methods and Results: A total 401 Italian unrelated index HCM patients underwent screening for myofilament gene mutations by direct sequencing of 8 genes, including MYBPC3, MYH7, TNNI2, TNNI3, ACTC, TPM1, MYL2 and MYL3. In 135/401 (34%), a MYBPC3 mutation was identified. Of them, 42 were consecutive unrelated probands born in the Mugello valley in Tuscany, who harboured the same MYBPC3 Glu258Lys pathogenic mutation. Haplotype analysis examined in 4 families using 9 intragenic SNPs or STRs, showed a unique haplotype covering a 2Mb genomic region. To confirm these results, haplotype analysis was performed all 42 index cases and 100 healthy adult subjects, born in the same geographical region of Tuscany.
Conclusions: We have identified a novel founder mutation in the MYPC3 gene (Glu258Lys) causing HCM in a Tuscan valley. The presence of a common haplotype suggests that all affected families share the same ancestry.

P12.039
Mitochondrial $tRNA^{Gln}$ (m.4395A>G) mutation manifesting as hypertrophic cardiomyopathy

S. MAHJOUB[1,2], *s. MEHRI*[1,2], *F. OUARDA*[3], *C. JARDEL*[4], *J. FINSTERER*[5], *M. HAMMAMI*[6], *S. BEN ARAB*[1];
[1]*Faculté de Médecine de Tunis, Tunis, Tunisia,* [2]*Faculté de Mèdecine, Monastir, Tunisia,* [3]*Service de cardiologie pédiatrique, CHU la rabtaTunis, Tunisia,* [4]*Laboratoires de Biochimie et de Génétique. Service de Biochimie Métabolique - Unité de Génétique, Hôpital Pitié-Salpêtrière, Paris, France,* [5]*FaKrankenanstalt Rudolfstiftung, Danube University Krems,, Vienne, Austria,* [6]*Faculté de Médecine, Monastir, Tunisia.*
Background: Defects of the mitochondrial genome are responsible for a heterogeneous group of phenotypes, including cardiomyopathies (CMPs). Several point mutations of the mitochondrial deoxyribonucleic acid (mtDNA) have been identified as a cause of hereditary CMP. The majority of pathogenic mutations are heteroplasmic, with mutated and wild-type mtDNA coexisting within the same mitochondrion. Homoplasmic mutations are challenging in terms of diagnosis and assigning pathogenicity, as human mtDNA is highly polymorphic.
Hypothesis: The present study concerns a family with hypertrophic cardiomyopathy (hCMP), which segregated with matrilinear transmission.
Methods: Double-stranded DNA products generated for denaturing gel electrophoresis (DGGE) analysis were subjected to direct sequencing using a 48 capillaries Abiprism 3730 sequencer (Applied Biosystems®) with Big Dye terminator v3.1 sequence kit and SeqScape2.5 software for sequence analysis".
Results: The 14-year-old index male presented with hCMP, preexcitation syndrome, and severe ventricular arrhythmias. mtDNA sequencing revealed the m.4395A>G transition in the mitochondrial $tRNA^{Gln}$ gene, which was shown to be homoplasmic by DGGE. The m.4395A>G mutation altered an evolutionary conserved nucleotide and affected a highly conserved U.G pair in the secondary structure of $tRNA^{Gln}$. The mutation was absent in 350 healthy subjects and was

scored as “possible pathogenic” by the Clustal-W-program.
Conclusions: This study shows the association of the homoplasmic m.4395A>G mutation in the $tRNA^{Gln}$ gene with hCMP. To study the impact of this mutation and its contribution to the pathophysiology of mitochondrial hCMP, transgenic mice with distinct mutations could be helpful.

P12.040
Expansion of a diagnostic service for hypertrophic cardiomyopathy using next generation sequencing.

J. Woodley[1], *S. Reid*[1], *K. Kaur*[2], *K. Thomson*[1], *J. Taylor*[1], *E. Blair*[3], *J. Taylor*[2], *H. Watkins*[4], *A. Seller*[1];
[1]*Oxford Molecular Genetics Laboratory, Oxford, United Kingdom,* [2]*Biomedical Research Centre, Oxford, United Kingdom,* [3]*Department of Clinical Genetics, Oxford, United Kingdom,* [4]*Department of Cardiovascular Medicine, Oxford, United Kingdom.*

Since 2003 the Oxford Molecular Genetics Laboratory (OMGL) has provided a diagnostic service for hypertrophic cardiomyopathy (HCM); a condition with an estimated prevalence of 1/500, reported to be the most common cause of sudden cardiac death in young athletes and people under 35 years of age. Currently, mutation screening of the four most commonly associated genes (*MYH7, MYBPC3, TNNT2* and *TNNI3*) is undertaken using a high resolution melt analysis (Lightscanner™)/ Sanger sequencing approach. To date, analysis has been undertaken in >1300 probands; clinical sensitivity in this cohort was ~47%.
A next generation sequencing approach has the potential to increase clinical sensitivity by expanding the number of genes that can be screened in parallel whilst also reducing reporting times for a similar cost.
In collaboration with the OMGL, the Oxford Biomedical Research Centre (BRC) has validated a next generation sequencing protocol. Using the Roche 454 GS-FLX platform a significant increase in clinical sensitivity was observed in a cohort of 231 patients using an expanded gene panel including *TPM1, ACTC1, MYL2, MYL3, CSRP3, PRKAG2, PLN, GLA, LAMP2, FHL1* and the mitochondrial genome in addition to those previously analysed.
Implementation into the diagnostic laboratory requires stringent validation in order to meet quality and regulatory requirements. The process from sample receipt to reporting must be robust to be useful in the routine environment. Here we present the development of a workflow algorithm incorporating robotics and third party analysis software which demonstrates that this sequencing technology has clinical utility as a diagnostic strategy for HCM.

P12.041
Minigene functional assay of a splice mutation of the MYBPC3 gene in hypertrophic cardiomyopathy

E. Maioli[1], *M. Marini*[2], *M. I. Parodi*[1], *M. L. Galli*[1], *M. Castagnetta*[1], ***D. A. Coviello***[1], *R. Ravazzolo*[2], *P. Spirito*[1], *L. Perroni*[1];
[1]*E.O. Ospedali Galliera, Genova, Italy,* [2]*IRCCS, Istituto Giannina Gaslini, Genova, Italy.*

Hypertrophic cardiomyopathy (HCM) is a very common genetic cardiac disease and represents the most common cause of sudden cardiac death in the young. The main genes involved are MYH7, MYBPC3, TNNT2, TNNI3, TPM1and ACTC1. HCM is characterized by a marked genetic and phenotypic heterogeneity. In case of novel mutations at splice sites or adjacent regions, analysis of mRNA is virtually unfeasible because of the lack of cardiac tissue, where sarcomeric genes are expressed. Here we report on a minigene assay used to overcome this problem in a case of an undescribed putative splicing mutation in the MYBPC3 gene. A HCM affected newborn, deceased at 15 days, was double heterozygous for two mutations of the MYBPC3 gene c.772G>A and c.2414-1G>A. The paternal mutation c.772G>A was reported as causative of HCM. The c.2414-1G>A mutation, involving a splice site was inherited from the unaffected mother and never reported in the scientific literature. It was absent in 500 control chromosomes. As no cardiac tissue of the proband was available, mRNA could not be tested. Therefore a minigene assay was performed. Fragments corresponding to exons 25-26 of the MYBPC3 gene from the wild type and the mutant alleles were separated by TA cloning using the proband’s mother genomic DNA. The two allelic fragments were inserted into the pSPL3 eukaryotic vector. The plasmids were transfected into HeLa cells. After reverse transcription of the extracted RNA, the resulting cDNAs were sequenced and compared. The mutant construct generated a product in which exon 26 was skipped.

P12.042
Identification of seven novel CRLF1 mutations in Crisponi Syndrome and of a founder mutation in the French gypsy population

A. S. Lebre[1,2,3], *S. J. Dumas*[2,4], *N. Dagoneau*[3], *Y. Alanay*[5], *A. Baban*[6], *E. Bieth*[7], *B. Isidor*[8], *E. Kiliç*[5], *B. Leheup*[9], *A. Moncla*[10], *S. Sigaudy*[10], *J. P. Bonnefont*[1,2,3], *A. Munnich*[1,2,3], *V. Cormier-Daire*[1,2,3];
[1]*Université Paris Descartes, Paris, France,* [2]*APHP, Paris, France,* [3]*Inserm U781, Paris, France,* [4]*Université Paris-Sud XI, Chatenay-Malabry, France,* [5]*Hacettepe University, Ankara, Turkey,* [6]*Gaslini Children Hospital, Genova, Italy,* [7]*CHU de Toulouse, Toulouse, France,* [8]*CHU de Nantes, Nantes, France,* [9]*CHU de Nancy et EA4368 - PRES de l’Université de Lorraine, Vandoeuvre-les-Nancy, France,* [10]*Hôpital Timone-enfants AP-HM, Marseille, France.*

Crisponi syndrome (CS) is a rare and severe autosomal recessive disorder (MIM ID #601378) characterized by contractions of the facial muscles in response to stimuli or during crying, facial dysmorphic features, camptodactyly, major early feeding, respiratory difficulties and hyperthermic episodes, frequently leading to early death from hyperthermia or apnea during the first year of life. CS is caused by mutations in the cytokine receptor-like factor 1 (CRLF1 gene) and is allelic to Cold-Induced Sweating Syndrome type 1 (CISS1). We describe here the clinical and genetic features of ten patients with CS from eight families and seven new CRLF1 mutations. For a further delineation of CS, we performed a meta-analysis of the literature and describe the phenotypic spectrum of all patients with CRLF1 mutations. CS and CISS1 are most probably a single clinical entity with common symptoms and different presentations depending on the patients’ age at diagnosis.
In addition, the homozygous duplication c.713dupC was identified in three patients from French Gypsy families with CS. A common haplotype that segregated with the disease in the three families was detected by haplotype reconstruction with six markers (microsatellites) which span ~4 Mb of DNA covering the CRLF1 locus. In conclusion, we report new CRLF1 mutations and the first founder mutation in the French Gypsy population.

P12.043
The first experience of molecular-genetic analysis of CADASIL in Serbia

M. Z. Jankovic[1], *V. Dobricic*[2], *I. Novakovic*[1,2], *E. Dzoljic*[2], *N. Stojsavljevic*[2], *A. Pavlovic*[2], *V. Kostic*[1,2];
[1]*School of medicine, University of Belgrade, Belgrade, Serbia,* [2]*Institute of Neurology, Clinical Center of Serbia, Belgrade, Serbia.*

Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencaphalopathy (CADASIL) is hereditary form of stroke with prevalence of 2/100.000 adults. Beside stroke-like episodes, cognitive disturbance, behavioral abnormalities and migraine with aura are common features of CADASIL. CADASIL is caused by mutations in *NOTCH3* gene and more than 150 *NOTCH3* mutations have been described so far. Majority of them are missense mutations, leading to loss or gain of cysteine and resulting in odd number of cysteine residues within one of the EGF-like domains. It has been shown that almost 90% of mutations occur in exons 2-6. Therefore, as the first step in establishing molecular genetic testing for CADASIL in our country, we performed direct sequencing of those five exons of *NOTCH3* gene. We analyzed DNA samples of 40 patients clinically suspected to CADASIL. DNA sequencing was performed using ABI 310 Genetic Analyzer. Four different mutations in seven patients (one sibling pair, one sibling trio, and two single cases) were detected: Cys65Tyr (exon 2), Gly89Cys (exon 3), Arg90Cys (exon 3) and Ala319Cys (exon 6). According to our data, mutation Cys65Tyr has not yet been described in the literature.
In conclusion, we have successfully started with genetic testing of CADASIL in Serbia. However, relatively low frequency of mutations in tested patients (18.92%) indicates that in the further CADASIL testing stricter clinical criteria should be introduced and also mutation analysis of the remaining *NOTCH3* exons should be developed.

P12.044

Very High Sensitivity Somatic Mutation Detection using Ice COLD-PCR and BLOCker Sequencing

***P. Eastlake**, B. Legendre Jr, G. Wu, Y. Shi, R. Lin, T. Woodford, K. Echtenkamp, J. Scott, S. Peterson, K. Richardson;*
Transgenomic, Inc., Omaha, NE, United States.

Transgenomic has developed very high sensitivity methods for detecting somatic mutations notably in the discipline of cancer therapy where key genetic changes are associated with EGFR antagonists' effectiveness, e.g. in the genes EGFR, K-RAS, PIK3CA, BRAF, p53 and NRAS. The novel techniques of Ice COLD-PCR and BLOCker Sequencing preferentially enrich mutant alleles compared to wild-type alleles. These are not allele-specific techniques; therefore all mutations, both known and unknown, are enriched and identified in a single reaction. Together these methods allow mutations at concentrations as low as 0.01-0.05% in background of wild-type to be confirmed by sequencing. Additionally Ice COLD-PCR and BLOCker Sequencing require no special equipment using only standard DNA thermocyclers and Sanger sequencing equipment. Data will be presented showing how these methods allow DNA sequencing confirmation of somatic mutations in samples such as low tumor-load biopsies, formalin-fixed paraffin-embedded slides, fine-needle aspirates, circulating tumor cells and circulating free tumour DNA in plasma and serum. These methods can also be used to confirm low signal Pyrosequencing and next-generation deep-sequencing results. Using these techniques routine, rapid, simple and inexpensive detection of somatic mutations in (1) cancer patients' plasma or serum or; (2) samples where very limited tumour tissue is available, offers a non-invasive option for cancer biomarker detection as well as monitoring remission, relapse and emergence of resistance mutations post-treatment. Finally Ice COLD-PCR and BLOCker Sequencing can be applied to analysis of mixed viral infections and mitochondrial heteroplasmies.

P12.045***

Detection of low frequency variation in heterogeneous samples using an accurate and sensitive next generation sequencing platform

*M. Storm[1], **R. Padilla**[1], J. Ichikawa[1], M. Rhodes[1], Y. Sun[1], L. Joe[1], M. Matvienko[1], D. W. Craig[2], J. Aldrich[2], A. Christoforides[2], D. Taverna[2], T. Moses[2], J. D. Carpten[2], D. Duggan[2], F. Hyland[1];*
[1]Life Technologies, Foster City, CA, United States, [2]The Translational Genomics Research Institute (TGen), Phoenix, AZ, United States.

Cancers often display biological and molecular heterogeneity with a variety of genetic abnormalities. Specific genetic mutations can alter the course of disease progression, metastasis, and drug resistance. Some mutations in cancer are prevalent at a low frequency in clinical samples, often due to contamination of tumor samples with normal alleles from adjacent non-malignant cells. The identification of genetic variants resulting from sub-populations is important to better understand the causal biology of cancer. Second-generation sequencing can identify low frequency alleles resulting from cellular sub-populations. Here we describe the reliable detection of alleles occurring at very low frequencies in heterogeneous samples by utilizing the accuracy of the SOLiD System. We demonstrate that the SOLiD System with Exact Call Chemistry (ECC) provides a highly accurate approach to detecting low frequency variants in cancer research and other applications.

P12.046

Mutation screening of CRYAA, CRYGC, CRYGD and GJA8 genes associated with congenital cataract in Indian patients

***M. Kumar**[1], T. Agarwal[2], S. Khokhar[3], R. Dada[1];*
[1]Lab for Molecular reproduction and Genetics, All India Institute of Medical Sciences, New Delhi, India, [2]Dr. RP Center for Ophthalmic Sciences, All India Institute of Medical Sciences, New Delhi, India, [3]Dr. RP Centre for Ophthalmic Sciences, All India Institute of Medical Sciences, New Delhi, India.

The purpose of this study was to investigate mutations in CRYAA, CRYGC, CRYGD and GJA8 in Indian patients with congenital cataract. Thirty clinically diagnosed congenital cataract cases below 3 years of age from northern India were enrolled in this study. Genomic DNA was extracted from peripheral blood, all coding and exon/intron regions were amplified using PCR and direct sequencing was performed to detect any nucleotide variation. ProtScale and Discovery Studio programs were used for insilico and structural analysis. DNA sequencing analysis of CRYAB, CRYGC, CRYGD and GJA8 showed total of six variations of which two were novel (CRYGC:p.R48H), (GJA8:p.L281C) and four have been previously reported (CRYAB: rs11603779T>G) (GJA8:p.L268L,), (CRYGD:p.R95R, c.T564C). Both the novel changes, in CRYGC and GJA8 genes were found in 16.6% of the patients. Previously reported nucleotide alterations (CRYGD:p.R95R, c.T564C) were found in 90% of the patients. Insilico and structural analysis data suggested that two novel non-synonymous mutations altered the stability and solvent accessibility of CRYGC and GJA8 proteins which may lead to lens opacification. We observed two novel nonsynonymous variations and four reported variations in CRYAB, CRYGC, CRYGD and GJA8 genes. The p.R48H variation in γ-crystallins C may disrupt the normal structure of lens and can cause cataract. Cx50 is responsible for joining the lens cells into a functional syncytium and mutation (p.L281C) in this gene may lead to lens opacification resulting in cataract formation. This study further expands the mutation spectrum of congenital cataract and help understanding how mutant proteins can lead to opacification of lens.

P12.047

Novel missense mutations of RYR2 gene in catecholaminergic polymorphic ventricular tachycardia patients.

***I. Valášková**[1,2], J. Kadlecová[1,2], E. Švandová[1], R. Gaillyová[1,2], T. Novotný[3];*
[1]University Hospital Brno, Medical Genetics Dpt., Brno, Czech Republic, [2]Masaryk University, Faculty of Medicine, Brno, Czech Republic, [3]University Hospital Brno, Internal and Cardiological Dpt., Brno, Czech Republic.

BACKGROUND: Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a rare inherited heart disease, which can lead to life-threatening ventricular arrhythmias in patients with a structurally normal heart., and may provide a candidate for sudden cardiac deaths CPVT is caused by mutations in the RyR2 gene encoded the ryanodine receptor isoform 2 (RyR2), This calcium release channel is an essential intracellular ion channel that is central to Ca(2+) signaling and contraction in the heart .

METHODS: We screened 35 patients with CPVT and available family members for mutations in the RyR2 gene Mutation screening of RyR2 gene was performed on genomic DNA samples extracted from peripheral blood. PCR amplified fragments covering areas mutative critical exons 2-4, 6-15, 17-20, 39-49, 83, 84, 87-97-105 were analyzed by sequencing. For mapping of the deletions RYR2 exons, we used probes for multiplex ligation-dependent probe amplification (MLPA) analysis.

RESULTS: We identified three novel RyR2 missense mutations M4107V, E4182A and S4122R in three CPVT patients. These RYR2 variants were found in evolutionally conservative area of RYR2 genomic sequence. The carriers of these mutations exhibited frequently syncope, their age of onset was between nine and 10 years and their treatment consists of beta blockers.

CONCLUSIONS: Based on their character it can be assumed that identified sequential changes are causal mutations, thus the mutations responsible for the CPVT phenotype. However, the proposed theory must be proved within a group of 100 healthy controls.

P12.048

Molecular analysis of the *SEC23B* gene in patients affected by Congenital Dyserythropoietic Anemia Type II (CDAII)

***F. Punzo**[1], S. Scianguetta[2], A. M. Bertoli-Avella[1], M. Casale[2], B. A. Oostra[1], A. Iolascon[3], S. Perrotta[2];*
[1]Department of Clinical Genetics, Erasmus Medical Centre, Rotterdam, Netherlands, [2]Pediatric Department, Second University of Naples, Naples, Italy, [3]CEINGE-Advanced Biotechnologies, Naples, Italy.

Congenital Dyserythropoietic Anemia type II (CDAII), the most frequent type of CDA, is an autosomal recessive disease characterized by ineffective erythropoiesis, peripheral hemolysis, erythroblast morphological abnormalities and hypoglycosylation of some red blood cells membrane proteins. Recently, we and others identified mutations in *SEC23B* as responsible for CDAII. SEC23B is a member of the SEC23/SEC24 family, a component of COPII coat protein complex

which is involved in protein trafficking through membrane vesicles from the endoplasmic reticulum to the Golgi apparatus. The aim of the study was to characterize the molecular defect in CDAII patients of Italian origin.
Sixteen CDAII index patients from unrelated families were analyzed by direct exon sequencing. We identified 15 different mutations, four of which were novel (p.Gln214Stop, p.Thr485Ala, p.Val637Gly, p.Ser727Phe). In particular, four patients were carrying homozygous missense mutations and 10 patients were compound heterozygotes (five patients carried a missense and a non-sense mutation and five carried two different missense mutations). The new mutations affected highly conserved aminoacids and were not found in 200 controls. The mutations lead to a 50% decrease in mRNA expression levels of *SEC23B* in lymphocytes and erithroid precursors of patients with missense/non-sense mutations compared to controls. Despite the sequencing of all exons and flanking intronic regions, two patients displayed a single heterozygous mutation, suggesting that mutations could also be located in non-coding regions. Other possibility could be the presence of copy number alterations within the gene. Alternatively, we cannot exclude that a second gene could be involved in the pathogenesis of CDAII.

Rett syndrome is a progressive neurologic disorder that represents one of the most common causes of mental retardation in females. Mutations in *CDKL5* gene have been identified in females with the early onset seizure variant of Rett syndrome and also in males with X-linked epileptic encephalopathy. CDKL5 is a kinase protein highly expressed in neurons, but its exact function inside the cell is unknown. To address this issue we established a human cellular model for *CDKL5*-related disease using the recently developed technology of induced pluripotent stem cells (iPSCs). iPSCs can be expanded indefinitely and differentiated in vitro into many cell types, including neurons. These features make them the ideal tool to study disease mechanisms directly on the primarily affected neuronal cells. We successfully derived iPSCs from fibroblasts of two CDKL5-mutated female patients affected by early onset seizure variant of Rett syndrome and one male with X-linked epileptic encephalopathy. We demonstrated that our female *CDKL5*-mutated iPSCs maintain X-chromosome inactivation and we identified clones expressing either the mutant *CDKL5* allele or the wild type allele. These last clones represent the ideal experimental control since they are genotypically identical to those expressing the mutant allele and differ only for CDKL5 expression. Furthermore, our data indicate that both *CDKL5*-mutated iPSCs can be differentiated into neurons and are thus suitable to model disease pathogenesis in vitro.

CFHR5 nephropathy: a new inherited hematuric glomerulopathy with increased frequency in Cyprus due to a founder mutation

***K. Voskarides**[1], Y. Athanasiou[2], D. Gale[3], L. Damianou[4], P. Maxwell[5], P. Demosthenous[1], A. Pierides[6], C. Deltas[1];*
[1]University of Cyprus, Nicosia, Cyprus, [2]Nicosia General Hospital, Nicosia, Cyprus, [3]Imperial College Kidney and Transplant Institute, London, United Kingdom, [4]Limassol General Hospital, Limassol, Cyprus, [5]University College, London, United Kingdom, [6]Hippocrateon Hospital, Nicosia, Cyprus.

Our team contributed to the molecular investigation of a new autosomal dominant renal disease, seeming to be endemic in Cyprus, which is characterized by microscopic and synpharyngitic macroscopic hematuria, renal failure and C3 glomerulonephritis. The only mutation found thus far in complement factor H related protein 5 (*CFHR5*) gene, is a duplication of exons 2-3 resulting in reduced affinity for glomerular-bound complement.
Here we present clinical data from 16 families, some being very large, with 105 patients sharing this common mutation due to an extended founder effect. Families originate mainly from one of two geographic regions of Cyprus. Heterozygous carriers of the duplication were detected via a simple PCR test using three specific primers. An additional gap PCR test was designed to detect probable homozygous carriers. No homozygous carrier was found. The most striking finding is the big difference between the two genders as regards progression to proteinuria, chronic renal failure (CRF) and end stage renal disease (ESRD). Proteinuria with CRF or ESRD developed on top of hematuria in 68% male patients instead of 14% female patients aged over 50-yo. Fifteen men reached ESRD compared to only three women. The disease penetrance is nearly 90%, as 10 mutation carriers were symptomless.
These data stress the wide clinical spectrum of *CFHR5* nephropathy, a new disease entity, characterized by high risk for renal failure especially in males. Based on our experience, it is probable that some patients with CFHR5 nephropathy and episodes of macroscopic hematuria may be misdiagnosed with IgA nephropathy.

P12.051
A DNA variant within the 3'-UTR of HBEGF alters the regulatory action of hsa-miR-1207-5p and is associated with progression of renal failure in CFHR5 nephropathy

***G. Papagregoriou**[1], H. Dweep[2], K. Voskarides[1], P. Koupepidou[1], Y. Athanasiou[3], A. Pierides[4], N. Gretz[2], K. N. Felekkis[5], C. Deltas[1];*
[1]University Of Cyprus, Nicosia, Cyprus, [2]Medical Research Center, University of Heidelberg, Mannheim, Germany, [3]Department of Nephrology, Nicosia General Hospital, Nicosia, Cyprus, [4]Department of Nephrology, Hippocrateon Hospital, Nicosia, Cyprus, [5]Department of Life and Health Sciences, University of Nicosia, Nicosia, Cyprus.

HBEGF (Heparin Binding Epidermal Growth Factor) is expressed in podocytes and was shown to play a role in glomerular physiology. MicroRNA binding sites on the 3'-UTR of HBEGF were predicted using miRWalk software followed by sequence analysis in 162 patients diagnosed with mild or severe glomerulopathy. A single nucleotide polymorphism, mirSNP C1936T (rs13385) of the 3'-UTR, was identified at the second base of the seed region of microRNA hsa-mir-1207-5p. AB8/13 undifferentiated podocytes were transfected with miRNA mimics of hsa-mir-1207-5p and HBEGF protein levels were reduced by 50%. An extensive sequence containing the mirSNP allele-1936C was then cloned into the pMIR-Report Luciferase vector and co-transfected with miRNA mimics of hsa-mir-1207-5p into AB8/13 undifferentiated podocytes. In agreement with the western blot data, transfection of mimic resulted in reduced luciferase expression demonstrating the ability of hsa-mir-1207-5p to regulate HBEGF expression by direct binding. On the contrary, in the presence mirSNP 1936T allele, this regulation was abolished. Collectively, these results demonstrate that variant 1936T of this mirSNP blocks the ability of hsa-mir-1207-5p to regulate HBEGF expression in podocytes. We hypothesized that this variant may have a functional role as a genetic modifier. Interestingly, in a cohort of 72 patients who were diagnosed with CFHR5 nephropathy, inheritance of the mirSNP 1936T allele was significantly increased in the group who demonstrated faster progression to chronic renal failure (p-value of 0.0485). No similar association was detected in a cohort of patients with Thin Basement Membrane Nephropathy. A larger cohort is required for further validation of these results.

P12.052
Diagnosis of Charcot-Marie-Tooth Disease

***C. Casasnovas**[1,2], I. Banchs[2], D. Laura[2], L. De Jorge[2], V. Volpini[2];*
[1]Unitat de Neuromuscular. Neurology Department. Hospital Universitari de Bellvitge - IDIBELL, Hospitalet de Ll, Spain, [2]Diagnostic Molecular Centre of Hereditary Diseases. Institut d'Investigacions Biomèdiques de Bellvitge (IDIBELL), Hospitalet de Ll, Spain.

Charcot-Marie- Tooth disease (CMT) is a genetically heterogeneous group of diseases that affect the peripheral nervous system. The most commonly used classification combines clinical findings with the inheritance pattern and either electrophysiological or anatomical pathology findings. The combination of these data allows the identification of several main categories of CMT. The majority of cases can be classified demyelinating forms (or CMT1, characterized by a low NCV in electrophysiological studies), CMT2 (axonal form caused

by specific effects on the axon itself, and conserved NCV) or CMT4 (recessive and severe forms). Recently, disease variants have been described that have intermediate NCV. Each of these types can be further divided into subtypes, depending on the underlying causative molecular defect. However, it should be noted that there is not a good genotype_phenotype correlation and that great variability exists, both within and between families, regarding the degree of clinical expression. The prevalence of CMT ranges from 10 to 30 per 100,000, depending on the geographical region of origin. The most common cause of CMT1 is CMT1A, which results from the duplication of a genomic fragment that encompasses the PMP22 gene on chromosome 17, followed by CMT1B, 1C, 1D and 1E. In the recent years, all the published studies identify CMT2A as the most common cause of CMT2 (which would account for 10- 33% of cases). We propose a diagnostic CMT algorithm including the recent molecular findings that allows the diagnosis of more than 80% of CMT1 patients and more than 40% of CMT patients.

Duplication of cis-regulatory DNA elements downstream of SHOX gene causes Leri Weill Syndrome

L. Capone[1], *A. Forabosco*[2], *M. Baldi*[2], *R. Bertorelli*[3], *L. Iughetti*[4], *B. Predieri*[4], *S. Vannelli*[5], *B. Stasiowska*[5], *D. A. Coviello*[2], *M. Baffico*[2];
[1]*Laboratorio di Biologia molecolare e Genetica medica, Fano, Italy,* [2]*E.O. Ospedali Galliera, Laboratory of Human Genetics, Genoa, Italy,* [3]*Laboratorio di Biologia molecolare e Genetica medica "Cante di Montevecchio", Fano, Italy,* [4]*Dipartimento di Pediatria- Università di Modena e Reggio Emilia, Modena, Italy,* [5]*S.S. Auxologia – Università di Torino, Torino, Italy.*

Leri-Weill syndrome (LWS) is a dominantly inherited skeletal dysplasia ascribed to haploinsufficiency of the SHOX protein caused by deletions or point mutations of the gene and to heterozygous deletions downstream the intact SHOX gene, involving conserved non coding cis-regulatory DNA elements (CNEs) showing enhancer activity.
We describe the first cases of "pure" duplications of the CNEs-containing region downstream the SHOX gene in two LWS families, suggesting the duplication of the cis-regulatory DNA elements as the possible cause of the LWS phenotype.
The precise mechanisms of the pathogenic effect caused by the microduplication of the CNEs-containing region are unclear. The disturbance of the long range regulation of gene expression, essential for producing the gene product in the proper time and place and in the correct quantity, has been proposed as the cause of a number of diseases in which the suspected target genes appeared to be completely normal. It is possible that duplication exerts a negative effect on SHOX transcription. Recently, it has been demonstrated that the proper gene regulation depends not only on the required transcription factors and associated complexes being present but also on the integrity, chromatin conformation and nuclear positioning of the gene chromosomal segments. On the basis of the above considerations it is not unlikely that the duplication alters the three dimensional chromatin spatial organization impeding in some way the enhancer to contact the promoter, resulting in a lack of gene activation resulting in a condition of haploinsufficiency.

P12.054
Screening for *COL4A3/COL4A4* mutations in 122 familial and sporadic cases of microscopic hematuria

L. Papazachariou[1], *P. Demosthenous*[1], *K. Voskarides*[1], *M. Arsali*[2], *A. Pierides*[3], *C. Deltas*[1];
[1]*University of Cyprus, Nicosia, Cyprus,* [2]*Limassol General Hospital, Nicosia, Cyprus,* [3]*Hippocrateon Hospital, Nicosia, Cyprus.*

Recently described mutations in glomerular basement membrane (GBM) related genes (*COL4A3, COL4A4, LAMB2*) in patients with hematuria and severe nephrotic syndrome give more evidence for the significance of the GBM in glomerular filtration. Familial microscopic hematuria, thought to be a benign disease, seems to be a frequent condition and *COL4A3/COL4A4* mutations explain about half of the cases. However, recent data from our laboratory subsequently confirmed by others, show that more than 50% of these patients develop chronic renal failure and even end-stage renal disease. We believe that this phenotypic heterogeneity is due to different mutation types or due to modifier genes action.
In order to investigate the "different mutation type" hypothesis and find the frequency of *COL4A3/COL4A4* inherited and *de novo* mutations we set up a *COL4A3/COL4A4* mutation screening in a large cohort of 122 familial and sporadic hematuria cases. The exons and flanking intronic regions of *COL4A3/COL4A4* are amplified with appropriate primers. Using SURVEYOR endonuclease for mutation detection we will have the genetics results in order to be able to investigate deeper the functional role of the collagen IV mutations. SURVEYOR digestion cleaves at mismatched base pairs in heteroduplexes. If cleavage is evident (on agarose electrophoresis), DNA re-sequencing is performed.
Preliminary results of our screening are the polymorphisms *COL4A3*-G43R, *COL4A3* IVS2+12GT, *COL4A3*-P74P, *COL4A3*-P414L and *COL4A3*-E162G. Possible phenotypic contribution of these SNPs as a functional haplotype cannot be excluded. Appropriate cell culture studies will be designed to investigate the functional role of polymorphisms and mutations in *COL4A3*, and *COL4A4* chains.

A novel NDUFV1 gene mutation associated with complex I deficiency by a genome-wide approach in consanguineous siblings with brainstem lesions and Leigh syndrome

C. N. Vilain[1], *C. Rens*[2], *A. Aeby*[3], *P. Van Bogaert*[3], *J. Smet*[4], *R. Van Coster*[4], *I. Pirson*[2], *M. J. Abramowicz*[1,2];
[1]*Center of Human Genetics, Université Libre de Bruxelles, Brussels, Belgium,* [2]*Institute of Interdisciplinary Research (IRIBHM), Université Libre de Bruxelles, Brussels, Belgium,* [3]*Neuropaediatrics Department. Hôpital Erasme. Université Libre de Bruxelles, Brussels, Belgium,* [4]*Department of Pediatrics, Division of Pediatric Neurology and Metabolism, Ghent University, Ghent, Belgium.*

While deficiency of complex I of the mitochondrial respiratory chain is a frequent cause of encephalopathy in children, only a few mutations have been reported in each of its subunits. Furthermore, in the absence of families large enough for conclusive segregation analysis, and of robust functional testing, it is difficult to unequivocally demonstrate the causality of the observed mutations and to delineate genotype-phenotype correlations, making additional observations of these very rare genetic defects necessary. We observed two siblings with an early onset encephalopathy with medulla, brainstem and mesencephalon lesions on brain MRI and death before eight months of age, caused by a complex I deficiency. The parents were first cousins and unaffected. Assuming that the disease was caused by homozygosity for an ancestral mutation in a nuclear-encoded gene, we used homozygosity mapping and identified 4 genomic regions that were homozygous and concordant in the two patients, encompassing 4 complex I genes, one of which only, NDUFV1, showing a missense mutation. The mutation, p.Arg386His, affects a highly conserved residue, contiguous to a cysteine residue known to coordinate a Fe ion. Another mutation of the same codon had been reported in similarly affected patient, yielding additional strong evidence for causality. This observation adds to our understanding of complex I deficiency. It validates the important role of Arg386, and therefore supports the current molecular model of iron-sulfur clusters in NDUFV1.

P12.056
Prevalence of Congenital Adrenal hyperplasia (CAH), due to 21-hydroxylase deficiency, in a Jordanian sample pool

H. Daggag, *D. Hiyesat, N. Khawaja, M. Abu-Jbara, A. Al-Batayneh, M. El-Khateeb, K. Ajlouni;*
National Center for Diabetes, Endocrinology and Genetics, Amman, Jordan.

CAH represents a family of autosomal recessive disorders. About 95% of the CAH cases are caused by 21-hydroxylase deficiency, resulting from a defect in the *CYP21A2* gene. The main aim of this study was to screen the Jordanian population for the 8 most common small *CYP21A2* mutations and introduce a prenatal and a neonatal genetic test for CAH in Jordan. Current sample study consisted of 37 clinically diagnosed index patients, including 20 males and 17 females. In most cases, DNA samples for family members were available, bringing the total number of samples to 140. As a screening method we implemented the amplification refractory mutation system (ARMS), identifying mutations in 33 index patients, 15 of which were heterozygotes for a single mutation, 5 were compound heterozygotes, 11 were homozygotes and 2 were compound homozygotes. Mutation

frequency was the highest for In2cs mutation at 37.8%, followed by Q318X at 24.3% and 13.5% for 8bp deletion. Also, in 25% of CAH cases due to *CYP21A2* gene defect, mutations are caused by large gene deletions (i.e. 30 kb gene deletion). Hence, to be able to obtain a true statistical representation of *CYP21A2* mutations in the Jordanian population, our sample pool needs to be tested for the 30 kb deletion. This will be achieved through Multiple Ligation-dependant Probe Amplification (MLPA) method, utilizing a CAH-MLPA kit. Once the analysis is complete, we can implement a prenatal and a neonatal testing on a national scale, hoping to reduce the overall incidence of CAH in a Jordanian population.

P12.057
Identification of CYP21A2 mutations in Czech patients with 21-hydroxylase deficiency - structural analysis of the chimeric CYP21A1P/CYP21A2 gene

***Z. Vrzalova**, Z. Hruba, L. Fajkusova, E. Stahlova Hrabincova;*
Centre of molecular biology and gene therapy; Masaryk University Brno, Brno, Czech Republic.

Congenital adrenal hyperplasia (CAH) comprises a group of autosomal recessive disorders caused by an enzymatic deficiency. Approximately 90% of all CAH cases is associated with mutations in the steroid 21-hydroxylase gene (*CYP21A2*). The *CYP21A2* gene and its inactive pseudogene (*CYP21A1P*) are located within the HLA region on chromosome 6p21.3. Their intergenic recombinations are responsible for about 95% of mutations.

In 267 Czech probands with 21-hydroxylase deficiency were identified 30 different *CYP21A2* mutant alleles (4 of them were not described so far). The most frequent mutation, a chimeric *CYP21A1P/CYP21A2* gene, was found in 33,7% of mutant alleles (a new type designated CH-7 was characterized). Small DNA rearrangements of the *CYP21A2* gene were present in 59,2% of mutant alleles (3 novel point mutations were detected). Total deletions of *CYP21A2* were detected in 4,9% and duplications of *CYP21A2* associated with a mutation on both copies were detected in 0,4% of mutated alleles.

In the set of 90 patients, we identified four types of chimeric *CYP21A1P/CYP21A2* genes. The most common type was the newly characterized CH-7 type (21,4% of mutant alleles). We performed a detailed sequence analysis of chimeric *CYP21A1P/CYP21A2* genes to determine the breakpoints in *CYP21A1P-CYP21A2* conversion areas. All chimeric genes have the CYP21A1P promotor and p.Pro30Leu mutation in exon 1 but differ in the presence of other mutations and polymorphisms.

Mutations in *CYP21A2* gene were determined using a long-range PCR, secondary PCR and restriction analysis, direct sequencing, and MLPA method.

This work was supported by grant MSMT LC06023.

P12.058
Molecular Diagnosis of Congenital Adrenal Hyperplasia due to 21-Hydroxylase Deficiency

***R. Cerqueira**, I. Miguel, H. Gabriel, M. Teixeira, A. Palmeiro, P. Rendeiro, P. Tavares;*
CGC Genetics (www.cgcgenetics.com), Porto, Portugal.

Introduction: 21-hydroxylase deficiency is the most common cause of congenital adrenal hyperplasia (90%-95% of cases), a family of autosomal recessive disorders with highly variable phenotypical expression involving impaired synthesis of cortisol from cholesterol by the adrenal cortex. The CYP21A2 gene is located on 6p, within the HLA complex, a region that displays a complex organization of genes with great variability in gene size and copy numbers. Approximately 30 kb from the functional gene of 21-OHD is located a nonfunctional pseudogene (CYP21A2P) that shares significant sequence homology with CYP21A2. Due to the complexity of large rearrangements that can affect *CYP21A2* and its pseudogene, correct genotyping of *CYP21A2* gene is difficult and requires not only the identification of *CYP21A2* common mutations but also the detection of *CYP21A2* deletions, *CYP21A2P/CYP21A2* chimeric genes (20% of mutant alleles, resulting from the common 30-kb deletion) or *CYP21A2* duplications (7% of the alleles). Therefore we developed a testing approach that combines the detection of *CYP21A2* common point mutations and large rearrangements, and allows the detection of approximately 80-98% of *CYP21A2* mutations associated with CAH.

Method/Results: 22 samples were tested by locus-specific PCR/multiplex minisequencing and MLPA (P050, MRC-Holland): 4 had no mutations, 9 had point mutations, 2 had large deletions and 7 had a common point mutation combined with a large deletion or duplication.

Conclusion: The present work stresses the importance of considering detection of *CYP21A2* point mutations and large rearrangements (particularly *CYP21A2* duplications that can be responsible for some false positive cases), for CAH diagnosis and counselling.

P12.059
First case report of *PHOX2B*-confirmed congenital central hypoventilation syndrome in Russia

***L. P. Nazarenko**[1,2], M. S. Nazarenko[1,2];*
[1]Research Institute of Medical Genetics, Tomsk, Russian Federation, [2]Siberian State Medical University, Tomsk, Russian Federation.

Congenital central hypoventilation syndrome (CCHS) is a rare autosomal dominant disorder of the autonomic nervous system characterized by the absence of adequate control of respiration with decreased sensitivity to hypoxia and hypercapnia. The paired-like homeobox 2B (PHOX2B) gene has been identified as the major gene involved in CCHS. Case presented in the newborn period with multiple episodes of apnoea and respiratory insufficiency that required ventilatory support. There was no family history of CCHS. A heterozygous insertion of 21 bp DNAs for coding 7 alanines was detected in exon 3. Analyses of the parents' *PHOX2B* genes were normal. To the best of our knowledge, this is the first report of clinical description and confirmation of CCHS by molecular genetic testing in Russia.

P12.060
Novel and recurrent *JAG1* mutations in patients with tetralogy of Fallot

***V. Guida**[1], F. Chiappe[2], R. Ferese[1], G. Usala[2], G. Maestrale[3], I. Chiara[1], E. Bellacchio[1], R. Mingarelli[1], M. Digilio[4], M. Uda[3], A. De Luca[1], B. Dallapiccola[4];*
[1]Casa Sollievo della Sofferenza Hospital IRCCS, Laboratorio Mendel, San Giovanni Rotondo, Italy, [2]Istituto di Neurogenetica e Neurofarmacologia, CNR, Cagliari, Italy, [3]Istituto di Genetica delle Popolazioni, CNR, Sassari, Italy, [4]Bambino Gesù Children Hospital, IRCCS, Rome, Italy.

Mutations in the ligand of Notch signaling pathway Jagged1 (*JAG1*) have been identified in patients with Alagille syndrome (AS) and in some patients affected by apparently non-syndromic tetralogy of Fallot (TOF). We analyzed the entire coding sequence of *JAG1* gene to determine the occurrence of small deletions, insertions and point mutations in 123 TOF individuals. None of the patients presented clinical features of AS, all cases had normal standard karyotype and 22q11 deletion was excluded. The patients' cohort included 112 subjects with non-syndromic TOF and 11 with multiple anomalies in the setting of an unidentifiable disorder. Mutation analysis of *JAG1* gene using dHPLC identified three different, possibly pathogenetic, aminoacidic substitutions in 4 unrelated patients, including 3 sporadic cases and one with familial congenital heart disease. One of the *JAG1* sequence changes (p.Gly309Arg) was novel, while two (p.Pro810Leu, p.Arg937Gln) were known. The p.Pro810Leu mutation was identified in a patient with TOF, cleft lip and palate and mild mental impairment, while p.Gly309Arg and p.Arg937Gln variants were detected in 3 patients affected by isolated TOF (3/112, 2.7%). All identified variants were excluded in 300 controls. The present results expand the *JAG1* mutational and phenotypic spectrum and confirm that these mutations occur in a subset of non-syndromic TOF individuals.

P12.061
High frequency of *NOTCH1* mutations in familal LVOTO : a study of 324 probands and their families

***W. S. Kerstjens-Frederikse**[1], R. M. F. Berger[2], M. W. Wessels[3], Y. J. Vos[1], R. M. W. Hofstra[1];*
[1]Department of Genetics, University Medical Centre,University of Groningen, Groningen, Netherlands, [2]Centre of Congenital Heart Disease, University Medical Centre,University of Groningen, Groningen, Netherlands, [3]Department of Genetics, Erasmus Medical Centre, Rotterdam, Netherlands.

Background: Left ventricular outflow tract obstructions (LVOTO) are highly heritable congenital heart diseases, with bicuspid aortic valve

(BAV), aortic valve stenosis (AVS), coarctation of the aortae (COA) and hypoplastic left heart syndrome (HLHS) being the most frequent diagnoses. The BAV may be undetected, but has a risk for serious complications and sudden cardiac death. Mutations in *NOTCH1* are reported to cause LVOTO, but data on prevalence and phenotypic spectrum in a large cohort have not been published.

Methods/Results: *NOTCH1* mutation screening was performed in a well documented cohort of 324 probands with LVOTO. Sixteen mutations were detected (5%): eight mutations are considered disease causing (one deletion, five truncating and two splice site mutations). Two of these 8 mutations are de novo, the other six occur in familial disease (6/76= 8%). Moreover we found 8 possible causative non-synonymous mutations. Apart from these 16 mutations, 69 unclassified variants were detected. The relatives of all mutation carriers were screened for mutations and for cardiac defects. We detected besides LVOTO, also non-penetrance, tetralogy of Fallot and pulmonary valve stenosis/atresia

Conclusion: Firstly, disease causing *NOTCH1* mutations are detected in 8% of familial LVOTO. Secondly, *NOTCH1* mutations cause all subtypes of LVOTO, but non-penetrance or right sided defects may occur like tetralogy of Fallot and pulmonary valve atresia. We recommend *NOTCH1* mutation screening in patients with LVOTO, especially in familial LVOTO, because it will help to detect relatives at risk for complications of a previously unknown heart defect and at risk for affected offspring.

P12.062
Centronuclear myopathy: 38 novel DNM2 mutations reveal hotspots and a genotype/phenotype correlation

Centronuclear myopathies (CNM) are associated with general skeletal muscle weakness. The histopathological findings involve muscle fiber atrophy, type I fiber predominance and abnormally centralized nuclei. The severe X-linked and the milder autosomal recessive CNM result from mutations in MTM1 and BIN1, respectively. The autosomal dominant form with mild to moderate etiopathology and childhood or adult onset is linked to DNM2 mutations. Specific DNM2 mutations are also associated with a peripheral neuropathy, Charcot-Marie-Tooth (CMT) disease, the most common inherited neurological disorder. DNM2 (19q13) encodes dynamin 2, a mechanochemical enzyme hydrolyzing GTP to apply forces on membranes and is therefore a key player for membrane trafficking at the plasma membrane and the trans-Golgi network.

Fourteen different CNM-related DNM2 mutations in 39 families have been reported so far. In this study we describe a cohort of 38 novel autosomal dominant CNM families harbouring 8 known and 2 new mutations including the first splice mutation, thereby expanding the genotypic CNM spectrum and confining regions more prone to mutations. Combining our results with the published data, distinct mutation hotspots became apparent in exons 8, 11, 14 and 16 and allow a reliable genotype-phenotype correlation. Notably, exon 16 mutations are invariably associated with a severe neonatal phenotype. None of the mutations are associated with both, CNM and CMT, suggesting that the pathomechanisms are amino acid-dependent and not linked to modifier genes. We established a sequencing hierarchy for hotspot-containing exons based on the patients clinical data and thereby help to guide genetic counselling and molecular diagnostics.

The molecular genetic study of gene *CFTR* for CF patients from Chuvash Republic

A. Stepanova[1], *A. Abrukova*[2], *E. Savaskina*[2], *A. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Ministry of Health and Social Development of Chuvash Republic, Presidential Perinatal Center, Cheboksary, Russian Federation.*

Cystic fibrosis (CF) is a common and generally severe autosomal recessive disorder of the European population. It's caused by mutations in the cystic fibrosis transmembrane conductance regulator gene (CFTR) on chromosome 7q31.

In this work we analyzed 11 CF Chuvashes families, consisting of 12 patients with classic form of CF and their 25 relatives.

We'd designed the multiplex system of direct PCR analysis and the multiplex system based on allele-specific ligation reaction PCR analysis and used it for most frequent mutation screening (ΔF508, ΔI507, CFTRdele2,3, 1677delTA, 2143delT, 2184insA, 394delTT, 3821DelT, L138ins, G542X, W1282X, N1303K, R334W, 3849+10kbc>t, 604insA, 3944 delTG, S1196X, 621+1g>t). There were found two CFTR mutations ΔF508 for two CF patients in this work.

We analyzed all patients and relatives by four intragenic SNP markers IVS1CA, IVS6aGATT, IVS8CA and IVS17BCA. The haplotype 22-7-16-13 was observed for 6 patients in the homozygous state and for 4 patients in the heterozygous state. By sequencing of the CFTR gene coding regions and exon-intron junctions the p.E92K mutation was found in homozygous state for two CF patients. The p.E92K mutation was determined for 10 patients with haplotype 22-7-16-13: 6 patients in the homozygous state, 2 patients in heterozygous state in compound with mutation ΔF508 and 2 patients in compound heterozygous with unidentified mutation.

After analyzing 343 unaffected unrelated Chuvashes we identified 5 heterozygous state p.E92K mutation and 4 heterozygous state ΔF508 ones.

Multicenter validation study of a novel StripAssay for cystic fibrosis

H. Puehringer[1], *M. Macek*[2], *A. Stambergova*[2], *L. Dvorakova*[2], *M. Duno*[3], *B. Tuemmler*[4], *S. Hedtfeld*[4], *M. Tzetis*[5], *M. Poulou*[5], *C. Oberkanins*[1];
[1]*ViennaLab Diagnostics GmbH, Vienna, Austria,* [2]*Department of Biology and Medical Genetics, Charles University, Prague, Czech Republic,* [3]*Department of Clinical Genetics, University Hospital, Copenhagen, Denmark,* [4]*Department of Pediatrics, Medical School, Hannover, Germany,* [5]*Department of Medical Genetics, National Kapodistrian University, Athens, Greece.*

Cystic fibrosis (CF), with an incidence of approximately 1 in 3000 live births in Caucasians, is caused by mutations in the cystic-fibrosis transmembrane conductance regulator (CFTR) gene. To date, more than 1500 CFTR mutations have been described, the majority being very rare or private. Worldwide, the most frequent mutation F508del accounts for 30-72% of CF chromosomes depending upon ethnicity. Overall there is great heterogeneity in the remaining pathogenic mutations, as type and distribution vary substantially between populations.

We have developed a reverse-hybridization assay for the rapid and simultaneous analysis of 23 CFTR mutations recommended by the ACMG plus 10 additional ones prevalent in different parts of Europe, as well as the IVS8 polyT (5T/7T/9T) variants. The CF StripAssay, showing a coverage of 70-93% almost all over Europe, is rapid, simple and accessible to automation. The test requires very small amounts of samples, which is of particular importance for prenatal diagnosis and newborn screening. In the first phase of a multicenter validation study genotyping results from 96 out of 111 (86.5%) previously tested samples were confirmed by the CF StripAssay. The remaining discrepant genotypes were due to missing mutant probes on the teststrips. Currently the assay is validated prospectively under routine diagnostic settings in the participating centers. (oberkanins@viennalab.co.at)

P12.065
IFRD1: a possible modifier gene for Cystic Fibrosis Lung Disease

A. R. Lo Presti[1], *F. Belpinati*[1], *M. D. Bettin*[1], *G. Malerba*[1], *L. Xumerle*[1], *C. Castellani*[2], *P. F. Pignatti*[1], *C. Bombieri*[1];
[1]*Section of Biology and Genetic, Department of Life and Reproduction Sciences, University of Verona, Verona, Italy,* [2]*Veneto Regional CF Center, Verona Hospital, Verona, Italy.*

Cystic fibrosis (*CF*), the most frequent autosomal recessive disease in the Caucasian population, is a lethal multi-system disorder caused by mutations in the CFTR gene. Severity of clinical manifestation, particularly, the pulmonary phenotype, is widely variable, even among patients with the same CFTR genotype or within the same family. This variability is only partially explained by allelic heterogeneity at the CFTR gene, therefore many genes have been investigated as possible CF phenotype modifier. Literature data reports the IFRD1 (*Interferon-Related Developmental Regulator 1*) gene as a possible modifier of cystic fibrosis lung disease severity (Nature 458:1039-42, 2009).
In this study we analysed the three SNPs (rs7817, rs3807213, rs6968084) of IFRD1 gene, previously described in association with a more severe lung phenotype, to confirm these data in a North-East Italian population.
To this purpose,146 CF patients attending the Veneto Regional CF Center of Verona were enrolled. All patients were diagnosed according to international criteria and clinically evaluated for respiratory and gastrointestinal parameters.
SNPs were genotyped by PCR and restriction enzyme analysis.
An association study between IFRD1-polymorphisms and qualitative parameters relatively to respiratory and gastrointestinal traits in CF patients was done. A significant association between the rs7817-CT heterozygote genotype and a higher FEV_1 value was found (p=0.0307). No other significant association was observed.
These results confirm that genetic variations in the IFRD1 gene, or at least other mutations in linkage disequilibrium with the studied SNPs, may contribute to the modification of pulmonary phenotype severity in CF patients.

P12.066
Next generation sequencing with Ion Torrent's PGM™ sequencer and the 5500 SOLiD™ system: targeted resequencing of the *CFTR* gene using sample multiplexing

R. Achmann[1], *R. Greither*[2], *R. Dixon*[2], *A. Rico*[2], *A. Sartori*[2], *S. Zahn*[1], *F. Stellmer*[1], *L. Argyriou*[1], ***B. Auber***[1];
[1]*MVZ genteQ GmbH, Hamburg, Germany,* [2]*Life Technologies GmbH, Darmstadt, Germany.*

Using high-throughput next generation sequencing platforms for resequencing of the *CFTR* gene requires highly accurate data in the coding and flanking intron regions of the gene. While PCR has proven to be a reliable method for amplification of gene specific target regions, it suffers from limited multiplexing capability. We describe a pilot study comprising 20 human samples with different known *CFTR* gene mutations, using a Multiplicon™ multiplexing assay for the *CFTR* gene, sample barcoding and subsequent Next-Generation Sequencing with the 5500 SOLiD™ System and the semiconductor-based IonTorrent Personal Genome Machine™ Sequencer. Results of the samples obtained from the two next generation sequencing platforms were validated by Sanger sequencing.

P12.067
Case of a simultaneous carriage of mutations R408W of *PAH* gene and delF508 of *CFTR* gene.

A. B. Maslennikov, *L. F. Mitrohina, A. R. Shorina, E. V. Maslova;*
State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation.

In Western-Siberian region cystic fibrosis (CF, MIM 219700) and phenylketonuria (PKU, MIM 261600) diseases meet on the average frequency 1:4000-1:7000 and 1:6000-1:10000 newborns accordingly. Molecular-genetic inspection of patients CF and PKU, living in the Novosibirsk region, has shown that frequency delF508 of *CFTR* gene among all mutations of this gene makes 0,425, and frequency R408W of *PAH* gene - 0,638. These mutations are revealed at patients, both in the homozygous form, and in a compound with other rare mutations.
At inspection of 246 healthy inhabitants of the Novosibirsk region the genital age, selected by epidemiological criteria, the R408W of *PAH* gene and delF508 of *CFTR* gene among all alleles of these genes have made frequencies of 0,0061 and 0,0041 accordingly. Testing mutations R408W of *PAH* gene and delF508 of *CFTR* gene has high diagnostic value at inspection of families burdened on CF and PKU and for revealing of heterozygotic carriers of the given diseases during mediko-genetic consultation.
In our practice in a family surveyed concerning reproductive health, at the woman presence in the heterozygotic form simultaneously mutation R408W of *PAH* gene (inherited from the father) and mutation delF508 of *CFTR* gene (inherited from mother) has been established. Thus, the patient is the carrier simultaneously two hereditary diseases (CF and PKU), and her family needs genetic inspection at planning and pregnancy conducting.The given fact confirms the importance testing mutations of the *PAH* and *CFTR* genes at mediko-genetic consultation of families planning pregnancy.

P12.068
Identification of *CFTR* splicing defects from mRNA analysis

M. Ramos[1], *J. Giménez*[1], *A. Álvarez*[2], *A. Moreno*[3], *J. De Gracia*[2], *T. Casals*[1];
[1]*Idibell, Barcelona, Spain,* [2]*Hospital Vall d'Hebron, Barcelona, Spain,* [3]*Hospital Parc Taulí, Sabadell, Spain.*

Cystic fibrosis (CF; OMIM 219700) is a multi-systemic disorder produced by mutations in the *CFTR* gene (*ABCC7*; OMIM 602421). So far, over 1,600 mutations determine its variable phenotypic expression. Splicing mutations account for 15% of CF alleles. However, missense, nonsense and synonymous SNPs have been found to affect the efficiency of the splicing process in CF and other genetic disorders. DNA analysis has allowed us to characterize 97% of the CF alleles; however, the effect of most mutations is not well understood. *In silico* analysis has being applied to different kind of mutations, although the information provided by the different software, sometimes controversial, needs further studies to be corroborated. The aim of this work is to define the optimal conditions to the implementation of mRNA analysis in our current CF strategy to assess the effect of mutations already identified as well as to search undetected mutations in our population. To this aim, nasal epithelial cells were collected by brushing from CF patients and controls. Total mRNA was extracted and reverse transcription performed following standard protocols. Six PCRs overlapping the complete *CFTR* mRNA (6.1kb) have been developed to identify normal and aberrant transcripts in 30 samples. The PCR products were sequenced to corroborate the nature of transcripts. Our results suggest that mRNA analysis is a powerful molecular tool to detect alterations in the splicing process and could contribute to the development of new therapeutic strategies in Mendelian disorders.

P12.069
Induced pluripotent stem cells (iPSC) from a lissencephaly patient with a DCX gene mutation

J. Schuster[1], *M. Sobol*[1], *T. Bergström*[1], *D. Raykova*[1], *S. Kundu*[1], *J. Dahlqvist*[1], *K. Forsberg Nilsson*[1], *A. Wanders*[1], *G. Annerén*[1], *B. Anderlid*[2], *N. Dahl*[1];
[1]*University Uppsala, Uppsala, Sweden,* [2]*Karolinska Institute, Stockholm, Sweden.*

Congenital neurological and neurodevelopmental disorders constitute a heterogeneous group affecting approximately 3% of the population. Genetic factors play a major role in a large proportion of cases. Studies of the underlying disease mechanisms have been hampered by the unavailability of the appropriate tissues as well as the lack of model systems. We have established somatic cells from a patient with a *DCX* gene mutation resulting in lissencephaly, a neuro-developmental disorder characterized by a smooth cerebral surface (pachy- or agyri), mental retardation and seizures. The disease is caused by insufficient migration of maturing neurons. Patient-derived fibroblasts were reprogrammed through forced expression of four transcription factors (Oct4, Kfl4, c-MYC and Sox2) and the resulting iPS cells (Liss-iPSC) were characterized by RT/PCR, immunostaining, karyotyping, methylation analysis as well as embryoid body and teratoma formation assay. Patient derived Liss-iPSC express stem cell markers and show de-methylation of the NANOG and OCT4 promoters and a normal karyotype. Analysis of a teratoma obtained after injection of Liss-iPSC

into a SCID-mouse showed all three germ layers. Liss-iPSC will be differentiated into neuronal cells and neuronal subtypes will be scored for growth, morphology, migration and apoptosis. iPS cells from normal individuals are used as controls. The expected results will provide novel and basic understanding about pathophysiological mechanisms underlying lissencephaly.

P12.070
Molecular analysis of the FOXP2 gene in Italian patients affected by specific language impairment

M. Amorini[1,2], *P. Romeo*[1], *L. Rigoli*[1], *C. Impallomeni*[1], *L. Bernardini*[3], *A. Capalbo*[3], *A. Novelli*[3], *M. Briguglio*[1], *V. Procopio*[1], *G. Tortorella*[1], *E. M. Valente*[3], *C. D. Salpietro*[1];

[1]*Department of Pediatric, University of Messina, Messina, Italy,* [2]*Department Farmaco-Biologico, School of Pharmacy, University of Messina, Italy, Italy,* [3]*CSS-Mendel Institute, Rome, Italy.*

The specific language impairment (SLI) are defined as primary disorders of language development. They are not associated with significant difficulties in cognitive development and relationship, neuromotor or neurosensory disorders and social deprivation. They are interested in children over the age of 4 years when the expression language is relatively developed. Because FOXP2 gene on 7q31 has been implicated in the etiology of severe speech and language disorders, we searched for FOXP2 gene mutations in 61 children with clinical diagnosis of SLI.

All probands underwent metabolic, neuro-physiological, psychometric and psycho-linguistic studies, as well as molecular analysis of the FOXP2 gene for the detection of point mutations. We also studied 5 intragenic microsatellites (7-113847; 7-113941; 7-114008; 7-114072; 7-114115) for the detection of maternal uniparental disomy. To search for deletions or chromosomal translocations involving the region of chromosome 7q containing the FOXP2 gene, we analyzed the DNA samples of the patients by FISH. The data were compared with normal control samples.

The analysis of the FOXP2 gene revealed no mutations in all patients included in our study. In 5 patients, we found two polymorphisms (IVS3+33 T>A; IVS5 +17 T>G) previously described. In 4 subjects, a nucleotide substitution (A183T) was detected. Moreover, by FISH and uniparental disomy analysis, we found no chromosomal aberrations.

Our data underline that the role of FOXP2 gene could be no essential in severe speech and language disorders and that could be necessary to examine other genes.

P12.071
Spectrums and frequencies of GJB2, GJB6, GJB3, 12SrRNA, tRNASer(UCN), SLC26A4, SLC26A5 and MYO7A genes mutation among patients with non-syndromic hearing loss from Bashkortostan (Russia)

L. U. Dzhemileva*, S. L. Lobov, E. K. Khusnutdinova;*

Institute of biochemistry and genetics USC RAS, Ufa, Russian Federation.

Introduction: Congenital hearing loss/deafness is the most common defect and the most prevalent sensorineural disorder in different countries but currently only a minority of genes is included in genetic diagnostics. Mutations in *GJB2*, *GJB6, GJB3, 12SrRNA, tRNASer(UCN)*, *SLC26A4* genes are responsible for more than half of all cases of prelingual nonsyndromic recessive deafness in Caucasians.

Method: Using a custom microarray panel (Arrays HHL - Asper Biothech) that contains 198 point mutations, identified in 8 main genes involved on congenital deafness it is possible to identify the molecular basis of the most common forms, both syndromic and nonsyndromic. The DNA samples of 204 unrelated patients' non-syndromic hearing loss from Bashkortostan had been analyzed.

Result: In group of 204 tested patients 97 patients (47,5%) were either homozygous of compound heterozygous, 56 patients (27,5%) carried only one detected mutation. Allelic frequencies for mutations were: *GJB2* (c.35delG (34%), c.35dupG (0,5%), c.167delT (2%), c.235delC (0,74%), q.-3179G>A (1,23%), c.358_360delGAG (0,5%), c.302A>G (0,25%), c.290_291insA (0,25%), c.299_300delAT (1%), c.333_334delAA (0,5%), c.310_325del14 (0,5%), c.312_327del14 (3%), c.101T>C (1%), c.109G>A (0,5%), c.139G>T (0,25%), c.380G>A (0,25%), c.224G>A (0,5%), c.95G>A (0,25%), c.551G>C (0,5%), c.250G>C (0,25%), c.79G>A+c.341A>G (0,25%)), *12SrRNA* (m.961insC$_{(n)}$ (0,25%), m.961delTinsC$_{(n)}$ (0,74%)), *tRNA*$^{Ser(UCN)}$ (m.7444G>A (0, 25%)), *SLC26A5* (q.-53-2A>G) (0,25%), *SLC26A4* (q.919-2A>G) (0,25%). Discussion: *GJB6, GJB3, 12SrRNA, tRNASer(UCN)*, *SLC26A4, SLC26A5* and *MYO7A* genes mutations are not major causes of hearing loss in patients with non-syndromic hearing loss from Bashkortostan. We suggest other genes may be causes of non-syndromic hearing loss in our region. However, *GJB2* gene should be checked for all patients, at first.

P12.072***
Brown-Vialetto-Van Laere syndrome: broadening the phenotypic spectrum

D. J. Josifova*, W. Roworth, C. Ridout, S. Abbs, D. Moore;*

Guy's Hospital, London, United Kingdom.

We have recently discovered that mutations in *C20orf54* are the principal cause of Brown-Vialetto-Van Laere syndrome (BVVLS), an autosomal recessive disorder characterised by progressive ponto-bulbar palsy and sensorineural deafness. The hearing loss is of insidious onset and precedes the neurological signs. The neurological phenotype is complex and precipitated by the onset of cranial nerve palsies in a previously healthy individual, followed by anterior horn neuronopathy and long tract signs. The disease course is progressive, but the rate of decline is variable. Rapid development of diaphragmatic weakness is a frequent complication in children and cor pulmonale secondary to chronic hypoventilation in adults.

There is increasing evidence that Fazio-Londe disease (FLD), clinically similar to BVVLS except for the deafness, is also caused by mutations in *C20orf54* and that BVVLS and FLD are effectively the same entity. We explored the possibility that some cases of Spinal Muscular Atrophy with respiratory distress (SMARD) may also be caused by mutations in this gene. SMARD patients present at birth with distal muscle weakness followed by sudden onset of respiratory distress secondary to diaphragmatic weakness. About 10% of SMARD patients carry mutations in *IGHMBP2*. We tested 95 *IGHMBP2* negative patients and confirmed that 5% harboured mutations in *C20orf54*.

We give an overview of the clinical features of BVVLS, FLD and SMARD, provide some evidence of genotype/phenotype correlation and discuss the clinical overlap. In view of the management implications, we emphasise the importance of considering mutations in *C20orf54* as the cause of motor neuronopathy in infancy and childhood.

P12.073
Detection of deletions/duplications in alpha-thalassemia by MLPA

N. Nezhat[1], *G. R. Javadi*[1], *F. Khordadpoor*[1], *M. T. Akbari*[2,3];

[1]*Department of Biology ,Science and Research branch,Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Tehran Medical Genetics Laboratory, Tehran, Islamic Republic of Iran,* [3]*Department of Medical Genetics ,Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

Although Iran is one of the countries with high frequency of thalassemia, few studies have been carried out on detection of different mutations in alpha thalassemia. There are patients suspected of having alpha thalassemia based on hematological indices but no abnormality in globin has been found by gap-PCR for the most common α-thalassemia deletions and no point mutations detected by ARMS and sequencing of the alpha genes . More studies are required to determine the mutation type in these patients. So the aim of the present study was to determine the mutations at the alpha globin gene cluster using MLPA (Multiplex Ligation-dependent Probe Amplification) method in patients who were suspected to be alpha thalassemia carrier but no mutations had been detected in them by conventional techniques.

Twenty patients, whose mutations were not identified, were selected. In addition, 10 samples in which deletions had been confirmed previously by gap-PCR and 5 normal samples were chosen as positive and negative controls respectively and. Following confirmation of the positive and negative controls by MLPA, suspected samples were investigated.

MLPA results demonstrated mutations in 15% of the cases which had been remained undetected by the conventional methods. One case showed the deletion of regulatory element HS-40 and in two other cases alpha triplication in alpha genes were determined.

In conclusion ,the simplicity, high accuracy ,low cost of MLPA makes

this method a superior alternative to gap-PCR for detecting common known and unknown deletions and duplications in alpha-thalassemia.

P12.074
The fifth DFNX1 family - possible neurodevelopmental disturbances and minor visual symptoms associated with reduced PRS enzyme activity

*C. Frykholm[1], S. Ekvall[1], L. Fairbanks[2], H. Larsen[3], U. Friberg[3], **M. Bondeson**[1]; [1]Departments of Immunology, Genetics and Pathology, Uppsala, Sweden, [2]Purine Research Laboratory, London, United Kingdom, [3]Department of Surgical Sciences, Uppsala, Sweden.*

Only 1-5% of nonsyndromic hearing impairment is X-linked. To date, four loci, DFNX1-4, have been mapped to the X-chromosome. The gene for DFNX1, *PRPS1*, was identified in 2010. The clinical phenotype in DFNX1 is related to an inborn error of purine metabolism in which the enzyme activity of phosphoribosylpyrophosphate synthetase (PRS) is reduced. Mutations in *PRPS1* have also been identified in Arts syndrome, X-linked Charcot-Marie-Tooth type 5 (CMTX5) and PRS superactivity. In Arts syndrome, the enzyme levels are close to zero affecting hearing, vision and psychomotor development. In CMTX5, the level is reduced resulting in peripheral neuropathy, hearing and visual impairment. In PRS superactivity, the high enzyme activity can be associated with hearing loss, hypotonia, ataxia, urinary stones and gouty arthritis.

Today, only four DFNX1 families have been published. The hearing impairment found in the studied male family members was highly variable ranging from congenital profound to progressive postlingual hearing impairment.

We present an five-generation Swedish family with postlingual, progressive X-linked hearing loss associated with a novel c.35A>T (p.H12L) mutation in *PRPS1*. Both affected male family members and female carriers had reduced PRS enzyme activity whereas unaffected family members had normal enzyme activity. No clear signs of auditory neuropathy or vestibular dysfunction could be found. The clinical picture in this fifth DFNX1 family also included strabismus leading in untreated cases to unilateral amblyopathy. In one individual, reduced gross and fine motor skills were noted. These additional findings could be related to the reduced PRS enzyme activity.

P12.075
Spectrum of point mutations in Czech DMD/BMD patients and their phenotypic outcome

***E. Zapletalova**[1], J. Sedlackova[1], M. Hermanova[1], J. Zamecnik[2], L. Fajkusova[1]; [1]University Hospital Brno, Brno, Czech Republic, [2]University Hospital Motol Prague, Prague, Czech Republic.*

Duchenne and milder Becker muscular dystrophies (DMD/BMD) are X-linked recessive neuromuscular diseases. Both are caused by mutations in the DMD gene. DMD is typically connected with mutations causing premature stop codon creation, while BMD is typically connected with in-frame deletions or duplications. Excluding 60% of deletions and 5% of duplications detected in DMD gene, we identified 63 different point mutations in 69 DMD/BMD patients and DMD/BMD female carriers. For mutation screening on the RNA level, we used reverse transcription-PCR, protein truncation test, and DNA sequencing. For screening on DNA level, we used PCR and sequencing. We describe patients with a mutation creating a premature termination codon but with a mild BMD phenotype, which present three different ways of rescuing the DMD phenotype. In one patient we detected the insertion of a repetitive sequence AluYa5 in intron 56, which led to skipping of exon 57. On the other hand, we present two patients with mutations deep inside the intron leading to severe DMD phenotype by creating pseudoexon and leading to frame-shift. Among presented mutations, there are 32, which are typical for Czech population.

This work was supported by grants MSMT LC06023 and 2B08060.

Dentatorubral pallidoluysian atrophy: clinical and genetic analysis of a Sicilian pedigree

***G. Annesi**[1], M. D'Amelio[2], P. Tarantino[1], V. Lo Re[3], P. Ragonese[3], G. Salemi[3], M. Gagliardi[1], A. Quattrone[4], G. Savettieri[3], P. Aridon[3]; [1]Institute of Neurological Science, National Research Council, Mangone (CS), Italy, [2]Dept. of Experimental Biomedicine and Clinical Neurosciences, University of Palermo, palermo, Italy, [3]Dept. of Experimental Biomedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy, [4]Neuroimaging Research Unit, National Research Council, Catanzaro, Italy.*

We describe clinical, radiological and genetic features of a three generation Sicilian family affected by DRPLA. We obtained clinical and genealogical information from twelve people of a three generation pedigree. Five out of seven affected living people were examined and blood samples were obtained. Neurological evaluations, neurophysiological and neuropsychological examinations, neuroimaging studies were performed. Genomic DNA was extracted from peripheral blood by standard methods. Triplet expansion in DRPLA was detected by PCR amplification with fluorescent primers. PCR products were separated onto a capillary sequencer (3130XL Applied Biosystems). The proband of the family, a 48-year-old man, at the age of 37, began to experience episodes of loss of consciousness with generalized seizures. Afterwards he developed an unsteady gait, involuntary movements of the head, face and limbs, in addition to cognitive and psychiatric symptoms. Neurological examination was characterize by choreiform movement, myoclonus and cognitive deterioration. His gate was ataxic and tandem walking was impossible. Cranial MRI showed mild diffuse atrophy. Somatosensory,motor and brainstem auditory evoked potentials were altered. Two sisters of the proband reported similar symptoms with different degree of gait, speech disturbance and choreoathetosis. The first son of the proband, a nephew and two young first cousins, at the age of 15 started to complain of myoclonic epilepsy, and variable degree of cognitive disturbance. Molecular analysis of all affected people revealed a heterozygous CAG repeats expansion in ATN-1 gene. We provided a detailed description of the main clinical, genetic and radiological features of the second Italian family with DRPLA.

P12.077
Detection of deletions and duplications in Dystrophin gene of male patients by Multiplex Ligation- dependent Probe Amplification (MLPA) method

***F. Khordadpoor-Deilamani**[1], M. Akbari[2,3], M. Hashemi[4], G. Javadi[5]; [1]Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran, [2]Department of medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran, [3]Tehran Medical Genetics Laboratory, No. 297, Taleghani Street, Tehran, Islamic Republic of Iran, [4]Tehran Medical Branch, Islamic Azad university, Tehran, Islamic Republic of Iran, [5]Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Duchenne muscular dystrophy and Becker muscular dystrophy are X-linked recessive disorders caused by mutations in dystrophin gene. DMD is more severe disease with progressive deterioration in muscle power, and most patients become confined to a wheelchair by the age of 12 and die early in their third decade of life from respiratory or cardiac failure.

BMD is a milder phenotype with age of onset around 12 years.

In the majority of DMD/BMD patients, the disease is due to deletions and duplications in the dystrophin gene. Determining the exact size of deletions and duplications can help to predict frameshift and phenotype of the patients. Also, in order to choose an appropriate treatment for the patients, knowing the exact mutation is important.

Here we used MLPA method to determine copy number of the exons of Dystrophin gene in 37 unrelated DMD/BMD patients in which the deletions were not detected by multiplex PCR designed for 27 exons and the promoter of dystrophin gene. Fragment separation was performed using a 3130 ABI capillary sequencer and the raw data was analysed by Gene marker software (v1.6).

MLPA enabled us to find deletions and duplications in 4 patients. Also the exact borders of deletions and duplications were determined.

In conclusion the method is accurate and reliable. It makes it possible to identify deletions and duplications of all 79 exons of dystrophin gene in patients. Therefore it provides a better diagnosis compared to the most of the common techniques like multiplex PCR and real-time PCR.

P12.078
Serum Matrix Metalloproteinase-9 (MMP-9) as a promising biomarker for disease progression in Duchenne Muscular Dystrophy (DMD)

V. D. Nadarajah[1], M. van Putten[1], A. Chaouch[2], P. Garrood[2], V. Straub[2], H. Lochmuller[2], A. M. Aartsma-Rus[1], G. J. B. van Ommen[1], J. T. den Dunnen[1], ***P. A. C. 't Hoen***[1];*

[1]Department of Human Genetics, Leiden University Medical Centre, Leiden, Netherlands, [2]Institute of Human Genetics, Newcastle University, Newcastle, United Kingdom.

Three proteins [MMP-9, Tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) and Osteopontin, (OPN)] implicated in inflammation, extracellular matrix degradation and tissue fibrosis were selected with the aim to identify serum biomarkers for monitoring the progression and treatment outcome of DMD.

Serum biomarker levels were determined using commercially available immunoassays. We observed serum levels of MMP-9 (median level= 1185.34 ng/ml, IQR= 966.56) and TIMP-1 (median level= 245.55 ng/ml, IQR= 69.57) to be significantly higher in DMD patients (N=63) compared to healthy controls (N=16)(MMP-9 median level= 73.22 ng/ml, IQR= 121.00 and TIMP-1 median level=164.77 ng/ml, IQR= 62.45). OPN levels however showed no significant difference between groups. MMP-9 levels were also significantly higher in older non ambulant (N=34) patients compared to younger ambulant DMD (N=29) patients suggesting an increase in MMP-9 levels with disease progression (ambulant MMP-9 median levels= 927.89ng/ml, IQR= 885.60; non ambulant MMP-9 median levels=1328.45ng/ml, IQR= 822.95). Pearson's correlation analysis confirms significant positive correlation between MMP-9 levels, age and duration of corticosteroid treatment in the 63 DMD patients. However linear mixed model analysis with nine DMD patients whose serum samples were collected longitudinally over four years showed significant and positive linear relationship exists between MMP-9 and age i.e. disease progression, and the duration of steroid treatment did not contribute significantly to this relationship.

In conclusion, we identify MMP-9 as a serum biomarker for DMD disease progression and as such will be useful to monitor response to therapies that are currently in clinical trials.

P12.079
Analysis of the dystrofin gene in Armenian patients

N. Nalbandyan*;*

Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.

Duchenne (DMD) and Becker (BMD) muscular dystrophy are allelic disorders caused by mutations in the dystrofin gene. The molecular genetic analysis of these disorders in among the most difficult encountered in a routine laboratory diagnostic. The deletios vary in size and location, but are clustered in three "hot spot", the major site encompassing exons 41-60, and a minor region including exons 3-19. Deletions are detected using a multiplex polymerase chain reaction method, in which 26 exons are analyzed in three separate PCR reactions. These exons were chosen to include the two deletions 'hot spots', and this system is estimated to identify approx 98% of all deletions.

There is no data of this mutation and frequencies of carriers in Armenian population. In 27 armeniam patients with a clinical suspicion of DMD/BMD molecular testing has been performed for 26 exons frequent mutations/deletions. The genotyping analysis of this patients revealed mutations in 10 cases.

The frequent detected mutations are in 3, 49 exons in 11% and 50 in 33% correspondingly. The other mutations were detected in 42-43: 46-47: 6: 13: and 52 exons.

P12.080
Ectodermal dysplasia-syndactyly syndrome (EDSS): broadening the spectrum of *PVRL4* mutations and phenotypic delineation among "nectinopathies"

F. Brancati[1,2]*, P. Fortugno[3], I. Kurth[4], K. Tsiakas[5], R. Santer[5], E. Agolini[2,6], E. Bellacchio[2], I. Bottillo[2], G. Zambruno[7];*

[1]Tor Vergata University, Rome, Italy, [2]IRCCS Casa Sollievo della Sofferenza Hospital, Mendel Laboratory, Rome, Italy, [3]IRCCS Bambino Gesù Children Hospital, Rome, Italy, [4]Jena University Hospital, Institute of Human Genetics, Jena, Germany, [5]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [6]"Sapienza" University of Rome, Department of Molecular Medicine, Rome, Italy, [7]IRCCS Istituto Dermopatico dell'Immacolata, Rome, Italy.

Ectodermal Dysplasia-Syndactyly Syndrome (EDSS; OMIM#613573) is a rare autosomal recessive condition with abnormal hair (pili torti), progressive alopecia, teeth dysplasia, and hands/feet cutaneous syndactyly. Recently, we identified PVRL4 mutations as the cause of EDSS in two families from Algeria and Italy. PVRL4 encodes nectin-4, a cell adhesion molecule relevant for cadherin-based adherens junction formation.

Four nectins have been described so far. Notably, PVRL1 (encoding nectin-1) mutations cause Cleft Lip/Palate-Ectodermal Dysplasia Syndrome (CLPED1; OMIM#225060) also known as Zlotogora-Ogur syndrome, suggesting the common term "nectinopathies" for this group of disorders.

We have ascertained a further consanguineous family with EDSS and identified a novel missense alteration in PVRL4. Affected individuals were homozygous for an evolutionary conserved p.Val242Met change (c.724 G>A), that was predicted to be pathogenic by computing analysis. Modelling analysis showed that the p.Val242 residue is part of a linker between the 2nd-3rd Ig-like domain and suggested that the replacement with the larger Met residue imposed new nectin-4 contacts with p.Arg251 and p.Glu273, potentially affecting homo-/heterophilic interactions with other Ig-like molecules.

This family adds to the two previously described easing the delineation of a very homogeneous phenotype resulting from PVRL4 mutations and characterized by: thick and fragile hair with pili torti, hair loss with patchy alopecia starting at childhood and affecting as well eyebrows and eyelashes, conical and abnormally spaced teeth, and partial cutaneous syndactyly of digits and toes (2-3 and 4-5).

Our description of EDSS reveals broad clinical overlap with the PVRL1-associated nectinopathy, with cleft lip/palate being a distinguishing feature.

P12.081
EGFR gene mutation testing in non-small cell lung cancer (comparison of different methods)

J. Simova[1]*, B. Kubová[1], M. Uvírová[1], D. Konvalinka[1], M. Jalůvkova[1], I. Urbanovská[1], I. Žebráková[1], J. Dvořáčková[2];*

[1]CGB laboratory Inc., Ostrava, Czech Republic, [2]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.

Targeted cancer therapy requires the rapid, sensitive and accurate identification of genetic abnormalities predicting the therapeutic response. Somatic mutations in the epidermal growth factor receptor (EGFR) gene are associated with the objective reponse to EGFR tyrosine kinase inhibitors (TKI). Non-small cell lung cancer (NSCLC) patients harboring EGFR mutations benefit from this specific inhibitors. Almost of all mutations are located within exons 18 - 21 of the EGFR gene (85-90% of the mutations occured at exons 19 and 21 in EGFR gene).

The analysis of EGFR mutations was performed on DNA isolated from cytology sample and formalin-fixed and paraffine-embedded (FFPE) tissues from NSCLC patients.

The aim was comparison of different methods and finding a sensitive, reliable, simple and fast method for routine screening of these mutations in clinical practice, because sometimes is difficult to obtain sufficient tumor sample of patients with NSCLC. EGFR gene mutations were analysed by following methods: direct sequencing, fragment analysis (exon 19 of the EGFR gene), primer extension analysis (SNaPshot assay), real-time PCR (Scorpions-ARMS) and mutant-enriched PCR targeting exons 19 and 21 of EGFR gene. We examined 43 tumor samples of patients with NSCLC.

SNaPshot assay and mutant-enriched PCR, simple and high sensitive assays, were proved as suitable methods for routine mutational analysis of EGFR gene in NSCLC patiens in our laboratory. This applies especially for the cytology samples with only few cancer cell and thus limited amount of DNA.

P12.082***

Loss-of-function mutations of *CHST14* cause a new type of autosomal recessive Ehlers-Danlos syndrome

N. Miyake[1], *T. Kosho*[2], *S. Mizumoto*[3], *T. Furuichi*[4], *A. Hatamochi*[5], *S. Ikegawa*[4], *S. Yamada*[3], *K. Sugahara*[3], *N. Matsumoto*[1];
[1]*Yokohama City University, Yokohama, Japan,* [2]*Shinshu University School of Medicine, Matsumoto, Japan,* [3]*Hokkaido University Graduate School of Life Science, Sapporo, Japan,* [4]*Center for Genomic Medicine, RIKEN, Tokyo, Japan,* [5]*Dokkyo Medical University, School of Medicine, Tochigi, Japan.*

Ehlers-Danlos syndrome (EDS) is a heterogeneous connective tissue disorder involving skin and joint laxity and tissue fragility affecting as many as 1 in 5,000 individuals. We reported a novel subtype of EDS similar to kyphoscoliosis type but without lysyl hydroxylase deficiency. Patients are characterized by distinct craniofacial characteristics, multiple congenital contractures, progressive joint and skin laxity, and multisystem fragility-related manifestations. As two of six patients are consanguineous families, we hypothesized this is autosomal recessive disorder. We mapped its locus at 15q15.1 by homozygosity mapping using two consanguineous families and identified a homozygous *CHST14* mutation in the two families and compound heterozygous mutations in four other sporadic cases. Transfection experiments of mutants and enzyme assays using fibroblast lysates of patients showed the loss of D4ST1 activity. *CHST14* mutations altered the glycosaminoglycan (GAG) components in patients' fibroblasts. Interestingly, dermatan sulfate (DS) of decorin proteoglycan, a key regulator of collagen fibril assembly, was completely lost and replaced by chondroitin sulfate (CS) in the patients' fibroblasts, leading to decreased flexibility of GAG chains. The loss of the decorin DS proteoglycan due to *CHST14* mutations may preclude proper collagen bundle formation or maintenance of collagen bundles while the sizes and shapes of collagen fibrils are unchanged as observed in the patients' dermal tissues. These findings indicate the important role of decorin DS in the extracellular matrix and a novel pathomechanism in EDS.

P12.083

Ellis-van Creveld syndrome - a new UKGTN service

L. Yarram[1], *T. Antoniadi*[1], *S. Smithson*[2], *J. Goodship*[3], *S. Batey*[3], ***M. Williams***[1];
[1]*Bristol Genetics Laboratory, Pathology Sciences, Southmead Hospital, Bristol, United Kingdom,* [2]*Clinical Genetics, St Michael's Hospital, Bristol, United Kingdom,* [3]*Institute of Human Genetics, Newcastle, United Kingdom.*

Ellis-van Creveld syndrome (EvC) is an autosomal recessive chondrodysplasia, characterised by short ribs, short limbs, postaxial polydactly, dysplastic nails and teeth and a range of dental anomalies. Congenital heart defects occur in 60% of cases.

EvC is caused by mutations in *EVC* (21 exons) and *EVC2* (22 exons) at 4p16. These genes are divergent in orientation separated by 2.6kb. EvC is a rare disorder most prevalent in the USA Amish. The birth prevalence in non-Amish is estimated as 0.7/100,000. Consanguinity is reported in 30% of cases (Ulucan *et al.* 2008, *BMC Med Genet* **9:** 92).

A new UKGTN service for Ellis-van Creveld has been established using high throughput semi-automated bidirectional sequencing of 44 fragments followed by analysis using Mutation Surveyor (Softgenetics). Sequencing of *EVC/EVC2* is expected to detect approximately 69% of EvC cases (Tompson *et al.* 2007, *Hum Genet* **120:** 663-670). The service has been validated using 17 EvC samples provided through our collaboration with Institute of Human Genetics, Newcastle.

The identification of unclassified variants remains a challenge for diagnostic laboratories. We present service results to date including two interesting cases found to be homozygous for novel variants. One patient of consanguineous parents with an antenatal diagnosis of EvC is homozygous for c.451-1_452del in *EVC2*; this deletion at the intron-exon boundary of exon 4 is predicted to alter the acceptor splice site, resulting in exon skipping. The second patient is homozygous for a c.2507C>A; this results in a premature STOP codon in exon 17 of *EVC*.

P12.084

A novel homozygous mutation of the ENPP1 gene causes generalised arterial calcification in infancy

N. Marziliano[1], *V. Motta*[1], *F. Orsini*[1], *P. Faldini*[1], *L. Ilardi*[1], *A. Proto*[1], ***G. Chiesa***[2], *S. Martinelli*[1];
[1]*Azienda Ospedaliera Ospedale Cà Granda Niguarda, MILANO, Italy,* [2]*Azienda Ospedaliera Ospedale Cà Granda Niguarda, Milano, Italy.*

Generalized arterial calcification of infancy (GACI, MIM#208000) is a rare autosomal recessive disorder generally due to homozygous/compound mutations of the ENNP1 gene (6q22-q23). Classical features include calcification of large- and medium-sized arteries and marked myointimal proliferation leading to arterial stenosis. Extravascular signs include foci or periarticular calcifications. Most affected children die in the infancy as consequence of vascular occlusion (myocardial infarction) or congestive heart failure due to pulmonary hypertension. We here describe a child diagnosed with GACI harbouring a novel mutation of the ENNP1 gene.

Methods and Results. The proband was born preterm with a respiratory distress; he is a son of two consanguineous Turkish parents. Echocardiography showed increased echogenicity of the walls of pulmonary arteries, the aorta and the coronary arteries, patent foramen and thin pulmonary valve. Additionally, calcification foci have been localised within the aortic arch, thoracic aorta and both carotids. Because of the above features the ENPP1 gene was screened. Bidirectional sequencing of the gene showed a gene re-arrangement (Insertion and Deletion) within the exon 20 in the proband. Both parents were carriers of the above mutation.

Conclusions. This work identified a novel mutation of the ENNP1 gene linked to the GACI disease. When in heterozygous state this mutation leads to mild clinical sign such as short stature, facial dysmporhysms and hypophosphatemic rickets. In the homozygous condition GACI features are present. The identification of a ENPP1 mutation allowed prompt biphosphonate treatment and the establishment of a causative link between the GACI syndrome and the ENPP1 gene.

P12.085

Acid Fatty Metabolism: a new pathway involved in Epidermolysis Bullosa Simplex

M. Bchetnia[1], *M. Tremblay*[1], *G. Leclerc*[2], *A. Dupérée*[2], *J. Powell*[3], *C. McCuaig*[3], *C. Morin*[2], *V. Legendre Guillemin*[1], *C. Laprise*[1];
[1]*Université du Québec à Chicoutimi, Département des sciences fondamentales, Saguenay, QC, Canada,* [2]*Centre de santé et de services sociaux de Chicoutimi, Saguenay, QC, Canada,* [3]*Hôpital Sainte-Justine, Montréal, QC, Canada.*

Epidermolysis bullosa simplex (EBS) is the most common form of inherited epidermolysis bullosa. The disease is characterized by intraepidermal blistering due in most cases to mutations in cytokeratin 5 (*KRT5*) or 14 (*KRT14*) genes and patients present with widely varying severity.

In order to document the molecular biology of the disease, we established an EBS biobank including biological materials from six Canadian EBS patients (2 EBS-DM and 4 EBS-loc patients) and six unaffected individuals paired for the age and gender. We first characterized these patients at the genetic level and we identified six pathogenic mutations from which three are novels (I412F (K14), R125S (K14), and R559X (K5)). Then, we performed an expression microarray analysis of the EBS epidermis tissue in order to examine the broad spectrum of effects of *KRT5* and *KRT14* mutations "*in vivo*" and to identify potential regulatory networks and pathways altered in this disease. Expression profiling show that 28 genes are differentially expressed in EBS patients compared to control subjects (p value <0.05 and absolute fold change >2). Nine genes (*AWAT2*, *DGAT2L6*, *ELOVL3*, *THRSP*, *FADS2*, *FAR2*, *ACSBG1*, *AADACL3*, and *CRAT*) are implicated in fatty acid metabolism and three other genes (*SPRR2B*, *SPRR4*, and *KRT79*) in epidermal keratinisation. These two biological pathways contribute both to the formation of the cell envelope barrier structure. This study demonstrates, for the first time, the relevance of metabolic cluster, specifically fatty acid metabolism in EBS biology.

P12.086
Chromosome 15q13.3 region disruptions in idiopathic generalized epilepsy

A. V. Kirov[1,2], *P. Dimova*[3], *T. Todorov*[1,2], *A. Todorova*[1,2], *V. Bojinova*[3], *G. Saraylieva*[3], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*"St. Naum" Hospital, Medical University Sofia, Sofia, Bulgaria.*

We report on two patients with different phenotype of idiopathic generalized epilepsy (IGE) bearing microduplication and microdeletion of the 15q13.3 region, respectively, both inherited form their unaffected mothers.

A 13 years old girl suffering IGE with generalized tonic-clonic seizures was analyzed by MLPA for 15q13.3 deletions/duplications (MLPA kit P297-B1). A microduplication involving only the CHRNA7 gene was found. The molecular-genetic analysis of the family members showed that the mother and the sister carry this microduplication, but they did not report any history or presented symptoms of neurological disturbances. The father was healthy and negative for the microduplication. We also searched for 2 bp deletion polymorphism in the CHRFAM7A fusion gene and it was detected in both parents. The children did not carry this polymorphism. Unfortunately, at present it was not possible to determine the exact duplication breakpoints. The role of 2 bp deletion polymorphism in the CHRFAM7A fusion gene is unclear.

The second patient is a boy with idiopathic childhood absence epilepsy and mild mental retardation. MLPA analysis showed chromosome 15q13.3 deletion, covering [15q13.2 - MTMR15, TRPM1, KLF13, CHRNA7 - 15q13.4] gene probes. The genetic defect was inherited from the patient's mother, who did not report any past or present signs of neurological impairment.

Given the fact, that other similar reports exist and that there is no definite explanation for the phenotypic variability of 15q13.3 region disruptions, one possible hypothesis could be the so called "two-hit model".

Acknowledgements: The study was supported by the grant No29/2010, Sofia Medical University, Bulgaria

P12.087
Whole-exome sequencing to detect mutations causing light-sensitive epilepsy with jaw spasms in a large family

C. G. F. de Kovel[1], *I. J. Nijman*[2], *H. M. Schippers*[3], *D. Lindhout*[1], *A. C. M. Sonsma*[1], *A. Rapcencu*[1], *D. G. A. Kasteleijn - Nolst Trenité*[1], *B. P. C. Koeleman*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Hubrecht Instituut, Utrecht, Netherlands,* [3]*St Antonius Ziekenhuis, Nieuwegein, Netherlands.*

Aim: To identify the genetic variant(s) underlying light-sensitive epilepsy with jaw-spasms in a large Dutch family.

Methods: A large family showing strong light sensitivity up to the age of 50, and suffering from jaw-spasms when talking, was collected and described. We performed linkage analysis with a 6000 SNP-array (Illumina) to identify regions linked to the light-sensitivity. In the proband we performed whole-exome sequencing (Agilent/SOLID). Variants under the linkage peak passing filters of being novel, functional and predicted damaging were sequenced with Sanger sequencing in the family to identify segregation patterns. Genes with variants co-segregating with the phenotype are currently followed up by sequencing all exons in healthy controls and in other light-sensitive patients.

Results: The linkage analysis resulted in four linkage peaks with LOD-scores around 2.9. The total sequencing effort identified almost 380 exonic variants under the linkage peaks, of which around 30 were novel, and less ten than were predicted to be functional. An interesting variant was found in *SCNM1*, sodium channel modifier 1, and this variant was co-segregating with the phenotype. Follow-up of the variant, as well as other variants, is in progress.

Conclusions: *SCNM1* is a good positional and functional candidate for the phenotype in this family. Follow-up must shed more light on the probability of this variant as the cause (or one of the causes) of the phenotype in this family.

P12.088
One novel and one recurrent mutation in SCN1A gene

I. Yordanova[1,2], *T. Todorov*[3,2], *P. Dimova*[4], *D. Hristova*[5], *R. Tincheva*[6], *I. Litvinenko*[6], *O. Yotovska*[7], *I. Kremensky*[1], *A. Todorova*[3,2];

The range of disease phenotypes produced by mutations in the SCN1A gene is quite broad. SCN1A mutations have been linked to several epilepsy syndromes sharing some common clinical features of different severity and in rare cases of familial migraine and autism. We report on two patients with SCN1A mutations and severe epilepsy within the spectrum of generalized epilepsy with febrile seizures plus syndrome (GEFS+), the phenotypes being consistent with Dravet syndrome (DS) and myoclonic astatic epilepsy (MAE, or Doose syndrome), respectively. Analysis of SCN1A revealed a heterozygous de novo frameshift mutation (c.4205_4208delGAAA) in the patient with DS, and a recurrent missense mutation (c.3521C>G) in that suffering from MAE. The missense mutation has been reported in patients with neuronal diseases of various manifestations, which suggests that this variability is likely to result from the modifying effects of other genetic or environmental factors. To date, truncation mutations have been found exclusively in patients with DS, while manly missense mutations and very few nonsense mutations have been found in the milder GEFS+ phenotypes.

Twenty-four patients with dominant mutations in the *STXBP1* gene causing epileptic encephalopathy have been published. We report on three patients with *STXBP1* mutation/deletion. Two patients belong to a series of 29 patients with infantile epileptic encephalopathy selected for a sequencing of *STXBP1*. Identified *de novo* mutations were the recurrent p.Arg406His substitution and an insertion of six bases inducing a frameshift. The third patient was diagnosed with a deletion of *STXBP1* by CGH-array. All three patients had infantile spasms associated with partial seizures that responded to antiepileptic drug therapy, severe intellectual impairment, and a striking tremor.

Mutations in STXBP1 are relatively frequent in patients with infantile epileptic encephalopathies. STXBP1-related encephalopathy may present as drug-responsive infantile spasms with focal/lateralized discharges. Generalized tremor may be a clue to the diagnosis in some patients.

P12.090
Sorting defects of mutant CLC-Kb in Bartter syndrome.

E. Kamsteeg[1], *R. D. A. Weren*[1], *J. Schoots*[1], *J. Robben*[1], *N. V. A. M. Knoers*[2], *H. Scheffer*[1], *P. M. T. Deen*[1], *L. H. Hoefsloot*[1];
[1]*Radboud University Medical Centre, Nijmegen, Netherlands,* [2]*University Medical Centre Utrecht, Utrecht, Netherlands.*

Bartter syndrome is an autosomal recessive disorder characterized by renal salt wasting and hypokalaemic metabolic alkalosis. Bartter syndrome type 3 is caused by mutations in *CLCNKB*, encoding the renal chloride channel CLC-Kb. Defects of the *CLCNKB* variants may include a disturbed subcellular sorting or defective gating. Analysis of these variants in polarized epithelial cells is a valuable tool to assess their sorting properties. Here, we present the analysis of the subcellular distribution of eleven CLC-Kb missense variants in such cells.

MDCK type II cells were transfected with GFP-tagged CLC-Kb encoding constructs and subjected to imunnofluorescence studies and confocal laser-scanning microscopy. Of the eleven variants, five (S113T, A204T, M427V, G465R and R595Q) were transported to the basolateral plasma membrane, like wt-CLC-Kb. Five others (P124L, G164R V170M, G433E en L656P) were retained intracellularly, and colocalized to a major extend with an endoplasmic reticulum (ER) marker or vesicles (only V170M). The final variant (C626Y) showed a unexpected staining of both the nucleus and the basolateral plasma membrane.

These data indicate that a subset of the CLC-Kb variants is properly sorted to the basolateral plasma membrane. These variants may reflect non-pathogenic variants, or pathogenic variants that are functionally impaired (i.e. defective gating). However, another subset is retained in the ER, as is common with misfolded membrane proteins, such as CFTR or AQP2. One mutant (V170M) shows a yet to be determined vesicular staining. Altogether, studying the subcellular distribution of CLC-Kb variants in polarized cells is a valuable additive tool to test their pathogenicity.

P12.091
Facioscapulohumeral Muscular Dystrophy (FSHD1) - Simple Sequence Length Polymorphisms (SSLP) haplotype analysis which confirms pathogenicity on ‚permissive' chromosomal backgrounds.

R. Whittington[1], *S. O'Shea*[1], *A. Gardner*[1], *Y. Shamsah*[1], *P. Lunt*[2], *L. Yarram*[1], *M. Williams*[1];
[1]*Bristol Genetics Laboratory, Pathology Sciences, Southmead Hospital, Bristol, United Kingdom,* [2]*Clinical Genetics, St Michael's Hospital, Bristol, United Kingdom.*

FSHD (FSHD1; OMIM 158900) is an AD disease affecting 1 in 20,000 and is the third most common form of muscular dystrophy, characterized by progressive wasting of upper body muscles. FSHD1 is associated with a contraction of D4Z4 tandem repeat units in the subtelomere region 4q35. Diagnosis is complicated by the homologous nature of 4q and 10q D4Z4 arrays.

Bristol Genetics laboratory offers a UKGTN specialist diagnostic FSHD service for UKGTN and international laboratories and processes around 400 referrals annually for diagnostic, predictive, and prenatal testing. Molecular confirmation of FSHD1 is currently by EcoRI/BlnI/ApoI digests using probe p13E-11 (to confirm the chromosome of origin and size of the D4Z4 contraction), and distal 4qA/4qB haplotyping (4qA being associated with the pathogenic haplotype). Patients with a deletion of the p13E-11 region (~2%) can be identified using the D4Z4 1kb probe.

Lemmers et al (Science 2010; 329(5999):1650-3) has recently published a unifying genetic model for FSHD. FSHD patients were reported to carry specific single nucleotide polymorphisms (SNPs) distal to the last D4Z4 repeat, which create a polyadenylation site for transcripts derived from DUX4. Specific SNPs are suggested to result in efficient polyadenylation and increase DUX4 transcript stability thereby causing FSHD through a toxic gain of function. In FSHD1 the contraction of the D4Z4 repeat units is only pathogenic in 4 specific 'permissive' chromosomal backgrounds 4A161, 4A161L, 4A159 and 4A168.

We present cases and data for establishing SSLP haplotype analysis as an additional diagnostic service for FSHD1.

P12.092
Genetic Peculiarities of Juvenile Chronic Arthritis in patients with Familial mediterranean fever.

T. F. Sarkisian, *H. S. Hayrapetyan, G. G. Amaryan;*
Center of Medical Genetics, Yerevan, Armenia.

Familial Mediterranean fever (FMF) is the most common autosomal recessive autoinflammation disorder in populations of Mediterranean region ancestors. FMF is caused by MEFV gene mutations (homozygous and compound heterozygous genotypes). The frequency of the carriers of MEFV mutations is 1:3 in non-FMF Armenian population. Number of FMF and related disorders is very high in Armenians, formed as a founder population experienced genetic drift and social and geographical isolation. Clinical and molecular investigations in more than 16000 FMF patients demonstrated significant correlation between MEFV-genotypes and phenotype. Familial study showed the transmission of mutations in parents and siblings. Comparing the MEFV genotypes in two generations among the families was found.

Acute recurrent/chronic destructive arthritis is one of the common features of FMF and could be the first, single manifestation. We present the peculiarities of JCA (EULAR criterion) in FMF patients with different spectrum of *MEFV* mutations. *HLA B27* was identified in 58%. JCA manifested first in 58% of patients; FMF joined as short-term rare attacks of thoracalgia or isolated fever and/or hemorrhagic vasculitis with fever. In 42% of patients FMF developed in 2-3 years. In 33% of patients with atypical FMF athropathy and polyserositis was revealed. Patients with JCA should be investigated for familial anamnesis for FMF and *MEFV* mutations. In JCA patients early detection of *MEFV* mutations is important for on-time colchicinotherapy, improvement of arthritic syndrome and prevention of FMF complications. At the same time FMF patients with resistancy to treatment of arthritis should be tested for *HLA-B27.*

Comparative analyses of the Fanconi anemia core complex genes reveal conserved transcription regulatory elements

D. Meier, *D. Schindler;*
University of Wuerzburg, Department of Human Genetics, Wuerzburg, Germany.

The Fanconi anemia (FA) gene family is a recent addition to the complex network of proteins that respond to and repair certain types of DNA damage in the human genome. Since little is known about the regulation of this novel group of genes at the DNA level, we characterized the promoters of eight genes (FANCA, B, C, E, F, G, L and M) that assemble into the FA core complex. The promoters of these genes show characteristic attributes of housekeeping genes: high GC content, rich in CpG islands, and lack of TATA boxes. They function in a monodirectional way and are, in their most active portions, comparable in strength to the SV40 promoter in the reporter plasmids. They are marked by a distinctive transcriptional start site (TSS). In the 5' region of each promoter, we identified a region that, in isolation, is able to negatively regulate promoter activity in HeLa and HEK 293 cells. The central and 3' regions of the promoter sequences harbor binding sites for several common and rare transcription factors including STAT, SMAD, E2F, AP1 and YY1, indicating that there are cross-connections to several established regulatory pathways. Electrophoretic mobility shift assays and siRNA experiments confirmed shared regulatory responses between prominent members of the TGF-beta and JAK/STAT pathway and members of the FA core complex. We identified a bi-partite nature to these promoters and the results supported the hypothesis based upon a co-evolution of the FA core complex genes and was expanded to include their promoters.

Nowadays molecular genetics is inseparable part of classical medicine to proper diagnostics. Here we present Polish register of patients with the predisposition towards intestinal polyposis. The creation of the register is a result of cooperation between the many oncological, surgical and genetic centers in Poland. Bank comprises the total of 1097 DNA samples derived from 449 families with intestinal polyposis of which 945 samples come from persons in whose families Familial Adenomatous Polyposis (FAP) occurred. We collected the DNA samples from 30 Peutz-Jeghers families, 28 with juvenile polyposis families, 2 Cowden syndrome families and one Proteus syndrome case. Investigations were conducted on DNA isolated from cells of the peripheral blood. The search for mutations in APC, MUTYH , PTEN , BMPR1A, SMAD4 and STK11 genes preconditioning the occurrence of individual diseases was performed employing PCR-SSCP, PCR-HD, DHPLC as well as RFLP techniques and DNA sequencing. General the performed molecular investigations allowed identification of mutations in studied syndromes ranging from 44 to 50%. The mutations spectrum for the genes conditioning polypsis syndromes in Poland was established. The performed investigations also broadened our knowledge about correlations between the genotype and phenotype as well as cases of an atypical course of the disease.

The study was financed by the Ministry of Education and Science, Poland, grant number N N402 481537, N401 331936, N402 431438, N401 014435

Mutations in FHL1 impair expression and functionality of Kv1.5 in XMPMA patient myoblasts.

C. WINDPASSINGER[1], *I. POPARIC*[1], *W. SCHREIBMAYER*[2], *A. GORISCHEK*[1], *A. GORISCHEK*[2], *H. MIEDL*[3], *G. DESOYE*[3], *S. HOCHMEISTER*[4], *J. BINDER*[5], *S. QUASTHOFF*[4], *H. MÄCHLER*[6], *K. WAGNER*[1], *B. SCHOSER*[7], *E. MALLE*[8];
[1]Medical University of Graz, Institute of Human Genetics, Graz, Austria, [2]Medical University of Graz, Institute of Biophysics, Graz, Austria, [3]Medical University of Graz, Institute of Obstetrics and Gynecology, Graz, Austria, [4]Medical University of Graz, Institute of Neurology, Graz, Austria, [5]Medical University of Graz, Department of Cardiology, Graz, Austria, [6]Medical University of Graz, Institute of Cardiac Surgery, Graz, Austria, [7]Friedrich Baur Institute, Department of Neurology, Ludwig Maximilians University of Munich, Munich, Germany, [8]Medical University of Graz, Institute of Molecular Biology and Biochemistry, Graz, Austria.

Four-and-a-half LIM domain protein 1 (FHL1), predominantly expressed in skeletal and cardiac muscle, is suggested to play a role in sarcomere synthesis and assembly. Mutations in the FHL1 gene (leading to different FHL1 splice variants) were identified as the cause of different myopathies including X-linked myopathy with postural muscle atrophy (XMPMA). As FHL1 has been addressed to act as a likely modulator of human atrial potassium voltage-gated channel Kv1.5, we here describe physical and functional interaction between FHL1 and Kv1.5 in XMPMA patient myoblasts.

RT-PCR and Western blot techniques revealed almost complete absence of FHL1A and reduction/absence of Kv1.5 in myoblasts from XMPMA patients. Myoblast cell proliferation was decreased in patients compared to controls while an increased number of patient myoblasts was found to reside in the G0/G1 phase. Two-electrode voltage clamp experiments demonstrated that Xenopus laevis oocytes overexpressing Kv1.5 and FHL1 variants exerted markedly reduced currents when compared to oocytes expressing Kv1.5 only. The most pronounced effect was observed for FHL1C. Potential interaction between FHL1C and Kv1.5 was confirmed by a pull down assay. Immunohistochemistry confirmed colocalization of both proteins after overexpression in an atrial cardiomyocyte cell line.

We here describe functional interactions between FHL1 and Kv1.5 in myoblasts from XMPMA patients. Since Kv1.5 expression and activity is altered in XMPMA patient myoblasts it is likely to assume that FHL1 will regulate Kv1.5 channel activity in both cardiac and skeletal muscle leading to (patho)physiological alterations in XMPMA patients.

The role of the R92Q *TNFRSF1A* mutation in patients with familial Mediterranean fever

D. Yagel[1,2], *Y. Berkun*[3], *S. Padeh*[3], *M. Lidar*[4], *Y. Shinar*[4], *I. Bar-Joseph*[2], *H. Reznik-Wolf*[2], *P. Langevitz*[4], *A. Livneh*[4], *E. Pras*[1,2];
[1]Tel Aviv University, Tel Aviv, Israel, [2]The Danek Gartner Institute of Human Genetics, Sheba Medical Center, Israel, [3]Department of Pediatrics A, Sheba Medical Center, Israel, [4]Department of Medicine F, Sheba Medical Center, Israel.

Objective: To define the frequency of the R92Q Tumor Necrosis Factor Receptor-Associated Periodic Syndrome (TRAPS) mutation in patients with familial Mediterranean fever (FMF) and to study the role of this mutation in FMF.

Methods: Ninety two FMF patients and 250 controls were genotyped for the R92Q mutation. The frequency of R92Q was assessed among 5 groups of FMF patients.

Results: R92Q was found in 6% of the controls, with an especially high carrier rate among Moroccan Jews (8%). R92Q was found in 3 of the 92 FMF patients (3.2%), 1 homozygous for the MEFV M694V mutation and 2 heterozygous for M694V. All 3 patients showed partial response to colchicine. R92Q was not found in patients unresponsive to colchicine, nor was it found in patients with amyloidosis or in patients with FMF like disease without MEFV mutations.

Conclusion: The frequency of the R92Q mutation in FMF patients is comparable to that of controls. Despite the fact that TRAPS and FMF share common biochemical pathways we found no evidence for an interaction between these two genes.

[1]AP-HP, Groupe hospitalier Henri Mondor, Service de génétique, Créteil, France, [2]Faculty of Medicine, University Saint-Joseph, Beirut, Lebanon, [3]INSERM U676, Hôpital Robert Debré, Paris, France, [4]INSERM U955 IMRB équipe 11, Groupe hospitalier Henri Mondor, Créteil, France, [5]Service de Génétique, CHU, UFR de médecine, IFR53, Reims, France, [6]Université Paris-Est, Faculté de Médecine, Créteil, France.

Goldberg-Shprintzen syndrome (GOSHS, MIM #609460) is an autosomal recessive disorder associating severe intellectual disability, typical facial gestalt and Hirschsprung disease. KIAA1279 was identified as the disease causing gene with homozygous nonsense mutations. The encoded protein KBP (KIF-binding protein) was initially claimed to be located at the mitochondria, a subcellular localization not confirmed by a recent study. To assess the functional consequences of the KIAA1279 truncating mutations, degradation of the relevant transcripts by the nonsense mediated mRNA decay (NMD) was tested. Finally, because of the putative localization of the protein to the mitochondria, we also studied the effect of this mutation on the mitochondrial function.

We report two novel patients diagnosed with GOSHS, and homozygous truncating KIAA1279 mutations. In fibroblasts of one of the patients and his father (heterozygous) we quantified the KIAA1279 mRNA by RT-qPCR and the protein by Western blot, studied the subcellular localization by immunocytochemistry and the activities of respiratory chain complexes by spectrophotometry.

KIAA1279 mRNA was barely detectable in the patient's fibroblasts and a two-fold decreased was observed in the father's fibroblasts as compared to control, suggesting a NMD mechanism. KBP protein quantification confirmed these results. The activities of the respiratory chain complexes were normal in the patient's fibroblasts.

In conclusion, we report for the first time a KIAA1279 NMD as the molecular mechanism of GOSHS. The absence of normal KBP protein did not influence mitochondrial respiratory chain complex activity in human fibroblasts.

P12.098
Identification of Alu-mediated, large homozygous deletion of *HAX1* gene spanning exons 4-7 in a patient with severe congenital neutropenia

M. Kurnikova[1], *I. Shagina*[1], *M. Maschan*[2], *E. Dinova*[2], *A. Shcherbina*[2], *D. Shagin*[1,3];

[1]*Evrogen JSC, Moscow, Russian Federation,* [2]*Federal Research and Clinical Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [3]*Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation.*

Severe congenital neutropenia (SCN) is a rare primary immunodeficiency syndrome characterized by sustained neutropenia and early onset of severe bacterial infections. We report a case of a large homozygous *HAX1* deletion in a patient with autosomal-recessive SCN (Kostmann syndrome). The patient was a 2-year old boy who manifested with recurrent bacterial infections at three months of age. The parents and the older sister had no signs of SCN. While performing electrophoretic gel analysis of PCR-products of each exon of *HAX1* gene, we found an absence of PCR-products corresponding to exons 4 through 7 in the proband. For detection of the deletion, a genome-walking method with Universal Genome Walker Kit according to the manufacturer's instructions (Clontech) was used. Amplified products from the nested PCR were cloned using p-GEM®-T Vector System (Promega) and directly sequenced. We identified a homozygous gross deletion in the *HAX1* gene: NG_007369.1:g.(6484_6510)_(8526_8552)del2042. The analysis of the *HAX1* gene revealed that both 5' and 3' breakpoints were located inside Alu elements. Sequence alignment of the hybrid intron and normal introns 3 and 7 indicated recombination between these Alu elements. Each of the unaffected parents of the patient had the same deletion in a heterozygous state. The deletion was not found in a group of 100 healthy controls. Alu-element regions are known to be hot spots for recombination events. Gene rearrangements by Alu-mediated recombination have been reported previously as the molecular basis of some congenital disorders; SCN may now be considered as another example.

P12.099
Identification of a novel deletion in GATA3 gene in a French patient with HDR syndrome

M. LOUHA[1,2], *L. JONARD*[1,2], *V. DROUIN-GARRAUD*[3], *B. LETAVERNIER*[1,4], *C. BONNET*[1,2], *R. COUDERC*[1,2], *E. GARABEDIAN*[1,5,2], *F. DENOYELLE*[1,5,2], *S. MARLIN*[1,2,6];

[1]*AP-HP, PARIS CEDEX 12, France,* [2]*Centre de référence des surdités génétiques, Trousseau Hospital, Paris, France,* [3]*CHU ROUEN GENETIQUE MEDICALE, ROUEN, France,* [4]*APHP NEPHROLOGY UNIT HOSPITAL TROUSSEAU, Paris, France,* [5]*APHP ORL UNIT HOSPITAL TROUSSEAU, Paris, France,* [6]*APHP MEDICAL GENETICS UNIT HOSPITAL TROUSSEAU, Paris, France.*

HDR syndrome is a rare autosomal dominant congenital disorder characterized by hypoparathyroidism, sensorineural deafness, and renal dysplasia. This triad of symptoms does not occur in all patients. Indeed, renal abnormalities are heterogeneous with variable penetrance. HDR syndrome is caused by mutations in the GATA3 gene that belongs to a family of dual zinc-finger transcription factors that play a critical role in embryonic development. So far, various HDR-associated GATA3 mutations occurring throughout the gene have been reported.

Here, we report clinical and molecular findings in 2 French patients with heterozygous intragenic GATA3 mutations. The first patient is a 5 year-old boy. He was diagnosed with PTH-deficient hypoparathyroidism, bilateral sensorineural deafness and vesicoureteric reflux. Direct sequencing of GATA3 identified a duplication occurring in codon 145 (c.431dup), previously described. This frameshift mutation generates a premature stop codon at codon 303, and results in the loss of the nuclear localization signal of GATA3. The second patient is a 15 year-old male and was born with upper eyelid agenesis. He was diagnosed as having hypoparathyroidism, bilateral sensorineural deafness and kidney hypoplasia. Sequence analysis of GATA3 demonstrated a novel deletion c. 807_812del (p.Ser271_Thr272del) in the N- terminal zinc finger1 (ZnF1) of GATA3. ZnF1 is essential to stabilize the C-terminal zinc finger2 (ZnF2) DNA binding, and interacts with other zinc finger proteins, such as the friends of GATA (FOG).

In conclusion, we have identified a novel deletion of the GATA3 gene, associated with HDR syndrome, widening the spectrum of GATA3 mutations that cause this disease.

DFNB1 deafness, caused by mutations in the *GJB2* gene (connexin-26) on 13q12, is the most frequent subtype of autosomal recessive non-syndromic hearing impairment. Molecular testing for *GJB2* mutations is the standard diagnostic approach for subjects with this disorder. However, in 10-50% of affected subjects with *GJB2* mutations, only one mutant allele is found. Some of these unelucidated cases are just coincidental carriers of the most frequent *GJB2* mutations, but a variable proportion of cases across different populations carry in *trans* one of four different deletions at the DFNB1 locus. The number of *GJB2* heterozygotes that remain unelucidated after screening for the known deletions indicates that still unidentified DFNB1 mutations exist. It was hypothesized that all these deletions remove a cis-acting regulatory element that would control *GJB2* expression in the inner ear. Overlapping of all deletion intervals defined a 95.4 kb interval located more than 100 kb upstream from *GJB2* that must contain the regulatory element. To detect further DFNB1 deletions, we designed a multiplex ligation-dependent probe amplification (MLPA) assay featuring 9 probes evenly spaced across the critical interval. By using this assay, we screened a cohort of 236 unelucidated *GJB2* heterozygotes from Spain, the Netherlands, Brazil and Poland. We just identified one Polish subject harbouring the del(*GJB6*-D13S1854) allele, which had not been previously tested for in the entire Polish cohort. Our results imply that other deletions at the DFNB1 locus may be rare or that such deletions would be small enough (<10 kb) to escape detection by this MLPA assay.

P12.101
An overview of Mitochondrial Genetics in Hearing Loss : Research Progress in Iran

M. Montazer Zohour[1], *M. A. Tabatabaeefar*[2], *M. Raisi*[3], *F. Azadegan*[3], *S. Raisi*[3], *E. Farrokhi*[3], *M. T. Akbari*[1], *M. Hashemzadeh Chaleshtori*[3];

[1]*department of medical genetics-faculty of medical sciences -tarbiat modares university, Tehran , Iran, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics,Schoo of Medicine ,ahvaz jundishapur university of medical sciences, ahvaz, Islamic Republic of Iran,* [3]*Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran.*

Hereditary hearing loss (HL) is a heterogeneous trait. Mitochondrial DNA mutations are responsible for less than one percent of pre-lingual HL. Causative mtDNA mutations have been found in five percent patients with post-lingual non-syndromic HL . In this regard, mutations in 12S rRNA, RNA ser(UCN) and tRNA Leu(UUR) genes account for most cases of maternally inherited nonsyndromic HL .

In this research, one thousand Iranian HL subjects were included from 10 provinces of Iran . We have screened three common mtDNA mutations including A1555G , A3243G, and A7445G using PCR-RFLP technique. Altogether, 13 different mutation were identified. These mutations were as followed: A1555G (in 5 cases), A3243G (1 case),

G3316A (6 cases), and A7445G (1 case). Interestingly, the prevalence of common mtDNA mutations were different among different Iranian populations .
While a relatively high levels of A1555G were found in Azarbaijan Sharghi (4.91 percent) and Booshehr provinces (4.35 percent in post-lingual non-syndromic HL subjects, respectively. Other mtDNA mutations were detected in much less frequencies in other provinces . In general, mtDNA mutations are present in less than one percent of the children with pre-lingual HL. However, they are found in about 5 percent of children with post-lingual HL in Iran . Our results indicate that mtDNA mutations may play a more important role in maternally inherited non-syndromic post-lingual HL than in the pre-lingual cases in some Iranian populations. We believe, the findings must be considered in the genetic counseling of hereditary HL.

P12.102
Spectrum of mutations in majority of patients with hemophilia A in Slovenia

M. Debeljak, *L. Kitanovski, M. Benedik Dolnicar;*
University Children's Hospital, University Medical Center, Ljubljana, Slovenia.

The high mutational heterogeneity of hemophilia A is a challenge for provision of genetic services. Our aim was to create a confidential national database of mutations for improvement of genetic services in Slovenia. The factor VIII gene (F8) was analyzed in 139 of 178 hemophilia A patients. The mutations were identified by testing inversions of intron 22 and 1, sequencing part of the promoter, whole coding region and exon/intron boundaries of the F8 gene. There are 178 hemophilia A patients from 126 families in Slovene registry for Hemophilia. We determined mutations in 81/82 patients with severe, 14/16 with moderate and 44/60 with mild form of hemophilia A. The detection rate was 100%. In the Slovene population 40/139 have inversion of intron 22 (48,8% of severe cases) and another 99/139 have 52 different mutations in F8 gene. Of these, 16 are so far found only among Slovene patients. Inversion of intron 1 was not detected in Slovene population of hemophilia A patients. Interestingly, there were no large deletions and insertions. 30% of the small deletions and insertions occurred at stretch of adenines, codons 1191-1194 (8As). A T insertion in exon 26 extends FVIII protein by frame-shift mutation. The spectrum of mutations Slovenian hemophilia A patients was comparable to that found in the Italian and Austrian population, but differed from the spectrum in UK. The type of mutation is a predictor of clinical phenotype. The database is a powerful tool for genetic counseling and medical care of families with hemophilia in Slovenia.

P12.103
The Turkish Hereditary Angioedema Pilot Study (TURHAPS): The First Turkish Series of Hereditary Angioedema

B. Eroglu Kesim[1], *Z. Uyguner*[2], *A. Gelincik*[3], *F. Özşeker*[3], *S. Büyüköztürk*[3], *N. Mete Gökmen*[4], *Y. Laleli*[5];
[1]*Şişli Etfal Training & Education Hospital, Department of Medical Genetics, İstanbul, Turkey,* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, İstanbul, Turkey,* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Allergy, İstanbul, Turkey,* [4]*Ege University, School of Medicine, Department of Internal Medicine, Division of Immunology and Allergy, Izmir, Turkey,* [5]*Duzen Laboratuaries Groups, Ankara, Turkey.*

Background: No published genetic data presently exist concerning hereditary angioedema (HAE) in Turkey. The aim of the present study was to initiate a preliminary multi-centric evaluation about HAE and to identify the causative mutations in a group of patients with hereditary angioedema type I.
Methods: 10 patients with clinical diagnosis of HAE type I were sampled to analyze the entire coding and un-coding exons of *C1NH* gene for mutations by DNA sequencing. Identified new mutations were further evaluated by segregation with the first-degree relatives.
Results: Causative mutations were identified in 9 out of 10 patients, Three of the identified mutations were previously described while 6 were being first time described here in this study. One family showed autosomal recessive inheritance with a novel homozygous mutation , which is a very rare condition as being only one family described in the literature before. Others all had heterozygous mutations pointing out the autosomal dominant inheritance as anticipated. Mutations were found to occur *de novo* in 2 patients while in other 2 the occurrence could not be defined since the parents' DNA were not available. Causative mutation could not be identified in one patient.**Conclusion:**The identified mutations were found to be scattered in all of the exons except 4. It is observed that patients carrying non sense mutations had close to 90% decrease in their C1 esterase inhibitor levels. We hope that our findings in Turkish HAE patients will further support the clinical and molecular data underlying hereditary angioedema

P12.104
ACVRL1 germinal mosaicism with two mutant alleles in a family with Hereditary Haemorrhagic Telangiectasia associated with PAH

M. Eyries[1], *F. Coulet*[1], *F. Pires*[1], *M. Waill*[1], *B. Girerd*[2], *D. Montani*[2], *M. Humbert*[2], *P. Lacombe*[3], *J. Roume*[3], *F. Soubrier*[1];
[1]*Laboratoire d'Oncogénétique et d'Angiogénétique Moléculaire, Groupe Hospitalier Pitié-Salpétrière, Paris, France,* [2]*Centre National de Référence de l'hypertension pulmonaire sévère, Service de pneumologie, Hôpital Antoine Béclère, Université Paris-Sud 11, Clamart, France,* [3]*Service de Génétique, Hôpital Ambroise Paré, Boulogne, France.*

Germline mutations in genes encoding members of the TGF-beta/BMP superfamily are causal for two hereditary vascular disorders, hereditary hemorrhagic telangiectasia (HHT) and heritable pulmonary arterial hypertension (PAH). When the two diseases co-exist, Activin A receptor type II-like kinase-1 (ACVRL1, also known as ALK1) mutations are mainly involved. We report a remarkable ACVRL1 germinal mosaicism characterized by the presence of two mutant alleles in a woman initially diagnosed with PAH at age 21. She also met the Curaçao diagnostic criteria for HHT based on additional findings of telangiectases and epistaxis. Mutation analysis of ACVRL1 identified two closely located heterozygous deleterious mutations within exon 10: c.1388del (p.Gly463fsX2) and c.1390del (p.Leu464X). The two mutations were transmitted independently to the three sons of the index case. One son received the c.1388delG and two sons received the c.1390del. They all present symptoms of HHT, with various intensity, which needs to be interpreted with regards to their young age. Allele-specific PCR analysis demonstrated that c.1388del is the predominant mutation in lymphocytes of the index case. Haplotype analysis revealed that both mutant alleles have a common origin. The presence of these two distinct alterations might result of an incorrect repair of a larger de novo mutational event that occurred in the early stage embryo. An alternative hypothesis is that these two distinct alterations might be explained by a revertant mosaicism mechanism.

P12.105
Amplicon based high-throughput, pooled sequencing identifies mutations in CYP7B1 and Paraplegin in AR-HSP

N. A. Schlipf[1], *R. Schüle*[2], *O. Riess*[1], *L. Schöls*[2], *P. Bauer*[1];
[1]*Institute of Human Genetics, 72076 Tübingen, Germany,* [2]*Hertie Institute for Clinical Brain Research and Center of Neurology, 72076 Tübingen, Germany.*

Hereditary spastic paraplegia (HSP) is a neurodegenerative disorder defined clinically by progressive lower limb spasticity and weakness. HSP is a highly heterogeneous condition with at least 48 loci identified so far, involving X-linked (XL), autosomal recessive (AR) and autosomal dominant (AD) inheritance. For correct diagnosis molecular testing is essential since clinical parameters by themselves are not reliable to differentiate HSP forms. Thus, the purpose of this study was to establish amplicon based high throughput genotyping for AR-HSP. A sample of 187 index cases with sporadic or recessive spastic paraplegia were analyzed by applying an array based amplification strategy to generate amplicon libraries followed by a pooled next-generation sequencing (NGS) approach to investigate the CYP7B1-(SPG5) and Paraplegin-gene (SPG7). We identified one SPG5 and four SPG7 patients. All of them were compound heterozygous for two mutations. In total, three known CYP7B1 mutations and eleven mutations in Paraplegin, including five novel mutations (p.W29X, p.R139X, p.R247X, p.G344D and p.R398X), were detected through amplicon-based next generation sequencing. Discovering the molecular basis of the neurodegenerative disorder HSP is challenging given the increasing number of subtypes. Our study illustrates how amplicon based NGS can be used as a suitable platform to provide data on molecular mutations at a necessary throughput and accuracy.

P12.106
Homozygosity mapping of an Omani family affected with hereditary Spastic paraplegia overlaps with SPG24 locus

A. H. Alkhayat AlShehi[1], *R. Koul*[2], *A. Alfutaisi*[2], *F. AlMamari*[1], *F. AlSalmi*[1], *S. Raeburn*[1];
[1]*Sultan Qaboos University, Muscat, Oman,* [2]*Sultan Qaboos University Hospital, Muscat, Oman.*

Hereditary spastic paraplegia (HSP) is a group of neurodegenerative diseases genetically inherited from one generation to another. About thirty-four different loci have been mapped so far, among them 16 genes have been identified. Autosomal recessive forms of spastic paraplegias usually have clinically complex phenotypes but the SPG5, SPG24 and SPG28 loci are considered to be associated with pure forms of the disease. Stevanin G*, et al 2009*.

Two affected boys from a consanguineous family were diagnosed with HSP. The parents have two other kids a boy and a girl and both are normal. The symptoms were reported to start as early as six months of age. In one of them, spasticity is associated with epilepsy. The MRI showed abnormality in the brain.

The genomic DNA was typed for SNP markers in 10K SNP chip microarray using Affymetrix platform. The genotypes were viewed and sorted according to their chromosomal location and to their physical position in an Excel file. The homozygosity regions were determined using simple algorithm in Excel. Those regions were compared against known HSP loci in the literature to find out if any one of them is actually causing the disease.

The second largest region of homozygosity overlapped with a reported HSP locus, which is SPG24 identified by Hodgkinson et al (2002). No gene has been identified in the region yet. Although SPG24 have been reported as pure HSP but the symptoms in our case is associated with epilepsy and MRI changes. We are currently perusing candidate gene sequencing.

Molecular diagnosis of hereditary neuropathy with liability to pressure palsies

C. Casasnovas[1,2], ***I. Banchs***[3], *L. De Jorge*[3], *V. Volpini*[3];
[1]*Unitat de Neuromuscular. Neurology Department. Hospital Universitari de Bellvitge - IDIBELL, Hospitalet de Llobregat, Barcelona, Spain,* [2]*Diagnostic Molecular Centre of Hereditary Diseases. Institut d'Investigacions Biomèdiques de Bellvitge (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain,* [3]*Diagnostic Molecular Centre of Hereditary Diseases. Institut d'Investigacions Biomèdiques de Bellvitge (IDIBELL), Hospitalet de Llobregat, Barcelona, Spain.*

Hereditary neuropathy with liability to pressure palsies (HNPP) is an autosomal-dominant disease. Motor and sensory nerve dysfunction due to compression at common entrapment sites is the characteristic clinical presentation of this disease, even though there is a wide clinical spectrum of presentation, including asymptomatic individuals HNPP electrophysiological findings show a distinctive background polyneuropathy, independent of superimposed entrapment neuropathy. It is characterized by diffuse sensory nerve conduction velocity (SNCV) slowing and prolongation of distal motor latencies with relatively infrequent and minor reduction of motor nerve conduction velocities. This indicates disproportionate distal conduction slowing in the disorder.

Up to 84% of HNPP are due to the 1.5 Mb deletion at 17p11.2-12 containing the *PMP22* gene. This gene codifies for the membrane glycoprotein, Peripheral Myelin Protein 22, which plays an important role in the formation and maintenance of compact myelin in the peripheral nervous system. Small deletions in PMP22 (detected with microsatellite analysis or Multiplex ligation-dependent probe amplification studies), point mutations in the *PMP22* gene, point mutations at MPZ have been reported to cause HNPP. In addition, mutations in connexin32 gene present as a neuropathy with intermediate NCV that could mimicry HNPP. We propose a HNPP diagnosis algorithm including (microsatellite analysis, MLPA and direct sequencing analysis of PMP22, MPZ and Connexin32 gene) that allows the diagnosis of almost 90% of suspected HNPP patients.

P12.108***
Apolipoprotein B is a new target of the RET/GDNF signalling pathway

E. Bonora[1], *C. Evangelisti*[1,2], *A. Puliti*[3,4], *A. Goldoni*[1], *I. Sbrana*[4], *M. Rossi*[4], *F. Bianco*[1,5], *V. Naponelli*[5], *R. De Giorgio*[5], *G. Romeo*[1];

RET and glial cell line-derived neurotrophic factor (GDNF) regulate cell survival, differentiation, migration and proliferation of neural crest-derived cells. Many signalling mediators of RET have been characterized but the activated downstream genes at the end of the signalling cascade initiated by RET are largely unknown. Since the molecular basis of the interaction between RET and EDNRB (endothelin receptor type B) has been characterized, we used a Caenorhabditis elegans knock out strain of nep-1, homologue of human ECE1 (endothelin-converting enzyme-1) to identify new downstream genes.

Transcriptome comparison between wild-type and nep-1 strains identified vit-3 as a differentially expressed gene. We confirmed that Apolipoprotein b, the mammalian gene homologue of vit-3, is activated by the RET/GDNF signalling pathway in Neuro2a cells via the MAPK P38 kinase and it is inhibited by p53. We demonstrated that RET/GDNF and EDNRB/endothelin 3 (ET-3) cooperate in inducing neuronal differentiation resulting in Apob activation. In addition, ApoB expression is downregulated in mouse embryos homozygous for the mutation ret C620R, causing HSCR in humans, whereas the heterozygous mice show a significant increase in ApoB expression and do not show any HSCR phenotype, suggesting that ApoB has a significant role in ENS development.

The new finding that Apob is a downstream signalling target of RET opens up a new perspective in studying RET roles in human health and diseases.

P12.109
A study of the Huntington´s disease associated trinucleotide repeat in Slovak population

J. Bernasovská, *I. Boronova, I. Bernasovsky;*
University of Presov, Presov, Slovakia.

Huntington´s disease (HD) is a progressive neurodegenerative disorder, which is clinically characterized by motor dysfunction, cognitive impairments and psychiatric disturbances. The molecular basis of the disease is the expansion of the trinucleotide CAG in the first exon of the huntingtin gene in chromosome 4p16.3. Diagnosis of HD has been greatly simplified by the direct triplet repeat gene test. In the Prešov region (1998-2009) CAG repeat lenghts in the HD gene were tested in twelve patients with suspected diagnosis of HD. Genomic DNA was extracted from blood samples by standard extraction procedures using Jet Quick® (Genomed). Thermal cycling of PCR conditions were 95°C for three minutes, followed by 30 cycles of 94°C for one minute, 62°C for one minute, 72°C for one minute, with a final extension at 72°C for seven minutes performed in a the thermal cycler Biometra®. PCR products were resolved on capillary electrophoresis with ABI technology. In seven affected patients clinical diagnosis of HD was confirmed by molecular-genetic methods. The sex ratio in the cases, in which the diagnosis of HD has been confirmed was 4:3 in favor of female individuals. Mapping the occurance of HD in the Prešov region is a part of population-genetic analyses and monitoring of the Prešov region population health status.

Departement of Genetics and Cytogenetics, Paris, France.
Huntington disease (HD) is a dominantly inherited disorder, caused by a CAG repeat expansion in HTT gene resulting in a extended polyglutamine (polyQ) tract. Approximately 50-70% of the variability in age at onset is due to the CAG repeat length, with the remainder likely to be due to modifying genes. Hypothesizing the potentially additive toxic effect of other polyglutamine proteins, we investigated their influence on the age at onset and severity in HD.
We analyzed the length of the polymorphic polyQ stretches in 10 genes in 216 HD patients and 71 controls: HTT, DRPLA, JPH3, AR, SCA1, 2, 3, 6, 7, 17. Linear regression analysis was applied to assess the linear relation of the age at onset depending on the expanded CAG repeat length. Severity was quantified by dividing the motor score by disease duration.
As expected the HTT longer allele was significantly associated with age at onset ($p<0.0001$), but not the size of the shorter allele, nor their interaction. In addition, DRPLA longer and shorter alleles were significantly associated with age at onset variability ($p=0.0092$ and 0.0013, respectively) as well as their interaction ($p=0.0017$). The expansion length in the other genes tested did not modulate the age at onset in HD. However, disease severity was influenced by the size of the CAG repeat expansion in SCA2 ($p<0.03$).
In addition to the pathological HD expansion, normal CAG repeat lengths in DRPLA and SCA2 genes influenced significantly the age at onset and severity in HD, respectively.

P12.111
The contribution of the self PolyQ load [somatic mosaicism] in the CNS to the onset, disease duration and progression rate of SCA2.

***J. M. Laffita-Mesa**;*
Center for the Research and Rehabilitation of Hereditary Ataxias, Holguin, Cuba.
Introduction: SCA2 show strong relationship among CAG and the onset of ataxia. Other factors might accounts for the onset and other phenotypic features. The best modifier might be intrinsically depending/causing of the unstable nature of the CAG. Aims: 1) To compare the somatic mosaicism of the expanded CAG of SCA2 gene in CNS. 2) To determine the influence of somatic mosaicism on SCA2 phenotype and its relationship with CAG size and architecture and haplotype. 3) To gain insights about the dynamic of the CAG expansion in CNS of SCA2. Methods: We have analyzed CAG expansions in 12 different sites of SCA2 deceased patients with discordant phenotypes and somatic mosaicism indices, peaks number, CAG range and skewness of the CAG in each region was determined. Also, detailed clinical data using rating scales trough life with follow-up using neurophysiology biomarkers were used to generate phenotypic profiles. Results: Regions of the brain with greatest level of somatic mosaicism were motor cortex, occipital grey matter, olive, pons, and globus pallidus. While those regions more compromised in SCA2, like cerebellar cortex showed lesser somatic mosaicism. Early onset was associated with wide ranges of CAG in the CNS (with differences up to 10-17 CAG units respecting the major CAG) in contrast to delayed onsets. Sequence and STR haplotype altogether with phenotypic data are also presented. Conclusions: Our results bring data about the role of the somatic mosaicism as the major modifier of the SCA2 phenotype.

The molecular diagnostics of familial hypercholesterolemia in Czech Republic

***L. Tichy**[1], P. Zapletalova[1], E. Zapletalova[1], K. Stehlikova[1], O. Letocha[1], J. Porupkova[1], T. Freiberger[2], L. Fajkusova[1];*
[1]University Hospital Brno, Brno, Czech Republic, [2]St. Anne's University Hospital Brno, Brno, Czech Republic.
Familial Hypercholesterolemia (FH), a major risk factor for coronary heart disease (CHD), is autosomal dominant disorder associated with mutations in the genes encoding the low-density lipoprotein receptor (LDLR), apolipoprotein B100 (APOB), and proprotein convertase subtilisin/kexin type 9 (PCSK9). Predominantly, the clinical phenotype of FH is caused by mutations in the LDLR or APOB genes.
The frequency of heterozygotes is 1/500. The frequency of homozygotes or compound heterozygotes is 1/1 000 000. The high LDL-cholesterol level frequently gives rise to tendon and skin xanthomas, arcus corneae, and accelerated atherosclerosis resulting from cholesterol deposition in the arterial wall, thereby increasing the risk of premature CHD. The identification and treatment of FH patients and their affected relatives with effective lipid-lowering agents is important as this has been shown to significantly reduce both coronary morbidity and mortality.
Mutations in the LDLR and APOB genes were determined using exon by exon screening methods based on individual exon amplifications, restriction analysis, DHPLC, sequencing, and MLPA.
In the set of 2340 probands with the clinical diagnosis of FH, we detected 311 patients (13.3%) with the APOB mutation p.Arg3527Gln and 606 patients (25.9%) with a LDLR mutation. In 606 probands carrying a LDLR mutation, 133 unique allelic variants were detected: 69.9% of these variants were DNA substitutions, 16.5% small DNA rearrangements, and 13.5% large DNA rearrangements. Sixty-three variants were new, not described in other FH populations.
This work was supported by grant MSMT 2B08060 and LC06023.

P12.113
Mutations in *WNT10A* account for 26% of patients with an-/hypohidrotic ectodermal dysplasia

***A. H. van der Hout**, M. T. Meems-Veldhuis, A. J. van Essen;*
Department of Genetics, Groningen, Netherlands.
Hypohidrotic ectodermal dysplasia (HED) is a rare genodermatosis, affecting ectoderm-derived structures, like teeth, sweatglands, nails and hair. The condition can be caused by mutations in the X-linked *EDA* gene, or the autosomal *EDAR, EDARADD,* and *WNT10A* genes. We performed mutation scanning in index cases from 124 families from the Netherlands and Belgium who sought genetic counseling. Mutations in *EDA* were detected in 51% of the index cases, 26% had mutations in the *WNT10A* gene, 6% in the *EDAR* gene, and no pathogenic mutations were detected in *EDARADD*. These data are comparable to those published by Cluzeau et al (2011) in a smaller group of patients from France. Involvement of *WNT10A* has only been established recently. The inheritance pattern of *WNT10A* mutations is not clearly recessive, with some relatively severly affected individuals carrying only one mutation. We will present genotype-phenotype correlations in our group of patients and their relatives. Index cases either carry two nonsense mutations, one nonsense and one missense mutation, two missense mutations or only one missense mutation. Four missense mutations were novel. Notably, one of our patients had pili torti. It appears that a heterozygous nonsense mutation is not enough to cause *WNT10A* related ectodermal dysplasia, since none of the index cases carry only one nonsense mutation and relatives carrying one nonsense mutation are not or only very mildly affected. There is variable expression between relatives with the same genotype. The collection of clinical data from index cases and their heterozygous relatives is ongoing.

P12.114
Homozygousity mapping in a large Iranian pedigree affected with Autosomal Recessive Congenital Ichthyosis(ARCI) reveals linkage to region encompassing NIPAL4/Ichthyn

***A. Alavi**[1], M. Mirshams Shahshahani[2], H. Moazzeni[1], J. Fan[3], E. Elahi[1];*
[1]School of Biology, University College of Science, University of Tehran, Iran, Tehran, Islamic Republic of Iran, [2]Tehran University of Medical Sciences, University of Tehran, Iran, Tehran, Islamic Republic of Iran, [3]Illumina Inc, 9885 Towne Centre Drive, Tehran, Islamic Republic of Iran.
Ichthyosis is a genetically and clinically heterogeneous group of cornification disorders characterized by scaling of whole body skin. A subgroup of ichthyosis (ARCI) exhibits autosomal recessive inheritance. To date, seven genes and two additional loci have been associated with ARCI. Mutations in the seven genes account for disease in 70-75% of the patients.
We performed whole genome homozygosity mapping in a large Iranian ARCI family using high density SNP chips. A large homozygous region of 3.4 Mb on chromosome 5 was observed in all affected individuals. The NIPAL4/Ichthyn gene associated with ARCI lies within the region and mutation screening revealed a homozygous mutation causing p.G297R. Mutation in NIPAL4/Ichthyn has been reported in ARCI patients from Turkey, Syria, Pakistan, Algeria, Colombia and the

Scandinavia countries. Phenotypic similarities and variations among the mutation carrying patients are detected.

P12.115
Molecular analysis of the FLG gene in a sample of Mexican patients with ichthyosis vulgaris

F. Zuñig[1], *J. Cazarin*[1], *R. Rivera*[1], *L. Gonzalez*[1], *H. Urueta*[1], *R. Hernadez*[1], *S. Cuevas*[2];
[1]*HOSPITAL GENERAL DE MEXICO, MEXICO D.F., Mexico,* [2]*HOSPITAL GENERAL DE MEXICO, UNIVERSIDAD NACIONAL AUTONOMA DE MEXICO, MEXICO D.F., Mexico.*

The Ichthyosis vulgaris (IV) is one of the most common genodermatosis with a semidominant inheritance pattern. IV is characterized by light gray to dark brown scales in extensor areas of extremities and lower abdomen. IV has an incidence of 1:250 to 1:5300 births. FLG gene is located on 1q21, and encodes for the filaggrin protein. Mutations in FLG gene are the cause of IV, being the most frequent reported the R501X and 2282del4 mutations, both in exon 3. The aim of the present study was the molecular analysis of the FLG gene in Mexicans individuals with IV. We included 12 patients with clinical diagnosis of IV and normal activity of the steroid sulfatase (STS) enzyme from the Genodermatosis clínica of the General Hospital of Mexico. All IV patients were analyzed by PCR, RFLPs with NlaIII enzyme and DNA automated sequencing anaysis searching for the R501X and 2282del4 mutations. Based on the proposed clinical scale, 33.3% of patients were diagnosed as mild, 41.6% as moderate and 25% as severe. The molecular study revealed 3 positive patients (25%) for the mutation R501X whereas the rest showed no this type of mutations in the FLG gene. There was no relationship between phenotype and genotype. We found a lower frequency of R501X and 2282del4 mutations in IV in comparison with other populations

P12.116
Unraveling the origin and molecular pathogenesis of *TGM1* c.984+1G>A mutation

L. Fachal[1], *L. Rodríguez-Pazos*[2], *M. Ginarte*[2], *A. Blanco*[1], *M. Santamariña*[1], *J. Toribio*[2], *Á. Carracedo*[1], *A. Vega*[1];
[1]*FPGMX-SERGAS, Grupo de Medicina Xenómica-USC, CIBERER, IDIS, Santiago de Compostela, Spain,* [2]*Department of Dermatology, Complejo Hospitalario Universitario, Faculty of Medicine, Santiago de Compostela, Spain.*

Background. Lamellar ichthyosis (LI) is a nonsyndromic disorder of the cornification caused, in the majority of patients, by transglutaminase-1 (TGM1) deficiency resulting from mutations in both copies of the *TGM1* gene.
Objectives. To study the probably common origin of c.984+1G>A mutation in two apparently unrelated Galician families (NW Spain) carriers of c.984+1G>A at heterozygous and homozygous state. To assess the pathologic effect of the splice-site mutation by bioinformatic tools and splicing assays.
Materials and methods. Microsatellite and SNPs data spanning 12Mb on chromosome 14q11 were evaluated to unravel the common origin in families and 100 control individuals. The effect on splicing was assessed using bioinformatic prediction tools follow by analysis of mRNA from peripheral blood lymphocytes. Molecular modelling was performed to investigate the effect of the variation at the protein level.
Results. Both families shared a common haplotye spanning 0.93Mb no present in control population, confirming the origin from a single mutational event. c.984+1G>A lead to two alternative mRNA splice variants, that included 30 (p.Met329_Val330ins10) and 32 nucleotides (p.Val330MetfsX12) of the 5' of intron 6. This result was in accordance with the presence of two cryptic splice sites predicted by bioinformatic tools. The in frame insertion would create a new loop in the surface of the catalytic domain, which is likely to interfere with the proper folding yielding a structure more susceptible to proteolytic cleavage. Conclusion. Our results suggest that c.984+1G>A is a founder mutation for LI in the Galician population and unravels the molecular pathogenesis of this mutation.

P12.117
Localisation of a gene for rare immuno-osteodysplasia syndrome

S. A. Lynch[1], *J. Casey*[2], *P. McGettigan*[3], *R. Regan*[2], *J. Conroy*[2], *J. Nielsen*[4], *K. Butler*[5], *A. Cant*[6], *J. Kelleher*[7], *S. Ennis*[2];
[1]*National Centre for Medical Genetics, Dublin, Ireland,* [2]*School of Medicine and Health Science, UCD, Dublin, Ireland,* [3]*Animal Genomics Laboratory, UCD, Dublin, Ireland,* [4]*School of Biomolecular and Biomedical Science, UCD, Dublin, Ireland,* [5]*Dept of Infectious Diseases Our Lady's Children's Hospital, Dublin, Ireland,* [6]*Paediatric immunology and infectious disease, Newcastle-upon-Tyne, United Kingdom,* [7]*Department of Paediatric Radiology, Our lady's Childrens Hospital, Dublin, Ireland.*

We report high density mapping and sequencing results on a consanguineous family with an immuno-osteodysplasia (IDS). The 3 affected siblings, 2 females and 1 male, presented with a deficient innate immunodeficiency with hypogammagloulinaemia & partial antibody deficiency requiring regular IVIG replacement therapy. In addition, they have a renal tubulopathy leading to potassium and magnesium loss. They have proportionate short stature and abnormalities on X-rays, including epiphyseal delay, flattening of the proximal femoral, distal femoral and proximal tibial epiphyses. The two older children are maintained on oral antibiotic prophylaxia, subcutaneous immunoglobulins & potassium and magnesium supplements. The youngest child, a boy, developed pneumocytis pneumoniae & cryptosporidium positive diarrhoea. He unfortunately died following bone marrow transplantation. Runs of homozygosity (ROH) shared by the 3 affected siblings were identified and subsequently compared to the patterns of homozygosity in 7 unaffected relatives. The three IDS patients shared 450 ROH ranging in size from 7.1 kb to 4.1Mb. A total of 32 ROH, totalling 6.9 Mb and containing 79 genes, were exclusively shared by the IDS patients. The candidate loci were targeted using NimbleGen's sequence capture technology and sequenced in 3 affected and 3 unaffected individuals. We identified 34 homozygous variants (coding regions and utr's) in 18 different genes that segregated with the IDS phenotype. After excluding variants reported in dbSNP, 13 homozygous mutations in 11 different genes remained for further consideration as potential disease-causing mutations. Functional studies may help in elucidating which of the 11 candidate genes is predisposing to IDS.

P12.118
Genetic analysis on twenty eight families with inherited arrhythmogenic disorders: implications for a consanguineous population

Z. N. Al-Hassnan[1,2], *S. Wakil*[1], *S. Tulbah*[1], *Z. Shinwani*[1], *Y. Mallawi*[1], *B. Al-Ghamdi*[1], *W. Al-Manea*[1], *N. Dzimiri*[1], *M. Al-Fayyadh*[1];
[1]*King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia,* [2]*Alfaisal University, Riyadh, Saudi Arabia.*

Introduction: Implicated in the etiology of sudden death, inherited arrhythmogenic disorders (IAD) are a group of genetic conditions that are characterized by locus heterogeneity. The majority of IAD is caused by channelopathies and is inherited in autosomal dominant fashion. **Objective**: Molecular characterization of IAD in our highly consanguineous population. **Patients**: 28 Saudi families with various forms of IAD were recruited:13 with Romano-Ward syndrome (RWS), 5 with Jervell and Lange-Nielsen syndrome , 4 with Brugada syndrome, 2 with sick sinus syndrome, 3 with arrhythmogenic right ventricular dysplasia, and 1 with catecholaminegric polymorphic ventricular tachycardia. **Methods**: Direct sequencing for genes (*KCNQ1, KCNE1, KCNH2, KCNE2, SCN5A, GPD1L, DSP, PKP2, DSG2, DSC2, CASQ2*) known to be implicated in IAD and, in consanguineous families with negative gene sequencing, SNP-based genome-wide homozygosity mapping were performed. **Results**: Heterozygous mutations in *KCNQ1* (5 families), and *PKP2* (1 family), and homozygous mutations in *KCNQ1* (4 families), *CASQ2* (1 family), *SCN5A* (1 family) were detected. SNP-based homozygosity mapping identified a potential novel locus on chromosome 5q34 for RWS. Analysis of candidate genes in the region is in progress. **Conclusion**: Our work represents largest cohort of Arab patients with IAD. Our molecular data illustrates the impact of the high degree of consanguinity on the genotypes of IAD; a finding that has an important preventive implication.

P12.119
Mutation Spectrum of MLL2 in a cohort of Kabuki syndrome patients

*I. micale[1], **c. fusco**[1], b. augello[1], m. N. loviglio[1], e. V. d'addetta[1], a. calcagni[1], I. Kabuki syndrome Group[2], L. Zelante[1], g. merla[1];*
[1]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]different Institutions, different cities, Italy.

Kabuki syndrome is a rare, multiple congenital anomalies/mental retardation syndrome characterized by a peculiar face, short stature, skeletal, visceral and dermatoglyphic abnormalities, cardiac anomalies, and immunological defects. Mutations in the histone methyl transferase MLL2 gene have been identified as its underlying cause. Sanger sequencing of the coding region of MLL2 including intron-exon junctions was performed in 62 index patients. The putative causal and possible functional effect of each nucleotide variant identified was predicted by in silico tools. We identified 46 patients with MLL2 mutations; 42 are novel mutations. The majority are nonsense or frameshift predicted to generate a truncated polypeptide. Yet, we reported 3 indel and 7 missense mutations. Finally 3 MLL2 mutations affected the splicing process resulting in a shorter protein. 26 % (16/62) patients from our cohort with clinical evidences of Kabuki syndrome were negative for mutation in the coding region of MLL2 gene. Mutations in the regulatory regions of the gene, genetic heterogeneity of Kabuki syndrome, and exon micro duplications and/or micro deletions gene might be the possible causes for the lack of MLL2 mutations in such patients. This study emphasizes the relevance of the mutational screening of the MLL2 gene among patients with Kabuki syndrome to improve the actual knowledge on the clinical basis of this syndrome, to design functional studies to understand the molecular mechanisms underlying the disease, to establish genotype-phenotype correlations, to improve the clinical management, and to identify potential targets for therapy.

Detection by microarray-CGH of large rearrangements of the LAMA2 gene in 16.8% of MDC1A patients

***C. Guittard**[1], S. Chambert[1], R. Mein[2], S. Cirak[3], F. Rivier[1], J. Cuisset[4], S. Quijano-Roy[5], A. Toutain[6], P. Landrieu[7], F. Rousselet[8], M. Mayer[9], J. Urtizberea[10], J. Roume[11], M. Claustres[1,12,13], J. Chelly[14], F. Muntoni[3], N. Lévy[15,16,17], C. Béroud[1,12,13];*
[1]CHU de Montpellier, Montpellier, France, [2]Genetics Centre, Guy's Hospital, London, United Kingdom, [3]Dubowitz Neuromuscular Unit, Department of Paediatrics, Hammersmith Hospital, Imperial College, London, United Kingdom, [4]CHRU de Lille, Lille, France, [5]AP-HP, Hôpital Raymond Poincaré, Garches, France, [6]CHU de Tours, Tours, France, [7]APHP, Hôpital Bicêtre, Le Kremlin-Bicêtre, France, [8]CHU de Nancy, Nancy, France, [9]AP-HP, Hôpital Armand Trousseau, Paris, France, [10]Hôpital Marin d'Hendaye, Hendaye, France, [11]CHI Poissy, Poissy, France, [12]INSERM U827, Montpellier, France, [13]Université Montpellier1, Montpellier, France, [14]Institut Cochin, Paris, France, [15]AP-HM, Marseille, France, [16]INSERM, Marseille, France, [17]Université de la Méditerranée, Marseille, France.

The most frequent form of autosomal recessive Congenital Muscular Dystrophies (MDC1A) is caused by mutations of the LAMA2 gene that codes for the laminin alpha-2 protein. This large gene is composed of 65 exons and extends over a genomic region of 633,366 bp. The molecular diagnosis revealed that most mutations are private and therefore the sequencing of all exons is required. Using a series of 113 MDC1A families, we have identified two LAMA2 mutations in 79.7% of families. Therefore, for almost 1/5 of patients, the genetic counseling is difficult as secondary merosin deficiencies can be observed mainly as a result of abnormal O-mannosylation of alpha-dystroglycan as seen in the alpha-dystroglycanopathies associated with mutations in the LARGE, FCMD, POMGnT1, FKRP, POMT1, POMT2 and Fukutin genes.

We therefore developed a new method for detecting and characterizing large rearrangements in the LAMA2 gene based on high-resolution oligonucleotide array-CGH technology. The study of all patients with a clinically diagnosed MDC1A but harbouring only one or no LAMA2 small rearrangement revealed that they indeed harbour one or two large rearrangements of the LAMA2 gene in most cases (16.8% of all MDC1A patients). In parallel, because of the high-resolution of this technique, breakpoints were subsequently characterized by a simple polymerase chain reaction allowing a simple screening test for other family members. This approach, in combination with cDNA sequencing, allowed us to identify LAMA2 mutations in 96.5% of MDC1A patients therefore having a major impact on genetic counseling.

P12.121
Mutation analysis of the LDL receptor gene in Indian families with Familial Hypercholesterolemia

***S. S. Kulkarni**[1], S. Basavraj[1], S. V. Hiremath[2], P. B. Gai[1];*
[1]Research Center for DNA Diagnostics, Dharwad, India, [2]Dept. of Biotechnology,P.C.Jabin Science College, Hubli, India.

Background: Familial Hypercholesterolemia (FH) is a metabolic disorder inherited as an autosomal dominant trait characterized by an increased plasma low-density lipoprotein (LDL). The disease is caused by several mutations in the LDL receptor (LDLr) gene. Identification of individuals carrying the defective gene could be useful in reducing the risk of atherosclerosis and myocardial infraction. Our study presents mutation analysis of the LDLr gene in 24 Indian families with FH.

Methods: Genomic DNA was isolated from blood, exon-specific intronic primers were designed and used to amplify DNA samples from individuals.PCR products were directly subjected to automated DNA sequencing to detect the mutations. Alongwith the affected individuals, ten ethnically matched controls were also analyzed to determine the presence of the same mutations.

Result: All the 24 patients had total cholesterol level above 300mg/dl and LDL cholesterol level above 200mg/dl. Sequence analysis of the LDL receptor (LDLr) gene showed 3 novel mutations which have never been reported elsewhere. In exon 10 we reported g.29372_29373insC, which was found in all the 24 patients and was missence mutation coding for C (cysteine) instead of V (valine).

Conclusion: Our study reported 3 novel mutations in 24 Indian families. These novel mutations are predicted to produce change in the amino acid and thus leading to the conformational changes in the structure of LDLr protein. Change in the LDLr protein makes the LDL receptor unable to transport the cholesterol in to the cell and hence cholesterol starts accumulating in the blood stream and leads to FH.

P12.122
Phenotypic characterization of patients with deletions in the 3'-flanking SHOX region.

***M. Losekoot**[1], S. J. Broekman[1], C. C. de Wit[1], M. Bos[1], V. Janmaat[1], E. Bakker[1], J. Wit[2], S. G. Kant[1];*
[1]Department of Clinical Genetics, Leiden, Netherlands, [2]Department of Pediatrics, Leiden, Netherlands.

The *SHOX* gene is located on the short arm of the X-chromosome in the pseudoautosomal (PAR) 1 region and escapes X-inactivation thus showing a pseudoautosomal pattern of inheritance. Leri-Weill dyschondrosteosis is caused by haploinsufficiency of the *SHOX* gene in 60-70%, and in 15% by deletions of a putative enhancer sequence in the 3'-flanking region. The precise localization of the enhancer sequence is unknown.

We collected clinical data from patients and their relatives with different deletions in the 3'-PAR region, detected by the MRC-Holland MLPA kit (P018-D). PAR probes were numbered 1-12 where nr 1 is SALSA probe 5642-L05096.

Twelve individuals carried a large deletion starting in PAR1 and extending to PAR8/9 or to the flanking CSF2RA probe while 4 individuals had a PAR3-CSF2RA deletion. Thirty-two individuals carried a smaller deletion of 3 probes (PAR4-6), just 5' to the previously described common deletion interval.

Median height SDS, sitting height/height ratio SDS and the presence of Madelung deformity in patients with PAR4-6 deletions were -1.8, +1.4, and 67%, in comparison to -2.4, +1.9 and 42% in patients with larger deletions. The index patients had a median height SDS of -2.7, shorter than their affected parents (-2.0), but disproportion and the presence of Madelung deformity were similar. However, variability of the phenotype in the whole group of patients was remarkable.

We conclude that the critical interval of the enhancer region may be larger than previously suggested.

P12.123
Mutation Analysis of Limb Girdle Muscular Dystrophies in the Czech Republic

***K. Stehlikova**, Z. Hruba, L. Fajkusova;*
Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic.

Limb girdle muscular dystrophies (LGMDs) are a group of disorders characterised by atrophy and weakness of proximal limb girdle muscles.

Limb girdle muscular dystrophy type 2A (LGMD2A) is an autosomal recessive disorder caused by mutations in the *CAPN3* gene (15q15) that encodes the muscle specific protein, calpain-3 (p94). LGMD2A is the most frequent form of LGMDs in many European countries.

Another relatively common forms of LGMD are LGMD2I and LGMD2D. LGMD2I is caused by mutations in the *FKRP* gene (19q13.3) that encodes a protein which participates in the glycosylation of α-dystroglycan in the muscle fibre. LGMD2D is caused by mutations in the α-sarcoglycan gene (*SGCA*). *SGCA* (17q21) is an a integral membrane glycoprotein that forms part of the dystrophin associated glycoprotein complex.

We performed analysis of the *CAPN3*, *FKRP,* and *SGCA* genes in a cohort of patients with preliminary diagnoses of LGMD at both the mRNA level using reverse transcription-PCR or at the DNA level using PCR and direct sequencing.

We screened 203 unrelated patients. 50 patients were found to carry *CAPN3* defects. The homozygous occurence of the most common mutation in the *FKRP* gene (p.Leu276Ile) was found in 8 patients. Mutations in the *SGCA* gene was detected in 4 patients. In total, we determined mutations in 62 Czech LGMD patients (31 %).

This work was supported by grans MSMT LC06023 and 2B08060

P12.124
A novel CAPN3 gene mutation in a LGMD patient from southern Italy

***P. Spadafora**[1], M. Liguori[1], M. Caracciolo[1], I. Manna[1], V. Andreoli[1], R. Cittadella[1], F. Trecroci[1], A. Quattrone[2], A. Gambardella[1,2];*
[1]Institute of Neurological Sciences - National Research Council, CS, Italy, [2]Institute of Neurology -Department of Medical Sciences, University "Magna Graecia", Catanzaro, Italy.

Limb girdle muscular dystrophies ($LGMD_S$) is a heterogeneous group of inherited progressive muscle disorders affecting predominantly the shoulder and pelvic girdle muscles. There are at least 19 different subtypes of LGMD, 7 with autosomal dominant and 12 with autosomal recessive pattern of inheritance. Immunostaining performed on muscle biopsy and genetic analysis can discriminate between the LGMD subtypes.

LGMD2A is the most prevalent form of recessive LGMDs since it generally accounts for 30% of LGMD2 in Caucasian populations. In a LGMD patient from southern Italy we identified a novel mutation (Gln142Arg) in the exon 3 of the CAPN3 gene, in heterozygosis with the A236T variant previously described by others as polymorphism. We already reported another LGMD patient with the same A236T variant in heterozygosis with a null mutation (R748X) in the exon 21 of the CAPN3 gene. Both patients showed elevated serum Creatine Kinase level, late onset myopathy with subjective weakness of the lower limbs. We also found the A236T variant in 7 unrelated LGMD2 patients from the same geographic area.

These findings suggest that the combination of A236T polymorphism in heterozygosis with a mutation in the CAPN3 gene might be responsible for mild LGMD2A phenotypes. However, demonstration of the pathogenic nature of this variant required the examination of the transcription product.

P12.125
Clinical genetic analysis of LGMD2I in Russia.

***O. Ryzhkova**, E. Dadali, O. Schagina, A. Polyakov, I. Sharkova, G. Rudenskaya;*
Research Center for Medical Genetics, Moscow, Russian Federation.

The limb-girdle muscular dystrophy type 2I (LGMD2I) is caused by mutations in the FKRP gene. Being one of the most common forms of the autosomal recessive LGMDs in Europe, its prevalence, the mutation spectrum and symptoms of LGMD2I in Russia are unknown.

We characterized the frequency of LGMD2I in a cohort of 74 Rusian muscular dystrophy patients using DNA sequence analysis. FKRP mutations were found in 9,5% (7/74). Pathogenic changes in both alleles of the FKRP gene were found in 5 patients. In two cases, changes were found only in one allele. Of five founded mutations three were first described (missense: c.265C>T, c.1078G>C, stop codon: c.229C>T). The c.826C>A change, presented in four patients, was the most prevalent mutation.

All patients were women aged 4 to 52. An age of onset varied greatly (from 3 to 32 years). Correlations between the age of onset and the clinical presentation severity weren't found. Clinically, LGMD2I patients exhibit a great phenotypic variability ranging from a severe, rapidly progressive weakness and wasting of the limb-girdle muscles to mild disorders, but all clinical symptoms were typical for LGMDs. Of seven patients only one girl of 9 years old has been wheelchair-bounded since she was seven years old. None of them still has the cardiomyopathy. Three patients had a calf pseudohypertrophy. Contractures of large joints were found in two patients having manifestation in their childhood. The creatine kinase activity varied from 1590 to 14197IU and hadn't correlations between ones and a severity of clinical presentation.

P12.126
Investigation of *ECM1*(1,2,3,4,5,9 and 10 exons) mutation in lipoid proteinosis (*LP*) and genotype-phenotype correlation in Iranian patients

***S. Kalayiniya**[1], A. Bidmeshkipour[1], F. Eizadi[2], M. Farhadi[2], M. Tavakoli[2], S. Samanian[3], F. Mahjoubi[3];*
[1]Scince Faculty, Razi University, Kermanshah, Islamic Republic of Iran, [2]Hazrate Rasoul Hospital, Department & Research of Ear, Throat, Head & Neck Surgery and Related Science, Tehran, Islamic Republic of Iran, [3]Clinical Genetic Department, National Institute of Genetic Engineering & Biotechnology(NIGEB), Tehran, Islamic Republic of Iran.

Lipoid Proteinosis is an autosomal recessive disorder that results from mutations in extra cellular matrix protein(*ECM1*). The clinical signs of *LP* are hoarseness, skin lesions, beaded eyelid papules. During childhood, the skin may be easily damaged by minor trauma or fraction, resulting in blisters and scar formation in Pox-like or cuneiform scars are particularly visible on the face to hair loss. The mucosae of the pharynx, tongue, soft palate, tonsils and lips are also infiltrated and this may lead to respiratory difficulty, sometimes requiring tracheotomy.

We aimed to screen 10 Iranian families clinically diagnosis with *LP*. Genomic *DNA* was extracted from all the patients and the parents. *PCR* was employed to amplify all 10 exons of *ECM1* gene. The *PCR* products were then sequenced using *ABI* sequencer.In this report, we are going to present our data regarding *ECM1* gene mutations in Iranian *LP* patients. To our best knowledge this is the first reported molecular data of Iranian *LP* patients

P12.127
Exclusion of known lymphedema genes in two families with severe congenital lymphedema.

***M. Amyere**[1], S. Greenberger[2], D. Chitayat[3], E. Pras[4], K. Chong[3], T. Uster[3], H. Reznik-Wolf[4], D. Marek-Yagel[4], L. Boon[5], M. Vikkula[1];*
[1]Laboratory of Human Molecular Genetics, de Duve Institute, Université catholique de Louvain, Brussels, Belgium, [2]Vascular Biology Program and Department of Surgery, Children's Hospital Boston and Harvard Medical School, Boston, MA, United States, [3]The Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital; University of Toronto, Toronto, ON, Canada, [4]Danek Gartner Institute of Human Genetics, Sheba Medical Center, Ramat-Gan, Israel, [5]Centre for Vascular Anomalies, Division of Plastic Surgery, Cliniques Universitaires Saint-Luc, Brussels, Belgium.

Lymphedema is a soft tissue swelling resulting from abnormal accumulation of interstitial fluid
containing high molecular weight proteins due to abnormal drainage of lymph by the lymphatic vasculature. Primary lymphedema is due to an abnormal lymphangiogenesis which usually starts *in utero*. Some of the cases are inherited and in most cases have autosomal dominant or recessive mode of inheritance. Some of the autosomal dominant cases have incomplete penetrance and variable expression. Both syndromic and non-syndromic cases have been caused by mutations in genes with major role in lymphangiogenesis including FOXC2, VEGFR3, SOX18, CCBE1, PTPN14 and GCJ2.

We report two consanguineous families with recurrence of an autosomal recessive form of congenital lymphedema. One of the families is of Iranian-Jewish and Israeli descent and the other of Iraqi descent. Direct sequencing of the known lymphedema genes including coding sequences and intron-exon boundaries, did not identify any mutation. Whole genome scan using Affymetrix SNP-Chip 250K was thus performed in both families and no copy number change was identified in the affected members. Autozygosity mapping and parametric linkage analysis also excluded the candidate lymphedema-genes. Three overlapping autozygous regions were identified in the two families and were confirmed by linkage analysis.
Our findings provides evidence for the existence of new causative gene or genes associated with the autosomal recessive form of congenital lymphedema. (E-mail : Miikka.vikkula@uclouvain.be).

P12.128
Use of exome sequencing to identify GJC2; a gene responsible for causing autosomal dominant primary lymphoedema

P. Ostergaard[1], *M. Simpson*[2], *F. Connell*[3], *G. Brice*[1], *S. Mansour*[1], *K. Kalidas*[1], *P. Mortimer*[1], *R. Trembath*[2], *S. Jeffery*[1];
[1]*St George's, London, United Kingdom,* [2]*King's College, London, United Kingdom,* [3]*Guy's Hospital, London, United Kingdom.*

Genotyping array analysis was carried out on two families, all affected by four-limb, primary lymphoedema and linkage to chromosome 1 (LOD 3.54) was identified. The region was approximately 17Mb (150 genes). Instead of analysing these genes using traditional Sanger sequencing, Next Generation Sequencing was employed. Exome sequencing of a proband from one of the families was performed using the Agilent human All Exon Capture Assay and sequenced on the Illumina GAIIx platform with 76bp paired end reads. The sequence reads generated were aligned to the reference human genome sequence (hg18) and the location of variant substitutions and small insertion/deletions defined. Analysis of the region of the genome previously shown to cosegregate with the disease status (chromosome 1 delimited by rs10494988 to rs1043909) revealed only two novel nonsynonymous variants in *NVL* (V746M) and in *GJC2* (S48L). Both changes cosegregated with the affected status in the two families and subsequent sequencing of these genes in 19 unrelated individuals with four-limb lymphoedema revealed another two patients with the S48L change. Two additional nonsynonymous *GJC2* variants in two patients were identified, one unreported (M210R) and one published (P316L). Recently it has been suggested that *GJC2* is a pathogenic gene in lymphoedema (Ferrell et al 2010). Our report describes a novel variant in *GJC2* and confirms the S48L and P316L changes described by Ferrell et al (2010). We have therefore been successful in demonstrating how exome sequencing of one patient, together with linkage analysis, enabled rapid identification of a new gene for primary lymphoedema.

P12.129
Insertion of an SVA element, a non-autonomous retrotransposon, in *PMS2* intron 7 causes Lynch syndrome

H. M. van der Klift[1], *C. M. Tops*[1], *F. J. Hes*[1], *P. Devilee*[2,3], *J. T. Wijnen*[2,1];
[1]*Department of Clinical Genetics, LUMC, Leiden, Netherlands,* [2]*Department of Human Genetics, LUMC, Leiden, Netherlands,* [3]*Department of Pathology, LUMC, Leiden, Netherlands.*

Germ line mutations in the mismatch repair genes *MLH1*, *MSH2*, *MSH6* and *PMS2* cause Lynch syndrome, an autosomal dominant inherited form of cancer predisposition. With an RNA-based mutation detection protocol we found a 71 bp insertion between *PMS2* exon 7 and 8 in the mRNA of one suspected LS case. With Southern blot analysis a heterozygous 2 kb insertion in the genomic DNA of the patient had been found before but the insert could not be amplified at that time. A BLAST search of GenBank with the inserted 71 bp mRNA sequence returned a match with high homology against part of an SVA repeat on chromosome 7q11.23. We now report that the insert is a 2 kb long 5'-truncated SVA element consisting of a VNTR region of 1.4 kb, a SINE-R region and a polyA tail of $(A)_{66}$. This is the first report of an SVA insertion as cause of Lynch syndrome. The inclusion in the mRNA of the first 57 nucleotides of the SVA element together with 14 intronic nucleotides upstream causes a premature termination codon that triggers nonsense mediated RNA decay of the aberrant *PMS2* transcript. The SVA insert is not detectable by current diagnostic testing methods such as MLPA and direct Sanger sequencing on genomic DNA. Probably such a mutation will also be missed with next generation sequencing approaches.

P12.130
MtDNA dysfunction in a transgenic mouse model of Machado-Joseph Disease(MJD)

N. I. Kazachkova[1,2], *M. Raposo*[1,2], *R. Montiel*[3], *C. Bettencourt*[1,4,5], *T. Cymbron*[1,4], *P. Maciel*[6], *M. Lima*[1,4];

Background: We investigated the potential of mtDNA dysfunction as a biomarker of disease progression in MJD using a novel transgenic (TG) mouse model, expressing full-length human ataxin-3 and displaying a motor phenotype (strain FVB/N, line CMVMJD94).
Methods: DNA was obtained from affected (pontine nuclei - Pn) and non-affected tissues (hippocampus - Hp and blood - Bl) of TG mice. Three distinct age-groups were considered: 8, 16 and 24 weeks (before onset, at onset, and at well established phenotype, respectively). Wild-type mice (wt), serving as controls, were analyzed for the same tissues and age groups. Quantitative changes (changes in copy number) as well as qualitative changes (ΔmtDNA3867 deletion) in mtDNA were studied by Fluorescent based quantitative PCR (FQ-PCR) in a total of 177 samples (84 TG and 93 wild-type). The absolute quantities of mtDNA/nDNA were compared by the "absolute quantitation" method.
Results: A clear pattern of mtDNA copies decrease with age was observed for both wt and TG mice (1.06-2.53-fold and 1.24-2.58-fold, respectively). Affected tissue showed higher level of mtDNA copies decrease (1.21 times higher in TG mice) and higher level mtDNA deletions (6.05% more in TG mice). The highest amount of mtDNA deletions was observed in 8 weeks old mice, with higher values for TG mice (49.75-72.75% vs. 47.60-58% of wt animals), decreasing with age.
Conclusions: Our study confirms an association between mtDNA depletion with progression of phenotype in TG mice and indicates that the mtDNA 3,867 bp deletion may play a role in the early stage of the disease.

P12.131
Characterization of prelamin A isoforms accumulated in Mandibuloacral Dysplasia type A (MADA) cells

S. M. Lepore[1], *D. Postorivo*[1], *C. Capanni*[2], *S. Squarzoni*[2], *G. Lattanzi*[2], *N. M. Maraldi*[2,3], *M. R. D'Apice*[1,4], *G. Novelli*[1,4,5];
[1]*Department of Biopathology, Tor Vergata University, Rome, Italy,* [2]*CNR-National Research Council of Italy, Institute of Molecular Genetics, Unit of Bologna c/o IOR, Bologna, Italy,* [3]*Laboratory of Musculoskeletal Cell Biology, IOR, Bologna, Italy,* [4]*Fondazione Policlinico Tor Vergata, Rome, Italy,* [5]*San Pietro Fatebenefratelli Hospital, Rome, Italy.*

Mandibuloacral dysplasia type A (MADA) is a rare autosomal recessive disorder characterized by craniofacial defects, skeletal manifestations, cutaneous changes and partial lipodystrophy. MADA is caused by mutations in the LMNA gene encoding lamin A/C. The molecular features consist in the accumulation of the unprocessed lamin A precursor (prelamin A) at the nuclear rim and in nucleoplasm, with a linear increase of protein amount in older patients. The accumulation of 74 kDa protein, containing a histidine residue in position 527 in C-terminal domain, is caused by wrong process of post-translational modifications and cleavages with slowed down formation of intermediate forms and final mature lamin A.
To find out the prelamin A forms recovered in MADA cells, we performed the immunofluorescence analysis using three different antibodies detecting all forms of prelamin A, both non-farnesylated and farnesylated full-length prelamin A, and an intermediate product carboxymethylated prelamin A.
We show that full-length prelamin A either farnesylated or non-

farnesylated is detectable in middle and high passage fibroblasts, but it's not observed in cells at low passages. Carboxymethylated prelamin A is slightly expressed and detectable only in middle passages.
In conclusion, we show that protein processing changes depending on the passage numbers and the age of patients, suggesting the onset of a feedback mechanism.

P12.132
No evidence for involvement of excess free transforming growth factor-β in disturbed signal transduction in Marfan syndrome

I. Leistra[1], *U. Baylan*[2], *F. S. van Dijk*[1], *A. Maugeri*[1], *H. W. M. Niessen*[2], *G. Pals*[1];
[1]*VU University medical center, dept. of Clinical Genetics, Amsterdam, Netherlands,* [2]*VU University medical center, dept. of Pathology and Cardiac Surgery, ICaR-VU, Amsterdam, Netherlands.*

Background: Marfan syndrome is an inherited connective tissue disorder which is usually caused by mutations in the fibrillin-1(FBN1) gene. In the ethiology, transforming growth factor β(TGF-β) plays an important role. Inactive TGF-β is stored in the large latent TGF-β complex (LLC) in the extracellular matrix, bound to fibrillin-1. Mutations in the FBN1 gene are supposed to impair binding of LLC and cause increased free TGF-β and increased signalling. Activated TGF-β-receptors phosphorylate Smad3, to pSmad3, which in turn is transferred into the nucleus by Smad4, where it is involved in regulation of genes involved in growth, differentiation, inflammation and apoptosis.
Methods: We studied these proteins by immunohistochemical staining of paraffin embedded aortic tissue from 5 Marfan patients, all with a pathogenic FBN1 mutation, that underwent surgery for thoracic aortic aneurysms. Control tissue (n=5) was obtained at autopsy of individuals without aortic aneurysm. Quantification of immuno-staining was performed using Mirax-Scan(Zeiss) and 3D-Histech Pannoramic Viewer1.14.
Results: In controls and patients, TGF-β showed extensive staining in the tunica adventitia. In tunica media no TGF-β was detectable, except in areas adjacent to rupture. Intact areas of the tunica media showed no staining of TGF-β, but did show significantly increased staining of total Smad3 (p=0.006), Smad4 (p=0.001) and nuclear staining of pSmad3 (p=0.048), in patients compared to controls,
Conclusion: We conclude that TGF-β signal transduction is disturbed in Marfan patients with a mutation in FBN1, but the underlying mechanism is not clear. There is no evidence for involvement of excess free TGF-β.

P12.133
MLPA analysis of *FBN1* and *TGFBR2* gene in Marfan syndrome and associated disease: results of a large French study

N. Hanna[1,2,3], *L. Gouya*[1,3], *B. Grandchamp*[3], *C. Baumann*[4], *C. Francannet*[5], *D. Lacombe*[6], *B. Leheup*[7], *J. Lespinasse*[8], *L. Faivre*[9], *G. Jondeau*[3], *C. Boileau*[1,2,3];

Marfan syndrome (MFS) is a prevalent connective tissue disorder with manifestations in the skeletal, ocular, and cardiovascular systems. In most cases MFS is caused by heterozygous mutations in the gene encoding the extracellular matrix protein fibrillin-1 (*FBN1*). Heterozygous mutations in the genes coding for transforming growth factor beta receptors I (*TGFBR1*) and II (*TGFBR2*) have also been reported in patients with MFS2 and MFS-related disorders.
In classical MFS, mutation analyses fail to detect *FBN1* involvement in about 10% of cases, possibly suggesting the limitations of commonly used standard PCR-based screening approaches.
In this study, we searched for partial or complete deletions/duplications of *FBN1* and *TGFBR2* genes using MLPA technique in a cohort of 206 patients with suspected MFS or MFS-like phenotypes, negative for point mutations in the *FBN1, TGFBR1* and *TGFBR2* genes.
16 abnormal patterns were found representing 14 deletions and 1 duplication in *FBN1*, and 1 deletion in *TGFBR2*. Real-time quantitative PCR confirmed 15 abnormal patterns. In one case, the abnormal pattern was due to an insertion of an interspersed *Alu* element in the target sequence of the MLPA probe.
Taken together, the frequency of *FBN1 or TGFBR2* deletions or duplications in patients with suspected MFS without point mutation in *FBN1*, *TGFBR1*, and *TGFBR2* can be estimated as 15/206 (7%). *FBN1* and *TGFBR2* gross deletions or duplications could thus be responsible for 0.5 to 1% of MFS cases. However, the relatively high cost of the MLPA technique raises the question of its routine use in a diagnostic laboratory.

P12.134
Marfan syndrome with a complex chromosomal rearrangement including deletion of the *FBN1* gene

M. E. S. Colovati, L. R. J. da Silva, S. S. Takeno, T. I. Mancini, A. R. N. Dutra, ***M. I. Melaragno****, A. B. A. Perez;*
Universidade Federal de São Paulo, São Paulo, Brazil.

Mutations in the *FBN1* gene, mapped at 15q21.1, are the major cause of Marfan syndrome (MFS), an autosomal dominant connective tissue disorder, which displays variable manifestations in the cardiovascular, ocular, and skeletal systems. Only four cases with deletions of the whole *FBN1* gene detected by molecular cytogenetic techniques were found in literature. In only two of these patients, there was the presence of clinical features of the Marfan syndrome spectrum associated to mental retardation. Chromosomal alterations in Marfan syndrome, such as interstitial deletions involving the 15q21.1 band are rare. There is no described patient with MFS and complex chromosome rearrangement (CCR) involving more than two breakpoints on two or more chromosomes. We report a 16-year-old female with MFS spectrum (positive thumb and wrist sign, scoliosis, joint hyperlaxity, high-arched palate with dental crowding, dysmorphism, mitral insufficiency with dystrophic valve, striae) associated to intellectual deficiency. Due to atypical marfanoid phenotype, cytogenetic study was performed using G-banding that revealed a *de novo* balanced translocation involving chromosomes 6, 12 and 15 with breakpoints apparently at 6q22, 12q24 and 15q21. Whole genomic array using Cytogenetics Whole-Genome 2.7M Array (Affymetrix) showed a 1.9 Mb deletion in the 15q21.1 region, including the *FBN1* gene. Fluorescence in situ hybridization (FISH) with painting and bacterial artificial chromosome probes revealed a much more complex rearrangement with eight breakpoints as follows:
46,XX,t(6;12;15)(6pter→6q13::15q15.1→15q21.1::15q21.1→15q22.1::6q14.1→6q16.3::12q24.22→12qter;12pter→12q24.21::6q21→6q22.2::15q22.2→15qter;15pter→15q14::6q22.31→6qter).arr 15q21.1(45,466,733-47,335,104)x1. This is the first report of MFS with a complex chromosome rearrangement with a deletion of the *FBN1* gene and contiguous genes. (Financial support: FAPESP, Brazil).

P12.135
49 Novel mutations of Marfan syndrome in Czech population

E. Průšová*, R. Měch, H. Slavíková, A. Bóday;*
P&R LAB a.s., Nový Jičín, Czech Republic.

Marfan syndrome (MFS) is a heritable autosomal dominant disorder of connective tissue with prevalence of between 1 in 5-10 000. Approximately 25% of MFS patients are sporadic cases due to new mutations. MFS is noteworthy for its clinical variability. Major features of the MFS include cardiovascular disorders (dilatation and dissection of ascending aorta), eye disorders - *ectopia lentis*, defects of skeletal system - *pectus carinatum*, *pectus axcavatum* and/or other diagnostics criteria as *arachnodactyly*.
MFS is caused by mutations in fibrillin 1 gene (*FBN1*) resulting in defective glycoprotein fibrillin-1. *FBN1* is located on chromosome 15 at locus q15-q21.1. Recently, there are showed that three other genes *FBN2* (5q23-q31), *TGFBR2* (3p22) and *TGFBR1* (9q22) influence MFS. Mutations in these genes and their phenotype manifestations are also in Loyes-Dietz syndrome, Marfan syndrome type II. and thoracic aortic aneurysm.
The molecular analysis includes mlpa (multiplex ligation-dependent probe amplification), separation of PCR products by SSCP (single-strand conformation polymorphism) and sequencing.
We have performed mutation detection on 395 patients with suspected MFS. There were detected 49 novel mutations.

P12.136
Complex mutation screening of FBN1 and TGFBR2 genes in patients with Marfan and marfan-like syndromes by different highly sensitive methods (DCODE Universal Mutation Detection System, HRM, Sequencing)

R. Valiev[1], *R. Khusainova*[1,2], *E. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of biochemistry and genetics USC RAS, Ufa, Russian Federation.*

Marfan syndrome (MFS) is an inherited autosomal dominant connective tissue disorder. Abnormalities appear in skeletal, ocular and cardiovascular systems. The main cause of MFS are mutations in the fibrillin1 gene (FBN1). Recently, the transforming growth factor beta receptor 2 gene (TGFBR2) has been shown to be associated with a second type of this disorder with typically mild or absent ocular involvement (MFS type 2) as well as with classical MFS. Currently we analyzed some regions of FBN1 and TGFBR2 genes in 80 patients with MS and marfan-like syndromes from different areas of Russia by several methods: SSCP, TTGE, Heteroduplex Analysis on the BioRad DCODE Universal Mutation Detection System and HRM-method on Bio-Rad CFX96 system; and sequencing on MegaBace 1000. We identified two missense mutations (G1176Y in 28 exon and C2489Y in 60 exon) which affects cbEGF-like motifs of fibrillin-1 protein in two patients with classical MFS symptoms. We also found 9 polymorphisms both in coding and non coding regions of FBN1 gene, five of them are not previously described. One novel mutation (670C>T; T223M) has been found in TGFBR2 gene in two unrelated patients with marfan-like syndrome who did not fulfill Ghent nosology and who did not have mutations in FBN1 gene. Mutation T223M affects highly conserved serine/threonine protein kinases catalytic domain that leads to change phospho transferring status of TGFBR2 protein. In addition two novel polymorphisms have been found in intronic regions of TGFBR2 gene. Mutation screening of FBN1 and TGFBR2 genes will be continuing.

P12.137
Genetic analysis of Marfan syndrome

F. Fernández-Rosado[1], *E. Martínez-Espín*[1], ***M. Álvarez-Cubero***[2], *J. García-Pinilla*[3], *E. Rueda*[3], *F. Cabrera-Bueno*[3], *J. Lorente-Acosta*[4], *C. Entrala-Bernal*[1];

Department of Legal Medicine. University of Granada., Granada, Spain.*

The Marfan syndrome is a genetic disorder of the connective tissue which has many different clinical features most of them affecting the skeleton, skin, and joints. The varieties are known as type I (dominant autosomic disease related to FBN1 gene) and type II associated to gene TGFBR2. Whereas FBN1 gene codify for a protein known as fibrillin-1 which is needed for the formation of elastic fibers of connective tissue. However, TGFBR2 gene codify for the receptor 2 of a growth factor. The aim of this poster is to present the analysis done in these both genes in eight patients from an Andalusian population (South of Spain), diagnosed of Marfan syndrome. The extraction of DNA was done by an organic procedure with phenol/chlorophorm and the amplification method was using VariantSEQr® (Applied Biosystems). The sequencing process was done in adjacent codifying and intronic regions of both genes.

As a result, we could observe four Nonsense mutations in four to eight patients. Two of them (p.R2220X and p.R1125X), have been previously described in international data bases (HGMD, Uniprot) in Marfan syndrome type I. However, the others (p.E1133X and p.Q1419X) have never been cited in any data base. It has also described five Missense mutations in four to eight patients and similar results from the above described has been noted. Two of them are cited in data base (p.R122C and p.G343R) for causing Marfan syndrome type I, whereas the others (p.C830G, p.S1345I and p.P1258S) are the first time to be notice in this syndrome.

P12.138
Novel, recurrent mutations and a complex rearrangement in the MECP2 gene

T. Todorov[1,2], *A. Todorova*[1,2], *C. Motoescu*[3], *V. Bojinova*[4], *D. Iancu*[5], *D. Craiu*[3], *D. Stoian*[3], *L. Barbarii*[5], *P. Dimova*[4], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Pediatric Neurology Clinic, Alexandru Obregia Hospital, Bucharest, Romania,* [4]*"St. Naum" Hospital, Medical University Sofia, Sofia, Bulgaria,* [5]*Genetics Department - National Institute of Legal Medicine "Mina Minovici",, Bucharest, Romania.*

Rett syndrome (RTT) is caused by mutations in the methyl-CpG-binding protein 2 (MECP2) gene. The MECP2 gene has some unique characteristics: 1) it is mainly affected by de novo mutations, due to recurrent independent mutational events in a defined "hot spot" regions or positions; 2) complex mutational events along a single allele are frequently found in this gene; 3) most mutations arise on paternal X chromosome. The recurrent point mutations involve mainly CpG dinucleotides, where C>T transitions are explained by methylation-mediated deamination. The complex mutational events might be explained by the genomic architecture of the region involving the MECP2 gene. The finding that most spontaneous mutations arise on paternal X-chromosome supports the higher contribution of replication-mediated mechanism of mutagenesis. We present 9 types of mutations in the MECP2 gene, detected in a group of 22 Bulgarian and 6 Romanian classical RTT patients. Thirteen patients were clarified on molecular level (46.4%). The point mutations in our sample account for 61.5%. One intraexonic deletion was detected in the present study (7.7%). A novel insertion c.321_322insGAAG, p.(Lys107_Leu108insGluAlafs2*) was found (7.7%). Large deletions and complex mutations account for 23%. A novel complex mutational event c.[584_624del41insTT; 638delTinsCA] was detected in a Romanian patient. Complex gene rearrangements involving a combination of deletions and insertions have always been most difficult to detect, to specify precisely and hence to explain in terms of their underlying mutational mechanists.

P12.139
Exome sequencing in siblings with intellectual disability

J. H. M. Schuurs-Hoeijmakers*, A. T. Vulto-van Silfhout, L. E. Vissers, J. de Ligt, J. Y. Hehir-Kwa, R. Pfundt, J. A. Veltman, B. W. M. van Bon, H. van Bokhoven, H. G. Brunner, B. B. A. de Vries, A. M. P. de Brouwer;*
Department of Human Genetics, Nijmegen Centre for Molecular Life Sciences and Institute for Genetic and Metabolic Disorders, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

The extensive clinical and genetic heterogeneity of Intellectual Disability (ID) poses a major challenge for the identification of the underlying molecular causes both in research and diagnostic laboratories. Recent and fast technical developments allow to sequence the complete coding sequence of a human genome of one individual at once (exome sequencing). This has revolutionized clinical genetic research, offering new opportunities to identify the genetic cause in ID patients and is expected to become implemented soon in the clinical practice as a diagnostic tool.

We have collected families with at least two individuals with (non)-syndromic ID that are suggestive for an autosomal recessive inheritance pattern. In these families, we perform exome sequencing on genomic DNA of one individual of each family. Stringent filtering with an in-house developed pipeline allows fast identification of potential homozygous and compound heterozygous mutations. In addition, homozygosity mapping with a 250K SNP genotyping array has been performed to identify overlapping homozygous genomic regions in siblings because we expect a significant contribution of pathogenetic homozygous mutations. So far, exome sequencing has been performed for 15 families and potential mutations are being validated. Next, we aim to identify additional mutations in our candidate ID genes in a cohort of patients with a comparable phenotype to confirm involvement of the respective gene in ID.

This study will contribute to identification of genes that cause recessive ID and will help to implement exome sequencing for autosomal recessive ID into the diagnostic setting.

A first systematic evaluation of Intellectual Disability gene function in neuronal development

M. A. W. Oortveld[1], *E. van Engelen*[1], *T. Ellenkamp*[1], *A. Fernandes*[2], *J. M. Kramer*[1], *S. Keerthikumar*[3], *D. Haddad*[2], *B. Nijhof*[1], *A. Castells Nobau*[1], *H. van Bokhoven*[1], *C. Zweier*[4], *M. A. Huynen*[3], *P. Verstreken*[2], *A. Schenck*[1];

More than 440 genes have been implicated in Intellectual disability (ID) to date. They provide an exciting molecular window into the neurobiology of cognition and brain development. However, little is known about the role of most ID genes in the nervous system. To change dimensions of research in this field, we use *Drosophila* to systematically uncover ID gene function.

In order to reveal ID gene function in flies, large scale RNAi screens are performed in which relevant aspects of neuronal architecture, functioning and behavior are quantitatively assessed. Because genes that cause similar phenotypes likely operate together, our functional data are further subjected to bioinformatics analysis to predict groups of ID genes that act in the same pathways. We aim to dissect these pathways and identify novel molecular players and interactions.

In my PhD project, I have systematically dissected the role of all fly orthologues of human ID genes in neuronal function and development. My RNAi screen was focused on *Drosophila* photoreceptor neurons, for which I have established a phototaxis assay. This assay is used as a simple read out to measure photoreceptor functionality.

I have recently completed the primary RNAi screen, which yielded many interesting results. Ablation of ID genes resulted in morphological phenotypes in 40% of all cases and 9% gave functional/phototaxis phenotypes. Strikingly, many of these first hits appear to be related to microtubules, actin cytoskeleton, mitochondria or membrane/vesicle trafficking.

I will present these findings and my follow up approach using secondary assays such as histology and electrophysiology.

P12.141

Identification of MAN1B1 as a gene with elevated mutation frequency in non-syndromic autosomal recessive intellectual disability

M. Rafiq[1], *A. Kuss*[2,3], *L. Puettmann*[2], *A. Noor*[1], *H. Hu*[2], *M. Garshasbi*[2], *K. Moremen*[4], *G. Ishak*[5], *R. Weksberg*[6], *M. Ayub*[7,8], *R. Ullmann*[2], *A. Tzschach*[2], *K. Kahrizi*[9], *J. Vincent*[1,10], *H. Ropers*[2], *M. Ansar*[11], *H. Najmabadi*[9];

We have recently identified an overlapping homozygosity-by-descent locus on chromosome 9q34.3 (MRT15) by genome-wide genotyping in 4 consanguineous families with non-syndromic autosomal recessive ID (NS-ARID) from Pakistan, and 1 from Iran. Enrichment of the exonic regions within the respective linkage interval followed by next generation sequencing revealed a missense mutation (R334C) in the MAN1B1 gene, segregating with ID in the Iranian family. Mutation screening in the Pakistani families revealed a homozygous nonsense mutation (W473X) affecting MAN1B1 in one family, and an additional missense mutation (E397K) in this gene segregated in 3 families from the same village with likely shared inheritance. Both missense mutations affect amino acid residues that are conserved throughout the animal kingdom and potentially disrupt the oligosaccharide binding properties at the enzyme's catalytic domain. MAN1B1 encodes the mannosyl oligosaccharide alpha 1,2-mannosidase, which belongs to the glycosyl hydrolase family 47 (GH47). GH47 proteins are believed to be key enzymes in the maturation of N-glycans in the secretory pathway and seem to be involved in the timing and disposal of misfolded glycoproteins through the endoplasmic reticulum-associated degradation (ERAD) pathway. Unlike patients suffering from the lysosomal storage disease, mannosidosis (caused by mutations in lysosomal α-mannosidase enzyme MAN2B1, and lysosomal β-mannosidase enzyme MANBA) who present with a variety of syndromic features, the patients from all 5 families identified with MAN1B1 suffer from purely non-syndromic ID. Thus we presume that here a different pathological mechanism, e.g. disruption of the ERAD pathway, is involved.

P12.142

1qter microdeletion syndrome: molecular and clinical analysis of 8 patients and characterization of a critical region for mental retardation

A. Paubel[1,2,3], *C. Dubourg*[4], *C. Le Caignec*[5], *S. Blesson*[1], *M. Moizard*[1], *M. Delrue*[6], *D. Cailley*[6], *B. de Vries*[7], *S. Lynch*[8], *A. Toutain*[1,2,3];

The 1qter microdeletion syndrome with microscopically visible deletion of the distal part of the long arm of chromosome 1 (1q42, 1q43 and 1q44) has a well known phenotype which was characterized by Johnson *et al.* in 1985. It includes mental retardation (MR), severe progressive microcephaly, growth retardation, seizures, variable cerebral, cardiac, urogenital, gastro-oesophageal abnormalities and dysmorphic facial features (round face, epicanthal folds, upslanting palpebral fissures, short broad nose, smooth philtrum, downturned corners of the mouth and thin vermilion border of the lips, microretrognathia, palatal defects and low set ears).

Several studies have focussed on cerebral anomalies and have defined critical regions for MR, microcephaly and corpus callosum anomalies, however differing in size and location. Recently, in a series of 4 patients, Caliebe *et al.*, 2010 pointed out the *HRNPU* gene (1q44) as potentially involved in corpus callosum anomalies.

We report the characterization of the deletion in 8 patients with pure 1qter microdeletion syndrome by array-CGH (44K Agilent chip) and analysis of their phenotype. By pooling clinical and molecular data of our 8 patients with those of 65 patients from the literature, we were able to define in this largest series of 1qter microdeletion patients, a 450kb critical region for MR.

This region includes 3 genes *FAM36A*, *HNRPU* et *EFCAB2* which are candidates for brain development.

P12.143

Non-syndromic XLMR due to a novel frameshift mutation in *MED12*

G. Lesca[1,2], *D. Boggio*[1], *M. Moizard*[3,4], *W. Chen*[5], *H. Hu*[5], *S. Haas*[5], *H. Ropers*[5], *V. Kalscheuer*[5], *G. Bussy*[6], *P. Edery*[1,2], *M. Reynaud*[3,4], *J. Lespinasse*[7];

X-linked mental retardation (XLMR) is a common disease arising from many mutations along the X chromosome. They have been divided into syndromic and non-syndromic according to the association of

additional features. Identification of genes causing non syndromic XLMR has long been challenging but large-scale systematic resequencing has been shown to be promising for the discovery of rare, disease causing sequence variants.
We report on a family including 10 affected males with severe MR and several females with variable cognitive impairment consistent with X-linked recessive inheritance. Male patients all had severe mental retardation and behavior problems. Dysmorphic features included long narrow face, malar hypoplasia, large forehead, full nasal root, thin nose, small philtrum. Head circumference was normal. They had no marfanoid habitus or visceral malformations. Brain MRI, in two patients, showed isolated moderate cerebral atrophy. Most affected females were moderately mentally affected but one of them had severe MR with autistic features.
The initial linkage study revealed a localization region from Xp11.21 (AlaS2) to Xq22.3 (COL4A5) in 6 of 7 affected males. A novel, unreported frameshift mutation was identified in the *MED12* gene by exome sequencing performed within the EuroMRX consortium. The mutation segregated with disease in all affected males. *MED12* encodes a subunit of the mediator complex, which serves as an interface between transcription factors and RNA polymerase II. Two recurrent missense mutations in *MED12* have been previously reported in Lujan-Fryns syndrome and in FG syndrome type 1 (Opitz-Kaveggia). The present data extends the phenotypic spectrum associated with *MED12* mutations.

Search for mutations and pathogenic haplotypes in hemizygous genomic regions of patients with intellectual disability (ID)

E. Schroeck[1], *A. Rump*[1], *J. Hof*[1], *N. Tyshchenko*[1], *K. Cremer*[2], *D. Wieczorek*[2], *J. Hoyer*[3], *A. Reis*[3], *S. Berkel*[4], *U. Moog*[4], *M. Hempel*[5], *S. Tinschert*[1], *K. Hackmann*[1];
[1]*Institut für Klinische Genetik, TU Dresden, Dresden, Germany,* [2]*Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany,* [3]*Humangenetisches Institut, Universitätsklinikum Erlangen, Erlangen, Germany,* [4]*Institut für Humangenetik, Universitätsklinikum Heidelberg, Heidelberg, Germany,* [5]*Institut für Humangenetik, TU München, München, Germany.*

Background: Molecular Karyotyping in intellectually disabled children has revealed family-specific deletions which do not represent known CNVs. Such deletions could either be harmless familial variants or recessive mutations. If the latter is true, the affected child should carry an additional mutation on the homologous chromosome. Since autosomal recessive inheritance is supposed to account for nearly a quarter of all individuals with non-syndromic MR, the likelihood of finding a second mutation in children with an inherited deletion is substantial.
Experimental approach: Sanger-sequencing of coding exons of selected genes. Criteria for gene selection: complete or partial deletion of one allele plus expression in brain. Selected genes: *SYT11, NRXN1, ARPP-21, HIST1H2AG, HIST1H2AH, HIST1H2BJ, ANLN, EXOC4, LINGO2, VCL, ALDOA, DOC2A, ASPHD1, KCTD13, RAB37,* and *SULT4A1.*
Results: Besides several SNPs in various candidate genes we have identified three unclassified variants in *LINGO2* (p.Asp135Asp, p.Arg369Gln, p.Asn522Tyr) in three unrelated children with ID. Since all of these children have a partial *LINGO2*-deletion as well, the observed variants may represent recessive mutations.
Future work: Since LINGO1 was shown to be critical for CNS myelination in mice, the closely related LINGO2 may also be critical for mammalian brain development. As a first step to elucidate a clinical relevance of our *LINGO2* variations, we are going to quantify *LINGO2* expression on cDNA level in our ID-patients with a *LINGO2* deletion, as well as in the corresponding healthy family members. Furthermore, we will determine the allele frequency of the *LINGO2* variants mentioned above by genotyping 500 healthy individuals at these loci.

P12.145**

Pitfalls in the diagnosis of X-linked mental retardation: next generation sequencing reiterates the role of *ATRX* in both syndromal and non-syndromal XLMR

R. Michaelson-Cohen[1], *T. Walsh*[2], *M. Lee*[2], *F. Abidi*[3], *C. Schwartz*[3], *M. King*[2], *E. Levy-Lahad*[1];
[1]*Shaare Zedek Medical Center, Hebrew University, Jerusalem, Israel,* [2]*Departments of Medicine and Genome Sciences, University of Washington, Seattle, WA, United States,* [3]*JC Self Research Institute, Greenwood Genetics Center, Greenwood, SC, United States.*

We report the 15 year evolution of genetic analysis in a non-consanguineous Ashkenazi-Jewish family. Three male sibs were affected with mild-moderate MR, variable dysmorphism, and one also with microcytic-anemia partially responsive to iron replacement. Karyotypes, FraX testing were normal. Marker analysis demonstrated linkage to 47Mb X-pericentromeric region (DXS990-DXS1003; LOD score 1.8), two female sibs were predicted carriers, one bore an affected son. X-inactivation didn't reveal skewing in obligate/predicted carriers. Sequencing of *RSK2, ACSL4, ARX, FTSJ1, GDT1, IL1RAL1, JARID1C, OPHN1, PQBP1, ZNF41* and *ATRX* (helicase& zinc-finger domains), and array-CGH were normal. An Xq23 1.5Mb duplication was identified in affected and unaffected males, therefore regarded unrelated to MR. One affected male was included in large-scale Sanger-sequencing X-exon study (718 genes, Tarpey, Nature Genetics 2009); no mutation identified.
We performed unbiased capture& sequencing of all X-exons (Agilent SureSelect X-Exome kit, Illumina GAIIx platform), and identified a mutation in 5' region of *ATRX:* c.109C>T, p.R37X. This mutation has been reported by Guerrini (Neurology, 2000) in a family with mild MR and epilepsy, and subsequently identified in original Chudley-Lowry family (Abidi, European Journal Human Genetics, 2005). The mild phenotype of this nonsense mutation is related to downstream alternative-translation initiation. In contrast to other cases, this family didn't have skewed X-inactivation or epilepsy. In retrospect, it became clear that Tarpey's study did not include *ATRX* 5' exons. We have subsequently identified two other families with ATRX-R37X, and conclude that this could be an overlooked cause of mild XLMR, which may not be covered in XLMR testing-panels.

P12.146

Identification of novel X-Linked Mental Retardation mutations in Israeli population

D. Oz-Levi[1], *E. Ben-Asher*[1], *T. Olender*[1], *E. K. Ruzzo*[2], *K. Pelak*[2], *H. Resnik-Wolve*[3], *B. Ben-Zeev*[3], *D. Goldstein*[2], *E. Pras*[3], *D. Lancet*[1];
[1]*The Weizmann Institute of Science, Rehovot, Israel,* [2]*Duke University, Durham, NC, United States,* [3]*Sheba Medical Center, Tel-Hashomer, Israel.*

Mental retardation affects 1%-3% of the general population and is characterized by malfunctioning of the central nervous system, resulting in significant intellectual disability. Genetic etiologies are found in about half of the cases and include chromosomal or structural abnormalities, genomic disorders and single gene diseases. A significant portion of known mental retardation disease-causing genes resides on human chromosome X, whereby the affliction is more prevalent in males. Despite extensive investigations, the molecular basis for many X linked mental retardation (XLMR) cases has not been reveled by classical genetic approaches, leaving numerous families without prenatal diagnosis. Next-Generation-Sequencing techniques open new avenues in the elucidation of such Mendelian disorders. We have recruited 6 Israeli families of different ethnic origins, with a total of 21 affected males, showing both syndromic and non-syndromic XLMR. Among syndromic families, XLMR is accompanied with neurological anomalies causing a neurodegenerative disease and early death. To uncover the disease causing mutations, we design a novel X chromosome 'super-exome' capture kit, which includes all coding and non-coding exons, with extended splice junctions, RNA genes, as well as regulatory and highly conserved genomic regions. In parallel, we are developing next-generation-sequencing bioinformatics tools suitable for super-exome analyses. Deciphering the disease-causing mutations will shed new light on the mechanisms of mental retardation with implications to other neuronal deficits, and would provide such families with accurate genetic testing and prenatal diagnosis.

P12.147
Deletion or disruption of *CNKSR2*, a scaffold protein in the RAS/MAPK-pathway, causes X-linked mental retardation

G. Houge, *R. Hovland;*
Center for medical genetics and molecular medicine, Bergen, Norway.

In our diagnostic laboratory aberrations of *CNKSR2* were discovered in two boys with developmental delay: The first was a 5-years old boy with microcephaly and epilepsy. He had a 234 kb deletion removing 17 of 21 *CNKSR2* exons. The deletion was inherited from his healthy mother. Further family follow-up is ongoing. The second patient is a 12-years old boy with a *de novo* complex rearrangement in the Xp22.1 subdomain with a 517 kb duplications/triplications affecting the first part of *CNKSR2* followed by a 695 kb duplication of the last part of *CNKSR2* and the following four genes (*SMPX*, *MBTPS2*, *SMS* and *PHEX*). It is likely that the *CNKSR2* gene is disrupted by the rearrangement. This boy was born with septooptic dysplasia and no pituitary gland. He was probably moderately mentally retarded until age 6, when idiopathic malignant hyperthermia with rhabdomyolysis caused severe brain damage.
Our findings suggest that mutations in *CNKSR2* could be novel cause of X-linked mental retardation, an assumption supported by high expression in the brain and a role in RAS/MAPK-dependent signal transduction.

P12.148
X-exome sequencing of Finnish families with X-linked intellectual disability

F. Doagu[1], *M. Somer*[2], *M. Peippo*[2], *S. Haas*[3], *H. Hu*[3], *I. Järvelä*[1], *V. Kalscheuer*[3];
[1]*Department of Medical Genetics, University of Helsinki, Helsinki, Finland,*
[2]*Department of Medical Genetics, Family Federation of Finland, Helsinki, Finland,* [3]*Max Planck Institute for Molecular Genetics, Berlin, Germany.*

X-linked intellectual disability (XLID) is present in 2-3% of the population. To date, over 1000 human disorders are known that cause intellectual disability (http://www.ncbi.nlm.nih.gov/Omim/). In half of the cases with severe and in 70 - 80 % of cases with mild ID the cause is unknown. Genetic factors are estimated to cause about 50 % of severe ID. To date, over 90 genes have been identified to underlie XLID (http://xlmr.interfree.it/home.htm).
Here we have applied exome sequencing of the X-chromosome to identify causative genes in four Finnish families with affected males in different generations, suggesting an X-chromosomal mode of inheritance.
In all male patients of the analyzed families a total of 17 variants were predicted. Among them were novel mutations in the established XLID genes *DLG3*, CULB4 and GRIA3. In addition, a splice site mutation in a novel candidate XLID gene was found.
In the preliminary analysis the mutation found in the novel XLID candidate gene is perfectly co-segregating with the disease in the family in which it was found. Further studies are going on to establish the causative nature of the novel gene in XLID. Co-segregation analysis of the mutations in the established XLID genes is in progress.

P12.149
Case story: a boy with fragile X and two microduplications on chromosome Xp.

B. S. Kristiansen[1], *S. T. Moeller*[1], *J. Graakjaer*[1], *M. Rokkjaer*[2], *A. Bojesen*[1];
[1]*Department of Clinical Genetics, Sygehus Lillebaelt, Vejle, Denmark,*
[2]*Department of Paediatrics, Sygehus Lillebaelt, Kolding, Denmark.*

We describe a 2 year old boy with delayed motor and cognitive development, and suspicion of progressive muscle weakness. The boy had healthy unrelated parents, and no family history of mental retardation or muscle disease.
The boy was tested and found positive for Fragile X with both PCR and Southern blotting. He had 3 different CGG-repeats on 400, 500 and 900 repeats. The fragile site was inherited from the mother, who had a premutation. Additionally two small duplications were found by array-CGH analysis. Both duplications were located on chromosome X (Xp22.11 and Xp21.2). MLPA-analysis confirmed both duplications. It was found that both duplications were maternally inherited.
The duplication on Xp21.2 involves at least exon 53-67 of the DMD gene, which explains the muscular symptoms. A muscle biopsy showed muscle degeneration with Becker like immune reaction. Duplication within the DMD-gene is relatively well described and the phenotype mostly relates to changes in muscle biopsy.
As to dup Xp22.11 there has been other reports of patients with duplications in the same area, but not of the same size, although there is a strong link to X-linked MR. The extent of MR, is currently too early to evaluate due to the boys young age, but the contribution of dupXp22.11 will be difficult to assess.
In this case we found 3 different mutations that all could contribute to explain the phenotype of this patient. The parents are intending to use this prenatally in the next pregnancy. We are currently awaiting CVS.

P12.150
Retrospective evaluation and prospective routine use of PCR-based protocols for *FMR1* screening and sizing in a clinical setting

D. Heine-Suñer[1], *B. Sierra*[1], *C. Vidal*[2], *J. Rosell*[1], *N. Marlowe*[3];
[1]*Genetica-Hospital Universitari Son Espases, Palma de Mallorca, Spain,*
[2]*Sequenciació-Hospital Universitari Son Espases, Palma de Mallorca, Spain,*
[3]*Celera Corporation, Alameda, CA, United States.*

Fragile X is the most common cause of intellectual disability and is inherited via a dynamic expansion of a trinucleotide (CGG) repeat in FMR1. Historically, PCR assays have not adequately resolved large premutations, full mutations, male mosaics, and females with apparent homozygosity. Southern analysis can detect the full mutation, large premutations and evaluate methylation but it does not always detect small premutations. We have performed an evaluation of two protocols that utilize two different sets of *FMR1* PCR primers to establish preliminary evidence of reliability, robustness, sensitivity, specificity and suitability for routine testing. The study was divided into a retrospective part (enriched with expanded allele types) and a prospective (routine, unselected) part. We studied retrospectively DNAs of 200 patients that included a whole range of FMR1 expansion types (normal, grey zone, premutation, full mutation and mosaic samples of both genders). All samples had been previously characterised by in-house PCR and Southern blot. In addition, we studied 330 patients prospectively. Results obtained for prospective patients were verified with in-house PCR and/or Southern blotting. The results obtained were comparable. We were able to detect retrospectively all known expansions and prospectively 25 expanded alleles and reliably determine if female samples were homozygous, heterozygous (resolution of 1 repeat) or carriers of an expanded allele. We propose a workflow for the use of a combination of both sets of primers in a clinical setting and conclude that they can reliably detect all expanded alleles without the use of Southern blotting in female and male samples.

P12.151
Fragile X syndrome molecular diagnosis - 20-years experience from a single laboratory.

S. O. Rzońca, *M. Gos, M. Milewski, A. Szpecht- Potocka, M. Nawara, D. Szopa, D. Sielska, J. Czekajska, J. Bal;*
Medical Genetics Department, Institute of Mother and Child, Warsaw, Poland.

Fragile X syndrome (FXS) is the most common form of inherited X-linked mental retardation. More than 99% of FXS cases are caused by CGG triplet expansion (>200 repeats) in 5' untranslated region of the *FMR1* gene that leads to low expression or absence of the FMRP protein.
Our laboratory is a reference one for FXS diagnosis. Together, 4983 individuals with FXS clinical suspicion and their families were tested with PCR screening method and Southern Blot when necessary. Till 2011, 301 families with confirmed at least one FXS case were registered. Two hundred eighty five probands were diagnosed with *FMR1* mutation. The molecular analysis performed in their families revealed the presence of mutation in 161 relatives (82 males, 79 females) and premutation in 223 relatives (16 males and 207 females, among them 149 mothers).
In 4682 cases (3818 males, 864 females) dynamic mutation in the *FMR1* gene was excluded. The PCR screening method, implemented in 2001, was sufficient for FXS exclusion in 3003 (71.5%) males and 488 (32.2%) females. The implementation of GeneScan method, allowed for the reduction of the number of Southern Blot analyses performed for uninformative cases, from 67.8% to 23.0% ($p < 0,05$) of the total female individuals.

Although new methods are developed for FXS diagnosis, PCR screening with Gene Scan method followed by Southern blot analysis still seems to be the best protocol for this disease. Selected cases with excluded *FMR1* mutation undergo further studies of X-linked mental retardation in our laboratory.

P12.152
Clinical variability in fragile X syndrome

M. Macovei, *M. Panzaru, R. Popescu, L. Caba, L. Butnariu, E. Braha, R. Cojocariu, C. Rusu;*
"Gr.T.Popa" University of Medicine and Pharmacy, Iasi, Romania.

Fragile X syndrome is the most frequent cause of inherited mental retardation and the second most common cause of genetically associated mental deficiency after trisomy 21.
The majority of fragile X syndrome patients present a loss of function mutation in the FMR1 gene caused by the expansion (>200 repeats) of a single trinucleotide sequence (CGG) located in the FMR1 gene at Xq27.3.
Clinical features in males with fragile X syndrome are represented by developmental delay, intellectual disability, facial dismorphy (long face, large ears, prominent jaw) and macro-orchidism.
The cytogenetic test consists in identifying a "fragile site" on chromosome X from cells cultured in a folate deficient medium. The present standard diagnostic test involves molecular genetic techniques (Southern blot and PCR).
For illustrating the clinical variability in fragile X syndrome, we will present cases from 2 separate families.
The first case, R.D. (4 years old), male, presents cleft palate associated with severe mental retardation, high forehead, elastic decollated ears, mild retrognathism, accentuated plantar creases. The diagnosis was made using PCR; the karyotype did not identify any "fragile site".
The second case is B.D. (27 years old), male, with severe mental retardation, asymmetric elongated face, high and narrow palate, prognathism, big ears, macroorchidism, bilateral thumb hypoplasia, plantar crease. The cytogenetic test identified a 46, XY, fraXq27 karyotype.
The fragile X syndrome is phenotypically heterogeneous. This has important implications for clinical and differential diagnosis emphasizing also the necessity of performing molecular analysis of the FMR1 gene in mentally retarded patients.

P12.153
A new locus for autosomal dominant microcephaly associated with lymphedema

L. Van Laer[1], *G. Van Camp*[1], *E. Fransen*[1,2], *H. Desimpel*[3], *B. P. Leroy*[4], *J. G. Leroy*[5], *B. Loeys*[1];
[1]*Center of Medical Genetics, University of Antwerp and University Hospital of Antwerp, Antwerp, Belgium,* [2]*StatUA Center for Statistics, University of Antwerp, Antwerp, Belgium,* [3]*Revalidation Center 't Veld, Aartrijke, Belgium,* [4]*Department of Medical Genetics, University of Ghent and University Hospital of Ghent, Ghent, Belgium,* [5]*Department of Pediatrics, University of Ghent and University Hospital of Ghent, Ghent, Belgium.*

Microcephaly can occur as an isolated, mostly recessive abnormality or in association with ocular or systemic findings. Microcephaly associated with lymphedema is a rare syndromic variant (MIM 152950) with only few families reported. In some of the latter, ophtalmological findings, including microphthalmia, chorioretinopathy and cataract have been described. Although autosomal recessive inheritance has been suggested in some families, the prevailing hypothesis is that the microcephaly/lymphedema/chorioretinopathy syndrome is a single autosomal dominant entity with variable clinical expression.
Here we ascertained a four-generation family with autosomal dominant microcephaly associated with lymphedema. Lymphedema of hands and feet was apparent at birth but reduced or disappeared spontaneously during childhood in some affected individuals. No distinctive facial dysmorphism was noticed. The affected subjects presented with mild intellectual disability or low normal intelligence. No ophtalmological abnormalities were detected in any of the affected individuals. The proband had a normal male karyotype 46, XY and no copy number variants were detected by array comparative genomic hybridization analysis.
We collected DNA from eleven family members, including five affected subjects, and performed linkage analysis using the Linkage-24 DNA Analysis BeadChip (Illumina) containing 6000 Single Nucleotide Polymorphisms. Data were analyzed with Merlin. We identified a candidate region with a maximum LOD-score of 2.4 on chromosome 10q, measuring 40 MB and containing a total of 492 genes. We will apply whole exome sequencing to identify the responsible gene.

P12.154***
SMOC1 is essential for ocular and limb development in humans and mice

N. Matsumoto[1], *A. Megarbane*[2], *O. Cogulu*[3], *T. Tohma*[4], *I. Okada*[1], *H. Hamanoue*[1], *H. Saitsu*[1];
[1]*Yokohama City University Graduate School of Medicine, Yokohama, Japan,* [2]*Medical Genetics Unit, St. Joseph University, Beirut, Lebanon,* [3]*Department of Pediatrics, Ege University Faculty of Medicine, Bornova-Izmir, Turkey,* [4]*Division of Pediatrics, Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Okinawa, Japan.*

Microphthalmia with limb anomalies (MLA) is a rare autosomal recessive disorder, presenting with anophthalmia/microphthalmia and hand/foot malformation. We mapped the MLA locus to 14q24 and successfully identified three homozygous (a nonsense and two splice site) mutations in the SPARC (secreted protein acidic and rich in cysteine) related modular calcium binding 1 (*SMOC1*) gene in three families. *Smoc1* is expressed in the developing optic stalk, ventral optic cup and limbs of mouse embryos. *Smoc1* null mice recapitulated MLA phenotypes, including aplasia/hypoplasia of optic nerves, hypoplastic fibula/bowed tibia and syndactyly in limbs. A thinned and irregular ganglion cell layer and atrophy of the anteroventral part of the retina were also observed. Soft tissue syndactyly, resulting from inhibited apoptosis, was related to disturbed expression of genes involved in BMP signaling in the interdigital mesenchyme. Our findings indicate that SMOC1/Smoc1 protein is essential for ocular and limb development in both humans and mice. (Contributing doctors and researchers are really appreciated: Koji Terada, Eliane Chouery, Joelle Abou-Ghoch, Nadine Jalkh, Ferda Ozkinay, Kyoji Horie, Junji Takeda, Tatsuya Furuichi, Shiro Ikegawa, Kiyomi Nishiyama, Satoko Miyatake, Akira Nishimura, Takeshi Mizuguchi, Norio Niikawa, Fumiki Hirahara, Tadashi Kaname, Koh-ichiro Yoshiura, Yoshinori Tsurusaki, Hiroshi Doi, Noriko Miyake, and Takahisa Furukawa.)

Common molecular mechanism in homocystinuria: misfolding of cystathionine beta-synthase mutants and effect of chaperones

V. Kožich, *J. Sokolová, P. Melenovská, J. Kopecká, A. Hnízda, J. Krijt;*
Institute of Inherited Metabolic Disorders, Charles University- First Faculty of Medicine, Prague, Czech Republic.

Misfolding due to loss-of-function mutations is a common pathogenic mechanism in many genetic diseases including inborn errors of metabolism. To explore the role of misfolding in cystathionine beta-synthase (CBS) deficiency we studied a series of 27 disease-causing mutations located in different domains of the CBS molecule and representing ~70% of patient-derived mutant alleles. Expression in prokaryotic and eukaryotic cells showed a propensity of mutants to misfold/misassemble as evidenced by increased proportion of water-insoluble to water-soluble CBS antigen and decreased formation of correctly assembled tetramers accompanied by impaired catalytic activity (median activities of CBS mutants in *E.coli* and CHO-K1 cells were 3% and 18% of the wild type CBS, respectively; median amounts of tetramers in these expression systems were 12% and 35%, respectively). Proteolytic analysis of a subset of mutants with normal activity and tetramer assembly using thermolysin revealed distinct conformational alterations such as increased unfolding or- in contrast- increased global stability with rigidification. Co-expressional addition of osmolytes glycerol and betaine, and of the heme precursor delta-aminolevulinate to *E.coli* cultures increased activity and formation of tetramers for about one half of mutants; however, addition of phenylbutyrate as a stimulator of heat shock protein expression did not correct misfolding of the series of mutants in CHO-K1 cultures to a significant extent. These studies indicate that about one half of all known patient *CBS* alleles produce enzymes prone to misfolding/misassembly and that correction of misfolding by chaperones may

become an important future therapeutic target .
Supported by the Charles University Research Project MSM0021620806.

Mitochondrial gene mutation screening and related whit hearing loss in Hormozgan province in Iran

a. asgari[1], *M. Montazero Zohori*[2], *E. Farrokhi*[1], *M. Abolhasani*[1], *M. Akbari*[3], *F. Azadegan Dehkordi*[1], *M. Chaleshtori Hashmzadeh*[1];
[1]*cellular and molecular research center of shahrekord medical university of sciences, shahrekord, Islamic Republic of Iran,* [2]*Medical Genetics, school of Medical Sciences-Tarbiat Modares university, Iran., Tehran, Islamic Republic of Iran,* [3]*school of Medical Sciences-Tarbiat Modares university, Iran., Tehran, Islamic Republic of Iran.*

Background and aim: Hearing loss is the most frequent sensory disorder occurs in 1/1000 newborns. About 50% of hearin loss cases are due to genetic causes. Mutation in MTRNR1(A1555G), MTTL1(A3243G) and MTTS1(A7445G) are known to be one of the important cause of nonsyndromic Sensorineural hearing loos in some populations.
this study aims to demonstrate the frequency of three mitochondrial mutations including A1555G, A7445G and A3243G in deaf subjects in Hormozgan province in south of Iran.
Method**:** we investigated the presence of three mitochondrial mutations including A1555G, A3243G and A7445G in a cohort of 110 nonsyndromic Sensorineural hearing loos subjects. DNA was extracted using standard phenol -chloroform method. The screening of gene mutations was performed by PCR-RFLP procedure. Finally, the possible mutations were confirmed by direct sequencing.
Results: None of the 110 subjects were found to carry A1555G, A3243G and A7445G mutations. How ever PCR-RFLP of the MTTL1 gene destroyed a restriction site due to G3316A substitution in a deaf subject.
Conclusion: We conclude that the association of A1555G, A3243G and A7445G mutations with hearing loss is very low in Hormozgan 's deaf subjects.

Molecular diagnostic - the new face of craniofacial disorders diagnosis

E. Severin[1], *C. Dragomir*[2], *A. Stan*[2], *L. Preda*[1], *L. Savu*[2];
[1]*Carol Davila Univ. Med. Pharm, Bucharest, Romania,* [2]*Genetic Lab, Bucharest, Romania.*

The great majority of dental health professionals recognized the importance and potential of genetic and genomic evaluations in the future, but little has been done to incorporate this knowledge extensively in clinical practice. More then that, quite a few physicians suggested that dental disorders are common but not lethal for patients. Thus, the subject is not of broad interest to genetic medicine research and is slow-moving field of medical genetics.
Applications of molecular diagnostics in craniofacial disorders will be described. We here report on 2 cases study: cherubism and cleidocranial dysplasia (CCD).
Objectives: The use of DNA samples and PCR assay to test for specific state of disease. The use of molecular genetic testing for diagnostic confirmation when diagnosis of cherubism / CCD is suspected based on clinical and radiological criteria.
Methods: PCR amplification and direct sequencing of the SH3BP2 gene / RUNX2 gene.
Results: Case 1 - of 5 family members, abnormal results were obtained for the patient and her mother. A c.1244G > A mutation was identified in exon 9 of the SH3BP2 gene. Case 2 - of 4 family members, abnormal results were obtained only for the patient. The mutation R225W was identified. A deletion of 7 Glutamines in exon 2 was also identified.**Conclusions**: Both identified mutations are disorder-causing mutations and have a variable expression. We suggest genetic counseling / molecular genetic testing for all patients with such clinical findings, but especially for those with non-familial or sporadic forms.

P12.158***
Identification Of Novel Genes For Autosomal Recessive Intellectual Disability (ARID) In Consanguineous Families

Z. Iqbal[1], *A. de Brouwer*[1,2], *K. Neveling*[1], *L. Vissers*[1], *C. Gilissen*[1], *N. Wieskamp*[1], *M. Kwint*[1], *S. Gijsen*[1], *J. Veltman*[1], *S. Riazuddin*[3,4], *H. van Bokhoven*[1,2];

Identification of the causative genes of autosomal recessive intellectual disability (ARID) has been challenging due to the extreme heterogeneity of the condition. Homozygosity mapping in consanguineous families has been proven to be very helpful in these type of disorders. Here, we have ascertained 60 ARID families from the Pakistani population in which there is a high degree of consanguineous marriages (>70%). Homozygosity mapping data revealed one or more homozygous regions per family ranging in size from 1-51Mb. No pathogenic copy number variations (CNVs) were found. On the basis of homozygosity mapping, we selected seven families with novel ARID loci for targeted massive parallel sequencing (MPS) of the specific homozygous regions, and six families for exome sequencing. Our MPS data revealed a number of potential mutations that are validated at the moment. In one family, PKMR07, this strategy has proven to be successful as we have identified an intragenic homozygous deletion of five exons (11-15) of the *TPO* gene. Mutations of *TPO* are frequent and irreversible cause of ID (if not treated in the early postnatal life), mostly in the developing countries as well as in the entire world. This result confirms that MPS is a powerful method to uncover submicroscopic structural variations that have escaped detection by microarray analysis.

P12.159
Characterization of deletions in Multiple Osteochondromas with arrayCGH

I. Jennes[1], *D. de Jong*[2], *P. C. W. Hogendoorn*[3], *K. Szuhai*[2], *W. Wuyts*[1];
[1]*Department of Medical Genetics, University and University Hospital of Antwerp, Antwerp, Belgium,* [2]*Department of Molecular Cell Biology, Leiden University Medical Centre, Leiden, Netherlands,* [3]*Department of Pathology, Leiden University Medical Centre, Leiden, Netherlands.*

Hereditary multiple osteochondromas (MO) is an autosomal dominant skeletal disorder characterized by the formation of benign cartilage-capped bone tumours arising from the growth plate area of children's long tubular bones. MO is genetically heterogeneous and is associated with mutations in the tumorsuppressor genes *EXT1* and *EXT2*. Gross *EXT1*/*EXT2*-deletions are responsible for up to 8% of cases. We characterized the breakpoints of such deletions in 10 unrelated MO-patients using an MO-specific tiling-path array, allel-specific PCR-amplification and sequencing analysis.
In 3 families (*EXT1* deletion exon 2-3 (2), *EXT2* deletion exon 8), both deletions breakpoints were identified in homologous sequences of respectively 36bp and 32 bp, located within larger homology regions (~300 bp) which are known Alu-sequence elements. The *EXT2* exon 8-deletion breakpoints were found to be recurrent in 2 families. Both deletions were most likely caused by non-allelic homologous recombination (NAHR).
In the 7 remaining families (*EXT1* deletion exon 2-11 (2), exon 6-7, exon 8, exon 11, *EXT2* deletion exon 2, exon 8), breakpoints were located within short homologous sequences (2-5bp). Consequently, these deletions were assumed to be caused by non-homologous end-joining (NHEJ), in some cases facilitated by the presence of the Alu-sequence elements in the vicinity of one or both breakpoints.
We conclude that gross MO-causing deletions are caused by different mutation mechanisms and that the majority is not recurrent. This study emphasizes once more the high genetic variability characterizing MO.

P12.160
qPCR-HRM applied to *MUTYH* screening : identification of the first large rearrangement in a attenuated familial adenomatous polyposis (AFAP)

*C. Lefol[1], T. Noguchi[2], A. Briaux[1], H. Zattara[3], V. Bourdon[2], H. Sobol[2], R. Lidereau[1], S. Olschwang[2], **E. Rouleau**[1];*
[1]INSTITUT CURIE - RENE HUGUENIN, ST CLOUD, France, [2]INSTITUT PAOLI-CALMETTES, MARSEILLE, France, [3]AP-HM, MARSEILLE, France.

Germline biallelic mutations on the *MUTYH* gene cause one third of attenuated familial adenomatous polyposis (AFAP). This biallelic inactivation is associated with a 28-fold increased risk of colorectal cancer. Despite recurrency in exon 7 and 13, it is more and more recommanded to develop a screening method of the entire gene. Here, we propose to apply the qPCR-HRM strategy as formarly published and show the validation process. The application of this approach reveals a large rearrangement. Material and method: 44 variants with at least one per exon were tested in validation set with 35 heterozygous and 9 homozygous variants. The protocol was designed in duplicate with two master mix with and without template DNA. The quantitative measure was based on delta-deltaCp method. 30 selected patients with attenuated polyposis were also screened. Results: All variants were detected with the HRM curve analysis. 4 homozygous variants (44%) were detected in HRM only with the template DNA mix. In the 30 selected patients, we found 2 homozygous mutations (c.[494A>G]+ [494A>G]) and 2 compound heterozygous mutations (c.[494A>G]+[891+3A>C] c.[1145G>A]+[307_1608del]). Variants and mono-allelic mutations were also identified (n=4). Discussion : The approach qPCR-HRM proposed combining point mutation detection and also large rearrangement identification helps to detect a large deletion (exons 4 to 16) associated to an attenuated polyposis family. This observation expands the spectrum of *MUTYH* alteration. Presently, the frequency of such event is not known. But, it reinforces the need for full screening, particularly in patients with homozygous mutations and with one single heterozygous mutation.

P12.161
Molecular, cellular and clinical heterogeneity of mosaic variegated aneuploidy syndrome

***S. Hanks**, K. Snape, E. Ruark, A. Murray, J. Douglas, N. Rahman;*
Institute of Cancer Research, Sutton, United Kingdom.

Mosaic variegated aneuploidy (MVA) syndrome is an autosomal recessive disorder characterised by mosaic aneuploidies, a variety of phenotypic abnormalities and predisposition to cancer. We previously identified biallelic *BUB1B* mutations as a cause of MVA. *BUB1B* encodes BUBR1 which has multiple, crucial roles in the mitotic spindle checkpoint. Our data supported a causal role for aneuploidy in cancer development and exemplifed the insights rare genetic syndromes can provide to our understanding of cancer. However, 60% of cases are not due to *BUB1B* mutations. There is a strong phenotypic overlap between *BUB1B*-positive and *BUB1B*-negative cases but there is a significantly higher risk of cancer in *BUB1B*-positive individuals. Analyses of mitotic checkpoint function demonstrated that the checkpoint defect was profound in *BUB1B*-positive cases. In contrast, the *BUB1B*-negative cases had intermediate or normal checkpoint function. In addition, there was no apparent correlation between the presence or absence of *BUB1B* mutations and the extent of aneuploidies. Taken together, our results clearly highlight the heterogeneous nature of this rare aneuploidy-cancer syndrome. The underlying molecular defect(s) in cases without *BUB1B* mutations have not yet been elucidated. We are currently utilising an exome sequencing strategy to identify further causative gene(s) and this work will also be presented.

P12.162
Genotype-phenotype correlation in cohort of patients with myotonia congenita and frequent CLCN1 gene mutation Arg894Stop

***S. A. Kurbatov**[1], V. P. Fedotov[1], E. A. Ivanova[2];*
[1]Genetic counseling, Medical Diagnostic Centre, Voronezh, Russian Federation, [2]Russian Research Center for Medical Genetics, Moscow, Russian Federation.

Myotonia congenita (MC) the most common form of nondystrophic myotonias which can be autosomal dominant or recessive. MC characterized by delayed relaxation of skeletal muscle after voluntary contraction, transitory weakness, skeletal muscle hypertrophy.
Twenty one CLCN1 gene mutations were detected in 33 from 39 patients with MC from MGC, Voronezh. We revealed 5 cases with heterozygous CLCN1 gene mutations and 28 with two mutant alleles. Mutation Arg894Stop was detected in 19 from 61 mutant chromosomes (31%). It is interesting to note a wide variety of clinical presentations in cohort of patients with detected Arg894Stop: from phenotypes ranging from pronounced myotonia to such mild symptoms that myotonia was only revealed upon careful clinical examination.
Neurophysiologically, considerable decrement (69%) of compound muscle action potential (CMAP) was revealed in all patients with Arg894Stop during high frequency repetitive nerve stimulation (50Hz for 200 stimuli). We marked correlation of allelic state of Arg894Stop with amplitude of CMAP. Posttetanic transitory depression (PTD) (after 50 Hg) of CMAP considerable fluctuates (43%) in all our MC patients. In compound heterozygous (Arg894Stop/...) PTD of CMAP decreased from 11,2±3,3mV to 7,1±5,5mV (37%). There is no PTD of CMAP in heterozygous and homozygous patients. PTD correlations allow to estimate efficiency of restoration CLCN1 function in patients with different state of mutant alleles with Arg894Stop and to optimize molecular-genetic diagnostic of MC patients.

P12.163
Simultaneous multiplex PCR based myotonic dystrophy type 1 and type 2 molecular testing

***J. Radvansky**[1,2], A. Ficek[1,2], M. Batova[3], L. Kadasi[1,2];*
[1]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia, [2]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [3]Department of Microbiology and Virology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.

Myotonic dystrophy type 1 (DM1) is caused by expansion of a (CTG) n repeat in the DMPK gene, while myotonic dystrophy type 2 (DM2) is caused by expansion of a (CCTG)n part of a complex repetitive motif (TG)n(TCTG)n(CCTG)n. The size of healthy range alleles is highly variable in both loci and expanded alleles may contain several thousands of repeats in both DM1 and DM2. Combination of conventional PCR and “triplet” or “tetraplet” repeat-primed PCR (TP-PCR) is a commonly used approach to characterize healthy range alleles and to prove the presence or absence of expanded alleles in molecular testing for both disorders. We have designed three multiplex PCR reactions for simultaneous characterisation of the DM1 and DM2 locus using PCR based analyses and capillary electrophoresis on automatic DNA analyser. The first reaction includes bi-directionally labelled conventional PCRs for both the DM1 and DM2 locus. The second reaction contains the reverse directional DM1 TP-PCR and the reverse directional DM2 TP-PCR, while the third reaction was designed to include the forward directional DM1 TP-PCR and the forward directional DM2 TP-PCR. These three reactions were designed to be performable under the same amplification and electrophoretic conditions allowing thus their parallelisation. The usefulness of our multiplex assay is underlined by suggestions from previous studies, which showed, that performing conventional PCR with bi-directional labelling of specific amplicons and TP-PCRs simultaneously from both sides of the repeat regions can increase the reliability and accuracy of the assays which are based on the described methods.

P12.164
A canine *Arylsulfatase G* (*ARSG*) mutation leading to a sulfatase deficiency is associated with neuronal ceroid lipofuscinosis

***M. Abitbol**[1], J. L. Thibaud[2], N. J. Olby[3], C. Hitte[4], J. P. Puech[5], M. Maurer[1], F. Pilot-Storck[1], B. Hédan[4], S. Dréano[4], S. Brahimi[1], D. Delattre[6], C. André[4], F. Gray[7], L. Charbonnier[5], F. Delisle[8], C. Caillaud[5], F. Bernex[1], J. J. Panthier[1], G. Aubin-Houzelstein[1], S. Blot[2], L. Tiret[1];*
[1]UMR955 INRA-ENVA de Génétique Fonctionnelle et Médicale, Université Paris-Est Créteil, Ecole nationale vétérinaire d’Alfort, Maisons-Alfort, France, [2]Unité Propre de Recherche de Neurobiologie, Université Paris-Est Créteil, Ecole Nationale Vétérinaire d’Alfort, Maisons-Alfort, France, [3]Department of Clinical Sciences, North Carolina State University, Raleigh, NC, United States, [4]UMR6061 Institut de Génétique et Développement, Centre National de la Recherche Scientifique, Université de Rennes 1, Rennes, France, [5]Laboratoire

de Biochimie Génétique, Assistance Publique–Hôpitaux de Paris, Université Paris Descartes, Paris, France, [6]Antagene, Limonest, France, [7]Laboratoire d'Anatomie et Cytologie Pathologique, Hôpital Lariboisière, Paris, France, [8]Centre de Radiothérapie-Scanner, Ecole nationale vétérinaire d'Alfort, Maisons-Alfort, France.

Neuronal ceroid lipofuscinoses (NCLs) constitute the most common group of inherited children's progressive encephalopathies, characterized by progressive loss of vision, mental or motor deterioration, epileptic seizures and premature death. All NCLs, but rare autosomal dominant adult-onset forms, segregate as autosomal recessive morbidity traits and are classified into 10 genetic forms designated CLN1 to CLN10. Eight of them (CLN1-3, CLN5-8 and CLN10) were molecularly characterized. Genes underlying CLN9 and adult-onset forms, known as Kufs' disease (CLN4), remained to be identified.

A spontaneous canine model of adult American Staffordshire Terriers developping a late-onset cerebellar abiotrophy with Purkinje cell loss has been previously described and we confirmed that US and French affected dogs suffer from an autosomal recessive adult-onset form of NCL. Through a combined genome-wide association and linkage study, we identified a polymorphism in exon 2 of the *Arylsulfatase G* (*ARSG*) gene, encoding a lysosomal sulfatase. The polymorphism caused a non-conservative p.R99H substitution in the protein. The missense change, in the vicinity of the ARSG catalytic domain, lead to a 75% sulfatase activity decrease in leucocytes from affected dogs, confirming at the functional level that the variant may be the NCL-causing mutation (PNAS 2010, vol 107, 14775-14780). Our results unraveled a key role, presently evaluated in human patients affected by NCL, played by ARSG in NCL and neuronal homeostasis. Additionally, collection of fully phenotyped affected dogs is ongoing and should help identify modifying genes that may be further considered as hard candidates for NCL pathogenesis.

Nucleotide Excision Repair (NER) is one of the major DNA repair mechanisms responsible for repairing DNA damaged by either UV-irradiation or by certain chemicals that form "bulky" DNA adducts. The NER pathway involves at least 28 genes. Mutations in 13 NER genes have been associated with Xeroderma pigmentosum (XP), Cockayne syndrome (CS) and Trichothiodystrophy (TTD), with complex and varying multisystem pathologies.

These diseases are rare worldwide, but are frequent in Israel and the Middle East, probably due to the high rate of consanguinity among certain populations.

The genotype phenotype correlation in those diseases has not been fully clarified. Each clinical phenotype can arise from mutations in more than one gene and conversely, different mutations in one gene can give rise to more than one clinical phenotype.

We have clinically characterized fifteen patients with NER defects and identified their causative genes and mutations. Our analyses revealed 4 XP patients, 8 CS patients, 1 XP/CS patient and 2 TTD patients. We have identified 6 novel mutations in *CSB, XPD, and XPG*. We have established a population screening program for CS in one of these villages where the carrier frequency was found to be 1:9.

Our data might contribute to the understanding of the phenotype genotype relationship and basic pathology of NER related diseases. Identification of the causative genes allows us to establish accurate genetic counseling and molecular diagnosis to couples at risk and high risk populations.

P12.166
Ketogenic diet accelerates the onset of disease in a PLA2G6 KO mouse model

D. Brunetti[1], *S. Dusi*[1], *F. Moda*[1], *A. Uggetti*[1], *C. Lamperti*[1], *Y. Tsujimoto*[2], *M. Morbin*[1], *V. Tiranti*[1];
[1]*IRCCS Foundation Neurological Institute C. Besta, Milan, Italy,* [2]*Laboratory of molecular Genetics, Osaka University Medical School, Osaka, Japan.*

A mouse model of neuroaxonal dystrophy, with targeted disruption of PLA2G6 gene (KO), characterized by a late onset and slow progression of the disease, was described by Shinzawa K. et al in 2008. In order to accelerate the onset of pathology we decided to stress genotype and lipid metabolism of these mice using a high-fat ketogenic diet (KD).

After 60 days of KD diet KO mice developed diffuse alopecia, hypotonia of dorsal muscles with hunched posture and several motor dysfunction that not appear in control animals.

KO animals showed a significant loss of endurance on treadmill test and a reduced stride length on foot print test. Autopsy revealed the presence of fat liver in KO but not in control animals.

Electron microscopy analysis of sciatic nerve ultrastructure was normal in control sample, whereas in the KO mouse disclosed the presence of Wallerian-like degeneration in different phases of evolution and a large number of myelinated fibres characterized by cytoplasmic accumulation of vesicular and tubulo-vesicular structures. Also un-myelinated fibres showed degenerative features and the presence of some swollen fibres resembling spheroid-like structures.

Histochemistry revealed a strong reduction of COX (cytochrome c oxidase) activity in peripheral nerve, a partial reduction in the muscle with some COX-negative fibres, and no deficiency in the brain. In brain cortex we also observed some apoptotic Tunel positive nuclei.

The KD diet is able to accelerate onset and disease progression, and to unravel a biochemical phenotype not present in PLA2G6 KO mice fed with standard diet.

The identification of mutations in the NF1 gene causing type 1 neurofibromatosis (NF1 - OMIM 162200) is still presenting a considerable amount of work mainly because of the large size of the gene and the restricted number of recurent mutations. The high frequency of NF1 which lead us to choose two complementary methods for NF1 gene analysis:

- the multiplex ligation-dependant probe amplification (MLPA P081, P082, P122C1)
- and the automated denaturing high performance liquid (dHPLC) screening method.

The MLPA method was validated by the detection of 19 known large NF1 gene deletions.

The dHPLC was optimised for a rapid screening of the 60 exons and the splice junctions of the NF1 gene. The sensitivity was evaluated in a MLPA/dHPLC analysis of a panel of 150 unrelated french NF1 patients.

Seven large deletions were first detected by P081/082 MLPA. Mutations were identified in 136 among the 143 patients left with a global mutation detection rate of 96% [CI95%: 91-98].

Then, the seven NF1 negative patients were associated to nine others adult patients with a mild NF1 phenotype (pigmentary changes but no neurofibroma) to be screened by direct sequencing for mutations of the SPRED1 gene. SPRED1 mutations were identified in 2 cases compatible with Legius syndrome phenotype.

Our results confirm that the association of the MLPA and dHPLC techniques provides an accurate and fast method for the identification of NF1 mutations

The results show also the interest of the SPRED1 analysis and the implication for the counselling of NF1 families.

P12.168
Characterization of the molecular mechanisms underlying atypical NF1 deletions

J. Vogt[1], *K. Bengesser*[1], *K. Claes*[2], *K. Wimmer*[3], *L. Messiaen*[4], *L. Kluwe*[5], *V. F. Mautner*[5], *D. N. Cooper*[6], *H. Kehrer-Sawatzki*[1];
[1]*Institute of Human Genetics, Ulm, Germany,* [2]*Center for Medical Genetics, Ghent University Hospital, Gent, Belgium,* [3]*Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [4]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States,* [5]*Department of Maxillofacial Surgery, University Medical Centre, Hamburg-Eppendorf, Germany,* [6]*Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

Large deletions encompassing the NF1 gene and its flanking regions constitute the most frequent recurrent mutations causing neurofibromatosis type-1 (NF1). Four types of large NF1 deletion (type-1, type-2, type-3 and atypical) have been identified to date. These differ with respect to the extent of the deleted region, the location of the respective breakpoints and the underlying causative mechanisms. Whereas type-1, type-2 and type-3 NF1 deletions are mediated by NAHR between low-copy repeats, atypical NF1 deletions appear to have non-recurrent breakpoints and differ quite markedly in terms of their extent.

In this study, we have collected a cohort of 16 patients with de novo atypical NF1 deletions. Our aim was to precisely map the deletion breakpoints and to characterize the breakpoint-flanking sequences in order to identify the mechanism(s) underlying these atypical deletions. Initial analysis using MLPA and PCR-based breakpoint mapping using somatic cell hybrids carrying only the chromosome 17 with the deletion of the respective patients generated several important findings: First, non-homologous-end-joining (NHEJ) is the major mechanism responsible for atypical NF1 deletions. Second, one of both deletion breakpoints maps to one of the LCRs located in the NF1 gene region. These observations imply that NHEJ is driven by the local genomic architecture, specifically the LCRs in the NF1 gene region. Our findings indicate that the impact of the repetitivity of the LCRs located in the NF1 gene region is not confined to replication-based mutational mechanisms such as FoSTeS and MMBIR but is also evident in the context of recombination-based NHEJ events.

P12.169
Epidemiological and molecular genetic study of Neurofibromatosis type 1 in the Republic of Bashkortostan

R. Mustafin, *M. Bermisheva, E. Khusnutdinova;*
Institut of biochemistry and genetics, Ufa, Russian Federation.

Neurofibromatosis type 1 (NF1) is a common autosomal dominant genetic disorder that affects 1 in 3500 individuals worldwide, in which affected individuals develop benign and malignant nerve tumors. This inherited disorder is due to germline mutations of the *NF1* gene, a 17q11.2-located gene that spans 280 kb, is composed of 61 exons.

In Bashkortostan Republic according to January 2011 revealed 245 NF1 patients from 196 families. The prevalence of the disease is 4.7 per 100 thousand population. 55% of NF1 disease are sporadic cases. DNA of 85 NF1 patients (66 families) was extracted from blood. All the patients were residents of Bashkortostan Republic. Currently we identified five mutations in 6 patients from 5 families, 4 of which were sporadic cases. We found: two missense mutations: c.733T>A C245S, c.2990 G>C R997W; 2 nonsense mutations: c.1278 G>A W426X, 4537 C>T R1514X; 1 splice site mutation c.4514+5 G>A 4646+5G>A. All identified mutations haven't been previously described. Also revealed two polymorphisms: A2877G (Gln) and T2898C (Ala) in 5 patients from 5 families.

In patients with identified missense and nonsense mutations the disease was characterized by multiple neurofibromas and pigmented spots on the body; in a patient with identified splice site mutation (sporadic case) neurofibromas was focal - single, spots all over his body.

P12.170
Analysis of the *NF2* gene in a cohort of 16 unselected patients suspected of having neurofibromatosis type 2

O. Abad, *J. Gardenyes, P. Fàbregas, V. Volpini, B. Campos;*
Center for Molecular Genetic Diagnosis (CDGM) – IDIBELL, L'Hospitalet de Llobregat, Spain.

Neurofibromatosis Type 2 (NF2) [MIM 101000] is an autosomal dominant disorder that is characterized by nervous system tumours and ocular abnormalities, affecting 1 in 40,000 individuals. The disease is caused by mutations in the *NF2* tumour suppressor gene, at 22q11.2.

The distinguishing clinical feature of NF2 is the presence of bilateral vestibular schwannomas. Patients with NF2 also develop schwannomas at other locations and other tumours such as meningiomas, gliomas and neurofibromas. NF2 should be distinguished from neurofibromatosis type 1 (NF1) and from schwannomatosis. Whereas neurofibromas are the cardinal manifestation of NF1, patients with schwannomatosis develop multiple schwannomas affecting the peripheral nerves and spinal nerve roots without vestibular schwannomas or other NF2 related tumours.

We screened for mutations in the *NF2* gene a panel of 16 unrelated patients referred to our laboratory because of clinical features that required the consideration of NF2, using direct cDNA sequencing complemented with MLPA analysis.

Possible disease causing mutations were identified in 3 (18%) cases. They consist in a 3'UTR reported sequence variant of unknown biological significance and two splice errors, one of them identified in a patient with bilateral vestibular schwannomas and a spinal astrocytoma. The 13 patients without any identified *NF2* mutation had a wide variety of nervous system tumours, but just one was suspected of having bilateral vestibular schwannomas.

Our experience evidences that diagnosis of NF2 is often difficult to make when based only on clinical characteristics. In this context, genetic testing helps clinicians to establish a more precise diagnosis.

P12.171
Novel and recurrent mutations in NF1 gene - the first genetic study in Croatian patients with neurofibromatosis type 1

Z. Sabol[1], *R. Gjergja Juraski*[2], *F. Sabol*[1], *M. Kovac Sizgoric*[1], *Z. Gjergja*[1], *L. Kipke Sabol*[1], *S. Bela Klancir*[1], *L. Cvitanovic-Sojat*[2];
[1]*Sabol Clinic For Sick Children, Zagreb, Croatia,* [2]*University Hospital Sisters of Mercy, Zagreb, Croatia.*

Background: Neurofibromatosis type 1 (NF1) is one of the commonest autosomal dominant disorders in man. The clinical manifestations of disease are diverse, heterogeneous in origin, and age-dependent. The clinical diagnosis of NF1 is based on the presence of clinical criteria developed by National Institutes of Health Consensus Conference. To date, a number of different novel and recurrent mutations of NF1gene have been found.

The aim of this study was to identify the spectrum of disease causing mutations in the NF1 gene in Croatian non-related patients who fulfilled only one NIH diagnostic criterion at the time of NF1 gene testing. All children with sporadic NF1 are continued to be followed-up prospectively.

Results: Of 21 NF1 gene analyses, 18 (85.71 %) were positive. In 16/21 patients the specific mutations were found by gene sequencing and in two children MLPA revealed the deletion of whole NF1 gene. Thirteen of 16 found NF1 mutations were novel: c.147C>G, c.205-2A>C (IVS2-2A>C), c.1260+1G>C (IVS9+1G>C), c.1393_1421dup, c.1659_1660dupTC, c.3144G>A, c.3445A>G, c.4076delC, c.4168C>T, c.4168C>T, c.4686delA and c.4756dupT, while 3 mutations have been previously identified: c.1721G>A, c.3827G>A, c.3827G>A. No mutational hot spots in NF1 gene were observed. Among NF1 patients we reported two monozygotic twins with c.4168C>T mutation and concordant clinical features so far.

Conclusion: The mutational spectrum showed mainly nucleotide substitutions, suggesting that the genotypic characteristics of Croatian NF1 patients may be distinct from that of other populations. We present this study as the first step in the routine diagnosis procedure for Croatian patients with NF1.

P12.172
Loss of PAK3 kinase activity underlies a novel form of X- linked neuroichthyosis

We report the identification of a gene potentially responsible for a novel X-linked form of syndromic neuroichthyosis, segregating in a family characterized by ichthyosis, corpus callosum agenesis, microcephalia, seizures, mental retardation and spastic tetraparesis.
Linkage analysis revealed a critical region of nearly 25 Mb in Xq21.33q24 including about 250 genes. Having observed a clinical overlap with the cardio-facio-cutaneous syndrome, we analyzed the genomic sequence of *PAK3*, a gene involved in K-ras pathway, coding for a serin/threonine kinase with an important role in the organization of cytoskeleton. We found the K389N substitution within the highly conserved kinase domain of the protein. This mutation segregated with the disease in the family and it has never been detected in more than 450 control chromosomes; moreover prediction tools described this aminoacidic substitution as probably damaging.
As mutations in *PAK3* have been already reported in association with isolated mental retardation (MR), we compared the kinase activity of the wild-type, the K389N and the MR forms, showing a complete loss of function for all mutants.
These data suggest a causative role of the K389N mutation in the pathogenesis of neuroichthyosis, although the underlying mechanism leading to a complex disease is not clear.
We can not exclude that another gene within the critical region could be involved, worsening the clinical picture caused by PAK3 mutations, but the relevant expression we observed in keratynocytes would suggest an implication of this gene also in the ichthyosis occurrence, possibly due to additional kinase-independent activities of PAK3.

P12.173
Next Generation Sequencing for the Analysis of Monogenic Traits

J. Klar[1], *A. Ameur*[1], *S. Hooper*[1], *S. Baig*[2], *U. Gyllensten*[1], *N. Dahl*[1];
[1]*Department of Immunology, Genetics and Pathology, Uppsala, Sweden,* [2]*Human Molecular Genetics Laboratory, National Institute for Biotechnology and Genetic Engineering, Faisalabad, Pakistan.*

Next Generation Sequencing (NGS) technology has opened up new avenues for the clarification of gene variants causing Mendelian disorders. Most monogenic disorders are caused by either exonic sequence variants or splice-site mutations. These variants can now be readily identified by sequencing all exons in the human genome (exome sequencing). However, identification of a disease causing variant is not trivial due to the extensive number of rare variants identified in individual exomes. Although databases such as dbSNP can be used to reduce the candidates by filtering out common variants, the remaining candidates are still often numerous.
We present here the results from exome-sequencing in five individuals of Pakistani origin affected by various monogenic disorders. We identified approximately 85,000 variants (synonymous and non-synonymous) in each individual. After database filtering on average over 12,000 variants could be described as novel and 3,300 of these are exonic. The majority of the novel exonic SNPs were non-synonymous (70%) whereas 3% were nonsense variations and 1.5% were splice site alterations. Furthermore, each individual carries on average six nonsense variants in a homozygous state and about 20 in a compound heterozygous state together with a novel nonsynonymous or nonsense variant.
Our findings illustrate the extensive number of rare and possibly disease causing variants that can be identified by exome sequencing in any individual. The main challenge using NGS sequencing for disease gene tracking is to differentiate between the many rare benign variants and disease causing mutations. Strategies to overcome this problem will be presented in more detail.

P12.174
Molecular Analysis of GJB2, GJB6 Genes and A1555G Mitochondrial Point mutation in Patients with Nonsyndromic Hearing Loss, the Italian Job.

E. Benzoni[1], *P. Castorina*[2,3], *F. Lalatta*[2], *C. Radaelli*[4], *L. Trotta*[4], *U. Ambrosetti*[3], *A. Cesarani*[3], *L. Garavelli*[5], *P. Formigoni*[6], *A. Murri*[7], *D. Cuda*[7], *M. Seia*[4], ***P. Primignani***[4];

Mutations in the *GJB2* gene, which encodes the gap-junction protein Connexin 26 (Cx26), are the most common cause of nonsyndromic hearing loss (NSHL) accounting for about 32% of cases.
The subjects referred to our North Italian Centre are affected by sensory neural deafness with various degrees of hearing loss. Since January 2001 we analyzed 1250 patients and identified mutations in 763/2500 chromosomes. We characterized more than 40 different mutations and nine polymorphisms in 435 NSHL subjects. Our data confirm 35delG as the most frequent *GJB2* mutation in the Italian population accounting for about 64% of all the Cx26 alleles we identified. In recent years we also observed in our cases an increase of the most frequent polymorphisms in Asiatic and South American populations. The *GJB6* gene deletion, del(*GJB6*-D13S1830), was identified in seven patients carrying a *GJB2* mutation in the other allele and in homozygote status in one subject, while the del(*GJB6*-D13S1854) was not observed in our cohort of patients. Moreover, 45 affected subjects were compound heterozygous for recessive GJB2 allele not including 35delG and 8 were carrying dominant mutations (T55N, P58A, D179N and R184Q), indicating that the complete sequence of the gene is needed for an appropriate molecular diagnosis. The analysis of the deafness-causing A1555G substitution in MTRNR1 mitochondrial gene was carried out in patients without Cx26 recessive mutations. We found 24 affected subjects carrying the A1555G and the subsequently family analysis performed in each case has led to the pre-symptomatic identification of this mutation in relatives.

P12.175
Spectrum of *CLCN1* and *SCN4A* mutations in Czech patients with non-dystrophic myotonias.

D. Paclova[1], *J. Sedlackova*[1,2], *S. Vohanka*[3], *R. Mazanec*[4], *L. Fajkusova*[1,2];
[1]*Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic,* [2]*Faculty of Science, Institute of Experimental Biology, Masaryk University, Brno, Czech Republic,* [3]*Clinic of Neurology, University Hospital Brno, Brno, Czech Republic,* [4]*Neurology, Second School of Medicine, University Hospital Motol and Charles University, Prague, Czech Republic.*

The non-dystrophic myotonias are a heterogeneous group of rare inherited diseases that demonstrate myotonia as their common feature, in reference to a delayed muscle relaxation after voluntary or evoked muscle contraction. The non-dystrophic myotonias are skeletal muscle ion channel diseases which are caused by mutations in the genes coding for the skeletal muscle chloride channel 1 (*CLCN1*) or the alpha subunit of voltage-gated sodium channel 4 (*SCN4A*).
Mutations of the *CLCN1* gene result in either autosomal dominant myotonia congenita (Thomsen type) or autosomal recessive myotonia congenita (Becker type). A subset of *CLCN1* mutations have been found to cause both recessive and dominant myotonia. Mutations of

the *SCN4A* gene are typically inherited as an autosomal dominant trait, regardless of the associated phenotype (paramyotonia congenita, hyperkalemic periodic paralysis, hypokalemic periodic paralysis, normokalemic periodic paralysis, potassium-aggravated myotonia, myotonia fluctuans, and congenital myasthenic syndrome).
Molecular-genetic diagnostics of non-dystrophic myotonias was initiated in our laboratory in 2009. Since then, DNA diagnostics was performed in 55 unrelated patients suspected to be myotonia congenita, and confirmed in 41 of them. Mutations in the *CLCN1* gene were detected in 28 patients (25 with recessive and 3 with dominant myotonia congenita), mutation in the *SCN4A* gene in 13 patients. We identified 20 types of *CLCN1* mutations (6 mutations were novel not described previously) and 6 types of *SCN4A* mutations, (3 mutations were novel).
This work was supported by grant MSMT LC06023 and 2B08060.

P12.176
Twelve-years investigation of DFNB1 (*GJB2*) mutations in Iranian population with non-syndromic hearing loss

N. Bazazzadegan[1], *C. Nishimura*[2], *N. Nikzat*[1], *M. Hildebrand*[2], *S. Arzhangi*[1], *N. Meyer*[2], *K. Jalalvand*[1], *M. Sobhani*[3], *F. Habibi*[4], *A. Khosh Aein*[5], *F. Mojahedi*[6], *P. Jamali*[7], *K. Kahrizi*[1], *R. J. H. Smith*[2], *H. Najmabadi*[1];
[1]*Genetic Research Center, USWR, Tehran, Islamic Republic of Iran,* [2]*Molecular Otolaryngology Research Laboratories, University of Iowa, Iowa, IA, United States,* [3]*Genetic Counseling Centre, Gilan, Islamic Republic of Iran,* [4]*Rasht Welfare Organization, Gilan, Islamic Republic of Iran,* [5]*Genetic Counseling Centre, Mazandaran, Islamic Republic of Iran,* [6]*Genetic Counseling Centre, Mashhad, Islamic Republic of Iran,* [7]*Genetic counseling centre, Shahrood, Islamic Republic of Iran.*

DFNB1 locus has been recognized to account for a large proportion of cases of non-syndromic autosomal recessive deafness and the gene that encodes connexin 26, *GJB2*, has been identified as causative in DFNB1. The *GJB2* gene is also involved in an autosomal dominant form of deafness, DFNA3. In present study, we investigate the prevalence of *GJB2* mutations in Iranian deaf population with different ethnic groups. Two thousand three hundred thirty individuals, who were referred to GRC, were subjected to *GJB2* screening. The study was approved by the regional ethics committee of the USWR for medical research. After signing consent form by all participants and clinical examination, patients were screened for 35delG, the most prevalent *GJB2* mutation. Further analysis was performed for normal or heterozygote individuals, by sequencing of *GJB2*-exon 2, as well as screening of exon1 for all heterozygote families. Total of 370 (~16%) families were affected with *GJB2*-related deafness including both recessive and dominant mutations in homozygote and compound heterozygote forms. Forty five different *GJB2* mutations including two novel mutations have been identified. *GJB2* mutations in both alleles have been found in 89% of chromosomes. However, 35delG was the most common *GJB2* mutation accounting for 64% of the mutations in population studied. Distribution of *GJB2* mutations varied in different parts of Iran. Our data suggest that there is a gradual decrease in the frequency of the 35delG mutation and *GJB2*-related deafness in general as we move from the Northwest to South and East through the Persian Gulf countries.

P12.177
First description of M504A mutation in PTPN11 gene detected in a spanish patient with noonan syndrome

A. Zuñiga*, G. Pi, Y. Bello, A. Guerrero;*
Hospital Universitario de la Ribera, Alzira (Valencia), Spain.

BACKGROUND: Noonan syndrome (OMIM 163950) is a rare disease, mainly presenting with malformations such as dysplasia and stenosis of the pulmonary valve, atrial septal defect and a typical pattern of hypertrophic cardiomyopathy. It may be sporadic or inherited as an autosomal dominant or recessive trait and occurs in 1 in 1000-2500 children. In more than 50% of patients with Noonan syndrome, mutations in the *PTPN11* gene have been identified. This gene encodes a tyrosine-protein phosphatase non-receptor type II (SHP-2).
CASE REPORT: We report the case of a 9-year-old girl. This patient was diagnosed at birth with severe pulmonary stenosis with a dysplastic valve, and mild supravalvular stenosis. She presented with a permeable oval foramen. A valvuloplasty was performed at 2 years of age with limited results due to supravalvular obstruction and the type of valve. As her phenotype presented characteristics that were typical of Noonan syndrome, we studied the *PTPN11* gene by automatic sequencing of all exons and intron boundaries.
CONCLUSIONS: The patient was heterozygous for the M504A mutation (c.1510A>G, p.Met504Val) in exon 13 of the *PTPN11* gene. This mutation is located in the PTP domain of PTPN11 and is in close spatial proximity to important residues that stabilize the protein. The pathogenic mechanism in Noonan syndrome involves altered N-SH2/PTP interactions that destabilize the inactive conformation without altering the SHP-2 catalytic capability. PTPN11 is a key molecule in the cellular response to growth factors, hormones, cytokines, and cell adhesion molecules. This is the first time that the M504A mutation has been reported in the Spanish population.

P12.178
Heterozygous germline mutations in the *CBL* tumor-suppressor gene cause a Noonan syndrome-like phenotype

RAS signaling plays a key role in controlling appropriate cell responses to extracellular stimuli, and participates in early and late developmental processes. While enhanced flow through this pathway had been established as a major contributor to oncogenesis, recent discoveries have revealed that aberrant RAS activation causes a group of clinically related disorders characterized by facial dysmorphism, a wide spectrum of cardiac disease, reduced growth, variable cognitive deficits, ectodermal and musculoskeletal anomalies, and increased risk for certain malignancies. Here, we report that heterozygous germline mutations in *CBL*, a tumor-suppressor gene encoding for a multivalent adaptor protein with E3 ubiquitin ligase activity mutated in myeloid malignancies, can underlie a phenotype with clinical features fitting or partially overlapping Noonan syndrome (NS), the most common condition of this disease family. *CBL* mutations were identified in four sporadic cases and two families from among 365 unrelated subjects with NS or suggestive features and negative for mutations in previously identified disease genes. Phenotypic heterogeneity and variable expressivity were documented. Four mutations were missense changes affecting the RING finger domain or the linker connecting this domain to the *N*-terminal tyrosine kinase binding domain. One splice-site nucleotide substitution, resulting in skipping of the exon coding for those domains, and one truncating mutation at the *N*-terminus were also identified. Mutations were shown to affect CBL-mediated receptor ubiquitylation and dysregulate signal flow through RAS. These findings document that germline mutations in *CBL* alter development to cause a clinically variable condition that resembles NS and that possibly predisposes to malignancies.

P12.179
Noonan Syndrome diagnosed by custom molecular microarray (Array CGC)

A. Palmeiro[1], *A. Lopes*[1], *L. Lameiras*[1], *L. Dias*[1], *J. Sá*[1,2], *P. Rendeiro*[1], *P. Tavares*[1];
[1]*CGC Genetics (www.cgcgenetics.com), Porto, Portugal,* [2]*Hospital Pediátrico de Coimbra EPE, Coimbra, Portugal.*

Introduction: Noonan syndrome is a congenital genetic disease that affects both males and females equally (1:1.000-2.500 newborns). Great clinical variability has been identified: heart disease, valvular pulmonary stenosis or hypertrophic cardiomyopathy, short stature of

postnatal onset, psychomotor development delay. Often this syndrome is not diagnosed, but it is related to many complex problems such as coagulation defects and lymphatic dysplasias. Differential diagnosis includes major diseases in the same metabolic pathway: Costello, Cardiofaciocutaneous and LEOPARD Syndrome.
Method: With a custom microarray panel (Array CGC - Pat. Pending) that contains a panel of 80 point mutations, in 8 main genes involved in Noonan (5 genes) and other genetically related syndromes (PTPN11, RAF1, SOS1, KRAS, HRAS, BRAF, MAP2K1 and MAP2K2) is possible to identify the molecular basis of the most frequent and severe forms.
Results: Using the array panel we analyzed 6 cases of Noonan syndrome, where mutations on the PTPN11, were detected by sequence analysis. All the mutations were also detected with the array. Additionally, 6 cases with clinical suspicion and a PTPN11 negative sequence analysis were also studied. In one case a mutation on the SOS1 gene was detected, making the molecular diagnosis possible.
Conclusion: This approach is an useful and valuable tool for diagnostics, since it detects the most common mutations associated with Noonan Syndrome, not only on PTPN11 gene but also in 4 other genes, improving the capacity for diagnosis. A broader clinical spectrum and a faster diagnosis are achieved, allowing an earlier decision-making process in patient management.

P12.180
Mutation analysis of the genes involved in the Ras-MAPK pathway in Polish patients with Noonan syndrome

***E. Ciara**, S. Łuczak, A. Tańska, M. Pelc, M. Kugaudo, D. Jurkiewicz, D. Piekutowska-Abramczuk, P. Kowalski, M. Borucka-Mankiewicz, J. Trubicka, A. Jezela-Stanek, K. Chrzanowska, M. Krajewska-Walasek;*
The Children's Memorial Health Institute, Warsaw, Poland.

Noonan syndrome (NS) is an autosomal dominant disorder characterized mainly by short stature, congenital heart defects, facial dysmorphism and chest deformities. Heterozygous gain of function mutations in various genes encoding proteins of the Ras-MAPK signaling pathway have been identified as the genetic basis of NS. Although NS is relatively commonly inherited disorder (1:1000-1:2500 live births), it has been molecularly characterized in only a small proportion of human populations throughout the world and there are no reports on the genetic background of Slavic patients with NS. Here we report the results of molecular and clinical analysis in a cohort of 59 patients affected by NS. Mutation analysis of PTPN11, SOS1, RAF1 and KRAS genes confirmed NS in 56 patients, including 40 probands and 16 affected relatives, with a total mutation detection rate of 67.8%. We identified missense mutations in PTPN11 for 28, SOS1 for 10 and RAF1 for 2 unrelated patients. All of the changes were already known, except for two novel substitutions in SOS1 and one in RAF1 gene. The correlation between genotype and phenotype is similar to that observed in other studies. Patients with SOS1 mutations showed higher frequency of macrocephaly, ptosis, webbed neck, mitral valve anomaly, renal and ectodermal abnormalities in comparison to the group with mutations in PTPN11. This study demonstrated that only three most common genes related to Ras-MAPK pathway (PTPN11, SOS1, RAF1) are involved in the pathogenesis of Polish NS patients.
The study was supported by MNiSW Project PB0056/B/P01/2008/35 and by CMHI Project 190/08.

P12.181
Novel sequence changes in the NOTCH1 gene in patients with bicuspid aortic valves

***B. Ravcukova**[1], M. Vanaskova[2], L. Grodecka[1], J. Nejedlik[1], M. Plotena[1], F. Stetka[1], T. Freiberger[1,3];*
[1]Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic, Brno, Czech Republic, [2]Dept. Medical Genetics, University Hospital Brno, Czech Republic, Brno, Czech Republic, [3]Dept.Clin.Immunol.Allergol.Masaryk University, Brno, Czech Republic.

Bicuspid aortic valve (BAV) is the most common congenital cardiac malformation occurring in 1-2% of the population. BAV is associated with significantly increased risk of developing thoracic aortic aneurysm and acute aortic dissection. It was shown that genotypic variations in the *NOTCH1* gene are associated with BAV and may contribute to the observed variability in aortic phenotype. We performed *NOTCH1* mutational analysis in 30 unrelated subjects with BAV and 20 unrelated controls from general Czech population using high resolution melting analysis and DNA sequencing. We focused preferentially on exons in which mutations associated with BAV have already been reported. In general population we detected one sequence change within exon and two intron variants which have not been described yet. The variant p.Asp1026Asn was found in one control sample and causes an amino acid substitution. The variant c.2587+20GtoA was detected in one sample from general population and also two patients with BAV. Its effect on alternative splicing of mRNA cannot be excluded. In addition, we discovered two novel sequence variants within exons in the patient group. The variant p.Cys570Arg causes amino acid substitution and probably disrupts a disulphide bond in the extracellular receptor domain. Another variant p.Cys144Cys is a silent mutation probably without a functional significance. Further studies are necessary to elucidate the potential role of detected changes in disease manifestation. In general, identification of aneurysm-predisposing susceptibility genes may lead to gene-directed surgical therapy for patients with BAV in the future.
This study was supported by grant MSMT CR No. 2B08060.

P12.182
Cerebral dysgenesis does not exclude OFD I syndrome

***C. Thauvin-Robinet**[1,2], G. Lesca[3], B. Aral[4], N. Gigot[4], S. Lambert[4], L. Gueneau[2], M. Macca[5], B. Franco[6,7], F. Huet[8], M. Zabot[9], T. Attié-Bitach[10], J. Attia-Sobol[9], L. Faivre[1,2];*
[1]centre de génétique, Dijon, France, [2]Equipe émergente « Génétique des Anomalies du Développement », Université de Bourgogne, Dijon, France, [3]Département de Génétique Clinique, Hôtel-Dieu, Hospices Civils de Lyon, Lyon, France, [4]Laboratoire de Génétique Moléculaire, PTB, CHU, Dijon, France, [5]Department of Pediatrics of the Federico II University of Naples, Naples, Italy, [6]Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy, [7]Medical Genetic Services, Department of Pediatrics, Federico II University of Naples, Naples, Italy, [8]Pédiatrie 1, Hôpital d'Enfants, CHU, Dijon, France, [9]Département de Pathologie, Hôtel-Dieu, Hospices Civils de Lyon, Lyon, France, [10]Département de Génétique, Hôpital Necker-Enfants Malades, APHP, Paris, France.

Oral-facial-digital syndromes (OFD) are defined by the association of malformations involving the mouth, the face and the digits, with different modes of inheritance. Other organ systems can be involved, defining 13 specific subtypes. CNS malformations appear particularly associated with OFD I and VI syndromes. In OFD I syndrome, while corpus callosum agenesis appears common (40%), other malformations, including intracerebral arachnoid cysts, porencephaly, heterotopias, cerebellar malformations, and abnormal gyrations, are rarely described. Only molecular bases of the OFD I syndrome have been elucidated, when the OFD1 gene has been identified. However, mutations have also been identified in the TMEM216 gene in two patients with OFD VI syndrome and in the GLI3 gene in five patients with OFD syndrome and median anomalies. Few years ago, Lesca et al. [2006] described an OFD syndrome with cerebellar dysgenesis involving all the brain structures in a sporadic female foetus. We recently identified a causal c.400_403delGAAA mutation the OFD1 gene. This mutation has previously been reported in two sporadic cases with OFD I syndrome and normal neurological examination. The X chromosome inactivation pattern studied in three fetal tissues showed skewed X inactivation (0-100%) in all tissues. The identification of an OFD1 mutation permit to reclassify this patient as OFD I, instead of a new cerebral dysgenesis type as proposed by the authors. It illustrates also the high clinical variability in CNS features in OFD I syndrome. Therefore, sporadic severe CNS malformation associated or not with cerebellar findings does not exclude primarily OFD I syndrome.

P12.183
Multiplex ligation-dependent probe amplification (MLPA) in the diagnosis of 1p/19q deletions in oligodendroglial tumours.

***M. Grobler**, S. Butler, R. Taylor, M. Vast, K. Marks, K. Elderfield, L. R. Bridges;*
St George's Hospital, London, United Kingdom.

The combined loss of the short arm of chromosome 1 and the long arm of chromosome 19 is a molecular signature strongly associated with oligodendroglial tumours. Gliomas with a 1p/19q codeletion frequently respond favourably to chemotherapy and are associated with longer survival times. To date, the detection of 1p/19q loss has been most frequently carried out by fluorescent in-situ hybridisation or by loss of

heterozygosity testing. Recently, multiplex ligation-dependent probe amplification (MLPA) has been developed as an efficient, sensitive and specific alternative to these tests. This work describes the development and validation of the MLPA method for detection of 1p/19q loss in paraffin sections from glioma samples at St George's.
A total of 53 brain tumours were tested by MLPA for the 1p/19q deletions using the kit P088-B1 from MRC Holland: 5 glioblastomas with oligodendroglioma component (WHO grade IV); 19 anaplastic oligodendrogliomas (WHO grade III); 19 oligodendrogliomas (WHO grade II); 1 anaplastic oligoastrocytoma (WHO grade III); 4 oligoastrocytomas (WHO grade II); 2 anaplastic ependymomas (WHO grade III); 2 pilocytic astrocytomas (WHO grade I) and 1 central neurocytoma (WHO grade I). A comparison between MLPA and FISH is provided for 23 of the cases.
1p/19q codeletion was detected in 79% of the pure oligodendroglial tumours (WHO grades II and III) and 40% of the oligoastrocytomas (WHO grades II and III). Other results will be further discussed. Over 90% of MLPA and FISH results were concordant.
MLPA provides a cost effective and reliable method for diagnostic detection of the 1p/19q codeletion.

P12.184
OPA1 mutation in family with syndromic form of DOA from Russia

V. P. Fedotov[1], *S. Kurbatov*[1], *O. Schagina*[2];
[1]*VOCDC genetic counseling, Voronezh, Russian Federation,* [2]*Research Center for Medical Genetics, Moscow, Russian Federation.*

Mutations in OPA1, a dynamin-related GTPase involved in mitochondrial fusion, cristae organization and control of apoptosis, have been linked to non-syndromic optic neuropathy transmitted as an autosomal-dominant trait (DOA OMIM#165500). Here we report about four patients from three generation family with syndromic form DOA associated with sensoneural deafness, chronic progressive external ophthalmoplegia, ataxia, axonal sensory-motor polyneuropathy.
Proband is a 39-year-old woman with optic atrophy manifestation at the age of 10 years and with moderate sensorineural hearing impairment since the age of 22 years. At a recent neurological examination she showed bilateral ptosis, external ophthalmoplegia, severe optic atrophy and deafness and had an ataxic gait with positive Romberg sign. Neurophysiological studies suggested that deafness was caused by auditive neuropathy. Nerve conduction studies revealed an axonal sensorimotor neuropathy, without additional myopathic features on needle electromyography. Brain MR imaging revealed a number of small high-signal lesions in the frontal and temporal white matter on T2 imaging, thought to represent focal ischemic lesions. Younger brother, sister and nephew had similar symptoms in heavier form. The disease current was slowly progressing.
OPA1 gene was amplified by PCR with specific primers designed to amplify all exons and flanking intronic regions. All four affected patients with optic atrophy 'plus' clinical phenotypes underwent complete sequence analysis of the OPA1 gene. The c.1334 G > A (p.R445H) mutation in exon 14 caused disease in this family. This mutation introduce amino-acid changes in highly conserved positions of the GTPase domain.

P12.185
Production of a mutant oligophrenin 1 protein causes mental retardation and cerebellar hypoplasia in a three generation Italian family.

F. Pirozzi[1], *F. Di Raimo*[1], *G. Zanni*[2], *E. Tabolacci*[1], *T. Tartaglione*[3], *E. Bertini*[2], *A. Brancaccio*[4], *P. Chiurazzi*[1], *G. Neri*[1];
[1]*Istituto di Genetica Medica, Università Cattolica, Roma, Italy,* [2]*Unità di Medicina Molecolare, Ospedale Pediatrico Bambino Gesù, Roma, Italy,* [3]*Istituto di Radiologia, Università Cattolica, Roma, Italy,* [4]*Istituto di Chimica del Riconoscimento Molecolare (CNR), c/o Istituto di Biochimica e Biochimica Clinica, Università Cattolica, Roma, Italy.*

A three-generation family with two maternal cousins and an uncle affected by moderate to severe mental retardation and strabismus was referred to our clinic. One cousin presented during infancy with hydrocephalus and cerebellar hypoplasia, while the other cousin displayed marked hypoplasia of the cerebellar vermis and asymmetric hypoplasia of cerebellar lobes. The X-linked inheritance and the presence of cerebellar malformation suggested a mutation in the OPHN1 gene and mutational screening revealed a 2-bp deletion that abolishes a donor splicing site, resulting in the inclusion of 48-bp tract of intron 7. This mutation leads to the production of a mutant oligophrenin 1 protein with 16 extra aminoacids inserted in-frame in the N-terminal BAR domain. To our knowledge this is the first case of a mutation in OPHN1 that does not result in the production of a truncated protein or in its complete loss. OPHN1 (ARHGAP41) encodes a GTPase activating protein belonging to the GRAF proteins subfamily characterized by an N-terminal BAR domain, followed by a pleckstrin-homology domain and the GAP domain. GRAF proteins play a role in endocytosis and are supposed to dimerize via their BAR domain, that induces membrane curvature. The extra 16 aminoacids cause the insertion of 4.4 turns in the third alpha-helix of the BAR domain, which seems to impair the protein function. In fact, the clinical phenotype of these patients is identical to that of patients with loss-of-function mutations.

P12.186
Mutation and haplotype analysis of oculopharyngeal muscular dystrophy in Yakut population

A. V. Marusin[1], *K. A. Kurtanov*[2], *N. R. Maximova*[2], *V. A. Stepanov*[1];
[1]*Institute for Medical Genetics, Siberian Branch of the Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [2]*Yakut Scientific Center of Complex Medical Problems, Siberian Branch, Russian Academy of Medical Sciences, Yakutsk, Russian Federation.*

Oculopharyngeal muscular dystrophy (OPMD) is an inherited neuromuscular disease associated with a short trinucleotide repeat expansion in exon 1 of the *PABPN1* gene. OPMD (MIM 164300) is rather frequent in Yakut population (~1:11680), that is 1000 times higher as in Caucasoid populations. Patients (n=66) and 134 their healthy near relatives of 44 families were investigated. In all patients the mutation was confirmed by direct sequencing indicating the presence of 14 trinucleotide repeats (GCN), where as healthy individuals bear 10 repeats. Ten SNPs (rs2231301, rs1950252, rs1535094, rs7142474, rs2239579, rs8020117, rs2295126, rs2268330, rs7161120, rs4981469) in OPMD locus were examined. The genotype frequencies obeyed the Hardy-Weinberg equilibrium for all loci in both groups. Three SNPs (rs2231301, rs2239579, rs4981469) revealed strong association with OPMD ($p<10^{-3}$). Ten haplotypes with frequencies from 1.1 to 32.0% were found in control group and seven haplotypes (frequencies range 1.4 - 48.6%) were detected in patients. Patients and controls were characterized by different LD structure in OPMD locus. OPMD mutation is associated with 11 different haplotypes, including 3 major, 2 moderate and 5 rare haplotypes (>13, 6 and <3% frequncies, respectively) indicating possible modest founder effect for OPMD in Yakut population.

P12.187
Mutation analysis of COL1A1 gene in osteogenesis imperfecta patients from Russia

D. Nadyrshina, *R. Khusainova, E. Khusnutdinova;*
Institute of Biochemistry and Genetict RAS, Ufa, Russian Federation.

Osteogenesis imperfecta (OI) is a heritable disorder of connective tissue characterized by wide phenotypic variation mainly including bone fragility. The majority of patients (about 90%) with a clinical diagnosis of OI possess mutations in COL1A1 or COL1A2 genes.
The aim of our study was to identify mutations in COL1A1 gene in OI patients from three Russian populations (Russians, Tatars,Yakuts). We examined 54 patients with OI from 43 families and 50 healthy controls corresponding by age, gender, ethnicity and place of residence. DNA sequencing of 51 exons and exon-intron junctions in COL1A1 gene was performed.
For the first time previously unreported nonsense mutation c.967G>T (p.Gly323X)/1 in COL1A1 gene was identified in heterozygous state in two Russian patients and the novel frameshift mutation c.3541insC (p.Gly1181ArgfsX38) in COL1A1 gene was observed in Yakut patient. We also detected 3 previously described nonsense mutations in 5 Russian patients: c.1081C>T (p.Arg361X), c.1243C>T (p.Arg415X) and c.2869C>T (p.Gln957X), two frameshift mutations in two Tatar patients: c.579delT (p.Gly194ValfsX71) and c.2444delG (p.Gly815AlafsX293) and 1 splicing mutation in one Yakut patient:

c.4005+1G>T. Interestingly, individuals possessing these mutations were characterized by OI type I except for the patient with mutation c.1243C>T (p.Arg415X) clinically diagnosed by OI type 3/4.
The present study revealed two novel mutations in COL1A1 gene in patients with OI type I. Severe OI phenotype was observed in the patient with nonsense mutation c.1243C>T (p.Arg415X), while previously published findings described this mutation in individuals with OI type I.

P12.188
Null *CRTAP* Mutation Associated with Non-lethal OI and Minimal Collagen Deposition in Culture

*M. Valli[1], A. M. Barnes[2], W. A. Cabral[2], A. Gallanti[1], S. Viglio[1], M. Weis[3], D. Eyre[3], F. Antoniazzi[4], **J. C. Marini**[2], M. Mottes[4];*
[1]University of Pavia, Pavia, Italy, [2]NIH\NICHD, Bethesda, MD, United States, [3]Orthopaedic Research Laboratories, University of Washington, Seattle, WA, United States, [4]University of Verona, Verona, Italy.

Osteogenesis imperfecta (OI), or brittle bone disease, is characterized by bone fragility and deformity. Deficiency of any of the components of the collagen prolyl 3-hydroxylation complex causes recessive OI. The complex contains cartilage-associated protein (CRTAP), prolyl 3-hydroxylase 1 (P3H1) and cyclophilin B; it hydroxylates the α1(I) Pro986 collagen residue. Most *CRTAP* mutations cause a null allele and lethal OI (10/15), while 2 hypomorphic or missense and 3 null alleles were non-lethal. We report a 6 year old Egyptian boy with severe non-lethal type VII OI, who has the length of a 2.5 yr old and DXA z=-3. He is homozygous for a null insertion/deletion *CRTAP* mutation (c.118_133del16insTACCC). He received neridronate since 3 months of age. Similar to other *CRTAP* probands, his dermal fibroblasts synthesize fully overmodified type I collagen (40% OHL/L), which is well secreted into media. Only 5% of proband α1(I)Pro986 is 3-hydroxylated. On real-time RT-PCR, *CRTAP* transcripts are <15% of control. CRTAP protein is absent on Western blotting, with residual P3H1 and normal CyPB levels. Dermal fibril diameters were minimally increased vs an age-matched control, without loose fibril packing. We have noted a severe deficiency (10-15% of control) of collagen deposited in extracellular matrix by proband fibroblasts in long-term cultures, examined by immunofluorescence; the fibrillar network surrounding proband cells was also poorly organized. This data is corroborated by similar deficiency of radioactively-tagged collagen incorporated into matrix in deposition assays. Reduced collagen deposition in matrix is a novel finding which may play a role in the pathophysiology of *CRTAP* mutations.

P12.189
Recessive OI probands in a consanguineous Palestinian pedigree are each homozygous for mutations in a different gene (*FKBP10* and *PPIB*)

*A. M. Barnes[1], W. A. Cabral[1], E. Makareeva[2], M. Weis[3], W. Chang[1], L. Felley[1], D. Eyre[3], S. Leikin[2], **C. Trujillo**[4], J. C. Marini[1];*
[1]BEMB, NICHD/NIH, Bethesda, MD, United States, [2]SPB, NICHD/NIH, Bethesda, MD, United States, [3]Orthopaedic Research Laboratories, University of Washington, Seattle, WA, United States, [4]Genetics Unit, Dr. Erfan & Bagedo General Hospital, Jeddah, Saudi Arabia.

Recessive osteogenesis imperfecta (OI) is caused by defects in genes whose products interact with type I collagen for modification and/or folding. We identified a 5-generation Palestinian pedigree with both moderate and lethal forms of recessive OI caused by homozygous mutations in *FKBP10* or *PPIB*, which encode ER-resident molecular chaperone and isomerase FKPB65 and CyPB, respectively. One pedigree branch includes a child with moderate type XI OI and a homozygous *FKBP10* mutation (c.1271_1272delCCinsA); both parents and one sibling are carriers. *FKBP* transcripts in proband fibroblasts are 10% of control; the mutation is detectable in cDNA from fibroblasts cultured without emetine. FKBP65 protein is reduced in proband cells analyzed by Western blot and immunofluorescence microscopy. Transcripts for other proteins that interact with collagen, CRTAP, P3H1 and HSP47, are increased approximately 2.5 fold in proband cells, reflecting cell stress. Proband collagen gel electrophoresis reveals moderate band broadening, suggesting partial overmodification. Proband collagen α1(I)Pro986 3-hydroxylation is normal, as is collagen T_m. Collagen in proband cells is not aggregated on immunofluorescence. This compares to two cases reported by Alanay et al., in which cells lacking FKBP65 protein had collagen aggregation, while cells with an in-frame *FKBP10* deletion did not. A second pedigree branch includes two children with lethal OI. Both parents carry a 4 nt deletion in exon 5 of *PPIB* (c.563_566delACAG), predicting type IX OI in offspring. Mutant transcripts would likely escape NMD. Persistence of misfolded CypB would be predicted to cause severe dysfunction of the collagen 3-hydroxylation complex, compatible with the lethal outcome.

P12.190
Identification of a novel osteogenesis imperfecta locus in dogs

***M. Hytönen**[1,2,3], M. Snellman[1], K. Sainio[2], H. Lohi[3,1,4];*
[1]Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland, [2]Institute of Biomedicine, University of Helsinki, Helsinki, Finland, [3]Research Programs Unit, Molecular Medicine, University of Helsinki, Helsinki, Finland, [4]Department of Molecular Genetics, Folkhälsan Institute of Genetics, Helsinki, Finland.

Dog genome holds a wealth of information that will benefit human health since most of the canine inherited diseases have similar counterparts in human. We have characterized a novel severe congenital disorder involving multiple skeletal defects among Brazilian Terriers. Affected dogs have clinical symptoms including typical craniofacial features, growth retardation, joint hyperlaxity and osteopenia. Pathohistological analyses revealed abnormalities in bone formation which resemble that of human osteogenesis imperfecta (OI). After exclusion of the known OI genes we performed a genome-wide association study with 7 cases and 11 controls using Illumina 24k arrays and mapped the disease to a autozygous genomic region of 13 Mb in CFA6. The associated region is gene rich and being captured for resequencing to identify the causative mutation for the canine osteodysplasia. The identified locus is a novel OI locus and identification of the gene would provide a candidate for human OIs.

P12.191
The male phenotype in osteopathia striata with cranial sclerosis

The X-linked skeletal dysplasia Osteopathia Striata with Cranial Sclerosis (OSCS) is caused by truncating mutations in WTX. Females exhibit sclerotic striations on the long bones, cranial sclerosis and craniofacial dysmorphism. Males with OSCS typically have skeletal sclerosis, malformations (omphalocoele, kidney, heart defects), patterning defects and significant pre- and postnatal lethality. Males with milder phenotypes also have WTX mutations. In addition to skeletal sclerosis these individuals can have Hirschsprung disease,

joint contractures, cardiomyopathy and neuromuscular anomalies, but lack congenital malformations. This study seeks to draw genotype-phenotype correlations between these two groups.
WTX is alternatively spliced to encode two protein isoforms (WTXS1, WTXS2). WTXS1 contains binding domains for APC, ß-catenin, WT1 and a region implicated in binding PtdIns(4,5)P2 . WTXS2 excludes the PtdIns(4,5)P2 binding domains and one APC binding domain. Mutations in WTX leading to OSCS are exclusively truncating and cluster according to phenotype; with those producing a severe phenotype located in the 5' region of the gene before the ß-catenin binding domain. Mutations leading to survival but still significant osteosclerosis are, in general, located more 3' in the gene, implying more C-terminal domains also participate in bone accretion. Paradoxically mutations in two mildly affected males predicted to produce a severe phenotype indicate that a correlation between mutation position within WTX and the phenotype severity is not absolute. Characterising new mutations and identifying new phenotypic features help to define functional domains within WTX and provide new information about the cellular pathophysiology of OSCS and the role WTX plays in morphogenesis in general.

P12.192
Autosomal Recessive (ARO) and Autosomal Dominant Osteopetroses (ADO): results from a new UK diagnostic service, focusing on CLCN7-related Osteopetrosis.

M. E. Pennock[1], *M. Williams*[1], *L. Yarram*[1], *C. Steward*[2], *A. Villa*[3], *A. Pangrazio*[3], *E. Roberts*[1];
[1]*Bristol Genetics Laboratory, Pathology Sciences, Southmead Hospital, Bristol, United Kingdom,* [2]*Department of Paediatric Haematology/Oncology, Bristol Royal Hospital for Children, Bristol, United Kingdom,* [3]*Institute of Genetic and Biomedical Research (IRGB), National Research Council, Milan, Italy & Instituto Clinico Humanitas (IRCCS), Rozzano, Italy.*

The Osteopetroses are a heterogeneous group of disorders characterised by an increased bone density due to impaired bone resorption.
ARO (OMIM 259700) has a UK incidence of 1:250000. Affected patients may present in early infancy with generalized increase in bone density, predisposition to bone fractures, frontal bossing, progressive deafness/ blindness, hepatosplenomegaly, and severe anaemia. ARO is a heterogeneous disorder currently with 7 associated genes (TCIRG1, RANKL, CA2, CLCN7, OSTM1, PLEKHM1 and TNFRSF11A). Defining the genetic basis for ARO is important in determining whether HSCT therapy may be helpful or contra-indicated.
ADO type II (OMIM 166600) has an incidence of 1:20000 and typically has onset in late childhood or adolescence. Patients may exhibit sclerosis predominantly involving the spine with "sandwich vertebrae", pelvis and skull base. The main complications are fractures, scoliosis and osteomyelitis, particularly affecting the mandible. Hearing/visual loss may affect around 5% of individuals. The gene associated with ADOII is CLCN7.
In July 2010 theThe Bristol Genetics Laboratory launched its new UKGTN sequencing service for 3 of the genes implicated in ARO: CLCN7, RANKL and OSTM1 (using a 48 capillaryABI 3730). Together these genes account for approximately 16%-20% of ARO cases in the UK/European population. In addition, a common mutation in Exon 2 of OSTM1 has been identified in the Middle Eastern ARO population.
We have so far processed 7 patients to date, and found 4 (ADOII) patients positive for sequence changes in CLCN7 (p.Met584Val; p.Gly215Arg; p.Tyr99Cys; p.Arg286Trp). We present the clinical and molecular genetic findings from these positive cases.

P12.193
A patient with Ménierè's Disease is carrier of R822W mutation in *OTOF* gene.

A. Zuñiga, ***Y. Bello****, J. Gisbert, R. Ramirez, A. Guerrero;*
Hospital de la Ribera, Alzira (Valencia), Spain.

BACKGROUND: Meniere's disease is a disorder of the inner ear that affects balance and hearing. This condition is characterized by sudden episodes of vertigo, tinnitus, a feeling of pressure or fullness in the ears, and fluctuations in hearing. The cause of Meniere's disease is unknown, although it probably results from a combination of environmental and genetic factors. Otoferlin belongs to a small family of membrane-anchored cytosolic proteins. In the cochlea, otoferlin is believed to play a role in exocytosis of synaptic vesicles at the auditory ribbon synapse of inner hair cells. Otoferlin is encoded by *OTOF* (OMIM: 603681). Mutations in this gene are a cause of neurosensory non-syndromic recessive deafness
CASE REPORT: We reported a case of a 49-year-old male. The first contact with the service of otolaryngology was in 2000. The patient complained of tinnitus in the left ear and vertigo. In 2004, it was detected hearing loss in left ear. In 2005, he began to have bilateral hearing loss. In 2007, last tonal audiometry detected sensorineural hearing loss (60dB) in left ear and mild hearing loss on the right ear and he was diagnosed with Meniere's disease.
RESULTS AND CONCLUSIONS: Patient was heterozygote for R822W mutation (c.2464C>T) in OTOF gene. Role of this mutation in hearing loss is controversial; some authors associate this mutation with non-syndromic deafness, and others authors classify it as a polymorphism without a pathological role. We believe that this mutation may play a role in the developing of Meniere's disease.

P12.194
Digenic inheritance model in Pendred syndrome patients carrying only one disease causing SLC26A4 allele?

T. Rinne*, M. Tjon-Pon-Fong, L. Hoefsloot;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Pendred syndrome is one of the most common causes for autosomal recessive inherited syndromal deafness. It is characterized by sensorineural deafness, enlarged vestibular aqueduct (EVA) with or without cochlear hypoplasia and enlarged thyroid gland. Mutations in the SLC26A4 gene are known to cause syndromic and nonsyndromic hearing loss associated with EVA. Mutations in this gene explain approximately fifty-percent of the cases with hearing loss with EVA. A digenic model for hearing loss with the EVA phenotype has been established. Mutations in either the FOXI1 or the KCNJ10 gene in combination with a pathogenic mutation in the SLC26A4 gene have been reported to cause nonsyndromic hearing loss with EVA.
The aim of our study is to investigate the prevalence of the digenic inheritance in patients with hearing loss with the EVA phenotype, and whether FOXI1 and KCNJ10 genes can be included in the routine diagnostics of Pendred syndrome. We first investigated the FOXI1 gene in a group of patients carrying only one pathogenic mutation in the SLC26A4 gene. In a group of 32 patients only one possible splice site mutation was identified. Investigation of a group of 113 patients without pathogenic mutations in the SLC26A4 gene revealed two possible pathogenic mutations in the FOXI1 gene. The analysis of the KCNJ10 gene in the same patient cohorts is ongoing. Although this study is not yet completed, we can already conclude that yet unknown mutations in regulatory and non-coding regions or other gene(s) are also involved causing hearing loss with EVA phenotype.

Introduction: Next-generation DNA sequencing is empowering scientists to identify genetic variations associated with human disease at higher resolution and greater sensitivity than previously possible. The technology becomes a powerful tool for the diagnosis of genetic diseases and recently, whole exome sequencing was shown to be effective for disease-gene identification and was successfully used to determine the genetic basis of autosomal recessive disorders. Here we present recent data and results from a whole genome sequencing study focusing on a novel syndrome.
Materials and methods: We study two brothers and a sister in a Dutch non-consanguineous pedigree, who suffer from severe delay, epilepsy, microcephaly, and spastic tetraplegia. Dysmorphic facial features and overriding toes were noted. Brain imaging (MRI) revealed in all the

patients diffuse periventricular nodular heterotopia and hypoplasia of the cerebellum. Based on the pedigree an autosomal recessive inheritance was assumed. The genetic cause of this novel syndrome could not be identified using conventional genetic investigations (including candidate gene sequencing, linkage analysis, and expression exon arrays). We analyzed the whole-genome sequences (sequencing performed by Complete Genomics) of six family members and tested multiple inheritance models.

Results: Homozygous mutations in exons were excluded and subsequent analysis of compound heterozygous variants revealed predicted non-conservative changes in promising novel candidate genes of which one is undergoing functional validation.

Conclusion: Using whole genome sequencing we identified the candidate gene for a novel genetic syndrome. We describe the patients' phenotype, the analysis workflow, results and preliminary validation studies.

‚Perrault syndrome in a female manifesting carrier of mtDNA 11778G>A mutation'

*M. Badura-Stronka[1,2], W. Grotowski[3], B. Męczekalski[3], A. Wawrocka[1], K. Zawieja[4], M. Krawczyński[1,2], **A. Latos-Bieleńska**[1,2];*

[1]Chair and Department of Medical Genetics, Poznan University of Medical Sciences, Poznań, Poland, [2]Center for Medical Genetics GENESIS, Poznań, Poland, [3]Department of Gynecological Endocrinology, Poznan University of Medical Sciences, Poznań, Poland, [4]Centrum Medyczne Świętego Jerzego, Poznań, Poland.

Perrault syndrome (PS) is a rare autosomal recessive syndrome, characterized by ovarian dysgenesis, hearing loss and ataxia in female patients. Recently, pathogenic mutations in *HSD17B4* gene have been described in two affected sisters, however, lack of mutation in other families with PS suggests genetic heterogeneity of the syndrome.

We have performed sequencing of 24 coding exons of the *HSD17B4* gene in a 21-years old female with 46,XX karyotype and clinical symptoms of PS: hypergonadotropic hypogonadism, ataxia, intellectual impairment and hearing loss. The open reading frame was free of mutations.

Several patient`s mother`s male relatives are affected by Leber Hereditary Optic Neuropathy (LHON). A test for mtDNA 11778G>A mutation was positive in the affected males and in our patient. Further ophthalmologic assessment revealed advanced optic neuropathy in the patient.

This case is the first reported patient with PS and mtDNA mutation. The authors provide detailed clinical data. Possibility of causal relation between mtDNA mutation and PS and influence of hypogonadism on manifestation of LHON in females are discussed.

The research is funded by the European Community's 7th FP [FP7/2007-2013] under grant agreement n° 223692, CHERISH project.

The molecular-genetic study of phenylketonuria in Russia

***V. L. Akhmetova**[1], I. Sadrtdinova[2], M. Orasgalieva[3], I. Gilyazova[1], R. Khusainova[1], M. Bermisheva[1], E. Khusnutdinova[1];*

[1]Institute of Biochemistry and Genetics, Ufa, Russian Federation, [2]Bashkir State University, Ufa, Russian Federation, [3]The Scientific Center of Obstetrics, Gynecology and Pernintology, Almaty, Kazakhstan.

Phenylketonuria (PKU) is the most common inborn error of amino acid metabolism in Europeans which is caused by a large variety of mutations in the phenylalanine hydroxylase gene (PAH). We analyzed structural features of PAH gene in families with PKU from Bashkortostan Republic (N=124), North Caucasus (N=36) and Kazakhstan (N=20). Consequently we revealed 35 various mutations that spectrum was specific for each region. Our results indicated that R408W mutation accounted for 52% PKU in Bashkortostan and 45% in Kazakhstan. Mutation R261X of the PAH gene is found out only in patients from the North Caucasus with frequency of 38.9% whereas mutation R408W in the given region is revealed with frequency of 13.9%. The frequency of mutation R261Q of the PAH gene was also high in PKU patients from Bashkortostan and Kazakhstan (12.9% and 7.5%, respectively). Other mutations of the PAH gene were identified with frequencies from 3.3% to 0.27% on the average: c.1315+1G>A c.1066-11G>A, R158Q, c.663-664delAG, R252W, P281L, L48S, c.441+5G>T, S349P, I306V, c.47-48delCT, c.168+5G>A, c.208-210del3, R111X, P211T, R243X, A300S, E390G, R413P, Y414C, W169H, c.509+5delG, E280K, Y206X, R243Q, c.1089delG, S350Y, D415N. Four new mutations were revealed as well: R252P, c.116delT, c.1315+del4 in PKU patients from Bashkortostan, F331S - from North Caucasus.83.9% of the studied families with PKU have appeared completely informative for direct DNA-diagnostics, 12.8% - partially-informative, and 3.3% - absolutely not informative.Thus the data of mutational analysis of the PAH gene may be used for prenatal diagnostics and carrier screening in PKU families in studied republics.

P12.198
Identification of three novel single nucleotide changes in the PAH gene observed in Latvian patients with phenylketonuria

***N. Pronina**[1,2], R. Lugovska[1,2];*

[1]Children's University Hospital, Riga, Latvia, [2]Riga Stradins University, Riga, Latvia.

Molecular analysis of 70 Latvian PKU patients has revealed very high genotypic homogeneity, as 73% of the mutant alleles carry the R408W mutation typical for Eastern Europe. 51% (36/70) of patients are homozygous for R408W mutation; the remaining 34 patients are compound heterozygous. Analysis of these patients has revealed 16 different mutations E280K, R158Q, R261Q, P281L, A104D, A403V, E178G, R111X, IVS10-11G>A, IVS12+1G>A, G272X, R261X, E221_D22>Efs, I306V, V230I and three novel single nucleotide changes in the phenylalanine hydroxylase gene: P292T (c.874C>A), K371E (c.1111A>G) and IVS12-1G>A (c.1316-1G>A).

Mutation P292T (c.874C>A) in Exon 8 substitutes proline at residue 292 to thereonine; IVS12-1G>A (c.1316-1G>A) at he boundary of IVS12 and exon 13 affects the conserved dinucleotide at the 3' splice site. Both these mutations were found in association with R408W in patients with severe PKU.

Mutation K371E (c.1111A>G) in Exon 11 replaces lysine at residue 371 with glutamic acid. It was also observed in association with R408W in patient with mild hyperphenylalaninaemia (MHP), who does not need a low-phenylalanine diet. Thereby we suppose that this mutation causes MHP as R408W is a severe mutation with no residual activity of enzyme phenylalanine hydroxylase.

None of the mentioned novel single nucleotide changes had been previously detected in patients' chromosomes and 100 population controls. We assume that these variants are functionally relevant although this need to be confirmed by additional in vitro expression analysis.

P12.199
Neurologic and ocular phenotype in Pitt-Hopkins syndrome and a zebrafish model

***A. Brockschmidt**[1], A. Filippi[2], P. Charbel Issa[3,4], M. Nelles[5], H. Urbach[5], N. Eter[3,6], W. Driever[2], R. G. Weber[1];*

[1]University of Bonn, Institute of Human Genetics, Bonn, Germany, [2]University of Freiburg, Department of Developmental Biology, Freiburg, Germany, [3]University of Bonn, Department of Ophthalmology, Bonn, Germany, [4]University of Oxford, John Radcliffe Hospital, Nuffield Laboratory of Ophthalmology, Oxford, United Kingdom, [5]University of Bonn, Department of Radiology/Neuroradiology, Bonn, Germany, [6]University of Münster, Department of Ophthalmology, Münster, Germany.

TCF4 haploinsufficiency was recently identified to cause the Pitt-Hopkins syndrome (PTHS), a disorder characterized by severe mental and motor retardation, breathing abnormalities and distinctive facial features. The *Danio rerio* ortholog, *tcf4*, is expressed in several regions in the CNS and the retina during early development. The neurologic and ocular phenotype was characterized in a PTHS-patient with a uniallelic *TCF4* deletion and in a zebrafish model of the disease. While a cerebral MRI-scan in the PTHS-patient at age one year showed a markedly delayed myelination and ventriculomegaly, no structural cerebral anomalies including no evidence for white matter tract alterations were detected on high-resolution MRI with DTI at age 9 years. Structural ocular examinations showed highly myopic eyes and an increase in ocular length, while spectral domain optical coherence tomography (SD-OCT) imaging showed retinal layers and foveal configuration to be normal. Knockdown of *tcf4*-function by injection of morpholino antisense oligos into zebrafish embryos was performed,

and the morphant phenotype was characterized for expression of neural differentiation genes *neurog1*, *ascl1b*, *pax6a*, *zic1*, *atoh1a*, and *atoh2b* resulting in a developmental delay or defects in terminal differentiation of brain and eyes, small eyes with a relative increase in ocular length and an enlargement of the hindbrain ventricle. In summary, *tcf4*-knockdown in zebrafish embryos does not seem to affect early neural patterning and regionalization of the forebrain, but may be involved in later aspects of neurogenesis and differentiation. We provide evidence for a role of TCF4/E2-2 in ocular growth control in PTHS-patients and the zebrafish model.

P12.200
Genetic diagnosis of the Autosomal Dominant Polycystic Kidney Disease by specific sequencing of the PKD1 gene

J. Garcia-Planells, *M. Garcia-Hoyos, C. Ruiz, M. Bermejo, L. Rausell, I. Gómez, M. Perez-Alonso;*
Instituto de Medicina Genomica (IMEGEN), Paterna (Valencia), Spain.

Introduction: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most prevalent inherited disorders, with an incidence of 1:1000. ADPKD is a late-onset multisystem disorder characterized by bilateral renal cysts and cysts in other organs including liver, pancreas and seminal vesicles. Mutations in PKD1 gene (16p13) and PKD2 gene (4q21-q23) are present in 85% and 15%, respectively, of the ADPKD patients. Genetic diagnosis of the PKD1 gene is a tricky task because the presence of, at least, 5 pseudogenes with a 98% similarity with the 5' region of the PKD1 gene.
Objective: To offer an accurate genetic diagnosis to patients with clinical diagnosis of autosomal dominant polycystic kidney disease (ADPKD).
Methodology: Genetic testing of the PKD1 gene in ADPKD patients has been carried out by sequencing throught the 46 exons of the gene. To analyze specifically the 5' region of the PKD1 gene and discard the homologous regions of the known pseudogenes, five specific long PCRs were designed. Obtained fragments were used as templates for the amplification of the first 34 exons of the PKD1 gene by using intronic primers encompassing each exon.
Results and conclusions: This protocol allows obtaining specific sequences for the PKD1 gene excluding homologous regions of the pseudogenes in normal and ADPKD samples.
We can conclude that this validated protocol is a good methodology for genetic diagnosis of ADPKD, avoiding misinterpretation problems produced for the presence of pseudogene sequences. An accurate genetic diagnosis is essential to provide prenatal and preimplantational genetic diagnosis to ADPKD patients.

P12.201**
Altered Hippo signaling in polycystic kidney disease

H. Happé[1], *A. M. van der Wal*[2], *W. N. Leonhard*[1], *S. J. Kunnen*[1], *M. H. Breuning*[3], *E. de Heer*[2], *D. J. M. Peters*[1];
[1]*Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Department of Pathology, Leiden University Medical Center, Leiden, Netherlands,* [3]*Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is characterized by the formation of many fluid-filled cysts in the kidneys and progressive deterioration of renal function, finally leading to renal failure. Previously we showed that tubular epithelial injury accelerates cyst formation in inducible *Pkd1*-deletion mice. In these mice expression of the Planar Cell Polarity (PCP) component Four-jointed (*Fjx1*) is decreased during epithelial repair but at later stages, in cystic kidneys, *Fjx1* expression is increased.
Additional to a role in PCP-signaling, Four-jointed is also implicated in the Hippo-signaling pathway, which controls organ size by regulating proliferation and apoptosis. In humans, this pathway is also known from its involvement in several types of cancer, and in neurofibromatosis type 2 (NF2). The role of Hippo-signaling, together with the opposing expression pattern of *Fjx1* during epithelial repair and at cystic stages, led us to investigate the activity of the Hippo pathway during these processes.
Examining the Hippo pathway's final effector molecule, the transcriptional co-activator Yes-associated protein (YAP), we found no differential expression between *Pkd1*-deletion mice and controls during tissue repair. However, in epithelia of dilated tubules and cysts, strong nuclear YAP accumulation was observed, which was accompanied by up-regulation of the suspected YAP transcriptional targets *Birc-3*, *Ctgf*, *InhbA* and *Fjx1*. Altered Hippo-pathway activity was confirmed in human renal ADPKD and ARPKD tissues, as well as cystic renal tumors. These data support the notion that during epithelial repair Four-jointed is involved in PCP-signaling, while in cystic kidneys this protein is related to Hippo-signaling and cyst growth.

P12.202
Mutations of PKD1 and PKD2 genes in families with autosomal dominant polycystic kidney disease in Czech Republic

J. Stekrova[1], *J. Reiterova*[1], *V. Elisakova*[1], *M. Merta*[1,2], *V. Tesar*[1], *M. Kohoutova*[1];
[1]*General Teaching Hospital of 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [2]*Faculty Hospital, Hradec Kralove, Czech Republic.*

Autosomal dominant polycystic kidney disease (ADPKD) is the most common form of inherited kidney disease that results in renal failure. ADPKD is a systemic disorder, with cysts and connective tissue abnormalities involving many organs. The disease is caused by mutations of *PKD1* and *PKD2* genes. In the PKD database (http://pkdb.mayo.edu) 846 different variants of the *PKD1* gene and 139 different variants of the *PKD2* gene have been reported.
The direct detection of mutations in both *PKD* genes was performed within research projects in our laboratory. The mutation analysis of *PKD1* gene has so far detected probably causal mutations in 57 families. Only the described nonsense mutation p.R4021X was detected in three nonrelated families and the described missense mutation p.E2771K was detected in two families; other mutations are unique for individual families; 42 mutations are unique for Czech population.
The mutation analysis of *PKD2* gene has so far detected probably causal mutations in 36 families. The frameshifting mutation c.203_204insC was identified in 9 families, nonsense mutation p.Q160X in 6 families. Fourteen mutations are unique for Czech population.
Two families with highly variable clinical course were identified. Trans-heterozygous mutations in both *PKD* genes were found in the patient with end stage renal disease at 28 years. His 65-year-old father with only *PKD2* mutation has mild renal insufficiency and his mother died because of uremia at 45 years. In the second family were found the influence of mosaicism and hypomorphic allele in *PKD1* gene.
Supported by the grant project VZ MSMT 0021620806

Impairment of the tRNA splicing endonuclease subunit 54 (tsen54) gene causes neurological abnormalities and larval death in zebrafish models of Pontocerebellar Hypoplasia

P. Kasher[1], *Y. Namavar*[1], *P. van Tijn*[2], *K. Fluiter*[1], *A. Sizarov*[1], *M. Kamermans*[2], *A. Grierson*[3], *D. Zivkovic*[4], *F. Baas*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Netherlands Institute of Neuroscience, Amsterdam, Netherlands,* [3]*Department of Neuroscience, Sheffield, United Kingdom,* [4]*Hubrecht Institute, Utrecht, Netherlands.*

Pontocerebellar hypoplasia (PCH) represents a group (PCH1-6) of neurodegenerative autosomal recessive disorders characterised by hypoplasia and/or atrophy of the cerebellum, hypoplasia of the ventral pons, progressive microcephaly and variable neocortical atrophy. The majority of PCH2 and PCH4 cases are caused by mutations in the TSEN54 gene; one of four subunits comprising the tRNA-splicing endonuclease (TSEN) complex. We hypothesised that TSEN54 mutations act through a loss of function mechanism. At 8 weeks of gestation, human TSEN54 is expressed ubiquitously in the brain, yet strong expression is seen within the telencephalon and metencephalon. Comparable expression patterns for tsen54 are observed in zebrafish embryos. Morpholino knockdown of tsen54 in zebrafish embryos results in loss of structural definition in the brain. This phenotype was partially rescued by co-injecting the morpholino with human TSEN54 mRNA. A developmental patterning defect was not associated with tsen54 knockdown, however an increase in cell death within the brain was observed, thus bearing resemblance to PCH pathophysiology. Additionally, ENU mutant zebrafish homozygous for a tsen54 premature stop codon mutation die within 9 days post-

fertilisation. To determine whether a common disease pathway exists between TSEN54 and other PCH-related genes, we also monitored the effects of rars2 (PCH1, PCH6) knockdown in zebrafish. Comparable brain phenotypes were observed following inhibition of both genes. These data strongly support the hypothesis that TSEN54 mutations cause PCH through a loss of function mechanism. Also we suggest that a common disease pathway may exist between TSEN54 and RARS2-related PCH, which may involve a tRNA processing related mechanism.

P12.204
An integrated clinical, genetic and epigenetic approach of the Prader Willi syndrome phenotypes in Romanian population

C. Arsene[1], *M. Puiu*[2], *A. Botezatu*[3], *G. Anton*[3], *C. Badiu*[4], *C. Popa*[2], *N. Cucu*[1];
[1]*University of Bucharest, Faculty of Biology, Department of genetics, Epigenetics Center, Bucuresti, Romania,* [2]*University of Medicine and Pharmacy, Timisoara, Romania,* [3]*National Institute of Virology - Stefan Nicolau, Bucharest, Romania,* [4]*Endocrinology Institute - C.I. Parhon, Bucuresti, Romania.*

Prader Willi syndrome (PWS) is a complex disorder whose diagnosis may be difficult to establish on clinical grounds, because of the individual variations in the phenotype and because this one develops with age.

Molecular mechanisms that lead to this disorder could be chromosomal deletions, uniparental disomy (UPD), intragenic mutations and epigenetic modifications in the process of imprinting and rarely reciprocal translocations in 15q11-q13. A common defect is noticed in all cases: loss of parental contribution in this region. This feature coupled with clinical scores and classical karyotyping have been investigated in a group of 36 patients. They were screened for genetic factors, that is: chromosomal translocations (karyotyping), deletions (FISH, fluorescent in situ hybridization) and combined genetic and epigenetic factors: microdeletions and DNA methylation (MSPCR, methylation specific PCR and MS-MLPA, methylation specific multilocus ligation-dependent probe amplification). Among all clinically suspected cases, only 14 cases were confirmed by methylation analyses. The resulted MLPA scheme of microdeletions in the critical region 15q11-q13 in confirmed cases suggested the following mechanism: the imprinting defect can occur secondary to a DNA sequence modification or mutation in a *cis*-acting factor or as primary epigenetic modification in the absence of any DNA sequence change. Primary epigenetic modifications may occur after fertilization and lead to somatic phenotype mosaicism. An indirect *trans*-genetic factor implication, as the *mthfr* gene polymorphism, was investigated in the two families and in the 14 cases. The results of this approach suggested a further link of the PWS with the errors in the parental methylome.

P12.205
Is DMXL1 a Prader-Willi like gene?

N. Calmels[1], *C. Seifert*[1], *C. Gasnier*[1], *N. Haumesser*[2], *C. Vincent-Delorme*[3], *J. Böhm*[2], *J. Laporte*[2], *J. Muller*[1,2], *J. L. Mandel*[1,2,4];
[1]*Laboratoire de Diagnostic Genetique, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [2]*IGBMC, Illkirch, France,* [3]*Service de Génétique Clinique Guy Fontaine, Hôpital Jeanne de Flandres, Lille, France,* [4]*College de France, Paris, France.*

The DMXL1 gene, encoding a WD repeats protein of unknown function, has been proposed recently to be mutated in patients with a Prader-Willi like phenotype (Gokhale et al., abstracts at ASHG 2008 and 2009. Hegde et al, US Patent 2010/0136552 A1), with the finding of heterozygous missense variants in 12/114 patients (10.5%). Eight of these twelve variants occurred in exons 20-24 of this gene. Three of them were cited in the ASHG abstract as de novo mutations but without further confirmation.

We have sequenced either directly (the large exon 24) or after high resolution melting screening (exons 20-23) these exons that encode 20% of the protein, in 328 patients referred to our molecular diagnostic lab for a broadly defined Prader-Willi like phenotype without chromosome 15 anomaly. We have found one already described variant (M1589V) and six novel heterozygous missenses with five of them observed in a single patient each. Three out of these five variants were predicted as possibly or probably pathogenic using Polyphen. Parental samples have been obtained for one case: the R2131S substitution has been found in both affected and healthy relatives and is thus unlikely to be pathogenic. Other parental samples were not available yet.

Among the eighteen variants observed in American and French cohorts, five have since been reported in the dbSNP database and one is also found in an unaffected individual, questioning the implication of DMXL1 in the disease and suggesting a rarer frequency of possibly pathogenic variants than reported initially (2.7% at the most).

P12.206
Prevalence of FMR1 intermediate alleles among women with idiopathic POF in the Basque Country

M. Barasoain[1], *G. Barrenetxea*[2], *I. Huerta*[1], *M. Télez*[1], *E. Ortiz-Lastra*[3], *A. J. González*[3], *P. Flores*[4], *B. Criado*[5], ***I. Arrieta***[1];

School of Nursing, Bilbao, Spain,* [5]*Department of Genetics. Cooperativa de Ensino Superior Politecnico e Universitario (CESPU), Porto, Portugal.*

Fragile X syndrome is caused by the expansion of a CGG trinucleotide repeat in the 5' untranslated region of the fragile X mental retardation 1 (FMR1) gene. The FMR1 premutation (55-199 repeats) alleles have been associated with premature ovarian failure (POF) and earlier age at menopause. The FMR1 alleles in the intermediate range (45-60 repeats) and in the high end of the normal range (>35) have also been found to be related with POF and early menopause. It has been estimated that approximately 20% of FMR1 premutation women have POF and among females with idiopathic POF, about 3.2% carries the premutation allele. These values are in accordance with our previous results in a sample from the Basque Country (3.5%). To complete the investigation, we have analyzed the prevalence of the intermediate alleles in patients with POF from the Basque Country. We have found that 4,76% of them has an intermediate allele with more than 45 CGG repeats, but this percentage increases to 23,81% when we consider the 35-54 CGG repeats range. In the general Basque population previously analyzed, the percentage of alleles in this range (35-54 CGGs) was 6.8%. The results obtained reinforce the association between the alleles at the high end of the normal range, the intermediate alleles, and the ovarian dysfunction.

P12.207
Identification of a chromosomal locus associated with recessive Primary Ciliary Dyskinesia in a Bedouin family

M. Mazor[1,2], *R. Parvari*[1,2], *V. Chalifa Caspi*[2], *S. Alkrinawi*[3], *E. Manor*[4], *J. Beck*[5], *V. Sheffield*[5], *M. Aviram*[3];
[1]*Dept of Virology & developmental Genetics, Ben Gurion University, Beer-Sheva, Israel,* [2]*The National Institute for Biotechnology in the Negev, Beer-Sheva, Israel,* [3]*Pediatric Division Soroka medical Center, Beer-Sheva, Israel,* [4]*Institute of Genetics, Soroka Medical Center, Beer-Sheva, Israel,* [5]*Dept. of Pediatrics - Division of Medical Genetics; Howard Hughes Medical Institute, University of Iowa, Iowa, IA, United States.*

Primary ciliary dyskinesia is a rare autosomal recessive genetic disorder, caused by inherited defects of ciliary structure and function. The clinical features reflect the distribution of dysmotile cilia and include neonatal and chronic respiratory distress due to lack of coordinated ciliary movement. In approximately half of PCD patients, there is apparent randomization of left-right axis development, or situs inversus totalis proposed to result from defective function of embryonic nodal cilia.

We have characterized a consanguineous Bedouin family from the Negev, who has two siblings diagnosed with situs inversus and respiratory symptoms and numerous healthy siblings. Linkage to the 13 genes known to be associated with the disease was negated. Further genome wide linkage analysis using the Affymetrix GeneChip mapping 250K array and microsatellite markers was performed.

Homozygosity mapping identified a chromosomal region larger than 16cM. Genotyping the region by analyzing polymorphic markers to all family members has defined a locus of 30Mb on chromosome 18q with a Lod score of 3.0 for multipoint analysis.

Prioritizing genes for search of the mutation and initial sequencing,

was preformed according to the databases of proteome collections, and derived from evolutionarily distant organisms which combines independently assembled ciliary, basal body and centrosome.
Identification of additional genes involved in cilia function will provide new insights into the molecular mechanisms of the cilia and help to develop much needed novel techniques to diagnose subjects with PCD

P12.208
A novel *ABCB11* mutation in an Iranian girl with progressive familial intrahepatic cholestasis

E. Bagherizadeh[1], *R. Vazifehmand*[2], *S. Saber*[1], *M. Kasiri*[1], *H. Bikker*[3];
[1]*Sarem Cell Research Center, Sarem Women Hospital, Tehran, Islamic Republic of Iran,* [2]*Young Researchers Club , Islamic Azad University, Rasht, Islamic Republic of Iran,* [3]*Academic Medical Center Department of Clinical Genetics, Amsterdam, Netherlands.*

Progressive familial intrahepatic cholestasis is an autosomal recessive liver disorder originated from biallelic mutation in ABCB11 gene. A 9 year-old girl with cholestasis referred for genetic counseling. The patient was affected by icterus and pruritis from newborn period. She had a family history of cholestasis in two previous expired siblings. Hepatocellular swelling with multi nuclearative canalicular and hepatocellular cholestasis, portal lymphocytic infiltration and fibrosis, newly formed liver nodules, bridging necrosis, bile duct proliferation, giant cells and micro vesicular fat droplet can be seen in proband liver biopsy. Genetic analysis on ABCB11 gene led to identifying of a novel mutation in exon 26. The homozygous mutation was found in sequence 3593 A>G, the mutation lead to a missense mutation at the amino acid level (His1198Arg). This mutation caused PFIC2 due to abnormal function in the bile salt export pump protein (BSEP).

Basal-cell carcinoma (BCC) is the most common type of skin cancer, and shows a continuously increasing incidence. BCCs occur predominantly on head and neck of elderly fair-skinned people, with increased occurrence on the trunk (torso) in recent years. Patched (*PTCH1*) gene is a tumor suppressor gene most often associated with development of BCCs. It is a member of the Hh-Gli signaling pathway, a pathway that plays a major role in embryonic development and stem cell maintenance. Loss of heterozygosity (LOH) of tumor suppressor genes is a frequent event in tumorigenesis, and is most often analyzed by microsatellite typing. Here we offer a fast and efficient method for simultaneous SNP genotyping and mutation scanning, which can also be used for LOH detection. High resolution melting (HRM) analysis is based on differences in melting curves caused by variations in nucleotide sequence during the heating (melting) of the PCR product in the presence of the intercalating dye. Based on our previous experience with HRM, we expanded our mutation screening to LOH analysis with a study of 25 BCC samples. We also compared the LOH results obtained with HRM with those of the conventional microsatellite typing for several STR markers in *PTCH1* region. HRM is an excellent method for both point mutation detection and LOH analysis, with point mutations found in 40%, and LOH in 50% of samples, and the inter-rater agreement between microsatellite and HRM LOH analyses of κ value of 0.869, what can be interpreted as very good agreement between the methods.

P12.210
Gorlin syndrome and PTCH1 gene mutation in two Bulgarian cases

A. Todorova[1,2], *P. Dimova*[3], *V. Dimitrova*[4], *A. Kirov*[1,2], *T. Todorov*[1,2], *B. Veneta*[3], *E. Slavkova*[3], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory "Genica", Sofia, Bulgaria,* [3]*Clinic of Child Neurology, "St. Naum" Hospital, Medical University Sofia, Sofia, Bulgaria,* [4]*University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.*

The nevoid basal cell-carcinoma syndrome (NBCCS), also known as "Gorlin syndrome", is an autosomal dominant disorder of high penetrance, but variable expression. Clinical manifestations are extremely variable and include various skin changes and congenital malformations, as well as predisposition to different neoplasms. Multiple BCCs, odontogenic jaw keratocysts (OKCs), palmar and plantar pits, and falx calcifications are major criteria of the disease.
NBCCS is caused by mutations in the PTCH1 gene
Here we report two patients with NBCCS, caused by frameshift PTCH1mutations. The first patient is a 12-years old girl with craniofacial dysmorphism - macrocephaly, frontal bossing, malformed ears, high arched palate, and multiple nevi. The central nervous system (CNS) manifestations included multiple falx and tentorium calcifications, cavum vergae, cavum septi pellucidi, and occipital arachnoid cysts, mild mental retardation. Family history was positive for Gorlin syndrome (mother and grandmother with multiple BCCs and OKCs; uncle with severe mental retardation, epilepsy, BCCs, OKCs and temporal lobe tumor; an older brother with lethal outcome in early infancy due to congenital hydrocephalus and cerebellar tumor). Molecular-genetic analysis in the proband revealed 2bp deletion in exon 2 of the PTCH1 gene - c.257_258delTC, p.(Leu87Ilefs*1).
The second patient is a 36-years old woman with negative family history. She has been operated for BCCs and OKCs. No CNS or other symptoms were registered so far. The screening for PTCH1 mutations revealed a splice site mutation g.1602+1G>T.
Both established mutations are frameshifting, but they showed different phenotypic expression especially in regard to the CNS manifestations of the disease.

All forms of the heritable blistering disorder dystrophic epidermolysis bullosa (DEB) result from mutations in the type VII collagen gene, *COL7A1*. Clinically, DEB is heterogeneous and a spectrum of *COL7A1* mutations has been reported. In spite of paradigms for genotype-phenotype correlation, however, the molecular basis of some rare DEB forms, such as the inversa subtype of recessive DEB (RDEB-I), has not been clearly documented. RDEB-I is characterized by predominant blistering in the body flexures and variable mucosal involvement. To characterize RDEB-I in more detail, we screened *COL7A1* in a cohort of 18 Dutch and UK patients and determined genotype-phenotype correlation. All patients carried homozygous, functionally hemizygous, or compound heterozygous arginine or glycine substitutions within the THD of type VII collagen. However, no clear differences in position of mutated codon or nature of substituting amino acids were evident between these RDEB-I mutations and missense mutations causing other RDEB phenotypes. Our results do not support recent data that have suggested that glycine substitutions close to THD non-collagenous imperfections might underlie RDEB-I, as 7/11 (56%) of mutated glycine codons were sited in the central parts of THD collagenous subdomains. Our data demonstrate that RDEB-I is caused by specific arginine and glycine substitutions within the type VII collagen THD, but the precise pathophysiological mechanism by which they lead to the curious inversa distribution remains obscure. It is plausible that these mutations only lead to disease in body areas

with higher skin temperatures, but functional data to substantiate this are still required.

The National Institute of General Medical Sciences (NIGMS) Human Genetic Cell Repository at the Coriell Institute for Medical Research supplies scientists worldwide with high-quality, well-characterized cell lines and DNA for use in biomedical research. Continually expanding, the NIGMS Repository currently offers more than 10,500 different cell lines through its web-based catalog, accessible at ccr.coriell.org. The majority of the Repository is comprised of lymphoblastoid and fibroblast cell lines and DNA from individuals with inherited disorders or chromosomal aberrations, and from apparently healthy individuals representing specific ethnic populations. Induced pluripotent stem cells (iPSCs) are a new addition to the collection: both disease-specific and apparently healthy iPSCs will be available to investigators in 2011. Most of these iPSCs have been reprogrammed from NIGMS Repository fibroblasts. The Repository has also established various differentiated cell lines. In collaboration with the Centers for Disease Control and Prevention's Genetic Testing Reference Material Coordination Program and members of the genetic testing community, genomic DNA reference materials characterized by multiple laboratories using different testing platforms have been developed and are available through the NIGMS Repository. Available reference materials include panels for disorders common in individuals of Ashkenazi Jewish descent, cystic fibrosis, and pharmacogenomic testing. Reference materials for myotonic dystrophy and chromosomal aberrations are now being developed. Genome-wide genotyping of approximately 1,100 samples in the collection has been completed, with data available to researchers through dbGAP. The NIGMS Repository is currently recruiting urea cycle disorder and congenital muscle disease biospecimens through the Urea Cycle Disorders Consortium and Cure CMD, respectively.

[1]*A.O. Niguarda Ca' Granda, Milano, Italy,* [2]*Applied Biosystems, Life Technologies, Monza, Italy.*

BACKGROUND: Pure restrictive cardiomyopathy (RCM) is a very rare disease clinically characterized by impaired relaxation and left ventricular (LV) filling, dilation of both atria and absence of significant LV hypertrophy. Mutations that cause RCM have been identified in several genes that encode contractile proteins like Desmin (DES), Troponin I (TNNT3) and Troponin T (TNNT2). TNNT2 is the tropomyosin-binding subunit of troponin, the thin filament regulatory complex which confers calcium-sensitivity to striated muscle actomyosin ATPase activity. To date no benign mutations of the TNNT2 gene have been reported. Six mutations (p.I79N, p.R92Q, p.R92W, p.A104V, p.D160E and IVS15-1G>A) are characterized by a incidence of sudden death in the setting of hypertrophic cardiomyopathy (HCM). In addition, one family with two affected individuals carriers of the p.F110L mutation has been reported. We here describe the clinical phenotype associated with the mutation p.F110L of theTNNT2 gene within an italian family in which the proband, who showed RCM, was carrying the above mutation in homozygous status.

METHODS: Total DNA was extracted from whole blood. Pre-mutation analysis of the TNNT2 was carried out by means of HRM on the VIIA7 platform. Anomalous melting profiles were subsequent sequenced on the ABI PRISM 3130xl. The proband and relatives underwent clinical and physical workup including cardiac magnetic resonance.

CONCLUSIONS: Althought previously reported, the p.F110L mutation demonstrated to be causatively linked to the RCM phenotype in homozygous status: The carriers of the investigated family did not show any disease sign of the cardiac imaging even in adulthood.

P12.214
Molecular diagnosis of autosomal recessive retinal dystrophies by homozygosity mapping with SNP arrays

F. Coppieters[1], *K. Van Schil*[1], *S. Lefever*[1], *E. De Vlieghere*[1], *F. Meire*[2], *B. P. Leroy*[1,3], ***E. De Baere***[1];

[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Hôpital Des Enfants Reine Fabiola, Free University of Brussels, Brussels, Belgium,* [3]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium.*

Identity-by-descent **(**IBD) mapping has been instrumental in gene discovery of several autosomal recessive (AR) retinal dystrophies (RDs). The increasing use of genomewide SNP chips makes IBD mapping an accessible tool in a clinical context. We aimed to apply this approach as a molecular diagnostic tool in consanguineous families with several RDs.

In total, 35 patients out of 29 families underwent IBD mapping using 250K SNP chips. Twenty probands were diagnosed with one of the following RDs: Leber Congenital Amaurosis (6), early-onset retinal dystrophy (2), AR retinitis pigmentosa (9) or cone-rod dystrophy (3). In addition, nine probands presented with a syndromic RD: Senior-Loken syndrome (2); LCA with mental retardation (MR) (2) or deafness (1); Usher syndrome type I (1) and II (2) and ARRP in combination with mild MR, growth hormone defect and acromelic dysplasia (1). RD candidate genes located within major IBD regions were screened for mutations by Sanger sequencing. In patients in whom a mutation was found, the clinical record was revisited.

This approach revealed mutations in nine families so far (31%), thereby overcoming the need for laborious gene-to-gene testing of all known disease genes and the need for a well-established phenotype prior to testing. New mutations were found in the following genes: *RDH12* (3), *IQCB1* (3), *USH2A, ABCA4, CNNM4*. In addition, a reappraisal of the clinical diagnosis was made in patients with mutations in *RDH12* and *CNNM4*. Finally, we showed that IBD mapping could also be used in families with a single affected individual.

First genetic study of Retinitis Pigmentosa in Italian population by microarray technology.

L. Berti[1], *S. Palchetti*[1], *I. Passerini*[1], *A. Sodi*[2], *B. Boschi*[1], *U. Menchini*[2], *F. Torricelli*[1];

[1]*SOD Diagnostica genetica, AOU Careggi, Florence, Italy,* [2]*Eye Clinic, University of Florence, Florence, Italy.*

Autosomal recessive Retinitis Pigmentosa (AR-RP) displays a high degree of genetic and clinical heterogeneity. The mutations spectrum can vary among different ethnic groups; we report a molecular analysis of Italian AR-RP patients, performed with microarray technology.

94 AP-RP patients originating from different part of Italy were included in the study. Diagnostic criteria were early onset retinal dystrophy with typical pigment clumping, electroretinogram (ERG) severe abnormalities, visual field concentric restriction. All the patients underwent a standard ophthalmic examination. Mutation analysis was performed by a microarray chip APEX (Arrayed Primer Extension), including the most frequent mutations associated with AR-RP (501 mutations in 16 genes). In the cases where the microarray screening detected only one mutation, the whole gene was sequenced. The samples of the patients where the chip could not identify any mutation were analysed for ABCA4 gene with automated sequencing system.

13 sequence variants (in the genes CRB1, USH2A, PDE6A, CERKL, CNGA1, RGR, RDH12, RPE65, MERTK) were identified by means of the microarray technology and other 10 sequence variants could be detected by sequencing. 9 ABCA4 mutations were identified in 8 patients. The protocol allowed the identification of sequence variants out of 34/94 AP-RP patients (36%). USH2A was the most frequently mutated gene. Altogether were characterized 15/94 patients, that were homozygous for one sequence variant in one gene, or heterozygous for two different sequence variants.

Microarray technology may represent a cheap and fast method

for mutation analysis, providing useful information for prognostic evaluation and patients' recruitment for trials of gene therapy.

P12.216
Mutation spectrum of RP1 gene in Saudi Retinitis Pigmentosa patients

M. Alrashed[1,2,3], *L. Abu Safieh*[1], *M. Aldahmesh*[1], *H. Alkuraya*[4], *S. Al-Hazzaa*[5], *F. Alkuraya*[1,6,7];
[1]*Department of Genetics, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia,* [2]*PhD student, Institute of ophthalmology, UCL, London, United Kingdom,* [3]*Department of Clinical Laboratory Sciences, College of Applied Medical Sciences, King Saud University, Riyadh, Saudi Arabia,* [4]*4Department of Retina, King khalid Eye Specialist Hospital, Riyadh, Saudi Arabia,* [5]*5Department of Ophthalmology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia,* [6]*Department of Anatomy and Cell Biology, College of Medicine, Alfaisal University, Riyadh, Saudi Arabia,* [7]*Department of Pediatrics, King Khalid University Hospital and College of Medicine, King Saud University, Riyadh, Saudi Arabia.*

Introduction: The RP1 locus was mapped using linkage analysis in a large autosomal dominant retinitis pigmentosa (RP) family. Mutations in RP1 can cause both autosomal dominant and recessive forms of RP. The RP1 gene encodes a protein of 2156 amino acids and localized in the connecting cilia of photoreceptors.

Method: Familial and single RP cases were enrolled in this study, all came from consanguineous families. DNA samples from all affected individuals were genotyped using the Affymetrix GeneChip Human Mapping 250K Arrays. Genome-wide scan was done using easylinkage software, multiple loci were suggested and evaluation of the potential loci was aided by homozygosity analysis. Direct sequencing of all exons of RP1 was done.

Results: Three novel mutations were identified in RP1 gene in 3 different consanguineous families, and one sporadic case. All mutations identified were clustered in exon 4; two nonsense mutations (p.K1517X, p.W1131X) in families arRP-F028, sRP-19, respectively and one deletion (p.N1143l fs X25) in two unrelated families arRP-F043, arRP-DF01. These mutations were predicted to truncate the RP1 protein by approximately 50% of the full length and make it insensitive to nonsense-mediated decay, leading to the production of truncated proteins which lacks the C terminal.

Discussion:

To date approximately 47 truncation mutations have been identified in RP1, all of which are located on exon 4. Among the truncation mutations only two mutations have been implicated in arRP. Here we are reporting three novel mutations to cause arRP which provides supporting evidence that mutations in RP1 can result in arRP.

P12.217
Mutation analysis of FAM161A in Jewish patients with autosomal recessive Retinitis Pigmentosa and protein localization experiments

D. Bandah-Rozenfeld[1], *L. Mizrahi-Meissonnier*[1], *A. Obolensky*[1], *T. Ben-Yosef*[2], *S. B. Schwartz*[3], *A. V. Cideciyan*[3], *E. Banin*[1], *S. G. Jacobson*[3], *D. Sharon*[1];
[1]*Hadassah-Hebrew University Medical Center, Jerusalem, Israel,* [2]*Genetics Dept - Faculty of Med, Technion, Haifa, Israel,* [3]*Scheie Eye Institute, Philadelphia, PA, United States.*

We recently reported the identification of the FAM161A gene as a cause of autosomal recessive retinitis pigmentosa (arRP) in the Israeli population due to null mutations. Aiming to further evaluate the role of FAM161A in arRP, we genotyped the two most common mutations we identified, p.Thr452SerfsX3 and p.Arg523X, and found a prevalence of 11% (21/193) and 3% (5/193) respectively, in a large cohort of Jewish RP patients from Israel and USA. Clinical manifestations of patients with FAM161A mutations varied: the majority had RP phenotype ranging from an early onset (at childhood) to relatively mild sector RP. One of the patients manifested an atypical retinal degeneration.

Due to the high carrier frequency of the p.Thr452SerfsX3 mutation in some Jewish sub-populations (carrier frequency of 1 out of 32 individuals), homozygosity for this mutation was also identified in families with an autosomal pseudo-dominant pattern of inheritance.

To study the localization of the FAM161A protein in the human and mouse retinas, we performed immunohistochemistry and Western Immunoblotting using a commercial antibody as well as custom-made antibodies raised against the C-terminal and an alternatively-spliced exon 4. The analysis in both species revealed a positive and intense signal in the photoreceptors inner-segments as well as a weaker staining in the outer plexiform layer. No expression was evident in the outer-segments. FAM161A mutations are currently the most common cause of arRP in the Jewish population (14%). The function of the encoded protein is currently unknown and additional experiments are needed to clarify its role in the retina.

P12.218
Mutational analysis of RPE65, ABCA4 and RHO genes on Greek patients with retinitis pigmentosa, Leber congenital amaurosis and Stargardt's disease.

M. Tsipi[1], *M. Tzetis*[1], *S. Kitsiou*[1], *E. Tsina*[2], *E. Kanavakis*[1];
[1]*Department of Medical Genetics, University of Athens, Athens, Greece,* [2]*1st Pediatric Department, "Aghia Sophia" Children's Hospital, Athens, Greece.*

Inherited retinal dystrophies are a phenotypically and genotypically heterogeneous group of diseases that affect more than two million people worldwide. Clinical and genetic heterogeneity have an important impact on genetic testing and counseling of affected families. Typical examples of hereditary retinopathies are Leber congenital amaurosis, retinitis pigmentosa and Stargardt's disease.

In this study we focused our research on the elucidation of the possible role of three genes (*RPE65, ABCA4* and *RHO*) on the pathogenesis of hereditary retinal dystrophies in the Greek population. Mutations in these genes have been associated with several forms of retinal dystrophies. There is no previous study in the Greek population on the correlation between genetic aberrations in the above mentioned genes and clinical phenotype. The first gene that was sequenced was *RPE65* in families with Leber congenital amaurosis and retinitis pigmentosa. Three exons of *ABCA4* in families with Stargardt's disease and retinitis pigmentosa and three exons of *RHO* in families with retinitis pigmentosa, were also sequenced.

Mutation c.272G>A (p.R91Q) in exon 4 of *RPE65* was found in a patient with retinitis pigmentosa and in his healthy mother. This mutation has been associated with retinitis pigmentosa. Another important finding was mutation c.52C>T (p.R18W) in exon 1 of *ABCA4.* This mutation was found in a patient with retinitis pigmentosa. The specific mutation has been associated with autosomal recessive retinitis pigmentosa and Stargardt's disease. We will also discuss additional findings such as polymorphic variants, which were identified in patients as well as in their relatives and possible phenotype/genotype correlations.

P12.219
A hotspot region for LINE1 endonuclease-dependent *de novo* insertion in the *NF1* gene

K. Wimmer[1], *T. Callens*[2], *A. Wernstedt*[1], *L. Messiaen*[2];
[1]*Division Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [2]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States.*

RNA-based *NF1* mutation analysis uncovered in 18 index patients splicing alterations, mainly exon skipping events, which were explainable neither by an underlying point-mutation nor by a deletion of genomic sequences. Improved PCR protocols that avoided allelic drop-out of the mutated alleles uncovered *de novo* insertions of 14 *Alu* elements, three LINE1 elements, and one poly-(T) stretch as causes of these splicing defects. All 18 inserted sequences showed the characteristics of LINE1 endonuclease-mediated retrotransposition: the integration sites match the reported LINE1 endonuclease consensus cleavage site; the elements were flanked by target site duplications and contained poly-(A) tails derived from their transcripts. Hence, these 18 pathogenic LINE1 endonuclease-mediated insertions substantially add to the so far ~60 published mutations of this type and represent the largest number of this mutation type characterized in one single human gene. Our findings show that the main effect of retrotransposon insertions within or close to exons is altered splicing. The integration sites were distributed over the entire 282-kb *NF1* gene. However, six different insertions clustered in a 1.5-kb region within the gene. This cluster region contained a specific integration site that was used in two unrelated patients to insert an *Alu*Ya5 element. A second site outside the cluster region was also used twice to insert an *Alu*Ya5 and an *Alu*Yb8 element, respectively. This supports the notion of non-

random insertion of retrotransposons in the human genome. The here identified integration sites may serve to elucidate features that make sequences particularly vulnerable to LINE1 endonuclease-mediated insertions.

P12.220
A Novel MECP2 Gene Mutation in a Tunisian Patient with Rett Syndrome

N. Fendri - Kriaa, *Z. Abdelkafi, F. Fakhfakh;*
laboratoire de genetique moleculaire humaine faculté de medecine Sfax, Sfax, Tunisia.

Patients with classical Rett show an apparently normal psychomotor development during the first 6-18 months of life. Thereafter, they enter a short period of developmental stagnation followed by a rapid regression in language and motor development. Purposeful hand use is often lost and replaced by repetitive, stereotypic movements. Rett syndrome (RTT) is an X-linked dominant disorder caused frequently by mutations in the methyl-CpG-binding protein 2 gene (MECP2). The aim of this study was to search for mutations in MECP2 gene in two Tunisian patients affected with RTT. The results of mutation analysis revealed mutations in exon 4 of MECP2 gene in the two patients. In one patient we identified a new mutation consisting of a deletion of four bases (c.810-813delAAAG), which led to a frame shift and generated a premature stop codon (p.Lys271Arg fs X15) in transcriptional repression domain-nuclear localization signal (TRD-NLS) domain of MeCP2 protein. With regard to the second patient, a previously described transition (c.916C>T) that changed an arginine to a cysteine residue (p.R306C) in TRD domain of MeCP2 protein was revealed. In conclusion, a new and a known de novo mutation in MECP2 gene were revealed in two Tunisian patients affected with RTT.

P12.221
Mutation analysis of MeCP2 Gene in Egyptian Patients with Rett Syndrome

A. K. Abdel Aleem[1,2], *W. Al saeed*[1], *I. Kamal*[3], *M. Zaki*[4], *L. Mansour*[5], *G. Rady*[3];
[1]*Medical Molecular Genetics Department-National Research Centre, Giza, Egypt,* [2]*Weil Cornell Medical College- Qatar, Doha, Qatar,* [3]*Faculty of Science-Cairo university, Cairo, Egypt,* [4]*Clinical Genetics Department-National Research Centre, Giza, Egypt,* [5]*Pediatric Neurology-Faculty of Medicine-Cairo University, Cairo, Egypt.*

This presentation describes molecular analysis of the MeCP2 gene in 15 Egyptian Patients with provetional diagnosis of having Rett Syndrome. The clinical presentations of postnatal microcephaly, regression of milestones, and autistic behaviour with the constant finding of abnormal hand movements (hand washing, flapping, and fingers into mouth) were the main criteria for the clinical geneticist and the neurologist to refere female patients suspected to have Rett syndrome for molecular diagnosis. Direct sequencing analysis of the coding region of MeCP2 gene revield pathogenic mutations in 6 patients out of the 15 ones (40%). Re-examination of mutation negative cases confirming the picture of classical Rett. Conclusion , Large genomic rearrangements or other genes involvement may contribute, to a larger extent than that previously described in other ethnic populations, to the etiology of Rett in Egyptian patients. This is still under further investigations.

P12.222
Study of SLC29A3 gene in Rosai-Dorfman histiocytosis associated with hearing impairment: the French experience.

L. Jonard[1,2], *v. Couloigner*[3], *S. Pierrot*[3], *M. Louha*[1,2], *S. Gherbi*[1,2], *R. Couderc*[1,2], *E. Garabedian*[1,4,2], *F. Denoyelle*[1,4,2], *S. Marlin*[1,2,5];
[1]*AP-HP, PARIS CEDEX 12, France,* [2]*Centre de référence des surdités génétiques, Trousseau Hospital, Paris, France,* [3]*APHP ORL UNIT HOSPITAL NECKER, PARIS, France,* [4]*APHP ORL UNIT HOSPITAL TROUSSEAU, Paris, France,* [5]*APHP MEDICAL GENETICS UNIT HOSPITAL TROUSSEAU, Paris, France.*

SLC29A3 is implicated in a syndromic form of genodermatosis: H syndrome. The major features encounters in H syndrome are Hearing loss, Hyperglycaemia, Heart anomalies, Hypertrichosis, Hyperpigmentation, Hepatomegaly and Hypogonadism. More recently, SLC29A3 mutations have been described in families presenting syndromes associating generalised histiocytosis to systemic progressive features: severe camptodactyly, hearing loss, hypogonadism, hepatomegaly, heart defect and skin hyperpigmentation. We have identified a homozygous novel missense SLC29A3 mutation in a patient presenting with only a progressive sensorineural hearing impairment and a single cervical node. The same mutation was revealed in another patient with Rosai-Dorfman histiocytosis, profound hearing impairment, chronic inflammation with pericarditis and ophthalmological disorders. Both patients originated from North Africa and their mutation may be related to a common ancestor. Our results suggest that SLC29A3 should be studied in patients presenting with histiocytosis and hearing impairment.

P12.223
Severe short-limb dwarfism resembling Grebe chondrodysplasia: report of a third case of the Teebi-Al-Awadi-Opitz-Spranger dysplasia and exclusion of *GDF5* as the causative gene.

D. R. Bertola[1], *G. Yamamoto*[1], *L. N. Oliveira*[1], *C. A. Kim*[1], *G. Nishimura*[2], *A. Superti-Furga*[3];
[1]*Instituto da Criança - HC/FMUSP, São Paulo, Brazil,* [2]*Tokyo Metropolitan Children's Medical Center, Tokyo, Japan,* [3]*University of Lausanne, Lausanne, Switzerland.*

We describe a severe, nonlethal short-limb bone dysplasia in a boy, the first of two twin boys, who was presented to us at age 7 ½ years. An abnormal phenotype was apparent at birth in the first twin with shortening of all limbs. Radiographs showed that while all long bones were affected, the humeri, tibiae and fibulae were particularly short and globoid- or pear-shaped. Moreover, there was marked dysmorphogenesis of the carpal and tarsal bones and phalanges of fingers and toes with delta-shaped phalanges and brachydactyly. No internal organ malformation was detected. His mother suspected deafness since infancy, and hearing loss was confirmed on audiometry; ear CT showed malformation of cochlea and semicircular canals. Sequence analysis of *GDF5* exons gave normal results.
The pattern of clinical and radiographic findings, including hypoacusis as well as the peculiar combination of rhizomelic shortening of the upper limb and mesomelic shortening of the lower limb, are identical to those of two unrelated patients reported in 1986 by Teebi, Al-Awadi, Opitz and Spranger (Hum Genet 74:386-390) . The peculiarity consists in most marked shortening of the rhizomelic segment in the arm and the mesomelic segment in the leg. This third observation seems to confirm this condition as a distinct, specific entity. Absence of mutations in the *GDF5* gene confirms the distinction between this disorder and the Grebe - Hunter-Thompson - DuPan dysplasia family. The molecular basis remains to be determined.

P12.224
Novel mutations in FATP4 associated with Ichthyosis Prematury Syndrome

M. Sobol[1,2], *N. Dahl*[1], *J. Klar*[1];
[1]*Uppsala University, Uppsala, Sweden,* [2]*National Taras Shevchenko University of Kyiv, Kyiv, Ukraine.*

Ichthyosis Prematurity Syndrome (IPS) is an autosomal recessive disorder characterized by premature birth, non-scaly ichthyosis and atopic manifestations. The disease was recently shown to be caused by mutations in the gene encoding the fatty acid transport protein 4 (FATP4) and a specific reduction in the incorporation of VLCFA into cellular lipids.
We screened probands from five families segregating IPS for mutations in the FATP4 gene. Four probands were compound heterozygous for four different mutations of which three are novel. Four patients were heterozygous and one patient homozygous for the previously reported non-sense mutation p.C168X (c.504c>a). We identified novel nonsense mutation p.G35X (c.103g>t) in exon 2. Another three sequence variants were predicted to result in missense mutations. p.Q300R (c.899g>a) missense mutation in exon 7 has been reported previously. Missense mutations p.V477D (c.1430t>a) in exon 10 and p.R504H (c.1511g>t) in exon 11 appeared to be novel. All patients had clinical characteristics of IPS and a similar clinical course. All variants were excluded as common variants or polymorphisms by comparing to databases (dbSNP 131) and by the analysis of 200 Scandinavian control chromosomes.

Conclusions: Missense mutations and non-sense mutations in FATP4 are associated with similar clinical features suggesting that missense mutations have a severe impact on FATP4 function. The results broaden the mutational spectrum in FATP4 associated with IPS for molecular diagnosis of and further functional analysis of FATP4.

P12.225
Investigation of association between 5-HTT gene and response to antidepressant drug (Citalopram) in Iranian major depressant patients

S. Sahraian, *S. Hemati, H. NajmAbadi, K. Kahrizi, K. Kahrizi;*
Genetic Research Center,university of welfare and rehabilitation sciences, Tehran, Islamic Republic of Iran.

Background: The serotonin transporter (5-HTT) gene is known as the responsible gene for interindividual variation and the genetic susceptibility for psychiatric diseases, such as bipolar mood, schizopherenia and major depression. A common polymorphism in its upstream regulatory region is caused by difference in the number of GC rich, repetitive elements. Deletion or insertion in the 5-HTTLPR creates short (14 repeats), and long allele (16 repeats). Transcription of the L allele is 2 times more than the S allele. Since the serotonin and its transporter are involved in mood control, they can be targeted by antidepressant medications, and specially the selective serotonin reuptake inhibitor: Citalopram.

Materials and methods: In this study the response of 80 patients suffering from major depression disorder, to Citalopram, and its association with their genotypes has been investigated. On the other hand we estimated the allele frequency in Iranian population by analyzing the genotype of 100 normal samples. Our method included PCR followed by running on agarose gel.

Result: frequency of each allele in normal Iranian population is near to 0.5 (L: 0.48 and S: 0.52). 69% of the patients with allele L (L/L or L/S) respond to Citalopram, while just 44% of the S/S patients did not need to change the drug.

Conclusion: our study confirms the hypothesis that the L allele is associated with better response to antidepressant drug (P value=0.033. CI: 95%). But we could not prove any association between the S allele, and risk of major depression (add ratio: 0.923).

P12.226
Laboratory diagnosis of Smith-Lemli-Opitz syndrome in Hungary

I. Balogh[1], *E. Dzsudzsak*[1], *K. Hadzsiev*[2], *O. Torok*[1], *J. Kappelmayer*[1], *A. Olah V*[1];
[1]*University of Debrecen, Debrecen, Hungary,* [2]*University of Pecs, Pecs, Hungary.*

Introduction. Smith-Lemli-Opitz (SLO) syndrome is a severe monogenic autosomal recessive syndrome associated with mental retardation and multiple congenital anomalies. The responsible gene is the 7-sterol reductase (DHCR7). Both life expectancy and quality of life are severely affected by the disease. DHCR7 mutations show a large inter-ethnic variability. Our goal was to set up a diagnostic scheme that includes both biochemical and molecular genetic methodology to diagnose SLO and to detect mutations responsible for SLO in Hungarian patients.

Patients and methods. Ten Hungarian patients were analyzed. Serum 7-DHC and cholesterol levels were measured using an UV spectrophotometry method and using an enzymatic colorimetric method, respectively. For mutation detection, the entire coding region of DHCR7 gene was sequenced.

Results. All patients had elevated 7-DHC level (reference range <0.15 mg/L), ranging from 71.4 to 300.0 mg/L. Cholesterol levels were generally low (between 0.3 and 2.7 mmol/L). The cholesterol/7DHC ratio was abnormal in all cases. 9 patients were compound heterozygous for two causative mutations, while one patient was homozygous for a null allele. One splicing, one nonsense and 8 missense mutations were found. The detected alterations are known to be causative, except the previously unidentified c.374A>G (p.Y125C) which mutation lies in a phylogenetically conservative position. The closest known pathogenic mutations affect amino acid positions 119 and 138.

Conclusions. Using biochemical and molecular genetic methods, the molecular diagnosis of ten Hungarian SLO patients could be established. In addition to the known missense, nonsense and splicing mutations, a novel, most likely pathogenic mutation was identified.

Identification of seven new *RAI* mutations in Smith-Magenis syndrome patients without 17p11.2 deletions

C. Dubourg[1,2], *F. Bonnet-Brilhault*[3], *A. Toutain*[4], *C. Mignot*[5], *A. Jacquette*[5], *A. Dieux*[6], *M. Gérard-Banluet*[7], *C. Bendavid*[2], *C. Barthélémy*[3], *A. Verloes*[7], *V. David*[1,2];
[1]*Génétique Moléculaire, CHU Pontchaillou, Rennes, France,* [2]*UMR 6061 CNRS, Institut de Génétique, Université de Rennes I, Rennes, France,* [3]*Psychiatrie, Tours, France,* [4]*Génétique, CHU, Tours, France,* [5]*Génétique, CHU La Pitié Salpêtrière, Paris, France,* [6]*Génétique, CHU, Lille, France,* [7]*Génétique, CHU Robert Debré, Paris, France.*

Smith-Magenis syndrome (SMS) is a mental retardation syndrome with sleep disturbance, self injurious behaviours, and dysmorphic features. It is estimated to occur in 1/25 000 births and is associated with interstitial deletions of chromosome 17p11.2 in 90% of cases. RAI mutations are the second main molecular etiology, this gene being located in 17p11.2 in the SMS locus.

We evaluated 33 non-related individuals referred for molecular analysis due to a possible SMS diagnosis, none of these patients carrying any 17p11.2 deletions. Polymerase chain reaction and sequencing strategy identified mutations in *retinoic acid induced 1* gene (*RAI1*) in 7 cases (21%): two non sense mutations (p.Arg80X and p.Gln433X), four heterozygous frame shift mutations leading to protein truncation, and a missense mutation (p.Arg1172Cys). When parental samples were available, we could show that these mutations were *de novo*.

Patients had developmental delay (7/7), facial dysmorphy (7/7) and extremities abnormalities (4/7), major sleep disturbance (6/7) with an inverted rhythm of melatonin release, behavioural problems (6/7) including self aggressiveness, and overweight (6/7). Neither visceral anomalies nor seizures were observed.

All mutations occurred in exon 3 of *RAI1* which codes for more than 98% of the protein, as other mutations previously reported, but there is no hot spot and mutations are scattered all along this third exon.

Several polymorphisms were also observed.

P12.228
The rare parkinsonian phenotype of Machado-Joseph Disease (MJD/SCA3): Analysis of Parkinson's disease associated loci in two unrelated MJD patients

C. Bettencourt[1,2,3], *C. Santos*[4], *P. Coutinho*[1,5], *P. Rizzu*[6], *J. Vasconcelos*[7], *T. Kay*[8], *T. Cymbron*[1,2], *P. Heutink*[6], *M. Lima*[1,2];
[1]*Institute for Molecular and Cellular Biology, Porto, Portugal,* [2]*University of the Azores, Ponta Delgada, Portugal,* [3]*Banco de Tejidos para Investigaciones Neurológicas (BTIN), Madrid, Spain,* [4]*Universitat Autònoma de Barcelona, Barcelona, Spain,* [5]*Hospital São Sebastião, Feira, Portugal,* [6]*VU University Medical Center, Amsterdam, Netherlands,* [7]*Hospital of Divino Espirito Santo, Ponta Delgada, Portugal,* [8]*Hospital of D. Estefania, Lisbon, Portugal.*

Machado-Joseph disease (MJD/SCA3) is an autosomal dominant neurodegenerative disorder of late-onset, which is caused by a CAG repeat expansion at exon 10 of the *ATXN3* gene (14q32.1). Clinical heterogeneity observed in MJD, however, is not completely explained by the repeat size. Although Parkinsonism seems to segregate within some MJD families, only a few MJD patients develop parkinsonian features and, therefore, the clinical and genetic aspects of these rare presentations remain poorly understood. The main goal of this work was to investigate genetic variants, previously associated with Parkinson's disease (PD), in two MJD patients of Azorean background, displaying the rare parkinsonian phenotype. Patient 1 is a 40 year-old female (onset at 30 years of age), initially presenting as a pure parkinsonian phenotype (similar to the phenotype previously reported for her mother). Patient 2 is a 38 year-old male (onset at 33 years of age), presenting an ataxic phenotype with parkinsonian features (not seen either in other affected siblings or in his father). Both patients presented an expanded *ATXN3* allele with 72 CAG repeats. Screening of mutations and polymorphisms in PD associated loci, namely *PARK2*, *LRRK2*, *PINK1*, *DJ-1*, *SNCA*, *MAPT*, *APOE*, and mtDNA $tRNA^{Gln}$ T4336C, revealed the absence of PD mutations in the analyzed loci. Both patients, however, presented PD associated polymorphisms in *DJ-1* and *APOE* genes. Additional analysis in larger MJD series would be necessary to better ascertain the putative influence of these loci in the MJD phenotype.

P12.229
A new spastic paraplegia locus/gene (*SPG47*)

*C. Tesson[1], M. Salih[2], S. AlRasheed[3], M. Al Balwi[3], C. Goizet[1], A. Alswaid[3], A. Durr[1,4], A. Brice[1,4], **G. Stevanin**[1,4,5];*
[1]Institut du Cerveau et de la Moelle épinière, NEB, Paris, France, [2]Department of Pediatrics, College of Medicine, Riyadh, Saudi Arabia, [3]Department of Pediatrics, King Abdulaziz Medical City, Riyadh, Saudi Arabia, [4]APHP, Dpt of Genetics and Cytogenetics, GHU Pitié-Salpêtrière, Paris, France, [5]Ecole Pratique des Hautes Etudes, Paris, France.

Hereditary spastic paraplegias (HSP) are rare inherited neurological disorders. Our objective was to map the responsible gene in a large consanguineous family of Saudi-Arabian origin excluded for linkage to most autosomal recessive loci. A genome-wide scan was undertaken using 6090 SNP markers covering all chromosomes. The genome-wide search identified a single candidate region on chromosome 4, exceeding the multipoint LOD score threshold of +3 (Zmpt=4.6). Two additional Saudi Arabian families tested with microsatellite markers covering the candidate interval also showed linkage to this new locus (Zmpt=2.4 and +3.0). Patients from the smallest linked family carried the same homozygous haplotype as in the originally mapped kindred and allowed to narrow-down the interval to 3.3 cM containing 24 genes. Mutations in the coding region of 23 candidate genes were excluded and only one missense variant affecting a strongly conserved amino-acid was identified in patients and was absent in >500 Caucasian and North-African controls. Phenotypic presentation in 10 patients was suggestive of a relatively pure and early onset HSP, rarely associated with mental deterioration or thin corpus callosum at cerebral MRI. The mapping of a novel AR-HSP locus further demonstrates the extensive genetic heterogeneity of this condition.

P12.230
Mutations in *REEP1* Cause SPG31 with Alteration of Mitochondrial Functions

***C. Goizet**[1,2], C. Depienne[1,3], G. Benard[2], A. Boukhris[1], E. Mundwiller[1], G. Solé[2], E. Fedirko[3], D. Hannequin[4], P. Charles[3], I. Feki[1], J. Pinel[5], A. Ouvrard-Hernandez[6], S. Lyonnet[7], E. Ollagon-Roman[8], J. Yaouanq[5], A. Toutain[9], B. Fontaine[1], D. Lacombe[2], A. Durr[1,3], R. Rossignol[2], A. Brice[1,3], G. Stevanin[1,3,10];*
[1]Institut du Cerveau et de la Moelle, NEB, Paris, France, [2]Université Victor Segalen, Bordeaux, France, [3]APHP, Dpt of Genetics and Cytogenetics, GHU Pitié-Salpêtrière, Paris, France, [4]CHU, Rouen, France, [5]CHU, Rennes, France, [6]CHU, Grenoble, France, [7]Hôpital Necker-Enfants Malades, Paris, France, [8], Hôpital de la Croix Rousse, Lyon, France, [9]CHU, Tours, France, [10]Ecole Pratique des Hautes Etudes, Paris, France.

Hereditary spastic paraplegias (HSP) constitute a clinically and genetically heterogeneous group of neurodegenerative disorders characterized at least by slowly progressive spasticity of the lower extremities. Mutations in the *SPG31* gene, *REEP1*, were recently associated with a pure dominant form of the disease. We sequenced all exons of *REEP1* and searched for rearrangements by MLPA in a large panel of 175 unrelated HSP index patients from kindreds with dominant inheritance, with either pure (n = 102) or complicated (n = 73) forms of the disease, after exclusion of other known HSP genes. We identified 12 different heterozygous mutations, 11 of which were novel, in 12 different families, with either a pure or a complex phenotype; three mutations affected the splicing of the gene, two were exon deletions, four were missense mutations and three were small deletions or point mutations introducing premature stop codons. The overall mutation rate in our clinically heterogeneous sample was 4.5% in French families when taking into account HSP cases with other known genetic entities. The phenotype was restricted to pyramidal signs in the lower limbs in most patients but X had a complex phenotype associating cerebellar ataxia, tremor, dementia or a Silver. Interestingly, we evidenced, for the first time, abnormal mitochondrial network organization in fibroblasts of one patient in addition to mitochondrial energy production impairment in his muscle biopsy. Our results indicate that SPG31 is a relatively frequent form of HSP, with variable phenotype and incomplete penetrance associated with altered mitochondrial dynamics and functions.

P12.231
Allele-specific gene expression for evaluation of *SMN* functional efficiency

***S. Radovic**[1], G. Dubsky de Wittenau[1], N. Mandel[2], M. Morgante[1], R. I. Lonigro[3];*
[1]University, Udine, Italy, [2]University, Krems, Austria, [3]University and A.O.U., Udine, Italy.

Spinal muscular atrophy (SMA) is an autosomal recessive neurodegenerative disorder and a leading genetic cause of infantile mortality. In SMA, the *SMN1 is deleted or destroyed by mutation, while the neighbouring, nearly identical SMN2 fails to generate adequate levels of full-length SMN protein*. *SMN2* copy numbers is inversely correlated with the severity of the SMA phenotype. Total and SMN- FL RNA production was analyzed in peripheral blood of a reduced cohort of 24 subjects: 5 with homozygous deletion of *SMN1*, 11 healthy deletion carriers and 8 individuals from general population carrying 2 copies of *SMN1*, by using a new and highly accurate method that assesses allele-specific gene expression. We used base pair exchanges in exon7 and exon8 to distinguish between transcripts deriving from SMN1/2 genes. *SMN1* and *SMN2* resulted transcriptionally equivalent since observed proportions of total RNA transcripts deriving from the two genes were in line with the respective allelic copy numbers across different genotypes. However, they are not functionally equivalent since the production efficiency of SMN- FL RNA of *SMN1* and *SMN2* varied between 55-90% and 5-17%, respectively. Furthermore, the production of FL RNA is highly correlated (P<0.001) with *SMN1* copy numbers increase, while correlation with *SMN2* copy numbers is heterogeneous supporting that SMN2 alleles are not functionally equivalent. Finally, two asymptomatic subjects bearing homozygous deletion of *SMN1* showed significantly higher levels (P < 0.01) of FL RNA respect to affected individuals.
An accurate evaluation of allele-specific gene expression will significantly improve patients classification, follow-up and basic research .

P12.232
Study of the involvement of the poliovirus receptor (PVR) in childhood spinal muscular atrophy and postpolio syndrome

*S. Bernal[1,2], E. Also-Rallo[1,2], R. Martínez-Hernández[1,2], L. Alías[1,2], M. Baena[1,2], J. Gámez[3], M. J. Barceló[1,2], M. Baiget[1,2], **E. F. Tizzano**[1,2];*
[1]Department of Genetics, Hospital Sant Pau, Barcelona, Spain, [2]CIBERER U-705, Barcelona, Spain, [3]Department of Neurology, Hospital Vall d'Hebron,, Barcelona, Spain.

Spinal muscular atrophy (SMA) is an autosomal recessive neuromuscular disorder caused by mutations in the SMN1 gene. The highly homologous copy, SMN2, is considered a phenotypic modifier (when more copies, less severe) but is unable to prevent the disease. This correlation is not absolute and patients with the same number of SMN2 copies may manifest different SMA types (I, most severe, II or intermediate, and III the less severe) suggesting possible modifier genes in SMA. Postpolio syndrome (PPS) refers to manifestations that appear many years after acute poliomyelitis infection and occurs in approximately 50% of cases. Despite the clinical course of PPS is relatively slow, PPS can present with multiple symptoms and signs including fatigue and weakness. Given that SMA and poliomyelitis share some characteristics as motor neuron diseases, we proposed to investigate the involvement of the poliovirus receptor (PVR) in 95 healthy individuals, 94 PPS, and 126 patients with different SMA types but the same SMN genotype (homozygous absence of SMN1 and three SMN2 copies). We analysed seven tagSNPs of the PVR gene (rs1042640; rs1058402; rs17714931; rs203709; rs203710; rs3538129; rs714948). In SMA chronic patients, the presence of the T allele of the rs714948 polymorphism was significantly associated with a milder phenotype (type III) (chi square test p=0.041). Furthermore, there were no significant differences in the genotype distribution of the PVR SNPs between SMA or PPS patients and healthy individuals. Further investigations are warranted to unravel a possible effect of the PVR receptor in SMA. Supported by FIS 08-0729.

P12.233
A leaky splicing mutation affecting SMN1 exon 7 inclusion explains an unexpected mild case of spinal muscular atrophy

*M. Vezain[1], B. Gérard[2], S. Drunat[2], B. Funalot[3,4], S. Fehrenbach[5], V. N'Guyen-Viet[5], J. Vallat[6], T. Frebourg[1,5], M. Tosi[1], A. Martins[1], **P. Saugier-Veber**[1,7];*
[1]Inserm U614, Faculty of Medicine, Rouen University, Institute for Biomedical Research and Innovation, Rouen, France, [2]Department of Genetics, Robert-Debré Hospital, APHP, Paris, France, [3]Department of Neurology, University Hospital, Limoges, France, [4]Department of Genetics, University Hospital, Limoges, France, [5]Department of Genetics, University Hospital, Rouen, France, [6]Department of Neurology, University Hospital, Rouen, France, [7]Department of Genetics, University Hospital, Rouen, France, Rouen, France.

Spinal muscular atrophy (SMA) is an autosomal recessive neuromuscular disorder with symptoms usually appearing during early childhood. The disorder is due, in most cases, to homozygous deletions of the *SMN1* gene or, in rare cases, to small hemizygous *SMN1* intragenic mutations. Here we describe the identification and characterization of c.835-3C>T,a novel SMA-causing mutation detected in the intron 6 of the single *SMN1* allele of a type IV SMA patient. This patient carries only 2 copies of *SMN*2, the partially functional *SMN1* paralog. We demonstrate both *ex vivo*, using minigene splicing assays, and *in vivo*, by comparative multiplex RT-PCR analysis of patient RNA, that c.835-3C>T is a deleterious splicing mutation that induces a modest but unequivocal exclusion of exon 7 from the *SMN1* transcripts. We suggest that this effect may be due to the creation of a high-affinity binding site for the splicing repressor protein hnRNP A1 overlapping the splice acceptor site of exon 7. Importantly, the "leakiness" of this splicing mutation explains the exceptionally mild phenotype of an ambulatory 70-year-old SMA patient. Our findings support the current therapeutic strategies aiming at correcting exon 7 splicing in SMA patients, and bring clues about the level of exon 7 inclusion required to achieve a therapeutic effect.

P12.234
Characterising the pro-survival function of the survival of motor neuron (SMN) protein.

R. S. Anderton[1,2], *B. P. Meloni[1,3], F. L. Mastaglia[1,2], S. Boulos[1];*
[1]Centre for Neuromuscular and Neurological Disorders/Australian Neuromuscular Research Institute, Perth, Australia, [2]School of Medicine and Pharmacology, University of Western Australia., Perth, Australia, [3]Department of Neurosurgery, Sir Charles Gairdner Hospital, Perth, Australia.

Purpose: Spinal muscular atrophy (SMA), a neurodegenerative disorder primarily affecting motor neurons, is the most common genetic cause of infant death. This incurable disease is caused by the absence of a functional *SMN1* gene which leads to a critical reduction in full length SMN protein. The SMN protein has been linked to numerous cellular functions, including snRNP assembly and survival in motor neurons. However, exactly how SMN protein imparts its cell survival function is still unknown. This study aimed to characterise the pro-survival function of SMN and the relationship between the anti-apoptotic protein Bcl-xL and SMN.

Methods: To assess the relationship between SMN and Bcl-xL *in* vitro, recombinant adenoviral vectors were used to over-express proteins. This relationship was also assessed *in vivo* using a transgenic mouse model over-expressing SMN. The pro-survival mechanisms used by SMN were also assessed in an Akt/PI3 kinase inhibition model. Cell homogenates and mouse tissue were analysed using western blot analysis and real-time RT-PCR, to determine protein and transcript levels respectively.

Results: We found a significant relationship between Bcl-xL and SMN proteins. We found Bcl-xL expression was significantly reduced in SMA patient fibroblasts. Over-expression of SMN could increase Bcl-xL levels by 6 fold, while Bcl-xL over-expression significantly increased SMN protein and transcript levels. Over-expressed SMN protein also protected against Akt/PI3 kinase pathway inhibition, and blocked caspase-3 activation by preventing calpain mediated cleavage of procaspase-3. This study has determined how SMN reduces caspase-3 activation and links the Bcl-xL protein to SMA pathogenesis.

P12.235
Genetic deficiency of tartrate-resistant acid phosphatase is associated with skeletal dysplasia, cerebral calcifications and autoimmunity

E. Lausch[1], *A. Janecke[2], M. Bros[3], S. Unger[1,4], B. Zabel[1], A. Superti-Furga[1,4];*
[1]Centre for Pediatric and Adolescent Medicine, University of Freiburg, Freiburg, Germany, [2]Department of Pediatrics II and Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria, [3]Department of Dermatology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, [4]Department of Medical Genetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Vertebral and metaphyseal dysplasia, spasticity with cerebral calcifications, and strong predisposition to autoimmune diseases are the hallmarks of the genetic disorder spondyloenchondrodysplasia (SPENCD). We mapped a locus in five consanguineous families to chromosome 19p13 and identified mutations in ACP5, which encodes tartrate-resistant phosphatase (TRAP), in 14 affected individuals and showed that these mutations abolish enzyme function in the serum and cells of affected individuals. Phosphorylated osteopontin, a protein involved in bone reabsorption and in immune regulation, accumulates in serum, urine and cells cultured from TRAP-deficient individuals. Patient-derived dendritic cells exhibit an altered cytokine profile and are more potent than matched control cells in stimulating allogeneic T cell proliferation in mixed lymphocyte reactions. These findings shed new light on the role of osteopontin and its regulation by TRAP in the pathogenesis of common autoimmune disorders. Pharmacologic modulation of osteopontin may thus provide a novel therapeutic angle for diseases like systemic lupus erymathosus and multiple sclerosis.

P12.236**
Tartrate resistant acid phosphatase deficiency causes a bone dysplasia with autoimmunity and a type I interferon expression signature

T. A. Briggs[1], *Y. J. Crow[1,2];*
[1]Manchester Academic Heath Science Centre, University of Manchester, Manchester, United Kingdom, [2]On behalf of affiliated researchers and clinicians worldwide, Manchester, United Kingdom.

Rare Mendelian disorders demonstrating overlap with common diseases are of interest because of the insights they can provide into complex-disease pathogenesis. To this end, we studied ten individuals showing features consistent with the immuno-osseus dysplasia spondyloenchondrodysplasia (SPENCD). Of particular note was the diverse spectrum of autoimmune phenotypes observed in these patients, including systemic lupus erythematosus (SLE), Sjögren's syndrome, haemolytic anaemia and thrombocytopenia. Haplotype data indicated the disease gene to be on chromosome 19p13 and linkage analysis yielded a combined multipoint lod score of 3.6. Sequencing of the *ACP5* gene, encoding tartrate resistant acid phosphatase (TRAP), identified biallelic mutations in each of the patients studied, and *in vivo* testing confirmed a loss of expressed protein. All eight patients assayed demonstrated elevated serum interferon alpha activity.

SLE patients frequently demonstrate an increased expression of type I interferon stimulated genes. To determine if a similar 'interferon signature' was present in SPENCD patients, we undertook whole-genome microarray analysis, followed by confirmatory qPCR. We identified 18 genes which were greater than four-fold over-expressed, 15 of which are recognized as interferon stimulated genes.

Our findings, recently published in Nature Genetics[1], reveal a previously unrecognised link between TRAP activity and interferon metabolism, and highlight the importance of type I interferon in the genesis of autoimmunity.

1. Briggs et al. Tartrate-resistant acid phosphatase deficiency causes a bone dysplasia with autoimmunity and a type I interferon expression signature. Nat Genet. 2011. **43**(2): 127-131.

P12.237
Mutational analysis of the NPHS1, NPHS2, PLCe1 and WT1 genes in Greek children with clinical diagnosis of steroid resistant nephrotic syndrome(SRNS)

E. Fylaktou[1], *S. Megremis[1], A. G. Mitsioni[1], A. Mitsioni[2], K. Stefanidis[2], S. Kitsiou-Tzeli[1], E. Kanavakis[1], J. Traeger-Synodinos[1];*
[1]Medical Genetics, Athens University, "Aghia Sophia" Children's Hospital,

Athens, Greece, [2]Department of Pediatrics Nephrology, "P. A. Kyriakou" Children's Hospital, Athens, Greece.

Several genes are implicated in the pathogenesis of autosomal recessive SRNS. The exons and intron/exon boundaries of the genes *NPHS1* (nephrin, 29 exons), NPHS2 (podocin, 8 exons), PLCe1 (phospholipase C epsilon 1, 29/31 exons) and *WT1* (Transcription factor Wilm's Tumour-1, exons 8&9) were directly sequenced in 38 (30 sporadic, 8 familial) SRNS patients (3months-18years). Two congenital NS patients had pathological *NPHS1* genotypes: one had three mutations (p.Cys217fsX in *cis* with p.P264R and *trans* to p.S366R), the other homozygous for p.S366R. Three sporadic SRNS patients had pathogenic *NPHS2* genotypes: p.R138Q homozygous, p.R168H homozygous and p.R229Q/p.A295T compound heterozygous. The novel p.A295T was predicted pathogenic in *silico* (SIFT http://blocks.fhcrc.org/sift/SIFT.html, polyphen http://genetics.bwh.harvard.edu/pph). *PLCe1* gene analysis revealed three homozygotes for the previously described p.R1246X (2 related/familial, 1 sporadic). Six patients carried de-novo *WT1* mutations, including 5 known: one case IVS9+5G>A, one case p.R394Q, one case p.D396N, two cases p.R394W. Mutation p.R366H in the sixth case was novel, predicted pathogenic in silico. Excluding the case with p.D396N who was phenotypically male (XY karyotype), all other cases were phenotypically female, with XX karyotype in four although one p.R394W case had an XY karyotype. Heterozygous mutations were found in several familial cases: 3 with the *NPHS2* gene p.R229Q mutation and 2 with the *NPHS1* gene p.N188I mutation, although no di-genic inheritance was observed. In conclusion 14/38 cases were characterized with pathogenic mutations in *NPHS1, NPHS2, PLCe1* or *WT1,* indicating that molecular investigation of these genes is useful to support definitive diagnosis and management of pediatric SRNS.

P12.238
Functional characterization of mutations in THAP1 causing dystonia 6

A. Erogullari[1], *A. Osmanovic[1], A. Dendorfer[2], A. Rakovic[3], N. Uflacker[3], D. Braunholz[1], M. Albrecht[1], M. Gil-Rodríguez[1], G. Gilessen-Kaesbach[1], C. Klein[3], K. Lohmann[3], F. J. Kaiser[1];*

[1]Institut für Humangenetik, Lübeck, Germany, [2]Institut für Pharmakologie, Lübeck, Germany, [3]Sektion für Klinische und Molekulare Neurogenetik an der Klinik für Neurologie, Lübeck, Germany.

Dystonias represent a group of heterogenous movement disorders, characterized by involuntary twisting, repetitive movements and abnormal postures. Dystonia 6, a monogenic form of primary (isolated) dystonia, is associated with mutations in the *THAP1* gene; however, its molecular pathophysiology is not well understood. THAP1 is a transcription factor with a sequence-specific DNA-binding zinc-finger domain at the N-terminus (THAP-domain) and a putative nuclear localization signal (NLS) towards the C-terminus. Recently, we demonstrated that THAP1 specifically binds to the *TOR1A*-promoter and represses *TOR1A*-expression. The *TOR1A* gene is involved in primary dystonia 1.

By screening a large cohort of 700 patients with dystonia, we identified several new mutations located within the THAP-domain as well as mutations resulting in truncated THAP1 proteins. To investigate the functional consequence of the missense mutations, we performed luciferase-reporter gene-assays demonstrating that missense mutations within the THAP-domain result in a decreased or almost abolished THAP1-mediated repression of *TOR1A* expression. In contrast, amino acid exchanges within the C-terminal region of THAP1 did not influence its activity.

Secondly, we analyzed the intracellular localization of GFP-tagged wildtype THAP1, THAP1 with truncating mutations, and a missense mutation within the NLS (I149T) via confocal laserscanning microscopy. Mutations in the NLS, its complete or partial loss, resulted in an impaired transport of THAP1 protein into the nucleus.

In summary, our data provide evidence that missense mutations in the DNA-binding THAP1-domain as well as mutations leading to a partial or complete loss of the NLS sequence both result in a disturbed transcription factor activity of THAP1.

P12.239
Mutations in the 5'UTR of *ANKRD26,* the Ankirin Repeat Domain 26 Gene, Cause an Autosomal-Dominant Form of Inherited Thrombocytopenia, THC2

THC2, an autosomal-dominant thrombocytopenia described so far in only two families, has been ascribed to mutations in MASTL or ACBD5. We found that ANKRD26, another gene within the THC2 locus, and neither MASTL nor ACBD5, is mutated in eight unrelated families. ANKRD26 was also found to be mutated in the family previously reported to have an ACBD5 mutation.We identified six different ANKRD26 mutations, which were clustered in a highly conserved 19 bp sequence located in the 5' untranslated region. Mutations
were not detected in 500 controls and are absent from the 1000 Genomes database. Available data from an animal model and Dr. Watson's genome give evidence against haploinsufficiency as the pathogenetic mechanism for ANKRD26-mediated thrombocytopenia. The luciferase reporter assay suggests that these 5'UTR mutations might enhance ANKRD26 expression. ANKRD26 is the ancestor of a family of primate-specific genes termed POTE, which have been recently identified as a family of proapoptotic proteins. Dysregulation of apoptosis might therefore be the pathogenetic mechanism, as demonstrated for another thrombocytopenia, THC4. Further investigation is needed to provide evidence supporting this hypothesis.

Identification of novel TAAD loci on 2q37 and 7p15 in a large Dutch family: further evidence of disease heterogeneity and support of a bi-or multigenetic inheritance model

A. F. Baas[1], *M. Harakalova[1], d. C[1], I. Nijman[2], W. Kloosterman[1], S. Lieshout[1], M. Mokrey[2], J. Medic[1], R. van 't Slot[1], J. Deckers[3], J. Roos-Hesslink[3], G. Pals[4], C. Wijmenga[5], D. Lindhout[1], E. Cuppen[1];*

[1]UMC Utrecht, Utrecht, Netherlands, [2]Hubrecht Laboratory, Utrecht, Netherlands, [3]Erasmus MC, Rotterdam, Netherlands, [4]VU Medical Center, Amsterdam, Netherlands, [5]UMC Groningen, Groningen, Netherlands.

Background: It is estimated that 20% of the non-syndromic thoracic aortic aneurysm and dissection (TAAD) cases is inherited in an autosomal dominant pattern with variable expression and reduced penetrance. With mutation analysis of the currently known TAAD genes; *TGFBR1*, *TGFBR2*, *ACTA2* and *MYH11*, less than 20% of the familial TAAD cases are solved, indicating that there are more TAAD genes to be found.

Methods and results: We have characterized a large Dutch family in which TAAD was inherited in a seemingly autosomal dominant inheritance pattern, with reduced penetrance and variable expression. No segregating alterations in the known TAAD genes were identified by routine diagnostic testing. Genome-wide linkage analysis followed by fine-mapping exposed two novel TAAD loci on chromosome 2q37.1 and chromosome 7p15.3-7p14.3. The coding sequence of all protein-coding genes within these loci was analysed using a targeted massively parallel sequencing approach, by two independent exon-centric enrichment methods. However, the causal mutation was not identified.

Conclusions:

The identification of two novel TAAD-loci within one family that do

not contain any of the known TAAD genes and do not overlap with formerly reported loci, emphasizes the heterogeneity of the disease and suggests an interaction of two or more genetic factors in the development of TAAD within this family. In general, this assumption would explain the reduced penetrance and variable expression in familial TAAD. In the reported family, causative alterations may be present in non-coding regulatory sequences.

P12.241
Myelination delay in MCT8 mutated patients: role of MCT8 and MCT10 in thyroid hormone transport in human oligodendrocytes

C. Vaurs-Barriere[1], *Y. Capri*[1], *A. Cizeron*[1], *S. Mirafzal*[1], *C. Gonthier-Guéret*[1], *E. C. H. Friesema*[2], *T. J. Visser*[2], *O. Boespflug-Tanguy*[1,3];
[1]*GReD UMR INSERM U931 CNRS 6247, Clermont-Ferrand, France,* [2]*Erasmus Medical Center, Rotterdam, Netherlands,* [3]*AP-HP, Centre de Référence « Leucodystrophies », Hopital Robert Debré, Paris, France.*

We have identified mutations in the Monocarboxylate Transporter 8 (MCT8) gene, which encodes a thyroid hormone (TH) transporter, in patients initially presenting a Pelizaeus-Merzbacher-Like Disease (PMLD) phenotype related to an early diffuse hypomyelination. In contrast with classical PMLD patients, MRI follow-up of those patients demonstrated an improvement of the white matter signal suggesting a severe delay in myelination rather than a permanent myelin defect. TH are known to play a major role during the central nervous system (CNS) development not only in neurons but also in oligodendrocytes, the myelinating cells of the CNS. Nevertheless, the way TH enters those cells remains unidentified. Different TH transporters have been described expressed in the CNS but only at the blood-brain barrier in endothelial cells (OATP1C1, MCT8) and in neurons (MCT8, LAT1/2). Another newly identified transporter, MCT10 would be expressed in CNS white matter.
The myelination delay observed in MCT8 patients suggests that MCT8 may play a role in oligodendrocytes maturation. Using the human MO3.13 oligodendrocyte cell line, we found that (1) in proliferating cells, both MCT8 and MCT10 are expressed; (2) MCT8 and MCT10 each ensure 40% of T3 transport, suggesting that at least a third transporter may be implicated; (3) during MO3.13 early differentiation, MCT8 and MCT10 are differentially regulated, MCT8 becoming the predominant transporter. Those results demonstrate for the first time that MCT8 and MCT10 are implicated in TH uptake in oligodendrocytes at least in proliferative progenitors and during early differentiation, when TH have been demonstrated promoting oligodendrocyte differentiation.

P12.242
Mutational analysis of the TRPC6 gene in adult patients with steroid-resistant idiopathic nephrotic syndrome

J. Reiterova[1], *P. Lněnička*[2], *L. Obeidová*[2], *J. Tekrová*[1], *V. Tesař*[1];
[1]*Department of Nephrology of 1st Medical Faculty and General Teaching Hospital of Charles University, Prague, Czech Republic,* [2]*Department of Biology and Human Genetics of 1st Medical Faculty and General Teaching Hospital of Charles University, Prague, Czech Republic.*

Focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD) are frequent cause of nephrotic syndrome (NS). TRPC6 mutations are the cause of idiopatic NS in about 2-7 % of steroid-resistant patients. Eleven different TRPC6 gene mutations were identified. These mutations lead to a late onset kidney disease and a variable rate of progression to end stage renal disease. The aim of the study was the identification of mutations/polymorphisms in adult patients with steroid-resistant FSGS/MCD.
Patients and methods: 40 patients (22 females, 18 males) with steroid- resistant FSGS/MCD were studied. The mean age of the onset of NS was 39±20.7 years.200 healthy Czech individuals formed control group with mean age 58.4±19.5 years. High resolution melting method (HRM) was established for all 13 exons of the TRPC6 gene. Suspected samples were analysed by direct sequencing on ABI Prism 3130 Genetic Analyzer.
Results: No TRPC6 gene mutation was identified. Two polymorphisms were described: in exon 1 C43T (P15S) with prevalence 32.5% of heterozygotes and in exon 4 C1211T (A404V) with prevalence 20% of heterozygotes (resp. 1% of T/T homozygotes). The prevalence of heterozygotes in control group was only 16.5% for C43T and 20.5% for C1211T (resp. 2.5% of T/T homozygotes). T allele of C43T polymorphism in exon 1 was significantly more frequent in patients with FSGS.
Conclusions: TRPC6 gene mutations are a rare cause of FSGS/MCD in adult patients in Czech Republic. The C43T polymorphism could have some influence on FSGS.
Supported by grant project IGA NS 9779-4 and research project ZZ MSMT 0021620806.

Tuberous sclerosis complex (TSC) is a genetically determined disorder with an estimated incidence of 1 in 6000 live births. The main features of TSC are benign tumors called hamarthomas frequently found in brain, skin and kidney. Convulsions, seizures and mental retardation are also common features of the entity.
A TSC2-PKD1 contiguous gene syndrome caused by complete or partial TSC2 and PKD1 genes has been reported in patients with typical TSC and polycystic kidney disease symptoms. TSC2 is located adjacent to PKD1, the gene for autosomal dominant polycystic kidney disease (ADPKD), in tail to tail orientation. Large deletions in TSC2 are relatively common (5.6%) and substantial fraction of them (50%) extends into PKD1 gene.
In five TSC patients with renal cysts we performed analysis for large mutations using commercial and home-made sets of Multiple Ligation-dependent Probe Amplification (MLPA) probes for TSC2-PKD1 genes and direct sequencing for TSC1-TSC2 genes. Cytogenetic and FISH assays were performed on metaphases derived from a culture of peripheral blood lymphocytes.
Two of five patients are carriers of large multi-exon deletions. A heterozygous deletion in TSC2 from exon 1-15 was found in a third patient but no visible alteration in PKD1. Another patient demonstrated a partial deletion in the joining region between TSC2 and PKD1 that was only detectable by FISH analysis. The last patient we examined was negative for all mutational screening.
Here we describe several patients with manifestation of TSC and ADPKD, suggesting contiguous gene syndrome but with substantial differences in their genetic alterations.

P12.244
Mutational analysis in TSC1 and TSC2 genes in patients with tuberous sclerosis complex

I. Maleva[1], *D. Plaseska-Karanfilska*[1], *V. Sabolic Avramovska*[2], *M. Kuturec*[2], *E. Sukarova-Angelovska*[3], *G. D. Efremov*[1];
[1]*Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Faculty of Medicine, Clinic of Pediatrics , Department of neurology, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Faculty of Medicine, Clinic of Pediatrics , Department of endocrinology, Skopje, Macedonia, The Former Yugoslav Republic of.*

Tuberous sclerosis complex (TSC) is an autosomal dominant disorder characterized by the development of multiple hamartomas in many organs, with an incidence of 1 in 6,000 to 1 in 10,000 live births. TSC is caused by mutations in tumor suppressor genes TSC1 and TSC2. Mutations in TSC2 are about five times more common than mutations in TSC1 in sporadic cases, whereas the ratio is 1:1 in large families with multiple generations affected. Mutations in TSC1 and TSC2 are very heterogeneous and no hotspots have been reported, making the molecular diagnosis of the disease extremely difficult. Here, we have studied eight patients from the Republic of Macedonia with a clinical diagnosis of TSC and their parents. The methodology included MLPA analysis for the detection of gross gene rearrangements and sequencing analysis of all exons and exon/intron boundaries of the TSC1 and TSC2 genes. We have detected five mutations, of which four in TSC2 and one in TSC1 gene. The TSC2 defects included

two gross deletions (deletion of exon 1 and upstream sequence and deletion of exons 1-15), one small deletion (c.4318delC) and one missense mutation (c.772A->T). The TSC1 mutation was small deletion (c.1431_1434del|AGAA). All mutations were *de novo* events and have been previously reported. The mutational spectrum among our patients suggests that the best approach for detection of mutations in TSC patients would be MLPA analysis of TSC genes for the detection of gross rearrangements, followed by sequencing analysis for the detection of point mutations.

[1]*Hôpital Armand Trousseau, Paris, France,* [2]*NIDCD, Bethesda, NY, United States,* [3]*CEA, Evry, France,* [4]*Hôpital St Antoine, Lille, France,* [5]*Hôpital Hautepierre, Strasboug, France,* [6]*CHU, Nantes, France,* [7]*Maternité Pinard, Nancy, France,* [8]*CHU, Angers, France,* [9]*CHU, Dijon, France,* [10]*Hôpital Hotel Dieu, Clermont Ferrand, France,* [11]*Hôpital Pellegrin, Bordeaux, France,* [12]*Hôpital Charles Nicole, Rouen, France,* [13]*Hôpital de la Timone, Marseille, France,* [14]*Hôpital intercommunal de Font-Pré, Toulon, France,* [15]*Institut Pasteur, Paris, France.*

Usher syndrome (USH) combines sensorineural deafness with blindness. It is inherited in an autosomal recessive mode. Early diagnosis is critical for adapted educational and therapeutic choices, and for genetic counseling. To date, nine causative genes have been identified for the three clinical subtypes (USH1, USH2 and USH3). Current diagnostic strategies make use of a genotyping microarray that is based on the previously reported mutations. The purpose of this study was to design a more accurate molecular diagnosis tool.

We sequenced the 366 coding exons and flanking regions of the nine known USH genes, in 54 USH patients (27 USH1, 21 USH2 and 6 USH3). **Results:** Presumably pathogenic mutations were detected in 48 patients (89%). In addition to biallelic mutations in one of the USH genes, presumably pathogenic mutations in another USH gene were detected in seven patients (13%), and another patient carried monoallelic mutations in three different genes. Notably, none of the USH3 patients carried detectable mutations in the only known USH3 gene, whereas they all carried mutations in USH2 genes. Most importantly, the currently used microarray would have detected only 30 of the 81 different mutations that we found, of which 39 (48%) were novel.

Based on these results, complete exon sequencing of the currently known USH genes stands as a definite improvement for molecular diagnosis of this disease.

P12.246

Ophthalmic status of patients with Usher syndrome

M. O. Mkheidze[1], *O. K. Janvareva*[2];

[1]*Medical Academy for Postgraduate Studies, St.Petersburg, Russian Federation,* [2]*Medical Centre of St.Petersburg University, St.Petersburg, Russian Federation.*

Usher syndrome (USH) is a relatively rare genetically heterogeneous autosomal recessive disorder with three clinical subtypes (USH I, II, III). It is due to some mutations in any of 10 genes (MYO7A, CDH23, PCDH15, SANS, USH1C, USH1G, USH2A, GPR98, DFNB31, CLRN1). The frequency of USH was estimated to be 1/12,500 (Germany), 1/23,000 (USA), 1/28,000 (Norway). Here we reported on 24 patients with USH aged from 6 to 38 yr. Nobody had clinical signs of vestibular dysfunction. Severe sensorineural deafness symptoms of the III-IV degrees were observed in all patients in their first year of life. Ophthalmic status included decrement in visual acuity, reduction of the peripheral visual field, defective dark adaptation, nyctalopia, disturbance of colour vision in their 4th- 5th year of life. Typical key findings of fundus disturbance for retinitis pigmentosa (RP) including bone spicules were found. Among children and youth aged from 5 to 25 years RP signs were clearly diagnosed as the disease process of the 1-II degrees. This stage was characterized by satisfactory visual acuity (0.7-0.5) and uninjured visual fields which did not result in patient disabling. Patients aged older than 30 yr had RP of the III-IV degrees with symptoms of the secondary optic atrophy including severe abnormality of visual fields down to its disappearance, visual acuity decreasing down to photoperception and loss of colour perception. Complex ophthalmic investigation and trophic medication(antioxidative, neuroprotective medicines, vitamin-mineral compex) were regularly applied.

P12.247

Intracellular localization of the Type 1 VWD candidate VWF gene variants

E. Berber[1], *C. Brown*[2], *D. Lillicrap*[2];

[1]*Istanbul Arel University, Istanbul, Turkey,* [2]*Queen's University, Kingston, ON, Canada.*

Von Willebrand Factor (VWF) is a multimeric glycoprotein that maintains hemostasis in the vascular system. VWF is secreted mainly from endothelial cells either constitutively or stored for regulated release in Weibel Palade Bodies (WPB). Partial quantitative deficiency of VWF is defined as Type I von Willebrand disease (VWD). Clinical diagnosis of Type I VWD is complicated due to incomplete penetrance and variable expressivity of VWF. Deficiency in the biosynthestic pathway or increased clearance of plasma VWF might be responsible for the decreased VWF levels. The purpose of the study is to explore the effect of four VWF mutations (p.M771I, p.L881R, p.P1413L, p.Q1475X), that were reported as candidate mutations in Type I VWD patients on the intracellular localization of VWF in a heterologous cell system. p.M771 and p.L881 and p.P1413 are located in D', D3 and A1 domains, respectively, implicated in multimerization and WPB storage. p.Q1475 is located in A2 domain. The candidate mutations were generated on VWF cDNA expression vector by in vitro site directed mutagenesis. Intracellular localization of the variants were analyzed in the transiently transfected HEK293 cells by immunoflourescence antibody staining and confocal scanning laser microscopy. Diffuse staining was observed for the recombinant p.M771I and p.Q1475X VWF variants. However, similar intracellular pseudo-WPB storage was observed as wild type recombinant VWF for the VWF variants having p.L881R and p.P1413L changes. This study demonstrated that while p.M771I and p.Q1475X mutations impair intracellular localization of the recombinant VWF, p.L881R and p.1413L mutations did not affect the pseudo-WPB storage in HEK293 cells.

Screening of *SOX10* and *MITF* regulatory regions in Waardenburg patients

V. Baral[1,2], *B. Duriez*[3], *Y. Watanabe*[1,2], *M. Goossens*[1,2,4], *T. Attie-Bitach*[5], *V. Pingault*[1,2,4], ***N. Bondurand***[1,2];

[1]*IMRB INSERMU955, Creteil, France,* [2]*Université Paris-Est, Faculté de Médecine, UMR-S 955, Creteil, France,* [3]*Institut Jacques Monod, UMR7592 CNRS, Université Paris Diderot-Paris 7, Paris, France,* [4]*AP-HP, Groupe Hospitalier Henri Mondor, Service de biochimie et génétique, Creteil, France,* [5]*INSERM U781 et département de Génétique, Hôpital Necker, Paris, France.*

Waardenburg syndrome (WS) is a rare auditory-pigmentary disorder that exhibits varying combinations of sensorineural hearing loss and pigmentation defects. Four subtypes are clinically defined based on the presence or absence of additional symptoms. WS2, which is defined by the absence of additional features, results from mutations within the *SOX10* and *MITF* genes. However, 70% of WS2 remain unexplained, suggesting that other genes could be involved and/or that mutations within the known genes escape screening performed so far. The crucial role of SOX10 and MITF during melanocyte development and the identification of several of their regulatory regions prompted us to search for mutations within some of these regions in 30 WS2 unexplained cases. In case of *MITF*, we tested the involvement of the well known melanocyte-specific (M) promoter region and a distal regulatory region (MDE) located 14.5 kb upstream from exon 1M. In case of *SOX10*, sequence conservation analysis led to the identification of at least 5 segments directing expression in overlapping populations of neural crest derivatives. Previous functional studies revealed the role of at least two of them (U1 and U3) during melanocyte development. No deletion was identified upon QMF-PCR analysis of the *MITF* promoter and the 5 *SOX10* regulatory regions. So far, sequencing of U1, U3 and the 2 *MITF* regions led to

the identification of 2 variations not previously reported in dbSNP: 1 in close proximity to the MDE sequence, and 1 within U1. Their functional consequences should be tested in the near future.

P12.249***

Identification and functional analysis of *SOX10* missense mutations in different types of Waardenburg syndrome

A. Chaoui[1,2], *Y. Watanabe*[1,2], *R. Touraine*[3], *V. Baral*[1,2], *M. Goossens*[1,2,4], *V. Pingault*[1,2,4], *N. Bondurand*[1,2];

[1]*IMRB INSERMU955, Creteil, France,* [2]*Université Paris-Est, Faculté de Médecine, UMR-S 955, Creteil, France,* [3]*CHU-Hôpital Nord, Service de Génétique, Saint Etienne, France,* [4]*AP-HP, Groupe Hospitalier Henri-Mondor, Service de Biochimie et Génétique, Creteil, France.*

Waardenburg syndrome (WS) is an auditory-pigmentary disorder that exhibits varying combinations of sensorineural hearing loss and pigmentation defects. Four subtypes are clinically defined based on the presence or absence of additional symptoms. In particular, the absence of additional features characterizes WS2, whereas the association with Hirschsprung disease defines WS4. WS is genetically heterogeneous with six genes already involved, including *SOX10*. Since 1998, about 50 heterozygous mutations or deletions of this gene have been described in patients presenting with WS2 or WS4, with or without myelination defects of the peripheral and central nervous system (PCWH). The mutations characterized so far are mostly truncating mutations, removing part of the protein. Only 3 missense mutations were described. Here, we report the identification of new SOX10 missense mutations in 11 patients, associated with a variety of phenotypes ranging from WS2 to PCWH, and describe the functional consequences of each of these mutations on the main SOX10 characteristics and functions. Altogether, our functional assays highlight deleterious effects of all the mutations tested. Some mutants present with partial cytoplasmic and/or subnuclear redistribution, some lose their DNA binding and/or their transactivation capacities on various tissue specific target genes. Intriguingly, several mutants were redistributed in nuclear foci. To our knowledge, such redistribution was not described so far during functional studies of patients' mutations identified in other SOX genes. Whether it is a cause or a consequence of the mutant pathogenicity remains to determine, but it could help identify new SOX10 function and mode of action.

Weill-Marchesani syndrome (WMS) is a rare disorder characterized by short stature, short and stubby hands and feet, stiff joints and dislocation of microspherophakic lens which causes severe myopia, glaucoma or cataract. Despite clinical homogeneity, two modes of inheritance have been reported: autosomal dominant and autosomal recessive. We first showed that Fibrillin 1 (FBN1) is responsible for the dominant form of WMS. We identified an in frame deletion of 24 nucleotides within a LTBP motif (exon 41, 5074_5097del) of FBN1. In the mean time, we identified three distinct mutations in ADAMTS10 (A Disintegrin-like And Metalloproteinase domain (reprolysin type) with ThromboSpondin type 1 repeats) responsible for the autosomal recessive form of WMS.

Following this initial study, we have collected the samples of 17 additional WMS families. We identified ADAMTS10 mutations in 2/17 patients comprising 3 novel mutations (2 missense and one nonsense mutations) and FBN1 mutations in 5/17 including 5 novel missense mutations. The screening of ADAMTS10 is still in progress for 3 cases and the screening of FBN1 is still in progress for 5 cases. Recently, three homozygous mutations in ADAMTS17 have been identified in 3 WMS cases. We therefore decided to screen ADAMTS17 in 2 cases unlinked to ADAMTS10 and FBN1. Finally we analysed the microfibrils of fibroblasts of WMS patients by EM and showed no major changes in their microfibrillar structure.

Our clinical and genetic findings suggest that ADAMTS10, ADAMTS17 and FBN1 play a critical role in crystalline lens and connective tissue formations.

P12.251

c.3402delC (p.Ala1135GlnfsX13) is the most frequent mutation among Venezuelan Wilson disease patients.

I. Paradisi, *L. De Freitas, S. Arias C.;*

Venezuelan Institute for Scientific Research (IVIC), Caracas, Venezuela, Bolivarian Republic of.

Wilson disease is an infrequent autosomal recessive disorder of copper transport, characterized by accumulation of intracellular copper, with consequent severe hepatic and neurological disturbances; the gene, *ATP7B*, encodes an ATPasa Cu(2+)-transporting beta polypeptide. To date, more than 380 mutations have been reported in many different populations, but a few ones show high frequencies in some areas; the most prevalent mutation in Europe is H1069Q, with frequencies over 65%; in Sardinia, c.-441_-427del accounts for 61.5% of mutated chromosomes; mutation M645R is present in 55% of patients in Spain, and mutation R778L is very frequent in Asians. Deletion c.3402delC at exon 15 has been reported in worldwide populations with very low frequencies (usually below 2%), and is not present in Asians; the only exception are Brazilian patients, with a mutation frequency of 31%. In Venezuela, DNA analysis in 21 independent Wilson disease families gathered during the last 24 years revealed 10 different mutations in the *ATP7B* gene; 80% of patients with detected mutations were compound heterozygotes, but mutation c.3402delC had a frequency of 21.4% and a very wide distribution in the country. Haplotype analyses using 5 intragenic single nucleotide polymorphisms (SNPs) apparently did not support a single ancestral origin for the mutation, despite all remote ancestors of the families came from Venezuela. Either a high mutation rate or gene conversion both in Brazil and Venezuela might suggest an Amerindian origin for it, but neither SNPs frequencies nor the specific Amerindian marker D9S1120*275 in Venezuelan carriers seem to support this hypothesis.

P12.252

Molecular basis of Tricho-Hepato-Enteric syndrome: characterization of mutations in *TTC37*

A. Fabre[1,2,3], *C. Martinez-Vinson*[4,5], *B. Roquelaure*[1], *C. Missirian*[1,2], *N. André*[1,2], *A. Breton*[6], *A. Lachaux*[7,8], *E. Odul*[9], *V. Colomb*[10,5], *J. Lemale*[11], *J. Cézard*[4,5], *O. Goulet*[10,5], *J. Sarles*[1,2], *N. Levy*[1,2,3], *C. Badens*[1,2,3];

The Tricho-Hepato-Enteric (THE) syndrome is an autosomal recessive condition marked by early and intractable diarrhea, hair abnormalities, IUGR, facial dysmorphy and immune defects. Mutations in *TTC37* which encodes the putative protein Thespin, have recently been associated with THE syndrome. Here, we extend the pattern of *TTC37* mutations by the description of 13 novel mutations in 10 patients

with a typical THE syndrome and report their potential effects on transcription. Different types of mutation were observed: frameshift mutations splice site altering mutations or missense mutations. Most of them are predicted to create a premature stop codon or to alter splicing, including missense mutations. The effects of splice sites mutations and missense on sequence transcripts were analysed by direct sequencing of RNA transcripts from lymphoblastoid cells, for 5 mutations. The tested samples exhibited abnormal sequences due to the modification of splicing. In particular, we observed skipping of exon 23 and exon 25, leading to transcripts and possibly deleted proteins, suggesting that these exons are encoding important functional regions in the protein. Quantitative expression was investigated on transcripts lacking exon 25 from lymphoblastoid cells and from hair root cells and showed that levels of expression were not significantly reduced as compared to heterozygous or normal controls. This sustained the hypothesis that the deleted proteins are expressed but are functionally altered.
Further mutational effect studies will lead surely to better characterize the localisation and functional properties of Thespin.

P12.253
Identification of a novel canine chondrodysplasia mutation

K. Kyöstilä[1,2], *H. Lohi*[1,2];
[1]*University of Helsinki, Helsinki, Finland,* [2]*Folkhälsan Institute of Genetics, Helsinki, Finland.*

Skeletal dysplasias are a heterogeneous group of disorders affecting the bone and cartilage tissues. Chondrodysplasias are characterized by disturbed endochondral ossification which often results in disproportionate short stature or dwarfism. We report here the identification of a recessive canine chondrodysplasia mutation in a gene that represents a new candidate for human chondrodysplasias. The novel mutation was identified in Norwegian Elkhounds which have been previously described to suffer from a generalized disturbance in the endochondral ossification process. Our pedigree analysis suggested a recessive mode of inheritance for the disorder. We genotyped nine cases and nine controls using Illumina's canine SNP chip of 22K SNPs to map the disease locus. Genome-wide association analysis revealed a 2 Mb disease associated locus on CFA17. Mutation screening of a plausible causative gene revealed a homozygous nonsense mutation in all affected dogs, predicted to result in a premature stop codon in the encoded protein. Segregation of the mutation was studied further in 157 unrelated population controls none of which were homozygous for the mutant allele. A genetic test has been developed and is offered to the breed to help identify carrier dogs. Furthermore, we have initiated screens in human patients with related phenotypes. We hope our findings will improve the understanding of the endochondral ossification processes and related molecular pathways in health and disease.

Detection of polymorphisms in the mannose-binding lectin gene and their influence on the phenotype in Slovak patients with cystic fibrosis

E. Tóthová Tarová[1], *H. Poláková*[2], *H. Kayserová*[3], *P. Celec*[4,1], *M. Zuzulová*[5], *E. Neščáková*[6], *&. Kádaši*[1];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University in Bratislava, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [3]*Cystic Fibrosis Center, University Hospital with Policlinic in Bratislava, Bratislava, Slovakia,* [4]*Institute of Pathophysiology, Faculty of Medicine of Comenius University in Bratislava, Bratislava, Slovakia,* [5]*Institute of Laboratory Medicine, St. Elisabeth Cancer Institute, Bratislava, Slovakia,* [6]*Department of Anthropology, Faculty of Natural Sciences of Comenius University in Bratislava, Bratislava, Slovakia.*

Cystic fibrosis (CF) is the most common lethal inherited disease among Caucasians. The cause of death in 90% of the CF patients is respiratory insufficiency due to chronic inflammation caused by bacteria (Pseudomonas aeruginosa, Burkholderia cepacia).
Mannose-binding lectin (MBL) protein is an important mediator component of the innate immune defense system. It has been shown that MBL variant alleles causing low MBL serum levels are associated with an increased risk of different types of infections. In exon 1 of the MBL2 gene, three single nucleotide polymorphisms (nucleotide substitutions) cause independently low serum levels of MBL at codon 52 (arginine with cysteine, allele D), at codon 54 (glycine with aspartic acid, allele B) or at codon 57 (glycine with glutamic acid, allele C). Y/X promoter polymorphism in codon -221 has a significant effect on the MBL serum levels.
Polymorphisms in exon 1 and promoter region were typed by single base primer extension assay (SNaPshot) in 91 Slovak patients with cystic fibrosis and 100 healthy controls. Concentrations of MBL protein were determined in 34 patients by a Sandwich enzyme-linked immunosorbent assay. Spirometric and microbiological data were collected from medical records.
No association was found for the MBL2 structural variants and severity of cystic fibrosis lung disease. But significant association was observed between MBL2 variants and protein levels and positive implications between MBL2 genotypes, immunoglobulin G and atopy. These findings provide correlation between MBL2 genotypes and protein level, but variant alleles are not associated with poor diagnosis in Slovak CF patients.

J12.02
A novel heterozygous mutation in a Spanish family with Best's vitelliform macular dystrophy

T. Piñeiro-Gallego[1], *A. Campo*[2], *S. Campos*[2], *D. Valverde*[1];
[1]*Departamento de Bioquímica, Xenética e Inmunoloxía. Universidade de Vigo, Vigo, Spain,* [2]*Servizo de Oftalmoloxía, Complexo Hospitalario Universitario de Vigo, Vigo, Spain.*

Best's vitelliform macular dystrophy (BVMD, OMIM#153700) is a dominantly inherited, juvenile onset form of macular degeneration with variable expresivity, which is characterized by abnormal accumulation of deposits of lipofuscin-like material in the subretinal space and a reduced Arden ratio of the electro-oculogram (EOG).
Mutations in the gene VMD2 are associated with BVMD. The gene VMD2 is expressed in the plasma membrane of the retinal pigment epithelium and encodes the besthrophin-1 protein. Besthrophin-1 is a transmembrane protein with underdetermined function although it has been proposed to act as a Cl− channel activated by intracellular Ca2+ and/or as a channel regulator.
We report a non consanguineous Spanish family with BVMD. Family members were examined ophtalmologically to assess their phenotype. After exclusion of the known mutations using the Vitelliform Macular Dystrophy (BEST-VMD) mutation array (Asper Biotech), direct sequencing of the eleven exons of VMD2 was performed to find possible mutations.
The affected sisters were heterozygotes for a novel VMD2 gene missense mutation p.I73L, (c.217A>C) in exon 3 and the father and paternal grandmother were heterozygous for the same mutation. This mutation was no present in their clinically unaffected mother. The father and the eldest sister presented typical lesions of Best's disease. The paternal grandmother presented central areolar atrophy consistent with the late stage of Best's disease.
In conclusion, a novel heterozygous mutation in VMD2 gene causative for Best's disease was found, proving that mutational screening is a useful tool in the molecular diagnostic of bestrinopathies.

J12.03
Characterization of a novel mutation in the GJB2 gene in congenital sensorineural hearing impairment

M. Rivera-Vega[1], *D. Castro*[1], *A. Totomoch*[1], *L. Gonzalez*[1], *P. Berruecos*[1], *S. Cuevas*[2];
[1]*Hospital General de Mexico, Mexico D.F., Mexico,* [2]*Hospital General de Mexico, Universidad nacional Autonoma de Mexico, Mexico D.F., Mexico.*

The hearing impairment is the most frequent sensory defect worldwide. More than half of children have a genetic origin and correspond to non-syndromic hearing loss (NSHL). Autosomal recessive is one of the most frequent pattern of inherited hearing impairment. Mutations in the GJB2 gene, encoding the conexin 26 gap-junction protein, are the principal cause of NSHL. Currently, more than 100 different recessive mutations have been found in the GJB2 gene; 35delG is a hot-spot in the white population, 235delC in East Asian and 167delT in the Ashkenazi Jewish. In the present study we ascertained 20 unrelated Mexican families with NSHL with an autosomal recessive inheritance

and identified the novel homozygous GTG/GCG mutation (V63A) in the *GJB2* gene. We also found a high prevalence of heterozygous. In this work we report a novel mutation in the GJB2 gene in NSHL.

J12.04
Genotype-phenotype correlation in compound heterozygote patient with severe salt wasting form of CAH

***V. Anastasovska**, M. Kocova;*
Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.

Eleven common pseudogene-derived mutations in the CYP21A2 gene, encoding the 21-hydroxylase enzyme, account for approximately 95% of all mutations causing congenital adrenal hyperplasia(CAH).
Here we present a patient with a salt wasting (SW) form of the disease. As a newborn he presented with a severe clinical symptoms: vomiting, failure to thrive, complete virilisation. Biochemical work up showed low sodium, high potassium, and elevated 17OHProgesterone level (>75 nmol/L) confirming CAH. Karyotype was 46.XX. Uretrocistography confirmed male urethra with small uterus and sinus urogenitalis. No testicular tissue was seen on ultrasound. We performed direct molecular detection of eleven CYP21A2 mutations by allele created restriction sight method (ACRS).
Our patient was compound heterozygote for three severe mutations: IVS2, Q318X, R356W and one mild V281L mutation in the CYP21A2 gene. Although the compound heterozygotes for different CYP21A2 mutations usually have a phenotype compatible with the presence of the milder gene defect, SW clinical presentation was probably a result of the influence of the other three severe mutations. His mother was homozygote for V281L and Q318W and heterozygote for R356W, without any signs or symptoms of the disease, while the father was heterozygote for IVS2. Interestingly, the brother harbored none of the tested mutations. It is likely that these complex findings probably resulted from small or large gene conversions, multiple mutations events or peculiar recombination events due to the tandem-repeat organization of the gene cluster.
The genotype-phenotype correlation observed in the patient and his mother suggest that the genotype cannot be completely predictive of phenotype.

J12.05
Molecular genetic characteristics of spinal muscular atrophies in Belarus

***S. Miasnikov**[1,2], N. Gusina[1], I. Naumchik[1];*
[1]National centre of research and applied medicine «Mother and child», Minsk, Belarus, [2]International Sakharov Environmental University, Minsk, Belarus.

Proximal spinal muscular atrophies (SMAs) are autosomal recessive diseases characterized by degeneration of the anterior horn cells of the spinal cord, resulting in symmetrical limb muscle atrophy and weakness. Carrier frequency is 1 in 40-60. Critical region involved in pathogenesis of SMA is 5q11.2-q13.3.
We performed analysis of common mutations of two main genes - SMN1 and NAIP. The presence of exons 7 and 8 of the SMN1 gene was determined using PCR and restriction enzyme digestion. For detection of gene NAIP deletion exons 4, 5 and 12 were amplified using triplex PCR.
Group of 59 probands was included in this study. Deletions was detected in 39 probands: both exons 7 and 8 of SMN1 gene and exons 4 and 5 of NAIP gene - 10 patients (26%), exons 7 and 8 of SMN1 gene - 23 (59%), exon 7 only of SMN1 gene - 5 (13%) and exons 4 and 5 only of NAIP gene - 1 (3%). Carrier status was established using MLPA method. All parents were heterozygous carriers of same mutation that was indentified in kids. Prenatal DNA-diagnosis of SMA was performed in six cases. Four fetuses were found homozygous carriers of mutations.

J12.06
Analysis of 3'-UTR region polymorphic variant +3379A/T of human angiopoietin-1 (Ang1) in sickle-cell disease (SCD) patients.

***G. Ananina**, F. Menaa, M. J. da Silva, M. Nueldo, M. A. Bezerra, F. F. Costa, M. B. de Melo;*
CBMEG, Universidade Estadual de Campinas, Campinas, Brazil.

SCD is a genetic disorder relatively common among Afro-descendants and caused by a missense mutation in the beta polypeptide chain of hemoglobin. SCD shows distinct clinical evolutions in different patients. Vasoocclusion induced by irregularly shaped sickle cells and subsequent endothelial activation may play the central role in the pathophysiological process. Ang1 regulates blood vessel development, remodeling, and maturation. Recently Ang1/Ang2/Tie-2 system has emerged as a non-redundant regulator of endothelial activation. The T/T genotype of the polymorphic variant +3379A/T in the 3∋-UTR region of human Ang1 was reported as associated with stroke risk reduction in Chinese Han population. As stroke is one of the major complications of SCD, we designed the present study to find out allele and genotype frequencies of this variant in a group of SCD patients from Brazil, with the objective of investigating its possible involvement in stroke risk.
We analyzed 92 SCD patients (S/S and S/C hemoglobin genotypes). The allele frequencies of the +3379A/T variant were: 0.71 of A allele, 0.29 of T allele. HWE test showed marginally significant deviation from equilibrium: p=0.044 (Pearson's goodness-of-fit chi-square, df=1), p=0.034 (likelihood ratio chi-square, df=1), p=0.06 (Exact test).
The observed allelic frequency of A allele is different from that previously reported for CEPH (0.47) and YRI (0.23; low coverage panel) populations of the HapMap project. As the next step, we plan to increase sample size of SCD patients with and without stroke incidents and include control individuals in order to evaluate the association of stroke risk with different genotypes.

J12.07
The role of SNPs in 5'HS4 beta globin LCR in modifying the thalassemia phenotype in Iranian patients

*M. Neishabury[1], **S. Zamani**[1], A. Azarkeivan[2], H. Darvish[1], S. S. Abedini[1], F. Zamani[1], H. Najmabadi[1,3];*
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]Thalassemia Clinic, Research Center, Iranian Blood Transfusion Organization (IBTO), Tehran, Islamic Republic of Iran, [3]Kariminejad and Najmabadi Pathology and Genetics Center, Tehran, Islamic Republic of Iran.

5'HS4 core region of beta globin LCR was analysed in 100 Iranian individuals with normal hematological indices and 100 patients with beta^0 mutation in both alleles. Coinheritance of three SNP alleles in 5'HS4 was observed in a normal individual in heterozygous state. We have recently observed and reported the same coinheritance in a carrier individual with unexpected thalassemia intermedia phenotype. Despite it's presence in the normal population, the role of this rare polymorphic pattern in altering the clinical picture of our reported patient cannot be ruled out as it may only exert its influence when at least one beta globin allele is affected. Furthermore, There was a statistically significant difference in the frequency of G allele in the polymorphic palyndromic TGGGG(A/G)CCCCA region of 5'HS4 between the normal population and thalassemia patients with two affected alleles. This suggests a linkage disequilibrium between the G allele in the palyndromic region of 5'HS4 and thalassemia mutations.

J12.08
New case of inherited Congenital Central Hypoventilation Syndrome in a family of the young girl with fatal central apnea

***K. Mosse**, N. Mosse;*
National Center of Research and Applied Medicine "Mother and child", Minsk, Belarus.

Congenital Central Hypoventilation syndrome (CCHS (MIM 209880)) is a rare disorder, characterised by absence of adequate autonomic control of respiration with decreased sensitivity to hypercapnia and hypoxia. Children with CCHS have normal ventilation while awake but persistent alveolar hypoventilation and/or apnea during sleep.
The paired-like homeobox gene (PHOX2B) was identifed as the gene

underlying CCHS, with a heterozygous expansion of +5 to +13 alanines in a 20 alanines stretch being present in about 90% of patients. Other mutations are found in a minority of cases.
Here, we report the results of mutation screening in a family having a young girl with fatal central apnea. DNA test revealed that the proband is a heterozygous carrier of +6 alanine expansion in the PHOX2B gene. Expansions of that size are always resulted in severe clinical symptoms with continuous ventilatory dependence.
More than 90% of PHOX2B expansions occur *de novo* in CCHS probands, with only 5-10% of unaffected parents showing somatic mosaicism for the gene defect seen in child. Analyses performed for both parents of the affected girl identified the same size expansion in asymptomatic father which means the rare case of parental transmission of the disease. Carrier father presented a mutant peak of lower intensity (35%) than the wild-type, which is highly suggestive of somatic mosaicism explaining his asymptomatic status.
This is the first case of CCHS analysis in Belarus, showing germinal expansion leading to central apnea and ventilatory phenotype in proband, and somatic mosaicism without any clinical symptoms in her father.

J12.09
Double heterozygosity in GJB2 heterozygots of autosomal recessive non-syndromic hearing impairment: assessment of GJB6 gene

D. Kooshavar[1], *E. Farrokhi*[2], *M. R. Noori-Daloii*[1], *M. Hashemzadeh Chaleshtori*[2];
[1]*Tehran University of Medical Science, Tehran, Islamic Republic of Iran,* [2]*Shahrekord University of Medical Science, Cellular and Molecular research center, Shahrekord, Islamic Republic of Iran.*

Hereditary non-syndromic hearing loss is inherited in autosomal recessive pattern in about 80% of cases. Up to 50 percent of all autosomal recessive nonsyndromic hearing impairment cases in different populations are caused by mutations in the GJB2 gene which encodes the gap-junction (GJ) protein connexin (Cx) 26. However 10 to 50 percent of patients with GJB2 mutations have only one mutant allele. GJB6 encoding Cx30 is expressed in the same inner-ear structures as GJB2, with which are normally co-assemble into GJs in the cochlea. This study aims to determine whether variations in GJB6 can be the second mutant allele causing the disease in the GJB2 heterozygous cases studied.
We examined 44 unrelated GJB2 heterozygous autosomal recessive non-syndromic hearing loss subjects for any sequence variations in GJB6, using polymerase chain reaction followed by direct sequencing. Sequence analysis showed a heterozygous substitution of c.173C>T in GJB6 in one of the cases which leads to the change of p.Pro58Leu in amino acid sequence.
So this allelic variation in GJB6 can be considered as the second mutant allele in patients with only one GJB2 mutant allele. Further examinations on control cases and co-segregational family studies are in progress to confirm the detected variation as the second mutation responsible for the disease.

J12.10
The prevalence of SCN5A mutation in Iranian Brugada Syndrome patients

S. Saber[1], *K. Banihashemi*[2], *M. Houshmand*[3], *M. Balali*[1], *S. Dadgar*[1], *O. Aryani*[1], *A. Fazelifar*[4], *M. Haghjoo*[4], *Z. Emkanjoo*[4], *A. Alizadeh*[4], *M. Eftekharzadeh*[5], *E. V. Zaklyazminskaya*[6];
[1]*Special Medical Center,Genetic Ward, Tehran, Islamic Republic of Iran,* [2]*IECF, Ministry of Science, Research and Technology,, Tehran, Islamic Republic of Iran,* [3]*National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [4]*Rajaie Cardiovascular Medical and Research Center, Tehran, Islamic Republic of Iran,* [5]*Tehran Arrhythmia Clinic, Tehran, Islamic Republic of Iran,* [6]*Petrovsky Russian Research Center of Surgery, RAMS,, Moscow, Russian Federation.*

Background. Brugada Syndrome (BrS) is an autosomal dominant disorder characterized by right bundle branch block (RBBB) and ST-elevations in V1-V3, apparently normal heart and high risk of sudden cardiac death (SCD). The *SCN5A* gene encodes the main cardiac sodium channel. Mutations of this gene were detected in 10%-30% of patients with BrS.
Material and Methods. Clinical investigations: Iranian patients with BrS and or familial history of SCD were examined by standard ECG, 24-hour HM, and procainamide challenge test (PCT). Genetic analysis: All coding exons of *SCN5A* gene were sequenced.
Results. Forty unrelated probands with BrS were studied. Mean age was 39 y.o., and M:F ratio was 13:1. Family history of SCD was 45.2%, and acute ventricular events were registered in 73.8% probands. Half of cohort had spontaneous Brugada type-1 ECG, the rest became positive on PCT.
Twenty-two probands were fully screened for SCN5A mutations. Sequencing of the rest is in progress now. We found 3 *SCN5A* mutations: A735V, Y1434X, and del_KPQ1505-1507 (14% of probands with complete screening). Familial analysis of delKPQ carriers reveals some patients with LQTS and BrS both.
Conclusion. In this study we detected *SCN5A* mutations in 14% of BrS probands with completly sequenced gene of interest. The mutation rate in Iranian BrS cohort is in accordance with data published worldwide. Deletion KPQ can produce different phenotype, and exact mechanism of clinical expression is to be clarified. Further molecular investigations are required to elucidate genetic background of BrS in Iran.

J12.11
Screening of LRTOMT gene mutations (DFNB63 locus) in Iranian patients with autosomal recessive nonsyndromic hearing loss

S. Ashoori[1], *E. Farokhi*[1], *N. Yazdanpanahi*[2], *F. Taghizade*[1], *D. Kooshavar*[1], *H. Taghizade*[1], *R. Heshmatifar*[1];
[1]*cellular and molecular research center,shahrekord university of medical sciences, shahrekord, Islamic Republic of Iran,* [2]*Islamic Azad university,Flavarjan branch, Esfahan, Islamic Republic of Iran.*

Background: Prelingual hearing loss occurs in 1 in 1000 newborns and is inherited in more than 60% of cases. Approximately more than 80% of inherited cases are nonsyndromic. Nonsyndromic hearing loss is so heterogene and more than 100 loci are known to be related to it.
Objectives: To determine LRTOMT gene mutation profile and frequency in Iranian patients.
Methods: 114 patients with nonsyndromic hearing loss from Hormozgan province in south of Iran were recruited for this study. DNA was extracted using Phenol-Chloroform method. The screening of the LRTOMT gene in exons 3,5 and 9 was performed using PCR and direct sequencing.
Results: These three sequenced exons (3 , 5 and 9) were studied using Chromas software and no mutation was detected in these three exons, in the samples studied.
Conclusions: Screening of 3 exons (3,5 and 9) of LRTOMT gene revealed no mutations, however we recommend to study the whole gene coding region in more samples.

J12.12
Mutational analysis of MFN 2 in hereditary motor and sensory neuropathy patients from Bashkortostan Republic (Russia)

I. Skachkova[1], *I. Khidiyatova*[1], *R. Magzhanov*[1], *A. Ahmetgaleeva*[2], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, RAS, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation.*

Hereditary motor and sensory neuropathy (HMSN) is a clinically and genetically heterogeneous disorder of peripheral nervous system. The HMSN frequency in Bashkortostan Republic (BR) is 10,3:100000. We examined HMSN patients from BR and detected spectrum and frequency of specific mutations in mitofusin 2 (*MFN2*) gene - cause the axonal subtype of CMTIIA. The MFN2 gene (1p36.22) codes a protein mitofusin 2 - an important factor in the fusion of mitochondria. Molecular-genetic investigation of HMSN in 165 unrelated families showed 9 different nucleotide changes in the *MFN2* gene. Four of them haven't been described previously. Four nucleotide changes are supposed to be disease causing mutations: c.776G>A (p.Arg259His) (0,6% among all HMSN types in total of patients sample) and c.2113 G>A (p.Val705 Ile) (1,2%) - previously described mutations, c.775C>T (p.Arg259Cys) (0,6% in total sample of patients, 2,1% - among patients of Tatar ethnic origin) and c.2171T>C (p.Ley724Pro) (0,6% in total sample, 2,1% - among Bashkirs) - new mutations, not detected among healthy family members and controls (n=80). Five revealed nucleotide changes appeared to be gene polymorphic variants:

c.892G>A (p.Gly298Arg), c.957C>T (p.Gly319Gly) and c.1039-222t>c - described polymorphisms, c.175+28c>t and c.2204+15t>c - new nucleotide changes in gene introns. It is found that the contribution of HMSN IIA type to general structure of HMSN among patients from BR is 5,1%. The received data will contribute to optimize medical and genetic consulting of HMSN families in our region.

J12.13
Molecular study of Leber's hereditary optic neuropathy in Brazilian patients

***E. L. Sartorato**, P. M. A. D. Miranda, M. S. A. Fernandes, S. M. Silva-Costa, A. T. Maciel-Guerra;*
Universidade Estadual de Campinas, Campinas - São Paulo, Brazil.

Leber Hereditary Optic Neuropathy (LHON) is a mitochondrial disease characterized by sudden loss of vision in both eyes, due to optic nerve degeneration. Currently, 17 main LHON associated mutations were published, three of which account for 95% of the cases (primary mutations) and fourteen different mutations account for only 5% of the total (secondary mutations). There is no official data about the frequency of LHON mutations in Brazilian patients. Screening of LHON mutations is important for confirmation of clinical diagnosis, provide prognostic information and more appropriate genetic counseling. Therefore, the aim of this study was to define the LHON mutations frequency in Brazilian patients. We evaluated 55 patients with LHON diagnosis or acquired optic neuropathy of unknown origin. Primary mutations (G11778A, T14484C and G3460A) and secondary mutations were screened. Primary mutations were screened by the method of enzyme restriction and secondary mutations by direct sequencing. Primary mutations were found in 19 patients. The frequencies found were 67% for the G11778A mutation (13 cases), 28% for the T14484C mutation (5 cases) and 5% for the G3460A mutation (only 1 case). The G11778A mutation was more frequent, as well as in others parts of the world. However, the frequency of T14484C mutation was higher while the G3460A mutation frequency was lower. No secondary mutation was found. The absence of these mutations can be attributed to the presence of mutations in regions not analyzed in this study. Analyze molecular allowed us to confirm LHON diagnosis in 38% patients studied.

J12.14
Novel coding variations in C20ORF54 in an Iranian BVVL patient

***M. Ansari Dezfouli**[1], S. Nafisi[2], E. Elahi[1];*
[1]School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, [2]Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Brown-Vialetto-Von Lear (BVVL) is a rare progressive neurological disorder typically characterized by pontobulbar palsy and associate with bilateral nerve failures usually involving the seventh and ninth to twelfth cranial nerves. Fifty eight cases have been reported in the literature. Clinical symptoms often begin with weakness and muscular atrophy and progress to mental and movement disorders. In last phases of disease, patients are unable to do daily activities and they suffer from respiratory and swallowing problems. BVVL is more common in females, with a sex ratio 1:3. However, clinical symptoms are more sever and more rapidly progressive in males. The age at onset of clinical presentations is variable, sometimes even between affected members of the same family. Heredity pattern in multi-case families is variable. Although most families exhibit autosomal recessive inheritance, X-linked and autosomal dominant inheritance with variable expression have also been suggested. In 2010, the C20ORF54 gene was identified to be the BVVL causing gene in all patients examined by autozygosity mapping; mutations were recessive. The protein product of C20ORF54 may be a membrane transporter for riboflavin in the small intestine. Here, we report identification of a new BVVL affected individual born to consanguineous parents. Mutation screening of C20ORF54 gene identified two novel coding variations.

J12.15
Partial duplication of the *PMP22* gene in a patient with hereditary neuropathy with liability to pressure palsies

***I. Banchs**[1], C. Casasnovas[2], L. De Jorge[1], A. Carvajal[3], V. Volpini[1];*
[1]CDGM. Idibell, 08907 L'Hospitalet de Llobregat, Spain, [2]Unitat de Neuromuscular. Neurology Department. Hospital Universitari de Bellvitge, 08907 L'Hospitalet de Llobregat, Spain, [3]Neurology Department. Hospital Universitario Virgen de las NIeves, Granada, Spain.

INTRODUCTION: Hereditary neuropathy with liability to pressure palsies (HNPP) is an autosomal-dominant disease. Motor and sensory nerve dysfunction due to compression at common entrapment sites is the characteristic clinical presentation. Electrophysiological findings show a distinctive background polyneuropathy, independent of superimposed entrapment neuropathy. It is characterized by diffuse sensory nerve conduction velocity (NCV) slowing. Spite of distal motor latencies are prolonged, there is a minor reduction of motor nerve conduction velocities. Up to 84% of HNPP are due to the 1.5 Mb deletion at 17p11.2-12 containing the *PMP22* gene. This gene codifies for the membrane glycoprotein, Peripheral Myelin Protein 22.
PATIENT: A previously healthy 31-years-old male presented with dropped food due to left peroneal neuropathy with clinical improvement after 3 months. At 17-years-old he presented an episode of dropped wrist. Electrophisiological studies revealed the typical HNPP findings.
METHODS: We performed the genetic testing of the CMT1A/HNPP region using allelotyping studies and MLPA technique.
RESULTS: An exon 3 duplication of *PMP22* gene instead of the common deletion was found.
DISCUSSION: The HNPP phenotype presented in this patient with a partial duplication could be explained because of a frameshift change resulting in a loss of function of the new truncated protein
CONCLUSION: HNNP is a genetically heterogeneous disease and can be due to partial duplications in *PMP22* gene

Low-density lipoprotein receptor mRNA level in freshly isolated human familial hypercholesterolemia leukocytes does not correlate with plasma serum cholesterol level

***T. Y. Komarova**, A. S. Golovina;*
Institute of Experimental Medicine, St-Petersburg, Russian Federation.

Aims. Familial hypercholesterolemia (FH) is a common (1:500) monogenic disease caused by low density lipoporotein (LDL) catabolism lowering due to dysfunction of the specific LDL receptor (LDLR). We aimed to investigate if the LDLR mRNA level in freshly isolated peripheral venous blood leukocytes was inversely correlated with plasma level cholesterol in patients with heterozygous FH.
Methods. Total RNA was prepared from 1-2 millions of freshly isolated viable white blood cells and approximately 100 ng of cDNA was used in real-time PCR TaqMan mRNA quantitation test. LDLR gene expression was normalized against ubiquitine C gene expression and plotted versus blood plasma total cholesterol figures.
Results. We found LDLR mRNA level to be highly variable in FH blood leukocytes ranging from 0.2 to 1.8 times content of LDLR mRNA in the control individual. We found that most possible mechanism of LDLR gene dysfunction in common deltaG197 (also known as G218del or FH-Lithuania mutation) variant heterozygous leukocytes is due to mRNA level lowering and not to defects in the intracellular protein maturation and transport. Patients taking up high dose of statins usually demonstrate the elevated level of LDLR mRNA.
Conclusions. We found no inverse correlation between LDLR mRNA level in peripheral blood FH leukocytes and plasma cholesterol level. So far, quantitation of LDLR mRNA in leukocytes cannot be used for prediction of disease severity and efficacy of hypocholestorolemic drug treatment in heterozygous FH.

Detection of two *CFTR* large rearrangements in Russian CF patients

***T. A. Vasilyeva**, E. E. Timkovskaya, N. V. Petrova;*
Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

To date more than 1800 mutations have been identified in the *CFTR* gene [http:www.genet.sickkids.on.ca].They involve coding, splicing

and regulatory regions of the gene. To date 48 large rearrangements in *CFTR* gene are found, some of them involves deletions spanning several introns and exons
Two new large rearrangements were found in Russian CF patients.
In family A a routine detection of *CFTR* mutations revealed that an affected child had a homozygous F508del genotype, a father had a heterozygous F508del genotype, whereas a mother didn't have F508del mutation. Intragenic *CFTR* markers analysis showed that an affected child "had lost" maternal alleles of polymorphic markers IVS6aGATT, IVS8CA, M470V (intron 6a, intron 8, exon 10), therewith he had the two alleles at locus IVS1CA, IVS17bCA (intron 1, intron 17b) inherited from the both of parents.
In family B neither of *CFTR* mutant alleles was identified. During intragenic *CFTR* markers analysis it turned out that an affected child failed to have paternal alleles at polymorphic loci IVS1CA, IVS6aGATT, IVS8CA, M470V, but he had two alleles at locus IVS17bCA in intron 17b inherited from the both of parents. Analysis of STR markers at loci D13S141 and DFNB1 on chromosome 13 proved genetic relationship within the family.
Segregation analysis of intragenic *CFTR* polymorphic markers in CF families revealed that deletion of maternal *CFTR* gene overlapped a region from intron 6a to exon 10 at least, and deletion of paternal *CFTR* gene embraced an area from intron 1 to exon 10.

First reported splice site mutation (c. 1935+3A>C) of the FGD1 gene in a patient with Aarskog-Scott syndrome

I. Arroyo Carrera[1,2], *M. J. García García*[1], *A. Izquierdo Martín*[1], *R. Martín Fernández*[1], *P. Lapunzina Badía*[3,2], *A. Orrico*[4];
[1]*San Pedro de Alcántara Hospital, Cáceres, Spain,* [2]*Centre for Biomedical Research on Rare Diseases (CIBERER), Madrid, Spain,* [3]*Section of Medical Genetics, University Hospital La Paz, Madrid, Spain,* [4]*Medicina Molecolare, Azienda Ospedaliera Universitaria Senese, Siena, Italy.*

Introduction: Mutations in the FGD1 gene have been shown to cause Aarskog-Scott syndrome (AAS) (OMIM 305400), an X-linked congenital disorder characterized by distinctive genital and skeletal abnormalities with a broad spectrum of clinical variability. To date, 29 distinct mutations, including a complete deletion, have been reported, and only one of them is a splice site mutation. We present the clinical data of this Spanish patient.
Clinical case: Male, born at term, birth weight 3,050 g, length 50 cm, OFC 34 cm. Unremarkable family history. Referred for clinical investigation because of a delay in global growth and dysmorphic features: frontal bossing, widow´s peak, hypertelorism, large and depressed nasal bridge, short nose, midfacial hypoplasia, long philtrum, brachydactyly and shawl scrotum. At 13 months-old weight 8.595 kg (3rd centile), height 72.5 cm (6th centile), OFC 45.5 cm (19th centile). Patent ductus arteriosus without hemodinamic effects. At 5 years, 4 months-old weight 16.8 kg (14th centile), height 103 cm (5th centile), OFC 49 cm (3rd centile), bone age 3 years-old. Normal/border line developmental outcome. Mutational analysis of the FGD1 gene: c. 1935+3A>C. His mother is carrier of the mutation. This mutation alters the donor splice site of the eleventh intron, possibly resulting in an improperly spliced mRNA.
Summary: We present the first example of an aberrant splicing mechanism of FGD1 as the cause of AAS. The clinical phenotype of the patient is indistinguishable from other patients supporting the evidence of no genotype-phenotype correlation derived from comparison of patients with different mechanisms of mutation.

J12.19
Study of mutation spectra in patients with familial hypercholesterolemia from two major cities in North-West Russia: St. Petersburg and Petrozavodsk

A. S. Golovina, *T. Y. Komarova;*
Institute of Experimental Medicine, Saint-Petersburg, Russian Federation.

Introduction: Familial hypercholesterolemia (FH) is a common monogenic disease leading to premature coronary and cerebral atherosclerosis. FH is caused by mutations in the low density lipoprotein receptor (LDLR) gene or in the APOB gene coding for the LDLR major ligand -apolipoprotein B-100. Aim of the present study was to compare spectra of mutations leading to FH development in patients from two major cities in North-West Russia: St. Petersburg and Petrozavodsk.
Methods: We used venous blood of 60 Petrozavodsk FH patients to extract DNA and different methods of molecular biology including PCR, SSCP-analysis, molecular cloning in Escherichia coli, and DNA sequencing. Data were compared with mutation spectra in 100 St.Petersburg FH patients.
Results: 1. R3500Q APOB mutation that is frequent variant in European populations does not occur in FH patients from both cities.
2. None of FH patients from Petrozavodsk carried mutation FH-North Karelia in the LDLR gene, that is typical for the residents of eastern Finland but found only once in St. Petersburg.
3. C139G and G197del LDLR gene mutations that are recurrent in St. Petersburg FH do not occur in Petrozavodsk sample.
4. We have identified new mutation c.192del10/ins8 in two unrelated patients from Petrozavodsk. This mutation represents a complex rearrangement in the 5 'part of the LDLR gene third exon.
Conclusion: New mutation c.192del10/ins8 results in shift of the reading frame and creates a premature stop codon in the LDLR gene fourth exon. Therefore, this mutation is a likely cause of FH in both heterozygous patients.

J12.20
GJB2 caused hearing loss in Armenia is infrequent

E. A. Bliznetz[1], *T. Manoukyan*[2], *T. F. Sarkisian*[3], *T. G. Markova*[4], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*"ARABKIR" Joint Medical Center & Institute of Child and Adolescent Health, Yerevan, Armenia,* [3]*Center of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [4]*National Research Centre for Audiology and Hearing Rehabilitation, Moscow, Russian Federation.*

Mutations in Connexin 26 gene (*GJB2*) are responsible for more than half of all cases of prelingual nonsyndromic recessive deafness (PNSRD) in Caucasians. The carrier frequency of the c.35delG mutation in *GJB2* gene was found to be as high as 1-4% in the European populations. The aim of this study was to estimate *GJB2* caused cases fraction and mutation spectrum in 70 Armenian patients with PNSRD. Three pathologic genotype were detected are c.[35delG]+[35delG] in 10 patients, c.[35delG]+[-3202+1G>A, also known as IVS1+1G→A] in 6 patients and [c.35delG]+[p.Glu120del] in one patient. Therefore, the portion of *GJB2* caused deafness is to be 24%. The c.35delG and IVS+1G>A mutations frequencies were most high and were found to be 79% and 18% in all chromosomes with mutations.

J12.21
Neonatal respiratory failure in Saudi's full-term newborn infants associated with *ABCA3* gene mutations

M. A. Al Balwi[1,2,3], *I. Al Abdulkareem*[2,3], *S. Al Saif*[4,2], *M. Al Fawaz*[3], *A. Al Masoud*[3];
[1]*King Abdulaziz Medical City, Department of Pathology & Laboratory Medicine, Riyadh, Saudi Arabia,* [2]*King Saud bin Abdulaziz University for Health Sciences, College of Medicine, Riyadh, Saudi Arabia,* [3]*King Abdullah International Medical Research Center, Molecular Biology, Riyadh, Saudi Arabia,* [4]*King Abdulaziz Medical City, Department of Pediatrics, Riyadh, Saudi Arabia.*

Neonatal Respiratory Distress Syndrome (RDS) is commonly occurs in preterm babies and may also seen in term babies with Surfactant protein B or protein C deficiency. ABCA3 (ATP-Binding Cassette, Subfamily A, Member 3) maintains pulmonary surfactant homeostasis through transport of phospholipids and proteins to the lung alveolar surface. Recently, ABCA3 mutation was described in pediatric interstitial lung disease patients, including those with chronic pneumonitis of infancy, desquamative instititial pneumonitis and non-specific interstitial pneumontitis. ABCA3 mutation is typically inherited in an autosomal recessive pattern. The incidence and prevalence of neonatal RDS due to ABCA3 mutations are unknown worldwide. In Saudi Arabia, consanguinity were common within the population community and we anticipated that in RDS related to ABCA3 mutations were under diagnosed due to the lack of ABCA3 studies. Here, in this study we investigate and report the ABCA3 mutations findings in seven full-term newborn babies diagnosed with RDS in our institute. Genomic DNA was extracted from patients' blood and sequenced bi-directionaly for all ABCA3 exons using ABI 3130xl Genomic Analyzer. We identified

novel nonsense and missense mutations in our patients that not described previously. Molecular characterization will help in offering families having such disorders a chance to do prenatal/preimplentation genetic diagnosis.

J12.22
The significance of detailed molecular analysis in prenatal diagnosis of Congenital Adrenal Hyperplasia

***N. S. Osinovskaya**, T. E. Ivaschenko;*
Ott's Institute of Obstetrics and Gynecology, St.Petersburg, Russian Federation.

A case of prenatal diagnostics in high risk family of congenital adrenal hyperplasia (CAH) is presented. Formerly the detection of two mutations in CYP21A2 gene was diagnosed as CAH. However it is not always correct. It is necessary to take into account the number of copies of the gene that is under consideration.

In the examined family index case was a boy with a neonatal simple virilizing form of the disease with the splice mutation of intron 2 (CYP21A2 gene) in homozygous. The farther had a second normal allele (not inherited by the patient) carrying the Q318X Dup variant (inherited by the fetus). Real-time PCR method was used to determine the copy number variation of CYP21A2 gene. The severe point mutation Q318X was detected in "normal" chromosome with a duplicated gene. The other fetal allele carried the splice mutation of intron 2 of CYP21A2 gene inherited from the mother. So, the fetus had two mutations, but 3 copy of CYP21A2 gene. Thus our final conclusion was the fetus would be healthy.

The correct definition of the Q318X variant as a severe mutation of a single functional gene or a gene-duplicated nondeficient allele is very important for genetic counseling and prenatal diagnosis.

J12.23
LMNA-associated congenital muscular dystrophy in Russian families

***T. B. Milovidova**, E. L. Dadali, O. A. Schagina, A. V. Polyakov;*
Research centre for medical genetics, Moscow, Russian Federation.

Mutations in *LMNA* gene cause a variety of diseases affecting striated muscle including autosomal Emery-Dreifuss muscular dystrophy (EDMD), *LMNA*-associated congenital muscular dystrophy (L-CMD), and limb-girdle muscular dystrophy type 1B (LGMD1B). Here, we describe two novel *LMNA* gene mutations identified in two unrelated patients with congenital muscular dystrophy from Russia.

Two unrelated Russian families with myopathy of onset in the first year of life were investigated by us. Clinical features of patient 1 were: diffuse wasting with predominance in proximal upper and distal lower limbs, the spinal stiffness with head drop, thoracic hyperlordosisl, knee contractures and distal contractures in upper limbs. Clinical features of patient 2 with compromised perinatal history were: full-blown muscular hypotonia and psychomotor retardation. This patient died in seven month.

Mutation analysis was performed by direct DNA sequence on PCR fragments of each exons and exon-intron junctions of *LMNA* gene amplified from genomic DNA. In result previously not described deletion Glu31del in exon 1 was found in both families. Also previously not described change Ser334Asn in exon 6 of *LMNA* gene was found in patient and his mother from second family. However these both alterations were not found in 240 chromosomes of healthy persons.

Thereby the cause of congenital muscular dystrophy was de novo mutation Glu31del in exon 1 of *LMNA* gene. The mutations Ser334Asn had modificating effect for clinical severity of patient 2.

J12.24
Mutation analysis of MPZ gene in patients with Charcot-Marie-Tooth disease in Belarus

***T. Asadchuk**, K. Mosse, N. Rumyantseva;*
Scientific-Practical Center "Mother and Child", Minsk, Belarus.

The myelin protein zero (MPZ) gene is expressed in the compact layer of the Schwann cells. Mutations in MPZ gene lead to the CMT1B disease, and 77% of them are localized in exons 2 and 3, coding for the extracellular domain, indicating the importance of this domain for proper functioning of the MPZ protein.

At the first stage CMT1A and CMT1X were excluded in a group of selected patients with clinical symptoms of neuropathy. DNA resequencing analysis of exons 2 and 3 of MPZ gene revealed mutations in 2 of 50 (4%) probands with CMT. Missense mutation Thr124Met was observed in one patient having a clinically suggestive CMT2 phenotype characterized by late onset (>33 years) with papillary abnormalities (Argyll-Robertson pupils), deafness and chronic cough. In the second case we identified new mutation IVS1-2A>C associated with the severe motor and sensory neuropathy phenotype: early onset (during the first decade), muscular hypotonia, walking difficulties, distal weakness, sensory loss. This substitution was also identified in proband's father and her two children (boys of 2.5 years and 4 months). New mutation was not detected in healthy members of the family and normal subjects which supports the hypothesis that it is responsible for the CMT1B phenotype. These cases illustrate the importance of family studies in this disease, and establish genotype/phenotype correlation.

J12.25
Mutation in GJB2 in Iranian children with hearing loss referred for cochlear implantation

***S. Morovvati**[1], H. Rabiee[2], F. Mirzaei[1];*
[1]Research Center for Human Genetics, Baqiyatallh University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Research Center of Molecular Biology, Baqiyatallh University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background: Mutation in GJB2 or Connexin 26 Gene is the most common mutation found in children with nonsyndromic hearing loss. Cochlear implantation (CI) is one approach to rehabilitation in such patients. Present study was designed for genetic assessment of children who were referred for CI.

Methods: Genetic analysis was performed on 42 Iranian children with nonsyndromic hearing loss who were referred for genetic consultation and CI. Genomic DNA was extracted from peripheral blood and the coding sequence of the GJB2 gene was PCR amplified and the products purified and directly sequenced.

Results: We found two homozygous and four heterozygous 35delG mutations in six of the patients (14.3%). The response to CI was better in the homozygous than in the heterozygoous patients.**Conclusion:** Mutation screening in *GJB*2 gene is a useful predictor of post-implantation speech perception.

J12.26
A novel GLA mutation H186P causatively linked to the Anderson-Fabry disease

***M. Valentina**[1], F. Orsini[1], P. Merlini[1], F. Notarangelo[2], M. Demola[2], C. Lauricella[1], A. Colosimo[1], F. Marra[1], E. Araldi[1], S. Veronese[1], M. Gambacorta[1], F. Mauri[1], D. Ardissino[2], N. Marziliano[1];*
[1]A.O. Niguarda CA' Granda, Milano, Italy, [2]Cardiology Unit , University Hospital of Parma, Parma, Italy.

Background: The Anderson-Fabry Disease is an X-linked (Xq22) heritable disorder due to mutations in the GLA gene that causes a reduced or absent activity of the lysosomal enzyme alpha-galactosidase A. The enzyme defect leads to the intracellular and plasma accumulation of neutral glycosphingolipids, primarily globotriaoslyceramide.

This progressive accumulation of glycosphingolipids leads to the systemic disorder. This study demonstrates that the novel missense substution p.H186P is a pathogenic GLA gene mutation.

Methods: A 54-year-old male patient with unexplained concentric left ventricular hypertrophy and recurrent ventricular tachycardia, come to our attention. The screening of classical genes linked to hypertrophic cardiomyopathy (HCM) tested negative. We thus additionally tested the GLA gene.

Results: Bidirectional sequencing of the GLA gene showed that the patient was hemizygous for a single base sequence change in the codon 186 (p.H186P). The peripheral leukocytes showed a decreased GLA activity. Clinical and physical examination of the patient revealed the presence of cornea verticillata and angiokeratoma on the back.

Conclusion: Data in this study contribute to Fabry mutation database with a new mutation (p.H186P), confirming the reported heterogeneity in Fabry disease genotypes. The potential pathogenic effect of this novel mutation is likely due to conformational change in the enzyme structure leading to a less stable enzyme with a loss of activity.

J12.27
Receptor expression-enhancing protein 1 gene (SPG31) mutations are rare in Italian patients with hereditary spastic paraparesis

A. Magariello[1], *L. Citrigno*[1,2], *A. Patitucci*[1], *A. L. Gabriele*[1], *R. Mazzei*[1], *F. L. Conforti*[1], *C. Ungaro*[1], *M. Caracciolo*[1], *W. Sproviero*[1,3], *A. Gambardella*[1,3], *M. Muglia*[1];

[1]*Institute of Neurological Sciences -CNR-, Piano Lago di Mangone (CS), Italy,* [2]*Department of Neurosciences, Psychiatric and Anesthesiological Sciences, University of Messina,, Messina, Italy,* [3]*Institute of Neurology, University 'Magna Graecia, Catanzaro, Italy.*

Hereditary spastic paraparesis (HSP), is a large group of inherited, heterogeneous neurologic disorders caused by the degeneration of corticospinal axons.. Mutations in the *SPG4* and *SPG3A* genes, which encode for spastin and atlastin, respectively, are responsible for approximately 40% and 10% of cases of ADHSP, respectively. The *SPG31* gene also known as the receptor expression- enhancing protein 1 gene (*REEP1*), has been suggested to be the third most common cause of ADHSP, and accounts for 2.3%-8% of patients.

We report an investigation carried out on forty-five unrelated Italian HSP patients. All of the patients fulfilled the Harding criteria for the diagnosis of HSP. After giving informed consent, exhaustive *REEP1* mutation screening was performed on all of the patients by PCR and direct sequencing. No mutations in the coding region of *REEP1* gene were identified suggesting that the *REEP1* mutation frequency may be very low in Italian patients. Different studies carried out in European population indicate that mutations in *REEP1* account for up to 8% of autosomal dominant HSP cases. The low frequency of *REEP1* gene mutations detected in our population could be limited by factors such as PCR-based approaches that are sensitive to point mutations, as well as small deletions and insertions. A *REEP1*-specific multiplex ligation-dependent probe amplification (MLPA) assay is necessary to exclude multi-exonic *REEP1* deletion/duplication. Furthermore, the study of additional samples may increase the mutation detection rate.

J12.28
High incidence of W24X GJB2 mutation among Macedonian Gypsy patients with nonsyndromic hearing loss

E. Sukarova Stefanovska[1], *M. Cakar*[2], *G. D. Efremov*[1];

[1]*Research Center for Genetic Engineering and Biotechnology, Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Audiology Center, Otorhinolaryngology Clinic, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of.*

Hearing impairment affects 1 in 650 newborns, making it the most common congenital sensory impairment. Despite extraordinary genetic heterogeneity, mutations in one gene, *GJB2,* encoding the connexin 26 protein involved in inner ear homeostasis, are found in up to 50% of patients with autosomal recessive nonsyndromic hearing loss (NSHL). The spectrum of mutations in GJB2 varies considerably between different ethnic populations. 35delG predominates in Caucasians, 176delT in Ashkenazi Jews, 235delC in Japanese, while W24X in Indian and R142W in African population.

The aim of our study was to determine the prevalence and spectrum of GJB2 mutations, including the (GJB6-D13S1830) deletion, in Macedonian Gipsy patients with NSHL. Thirty unrelated patients (17 sporadic and 13 familial) of Gipsy origin, with profound deafness were analyzed. Molecular studies were performed using Single strand conformation polymorphism analysis, direct sequencing of GJB2 gene and specific PCR analysis for del(GJB6-D13S1830) mutation.

GJB2 mutations were found in 21 (70%) of the Gipsy patients, in homozygote (11), compound heterozygote (6) or heterozygote state (4). Among these the predominant mutation was W24X mutation with allelic frequency of 70.3%, followed by R127H and 35delG with allelic frequency of 16.2% and 10.8% respectively. In one patient a compound heterozygosity of W24X and Cd120delGAG was detected. None of the patients carry del(GJB6-D13S1830).

These findings indicate that as in the other Gypsy deaf populations the predominant GJB2 mutation is W24X as the major cause of autosomal recessive NSHL and should be tested in each routine diagnostic approach in Macedonian Gypsy deaf population.

J12.29
Association Of TNF-ALPHA Gene Polymorphisms And Inflammatory Bowel Disease In Iran

T. Dadaei, *A. Farnood, N. Naderi, M. Habibi, H. Balaei, M. Zali;*

Research Center for Gastroenterology and Liver Disease, Shahid Beheshti M.C, Tehran, Islamic Republic of Iran.

Background and Aims: Assessment of tumor necrosis factor (TNF-α) gene polymorphisms in other countries, has shown an association with inflammatory bowel disease (IBD). Considering the genetic variety in different ethnic groups, the aim of present study was to investigate association of five important single nucleotide polymorphisms (SNPs) [-1031(T→C), -863(C→A), -857(C→T), -308(G→A) and -238(G→A)] in the promoter of the tumor necrosis factor (TNF-α) gene with inflammatory bowel disease in Iran.

Methods: Polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) methods were used in this study to genotype DNA samples from 156 Ulcerative colitis (UC) patients, 50 Crohn's disease (CD) patients and 200 sex and age matched healthy controls.

Results: The frequency of the mutant (-1031C) allele of the TNF-α gene was significantly increased in Iranian Patients with Crohn's disease compared to healthy controls (26.0% vs 15.5%, P= 0.018, OR= 1.92; 95% CI: 1.14-3.23). No association was observed between other evaluated SNPs and Crohn's disease in Iranian patients. None of the mentioned SNPs were more frequent in Ulcerative Colitis patients compared to healthy controls.

Conclusion: TNF-α gene polymorphisms could partly play a role in disease pathogenesis in Iranian Crohn's patients.

J12.30
β-thalassemia mutations in the Iranian Kurds

S. M. Khorshidi;

tabriz university, tabriz, Islamic Republic of Iran.

β-Thalassemia is the most common heredity disease in Iran and most part of the world. this disorder characterized by reduced (β+-thalassemia) or absence (β°- thalassemia) of the β- globin chain synthesis in Hemoglobin tetramer. Since the Iranian population is a mixture of different ethnic groups, it is necessary to determine the frequency and distribution of these mutations in our country. Therefore, in this study we determined the spectrum and the frequency of β-Thalassemia mutations in the population of Sunni Muslim Kurds in western Iran to set up a prenatal diagnostic laboratory.Genomic DNA was extracted by standard method. Mutations were studied in 120 chromosomes by Polymerase Chain Reaction- Amplification Refractory Mutation System (PCR-ARMS), and direct Sequencing methods. We found fifteen β- thalassemia mutations, and IVS-II-1 (G>A) mutation was the most common mutation with a frequency of 35%. Other mutations were FSC8/9 (+G) 15.7%, IVS-I-1(G>A) 8%, FSC8 (-AA) 6.75, FSC 5(-CT) 6.7%, IVS-I-110 (G>A) 6% , FSC 36/37 (-T) 4.2% , FSC 44 (-C) 3.4% , IVS-I-5 (G>C) 3.4% , IVS-I-6 (T>C) 3.4% , Codon 39 (C>T) 1.7% , Codon 15(T*G*G>T*A*G) 1.7% , IVS-I-128 (T>G) 1.7% , and +22 3'UTR (G>A) 0.8% , Codon 127(C*A*G>C*G*G) 0.8%+ 0.8%(one normal and one mutant allele).This report was the first comprehensive study in Kurdistan and western Azerbaijan provinces in Iran and could provide a reference for prenatal testing and genetic counseling in this population.

J12.31
Mutation detection of *GJB2* and *GJB6* and genetic linkage analysis of 3 common DFNB loci (DFNB4, DFNB3, DFNB59) in 9 large pedigrees with hearing loss in the Southern Khorasan in Iran

N. Jalilian[1], *M. A. Tabatabaiefar*[1], *F. Alizadeh*[1], *A. Ahmadi*[2], *M. R. Noori-Daloii*[1];

[1]*Departmetn of Medical Genetics,School of Medicine,Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Center for Genetic Counseling,Welfare and Rehabilitation Organization, Birjand, Islamic Republic of Iran.*

Hearing loss is the most common sensory disorder. The autosomal recessive non-syndromic form (ARNSHL) accounts for 72% of monogenic HL. DFNB1 is the most common cause of ARNSHL in many populations (50%) including Iran (20%).Most of the research on HL in Iran has focused on this locus. The fact that many loci are

involved together with the heterogeneity of the status, necessitate studying further loci in various Iranian ethnic groups. Nine large deaf pedigrees originating from the Southern Khorasan province of Iran were selected. The families analyzed for *GJB2*, exon II, mutations. Affected heterozygous for GJB2 mutations were analyzed for two GJB6 deletions (D13S1830, D13S1854). Pedigrees negative for *GJB2* mutations were then subject to linkage analysis for DFNB4, DFNB3 & DFNB59 loci. Individuals were genotyped for STR markers using touch-down PCR-PAGE. Three out of the 9 families showed *GJB2* mutations. One family carried homozygous c.35delG mutation. The other pedigree carried two different mutations; One patient was heterozygous for c.231G>A while another carried a heterozygous c.380 G>A mutation. The second alleles were not detected. The 3rd pedigree showed to carry heterozygote mutation of p.V27I+E114G/wt . GJB6 deletions were not detected among the GJB2 heterozygous population. None of the remaining families showed linkage to the 3 other loci studied. Our study showed that *GJB2* mutations accounts for about 33% of affected families. These results could provide further insight into the etiology of HL and may lead to better genetic diagnostics & counseling. This study proceeds with more loci and more families.

J12.32
Cerebrotendinous Xanthomatosis (Sterol 27-Hydroxylase Deficiency) - A Case Report from Iran

F. Hadipour[1], *Z. Hadipour*[2], *P. Sarkheil*[2], *M. Rohani*[3], *Y. Shafeghati*[1];
[1]*Sarem Cell Research Center & Medical Genetics Department, Sarem Women Hospital, Tehran, Islamic Republic of Iran,* [2]*Medical Genetics Department, Sarem Women Hospital, Tehran, Islamic Republic of Iran,* [3]*Tehran Medical Science University, Department of Neurology of Rasoul Akram Hospital, Tehran., Tehran, Islamic Republic of Iran.*

Cerebrotendinous xanthomatosis is a rare genetic metabolic disorder of cholesterol and bile acid metabolism that results in systemic and neurologic abnormalities. Mutations in the gene CYP27A1 were been known as cause of disease, more than 50 mutations have been implicated. Typically, the disease begins in infancy with chronic diarrhea. Cataracts become evident in childhood or adolescence, and xanthomata develop in the second and third decades of life. Significant neurologic impairment also occurs; this often includes seizures, dementia, and extra pyramidal dysfunction and typically begins in the third decade of life and progresses until death, often in the sixth decade of life if the condition goes untreated. The presentation and course widely varies, and treatment can dramatically alter the natural history, especially with early initiation.

Case Report We report here an Iranian family with two affected sibs who are suffering from Cerebrotendinous Xanthomatosis. Cardinal features were: Motor dysfunction, ataxia, spastic paresis. In the physical examination we found Xanthomas of the Achilles tendon and, ataxia, and cataract bilaterally. MRI of the brain showed diffuse cerebral atrophy and increased signal intensity in the cerebellar white matter on T2-weighted images**.** Cerebrotendinous Xanthomatosis, was confirmed by Molecular Analysis in this family. The result was a homozygous splice- mutation in intron 2 of the CYP27A1 gene.

Oxidative stress is a mechanism that might help to explain the phenotypic heterogeneity in the severity of sickle cell anemia (SCA) complications, due to vascular damage. The NADPH system is considered to be the most important source of super-oxide anion ($^{*}O_2^-$) in vascular cells such as smooth muscle and endothelial cells. The *CYBA* gene (16q24) encodes the essential subunit of the NADPH oxidase p22phox and has several allelic variants, some of them in the promoter region associated with higher transcriptional activity, as the -930A/G (rs9932581). Once there is no data regarding the frequency of this variant in the Brazilian population, it was determined in 135 SCA patients and 66 controls through direct sequencing. In the SCA group, the GG, AG and AA genotype frequency was 33.3%, 48.9% and 17.8%, respectively while in the control group it was 37.9%, 45.4% and 16.7%. The frequency of the G allele was 57.8% in patients and 64.4% in controls and of the A allele it was 42.2% in patients and 35.6% in controls, similar to the ones reported by the HapMap Project for CEU and ASW populations. There is no statistically significant difference in the genotype distribution between patients and controls although p value is equal to 0.053; the alleles are in Hardy-Weinberg equilibrium in both groups. These results suggest that there is no population subdivision in and between the studied groups and our population is suitable for further studies, as the association of the *CYBA* -930A/G polymorphism with severity in sickle cell anemia.

J12.34
Identification of genetic causes of Hearing loss in deaf GJB2 carriers in Iranian population

A. Kashef*;*
GRC (Genetic Research Center), Tehran, Islamic Republic of Iran.

Hereditary hearing loss is the most common neurosensory disorder in humans. Half of the cases have genetic etiology with extraordinary genetic heterogeneity. Mutations in one gene, GJB2, are the most common cause for autosomal recessive non-syndromic hearing loss (ARNSHL) in many different populations. GJB2 encodes a gap junction channel protein (connexin 26), and is located on DFNB1 locus on chromosome 13q12.11 which also involve another connexin gene, GJB6. Co-expression of GJB2 (connexin 26) and GJB6 (connexin 30) in the inner ear is thought to be prerequisite for the maturation of the cochlea. Mutation screening of GJB2 revealed that a high number of deaf patients carrying only one mutant allele.

In this study, using PCR-based direct sequencing; we searched for second mutant allele which leads to deaf phenotype. We assessed one hundred patients with ARNSHL through Iranian population bearing first mutation in their coding exon (exon-2) of GJB2, for mutations in non-coding exon of GJB2, promoter region (as the most important cis-regulatory elements) of GJB2 and GJB6, and 4 known deletions through DFNB1 locus. Passing the first step of study, to date we have identified the second mutant allele in splice site of exon-1 of GJB2 which is known as -3170G to A in 10 probands of 43.

Our findings confirm the results of last study on GJB2 mutations through Iran, which showed -3170G to A mutation as the most common after 35delG in Iranian population. Therefore, it is important to check GJB2 non-coding exon-1 in patients' heterozygote for GJB2 mutation.

Mutation spectra of the AAAS gene in Iranian families with Allgrove syndrome

V. R. Yassaee[1], *Z. Soltani*[1], *B. Malekafzali A.*[2];
[1]*Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Dept. of Dermatology, Boali Hospital, Faculty of Medicine, Tehran Branch, Islamic AZAD University, Tehran, Islamic Republic of Iran.*

Allgrove (OMIM#231550) or Triple-A syndrome is a rare, autosomal recessive disorder characterized by the triad of familial Adrenal insufficiency, Achalasia, and Alacrima. Approximately one-half of all patients with Triple-A syndrome have been shown to have mutations in the AAAS gene on chromosome 12q13, which result in loss or non-function of the encoded protein.

Five unrelated families clinically diagnosed as Allgrove syndrome were evaluated for sequence variations in the AAAS gene. Blood samples were collected after informed and written consent was received. Isolated DNA derived from subjects was amplified using intronic primers. The entire sequence of the AAAS gene including regulatory region, coding regions and exon-intron boundaries were analyzed for any alteration by PCR and direct sequencing.

In six probands of five families, four previously reported and two novel mutations were identified. Two heterozygote and homozygote mutations in exon 9 and the regulatory region respectively were

detected in one of the probands. In addition, SNPs analysis using SNPs plot's presented several previous reported variations in Allgrove families.
This is the first report of Triple-A syndrome from an Iranian population. Collectively, our study findings indicate that mutations scattered across the AAAS gene and upstream regulation elements. Various ethnic groups should develop a mutation database for their own rare genetic disorders. However, mutation databases should screen common mutated alleles initially.
Our families present the typical triad of symptoms and the mutation spectrum is similar to the other population studied. Further study is required for phenotype-genotype correlation in the Iranian population.

P13.02
Identification of Two Novel Mutations of *ASPA* Gene in Patients with Canavan Disease from Turkey

E. Karaca[1], *A. Gezdirici*[1], *S. Yilmaz*[1], *M. Ozen*[1], *A. Yuksel*[2];
[1]*Istanbul University, Cerrahpasa Medical School Department of Medical Genetics, Istanbul, Turkey,* [2]*Bezmialem University, Istanbul, Turkey.*

Canavan disease (CD) is a childhood, progressive, autosomal recessive neurodegenerative leukodystrophy, characterized by macrocephaly, lack of head control, developmental delays by the age of three to five months, severe hypotonia, failure to achieve independent sitting, ambulation, or speech. It is prevalent in Ashkenazi Jews with two predominant mutations in affecting aspartoacylase (*ASPA*) gene. Its frequency in other populations is low with one predominant mutation, (914C->A).
We describe here three Turkish patients from two families. Two of them are siblings from first cousin parents. They had clinical features of poor head control, developmental delay, lack of visual tracking, progressive macrocephaly, limb spasticity and seizures which supported Canavan disease as a preliminary diagnosis. Neuroimagings were also compatible with CD. In addition, they had facial dysmorphic features including low set ears, up turned nostrils, long filtrum and retrognathi. Sequence analysis of *ASPA* gene revealed a novel homozygous donor splice site mutation (c.432+1G>A) in exon 2 of *ASPA* gene in both patients.
The third patient was 6 month-old boy from first cousin parents of Turkish ancestor. He was referred to our clinic because of progressive macrocephaly, nystagmus and poor sucking. Cerebral magnetic resonance imaging (MRI) and MR spectroscopy strongly suggested CD. Sequencing of *ASPA* gene revealed no abnormality while multiplex ligation dependent probe amplification (MLPA) analysis showed a novel large homozygous deletion in exon 1. In conclusion, our findings showed two mutations not previously reported in patients with CD suggesting new insights for the role of *ASPA* gene in this disease.

P13.03
Metabolic cutis laxa

M. Mohamed[1], *T. Gardeitchik*[1], *J. Smeitink*[1], *B. Lace*[2], *S. Jagadeesh*[3], *E. Grycki*[4], *E. Berry-Kravis*[5], *J. Häberle*[6], *B. Albrecht*[7], *U. Kornak*[8], *B. Chan Lim*[9], *D. Lefeber*[1], *R. Wevers*[1], *E. Morava*[1];
[1]*Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Riga Stradins University, Riga, Latvia,* [3]*Fetal Care Research Foundation, Mylapore, Chennai, India,* [4]*Mayo Clinic, Rochester, MN, United States,* [5]*Rush University Medical Center, Chicago, IL, United States,* [6]*University Hospital for Children, Zurich, Switzerland,* [7]*University Hospital Essen, Essen, Germany,* [8]*University Hospital Charite, Berlin, Germany,* [9]*Seoul National University Hospital, Seoul, Korea, Republic of.*

Cutis laxa is a rare skin disorder characterized by wrinkled, redundant, inelastic and sagging skin due to defective synthesis of elastic fibers and other proteins of the extracellular matrix. Wrinkled, inelastic skin occurs in many cases as an acquired condition. Syndromic forms of cutis laxa, however, are caused by diverse genetic defects, mostly coding for structural extracellular matrix proteins. Surprisingly a number of metabolic disorders are associated with inherited cutis laxa. Since the discovery of the COG7 defect, linking cutis laxa to glycosylation, several inborn errors of metabolism with cutis laxa have been described. In spite of the evolving number of cutis laxa-related diseases, a large part of the cases remains genetically unsolved.
Here we report on the clinical and metabolic features of 5 novel patients with ATP6V0A2-CDG, 4 children with PYCR1 defect and a young adult with RIN2 defect. In metabolic cutis laxa syndromes the clinical and laboratory features might partially overlap, however there are some distinct, discriminative features. We offer a practical approach to the differential diagnosis of metabolic cutis laxa syndromes.

P13.04
A new CDG1h case with a severe neurological and gastrointestinal presentation

H. S. Sorte[1], *L. Mørkrid*[2], *O. K. Rødningen*[1], *M. A. Kulseth*[1], *A. Stray-Pedersen*[1], *D. Undlien*[1], *G. Matthijs*[3], *V. Race*[3], *T. Fiskerstrand*[4], *G. Houge*[4], *R. Lyle*[1], *T. Prescott*[1];
[1]*Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,* [2]*Department of Medical Biochemistry, Oslo University Hospital, Oslo, Norway,* [3]*Center for Human Genetics, University of Leuven, Leuven, Belgium,* [4]*Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway.*

Congenital disorders of glycosylation type 1 (CDG1) are autosomal recessive conditions characterized by a distinctive serum transferrin glycoform pattern. The molecular basis is known for CDG1a - CDG1q. CDG1h (OMIM #608104) is associated with mutations in *ALG8* and nine cases have been published previously. Presentation of CDG1h varies from isolated protein-losing enteropathy to severe combined neurological and gastrointestinal disease.
We present a female, the second child of healthy consanguineous parents, born at 39 weeks with BW 2210g, OFC 33cm, L 48cm. Hypotonia was present neonatally and initial feeding difficulties persisted. At eight months findings included: very significant global delay, OFC at the 2,5%, growth retardation, horizontal nystagmus, poor eye contact, prominent chin, excess nuchal skin, wrinkling around ankles and knees. No specific abnormalities were noted on cerebral MRI. Serum isoelectric focusing was indicative of a CDG1. At age nine months, acute viral gastroenteritis was complicated by massive protein-losing enteropathy with rapidly ensuing lethal multi-organ failure.
SNP analysis using Affymetrix genome-wide human SNP array 6.0 revealed two known CDG1 associated genes, *MPI* and *ALG8*, within homozygosity regions in the proband only. Exome sequencing (Agilent 38Mb exome capture and 2x75bp Illumina sequencing) detected homozygosity for the *ALG8* variants p.S267P and p.F270L. Sanger sequencing confirmed parental heterozygosity. Both variants were interpreted as pathogenic based on conservation and three previously reported mutations predicted to affect the same intraluminal protein domain.
This case illustrates the severe CDG1h phenotype, and reinforces the clinical utility of homozygosity mapping followed by targeted exome sequencing in rare recessive disorders.

P13.05
Mutational Analysis of Uroporphyrinogen III Synthase Gene in Iranian Families with Congenital Erythropoietic Porphyria

M. Moghbeli[1], *A. Arabi*[1], *M. Maleknejad*[2], *B. Naghibzadeh*[1], *M. R. Abbaszadegan*[1];
[1]*Division of Human Genetics, Immunology Research Center, Bu-Ali Research Institute, Mashhad University of Medical Sciences (MUMS), Mashhad, Islamic Republic of Iran,* [2]*Department of Pediatric, Musabne jafar Hospital, Mashhad University of Medical Sciences (MUMS), Quchan, Islamic Republic of Iran.*

Porphyrias are rare metabolic hereditary diseases originating from defects in specific enzymes involved in heme biosynthesis pathway. Congenital Erythropoietic Porphyria (CEP) is the rarest autosomal recessive porphyria resulting from deficiency of uroporphyrinogen III cosynthase (UROS), the fourth enzyme in heme biosynthesis, leading to an excessive production and accumulation of type I porphyrins in bone marrow, skin and several other tissues. Clinical manifestations are presented in childhood with severe cutaneous photosensitivity, blistering, scarring and deformation in hands and loss of eyebrows and eye-lashes in face. Less than 200 cases CEP reported to date.
Two families with 3 CEP patients and members of their family in Iran were studied for the first time showing severe clinical symptoms including anemia, hepatosplenomegaly and severe photosensitivity along with scarring. A missense mutation in UROS gene was identified in this family. A T to C change at nucleotide 34313, leading to a substitution of Leucine by Proline at codon 237, which observed in

the homozygous state in 3 patients and heterozygous state in their parents. This family was conseled for any future prenatal diagnosis. Our data from Iranian population emphasize the importance of codon 237 alone in performance of UROS and advantages of molecular genetic techniques as a diagnostic tool for detection of clinically asymptomatic heterozygous mutation carriers as well as CEP within families.

P13.06
Long term follow-up and treatment in nine boys with X-linked creatine transporter defect

J. M. van de Kamp[1], *P. Pouwels*[1], *F. Aarsen*[2], *L. ten Hoopen*[2], *D. Knol*[1], *J. de Klerk*[2], *I. de Coo*[2], *J. Huijmans*[2], *C. Jakobs*[1], *M. van der Knaap*[1], *G. Salomons*[1], *G. Mancini*[2];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Erasmus University Medical Center, Rotterdam, Netherlands.*

The creatine transporter (CRTR) defect is a recently discovered cause of X-linked intellectual disability which is associated with cerebral creatine deficiency. Treatment with creatine monohydrate has not proved effective. Supplementation with creatine precursors L-arginine and glycine might increase endogenous cerebral creatine synthesis. The effect of this treatment is still controversial.

We followed nine boys aged between 8 months and 10 years with molecularly confirmed CRTR defect with repeated ^{1}H-MRS and neuropsychological assessments during 4-6 years of combination treatment with creatine monohydrate, L-arginine and glycine. Treatment did not lead to a significant increase in cerebral creatine content as observed with H^{1}-MRS. After an initial improvement of locomotor and personal-social IQ subscales, no statistical significant clinical improvement was recorded. Unrelated to the treatment, we noticed an age-related decline of IQ subscales in boys affected with the CRTR defect.

P13.07
Cystic fibrosis and tuberculosis

I. M. CIUCA[1,2], *L. Pop*[1,2], *Z. Popa*[3], *L. Tamas*[4,2], *S. Turcu*[1,5], *I. Popa*[1];
[1]*Pediatric II Department, Timisoara, Romania,* [2]*University of Medicine and Pharmacy V Babes, Timisoara, Romania,* [3]*Cystic Fibrosis Center, Timisoara, Romania,* [4]*Biochemistry Department, Timisoara, Romania,* [5]*Great Ormond Street Hospital, London, United Kingdom.*

Background: Cystic fibrosis patients are predisposed to acquire significant respiratory pathogens. Mycobacterium tuberculosis is a common pathogen in our area, having an important morbidity in children. Associated CF complication like underweight, diabetes mellitus and liver disease are well-known risk factors for tuberculosis. The hypothesis of a frequent co-morbidity of tuberculosis(TB) in CF children occurred. The aim of the paper was to evaluate the frequency of TB in children with CF in the presence of risk factors. Methods: Thirty-eight patients followed in our CF Center were considered for a prospective five years study. For the retrospective information we used data records of CF Centre. Diagnosis criteria for tuberculosis were: positive Mantoux test, BAAR positive and/or bacteriological confirmation, additional to clinical and radiological signs. Results: Regarding TB only one patient (2.6%) with CF had all the criteria diagnosis. Tuberculin skin test was positive in 4 patients (10.5%), 3 of them being vaccinated. Despite the mandatory vaccination for TB in our country, merely in 84% from patients the vaccination was documented. Interestingly, almost 16% of patients (6 pts) were considered and treated as TB cases, before being diagnosed with CF. One patient had active TB, bacteriological confirmed (del F508 homozygous, *Pseudomonas* positive and poor nutritional status). Conclusion: We could not find a correlation between tuberculosis and CF children, despite the presence of distinctive risk factors. Although TB is a quit common condition in our area, CF children seemed to be protected against it. Further studies need to be done to evaluate this hypothesis.

P13.08**
Identification and characterization of a novel inborn error of metabolism caused by Dihydrofolate reductase deficiency

S. Banka[1], *H. J. Blom*[2], *J. N. Pelletier*[3], *J. Walter*[1], *J. Urquhart*[1], *G. I. Rice*[1], *Y. Crow*[1], *S. Jones*[1], *W. G. Newman*[1];
[1]*Manchester Academic Health Sciences Centre (MAHSC), St. Mary's Hospital, University of Manchester, Manchester, United Kingdom,* [2]*Institute for Cardiovascular Research, VU University Medical Center Amsterdam, Amsterdam, Netherlands,* [3]*Université de Montréal, Montreal, QC, Canada.*

Our proband, born to consanguineous British Pakistani parents, presented at 3½ months of age with pallor and poor feeding. Investigations revealed megaloblastic anemia/pancytopenia with normal serum B12, folate and homocysteine levels. Within one week, he developed intractable seizures and cerebral folate deficiency was diagnosed. Brain MRI showed cerebellar and cerebral atrophy. His symptoms improved dramatically on folinic acid. His biochemical profile was consistent with reduced activity of dihydrofolate reductase (DHFR), a critical enzyme for synthesis of DNA precursors. DHFR has been studied extensively as target of anti-neoplastic, antimicrobial and anti-inflammatory drugs, but no cases of DHFR deficiency have been previously described.

Mapping identified multiple regions of homozygosity including a 3Mb region encompassing *DHFR*. Sequence analysis identified homozygous c.238C>T (p.Leu80Phe) mutation in the proband. Same homozygous mutation was identified in the proband's affected deceased sibling and in an unrelated child with similar clinical features. This mutation alters a highly conserved residue and was absent in 146 ethnically matched controls. It results in normal expression, but significantly reduced enzyme levels and activity. Protein modelling suggested that the Phe residue could disrupt cofactor binding and/or destabilize the protein.

Our proband continues to be severely neuro-developmentally delayed and was found to have cerebral tetrahydrobiopterin deficiency unresponsive to folinic acid. DHFR is important for maintenance of BH4:BH2 ratio in vascular endothelium and our findings suggest that DHFR may also facilitate BH4 salvage in the brain. The affected children had normal development until three months, indicating the possibility of better outcome with earlier diagnosis and treatment.

P13.09
Decreased INSR autophosphorylation due to novel p.Leu795Pro mutation in β-subunit in a patient with Donohue syndrome

T. Hovnik[1,2], *J. Kovač*[1,2], *K. Trebušak Podkrajšek*[1], *N. Bratanič*[2], *T. Battelino*[2];
[1]*Center for Medical Genetics, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia,* [2]*Department of Pediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia.*

Donohue syndrome (former leprechaunism) is a rare, recessively inherited disorder of extreme insulin resistance due to mutation in the insulin receptor gene (INSR). The pathogenesis of insulin resistance is due to a cellular defect in insulin binding, receptor autophosphorylation and tyrosine kinase activity on insulin-stimulated biological activity. We have identified a newborn patient with Donohue syndrome caused by the novel homozygous missense mutation (p.Leu795Pro). The mutation is located in the extracellular portion of the β subunit of the insulin receptor. We aimed to functionally characterize the post-binding defect of the insulin receptor signaling in cultured fibroblasts from patient, patient's mother and control individual.

Functional characterization showed that novel INSR gene mutation in insulin receptor β subunit is causing a syndrome of extreme insulin resistance due to decreased insulin receptor autophosphorylation rather than insulin binding impairment.

P13.10
Familial Hypercholesterolaemia testing at the Bristol Genetics Laboratory

L. Yarram[1], *M. Greenslade*[1], *S. Burton-Jones*[1], *G. Bayly*[2], *M. Balasubramani*[2], *M. Williams*[1];
[1]*Bristol Genetics Laboratory, Pathology Sciences, Southmead Hospital, Bristol, United Kingdom,* [2]*Clinical Biochemistry, Bristol Royal Infirmary, Bristol, United Kingdom.*

Familial hypercholesterolaemia (FH) is an autosomal dominant disorder with UK incidence of approximately 1/500. FH is caused by mutations in the low-density lipoprotein receptor (*LDLR*), apolipoprotein B-100 (*APOB*) and proprotein convertase subtilisin/kexin type 9 (*PCSK9*) genes.

A comprehensive FH testing service is offered at the Bristol Genetics Laboratory; including 1) ARMS PCR to detect 20 common mutations, 2) sequencing of *LDLR* (promoter + 18 exons) 3) MLPA of *LDLR* and

4) extended gene screening of *PCSK9* (12 exons) and *APOB* (codons 3375-3570) by sequencing.
Cases are referred through lipid clinics; genetic testing is offered to 'definite' and 'possible' FH cases (Simon Broome criteria in accordance with NICE). 156 index and 55 cascade cases have been reported to date. 46 different mutations have been identified, including a compound heterozygote for p.[Asp589fs]+[Lys311Thr]. A mutation was identified in 44% of index cases; of these 47% were detected using ARMS, 49% by *LDLR* sequencing and 4% using MLPA.
Genetic testing enables a definitive diagnosis, and defines the patient group requiring more aggressive treatment to lower cholesterol. Cascade testing for at risk relatives, provides an accurate risk outcome for cases where cholesterol measurement alone can be unreliable. Case studies demonstrating the clinical utility of molecular genetic testing for FH and an audit of the service to date will be presented.

P13.11

Enzyme replacement therapy with agalsidase alfa (Replagal) slows the progression of renal dysfunction in male patients with Fabry disease: results of an integrated analysis

*M. West[1], R. Schiffmann[2], **A. Mehta**[3], D. Amato[4], N. Nair[4], D. Zahrieh[4], P. Huertas[4];*

[1]Dalhousie University, Halifax, NS, Canada, [2]Baylor Research Institute, Dallas, TX, United States, [3]Royal Free Hospital, London, United Kingdom, [4]Shire HGT, Lexington, MA, United States.

Introduction: Progressive kidney dysfunction is common in men with Fabry disease (FD). To estimate the effect of agalsidase alfa (agalα) enzyme replacement therapy on estimated glomerular filtration rate (eGFR), pooled data were analyzed post hoc from three similarly designed, prospective, randomized, placebo-controlled trials (RCTs TKT010/TKT005/TKT003).
Methods: 18-54-year-old males with FD received ≥1 infusion of agalα (0.2mg/kg; n=59) or placebo (n=58) every other week (EOW) for 6 months (analysis population). The Modification of Diet in Renal Disease (MDRD) equation was used to calculate eGFR in the analysis population at baseline and ≥3 follow-ups and in a subpopulation with chronic kidney disease (CKD) stages 2-3 (defined as eGFR 30−80mL/min/1.73m^2). Change in eGFR was calculated using a random slopes and intercepts model. This longitudinal analysis allows for serial measurements to exhibit within-patient correlations.
Results: Each RCT demonstrated numerical improvements in mean change in eGFR (agalα vs placebo). Pooled data showed statistically significant overall treatment differences (*P*=0.022), with kidney function deteriorated with placebo but not with agalα (although 95%CIs crossed 0; Table).
Conclusions: The results of this post hoc analysis of pooled RCT data support the hypothesis that agalα at a dosage of 0.2mg/kg EOW slows the progression of kidney dysfunction in male patients with FD.

eGFR rate of change during the 6-month treatment period.

	TKT010	TKT005	TKT003	All studies eGFR analysis population	All studies CKD 2/3

[a] Positive values favor agalα.

P13.12

First report of safety and tolerability of agalsidase alfa in Fabry disease patients formerly treated with agalsidase beta in a clinical trial setting

*P. Fernhoff[1], O. Goker-Alpan[2], M. Holida[3], K. Nedd[4], B. A. Barshop[5], R. Mardach[6], J. Ibrahim[7], Y. Lien[8], B. Rever[9], R. Hillman[10], N. Weinreb[11], E. Boyd[12], A. Desai[13], R. Forte[14], E. Crombez[15], **R. Martin**[15], D. Amato[15];*

[1]Emory University School of Medicine, Decatur, GA, United States, [2]Lysosomal Research & Treatment Unit, Springfield, VA, United States, [3]University of Iowa Health Care, Iowa City, IA, United States, [4]Infusion Associates, Grand Rapids, MI, United States, [5]University of California, San Diego, CA, United States, [6]Kaiser Permanente, Los Angeles, CA, United States, [7]St Joseph's Children's Hospital, Paterson, NJ, United States, [8]AKDHC, Tucson, AZ, United States, [9]Central Coast Nephrology, Salinas, CA, United States, [10]University of Missouri, Columbia, MO, United States, [11]University Research Foundation for Lysosomal Storage Disorders, Coral Springs, FL, United States, [12]Fullerton Genetics Center, Asheville, NC, United States, [13]Stuart Oncology Associates, Stuart, FL, United States, [14]North Shore University Hospital, Manhasset, NY, United States, [15]Shire HGT, Cambridge, MA, United States.

Introduction: The FDA accepted a Treatment Investigational New Drug protocol (tIND; HGT-REP-059) allowing early access to agalsidase alfa (agalα) for patients with Fabry disease (FD) during the agalsidase beta (agalβ) supply shortage. This analysis describes safety and tolerability over 3 months in 70 FD patients switched from agalβ to agalα.
Methods: This ongoing, multicenter, open-label tIND collected 3-month data on adverse events (AEs), serious AEs (SAEs) and other clinical parameters from FD patients treated previously with agalβ. 117 patients enrolled, of whom, 59.8% (n=70) had prior treatment with agalβ, but not agalα. Excluded were patients who were pregnant, breastfeeding, hypersensitive to agalα, received any investigational drug (≤30days before entering the tIND) or were on concomitant agalβ therapy. Patients received intravenous agalα (0.2mg/kg every other week).
Results: 70 patients received study drug (ages 5-84 years, male:female 39:31). Among 68 patients with available data, mean prior agalβ therapy duration was 4.8 years (range 0.3-12.3). 76 treatment-emergent AEs (TEAEs) occurred in 30 patients. Most AEs were mild/moderate in severity (93.3%; 28/30 patients). No deaths occurred. The table summarizes possible/probable treatment-related AEs, infusion-related AEs, most common TEAEs (≥3% agalα-treated patients), treatment-emergent SAEs and AE-related permanent discontinuations.

Adverse event profile of 70 agalsidase alfa patients formerly treated with agalsidase beta.

Adverse event (AE)	Agalα-treated patients, % (n)
Treatment-emergent AEs	42.9% (30)
Possibly/probably treatment-related AEs	22.9% (16)
Infusion-related AEs	20.0% (14)
Most common treatment-emergent AEs (≥3% of all agalα-treated patients)	
-- Dizziness	4.3% (3)
-- Headache	4.3% (3)
-- Vomiting	4.3% (3)
Treatment-emergent SAEs	5.7% (4)
-- Cerebrovascular accident	1.4% (1)
-- Adverse reactions to antibiotic and skin abscesses	1.4% (1)
-- Transient ischemic attack	1.4% (1)
-- Diarrhea, vomiting, nausea, extreme fatigue, & dehydration	1.4% (1)
Permanent discontinuations due to AEs	0

Conclusions: Following 3-month evaluation of 70 FD patients previously treated with agalβ, agalα was generally well tolerated. These data support that agalα may provide a clinical option for FD patients who switch therapies.

P13.13

Multicenter, open-label treatment protocol (HGT-GCB-058) of velaglucerase alfa enzyme replacement therapy (ERT) in type 1 Gaucher disease: safety and tolerability

*G. M. Pastores[1], B. Rosenbloom[2], N. Weinreb[3], O. Goker-Alpan[4], R. Mardach[5], M. Lipson[6], J. Ibrahim[7], **G. M. Cohn**[8], D. Zahrieh[8], P. K. Mistry[9];*
[1]NYU School of Medicine, New York, NY, United States, [2]Tower Hematology Oncology, Beverly Hills, CA, United States, [3]University Research Foundation for LSDs, Coral Springs, FL, United States, [4]LSD Research and Treatment Unit, Springfield, VA, United States, [5]Kaiser Permanente, Los Angeles, CA, United States, [6]Permanente Medical Group, Sacramento, CA, United States, [7]St Joseph's Children's Hospital, Paterson, NJ, United States, [8]Shire HGT, Cambridge, MA, United States, [9]Yale University School of Medicine, New Haven, CT, United States.

Background: Type 1 Gaucher disease (GD1), an inherited deficiency of lysosomal glucocerebrosidase, is the most common lysosomal storage disorder. In 2009, the FDA approved a treatment protocol to offer velaglucerase alfa (then, an investigational drug) to GD1 patients affected by the imiglucerase supply disruption.

Methods: A US multicenter treatment protocol enrolled GD1 patients (>2 years old, treatment-naïve [naïve] or previously on imiglucerase [switch], with no prior anaphylactic reaction to ERT. Naïve patients received velaglucerase alfa 60U/kg every other week (EOW); switch patients received the same dose as their prior imiglucerase regimen (15-60U/kg EOW).

Results: From Sept 2009 through Jun 2010, 211 patients commenced velaglucerase alfa treatment (baseline: age 6-89 years [8 patients <18 years old]; 101 male:110 female; 72 splenectomized; 6 naïve; 205 switch). . One serious AE was considered possibly drug-related (migraine) [Table]. Median (range) velaglucerase alfa treatment duration for naïve and switch patients was 106 (27-232) and 182 (1-365) days, respectively. Mean hemoglobin and platelets improved in naïve patients (n=4; 1.7g/dL and 62.3 10^9/L) and remained stable for switch patients.

Adverse events (AEs)		
	Naïve	Switch
Description	N=6 n (%)	N = 205 n (%)
Experienced ≥1 AE	3 (50.0)	89 (43.4)
Experienced ≥1 possibly/probably drug-related AE	1 (16.7)	35 (17.1)
Experienced ≥1 infusion-related AE	1 (16.7)	27 (13.2)
Experienced ≥1 severe or life-threatening AE	0	11 (5.4)
Experienced ≥1 serious AE	0	7* (3.4)
Discontinued due to an AE	0	3 (1.5)
Deaths	0	0
*1 serious AE was considered possibly drug-related (migraine).		

Conclusion: A clinically heterogeneous group of GD1 patients were successfully transitioned to velaglucerase alfa, which was generally well tolerated, supporting this enzyme replacement therapy as a treatment option for GD1.

P13.14

Multicenter, open-label study of velaglucerase alfa enzyme replacement therapy (ERT) in type 1 Gaucher disease (GD1): Safety evaluation of the first three infusions from the HGT-GCB-058 treatment protocol

*G. M. Pastores[1], B. Rosenbloom[2], N. Weinreb[3], O. Goker-Alpan[4], R. Mardach[5], M. Lipson[6], J. Ibrahim[7], G. M. Cohn[8], **D. Zahrieh**[8], P. K. Mistry[9];*
[1]NYU School of Medicine, New York, NY, United States, [2]Tower Hematology Oncology, Beverly Hills, CA, United States, [3]University Research Foundation for LSDs, Coral Springs, FL, United States, [4]LSD Research and Treatment Unit, Springfield, VA, United States, [5]Kaiser Permanente, Los Angeles, CA, United States, [6]Permanente Medical Group, Sacramento, CA, United States, [7]St Joseph's Children's Hospital, Paterson, NJ, United States, [8]Shire HGT, Cambridge, MA, United States, [9]Yale University School of Medicine, New Haven, CT, United States.

Background: GD1, an inherited deficiency of lysosomal glucocerebrosidase, is the most common lysosomal storage disorder. In 2009, disruption of imiglucerase supply resulted in an FDA request for a treatment protocol to offer velaglucerase alfa (velaα) ERT (then, an investigational drug) for patients in need.

Methods: A US multicenter treatment protocol enrolled GD1 patients (>2 years old; no prior anaphylactic reaction to ERT). Treatment-naïve ("naïve") patients received velaα 60U/kg every other week (EOW); "switched" (previously on imiglucerase) patients received the same dose as their prior imiglucerase regimen (15-60U/kg EOW). The present analysis evaluates the safety profile of first 3 in-clinic infusions of velaα. Switched patients were monitored during these 3 infusions; if therapy was well-tolerated, their physicians could recommend home therapy infusions thereafter.

Results: From Sep 2009-Jun 2010, 211 patients were treated (baseline: age 6-89 years [8<18 years]; 101 male:110 female; 72 splenectomized; 6 naïve; 205 switched patients). The majority of possibly or probably drug-related AEs were infusion-related. The AE profile in switched patients was similar across the velaα dose range (15-60 U/kg). Fifty-four (26.3%) switched patients have received ≥1 home velaα infusion.

Adverse events (AEs) during the first 3 in-clinic infusions		
	Naïve	Switched
Description	N = 6 n (%)	N = 205 n (%)
Experienced ≥1 AE	2 (33.3)	51 (24.9)
Experienced ≥1 possibly/probably drug-related AE	1 (16.7)	25 (12.2)
Experienced ≥1 infusion-related AE	1 (16.7)	18 (8.8)
Experienced ≥1 severe or life-threatening AE	0	4* (2.0)
Experienced ≥1 serious AE	0	1† (0.5)
Discontinued due to an AE	0	1‡ (0.5)
Deaths	0	0
*3 severe AEs were considered drug-related (2 patients with fatigue; 1 patient with pain in the extremities) †Severe cerebrovascular accident (considered unrelated to treatment) ‡Discontinued due to a grade 2 infusion-related AE (nausea)		

Conclusion: In this clinically heterogeneous GD1 patient population, velaα was generally well-tolerated during the first 3 in-clinic infusions. This experience suggests early transition to home therapy with velaα is a treatment option based upon individual patients' responses and recommendations of their treating physicians.

P13.15

Clinical and genetic testing of further three patients with GSD I from Hungary

***G. Miltenberger-Miltenyi**[1,2], S. Vale Pereira[2], J. Bókay[3], L. Balogh[3], G. Fekete[4], L. Szőnyi[3];*
[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, [2]Laboratório de Diagnóstico de Medicina Molecular (GenoMed), IMM, Universidade de Lisboa, Lisbon, Portugal, [3]1st Department of Pediatrics, Semmelweis University, Budapest, Hungary, [4]2nd Department of Pediatrics, Semmelweis University, Budapest, Hungary.

Introduction: Glycogen storage disease type I (GSD I) comprises a group of rare, autosomal recessively inherited disorders with impaired glucose homeostasis due to deficiency of glucose-6-phosphatase activity. The most common form of GSD I, GSD Ia, caused by mutations in the G6PC gene leads to decreased or absent enzyme activity causing fasting hypoglycaemia, hepatomegaly, growth retardation, fasting lactic acidosis, hyperlipidaemia, and hyperuricaemia. The second most common type, GSD Ib, is caused by mutations in the G6PT1 gene and shows usually neutropenia and recurrent infections. In a previous study we reported phenotypic variability in 12 Hungarian GSD I patients. In this study we studied further three Hungarian children with GSD I.

Methods: Clinical diagnosis of all three children was GDS Ia. Liver biopsies were performed in all three cases. Genetic screening was carried out by PCR and sequencing of the G6PC and the G6PT1 genes.

Results: All children were clinically diagnosed as GSD Ia. In two children we found three mutations in the G6PC gene, of which one

is novel. In the third child we found a homozygous mutation in the G6PT1 gene.
Conclusions: Our results confirm the phenotypic variability of GSD I and point out the importance of genetic screening the G6PT1 gene in GSD Ia cases where no mutation in the G6PC was detected. Moreover, genetic testing might substitute liver biopsy. The novel mutation together with the other mutations found in the Hungarian GSD I patients can contribute to genotype-phenotype association studies.

P13.16
Egyptian glycogen storage disease type III - identification of six novel AGL mutations

E. M. Fateen[1], *T. Podskarbi*[2], *Y. S. Shin*[2], *M. Okubo*[3];
[1]*National Research Centre, Cairo, Egypt,* [2]*Molecular Genetics and Metabolism Laboratory, Munich, Germany,* [3]*Department of Endocrinology and Metabolism, Tokyo, Japan.*

Background: Glycogen storage disease type III (GSD III) is caused by mutations in AGL which encodes for a single protein with two enzyme activities: oligo-1,4-1, 4-glucantransferase (transferase) and amylo-1,6-glucosidase. Activity of both enzymes is lost in most patients with GSD III, but in the very rare subtype IIId, transferase activity is deficient. Since the spectrum of AGL mutations is dependent on the ethnic group, we investigated the clinical and molecular characteristics in Egyptian patients with GSD III.
Methods: Clinical features were examined in five Egyptian patients. AGL was sequenced and AGL haplotypes were determined.
Results: Six novel AGL mutations were identified: a large deletion (c.3481-3588q1417del1525 bp), two insertions (c.1389insG and c.2368insA), two small deletions (c.2223-2224delGT and c.4041delT), and a missense mutation (p.L620P). p.L620P was found in a patient with IIId. Each mutation was located on a different AGL haplotype.
Conclusions: Our results suggest that there is allelic and phenotypic heterogeneity of GSD III in Egypt. This is the second description of a large deletion in AGL. p.L620P is the second mutation found in GSD IIId. Clin Chem Lab Med 2009;47:1233-8.

P13.17
The novel A175D mutation in SLC40A1 gene causes Ferroportin Disease in an Italian family

P. Fici[1], *E. Marasco*[1], *C. Fazio*[1], *A. Aquilano*[1], *D. Bastia*[1], *M. Cenci*[2], *F. Azzaroli*[3], *M. Seri*[2], *V. Mantovani*[1,2];
[1]*Center for Applied Biomedical Research (CRBA) S.Orsola-Malpighi Hospital, Bologna, Italy,* [2]*Unit of Medical Genetics S.Orsola-Malpighi Hospital, Bologna, Italy,* [3]*Unit of Gastroenterology S.Orsola-Malpighi Hospital, Bologna, Italy.*

Background. Type 4 haemocromatosis is a rare disorder of iron homeostasis, characterized by intracellular iron overload, hyperferritinemia and various levels of transferrin saturation, associated to mutations in ferroportin gene (SLC40A1), the sole known iron exporter in mammals. Loss of function mutations cause ferroportin disease (FD) (type 4a), whereas gain of function mutations cause a haemocromatosis clinically indistinguishable from that due to HFE gene (type 4b).
Aims and Methods. Aim of this study was to investigate the SLC40A1 gene in 86 patients with iron overload, in whom the mutation screening of HFE gene were negative and other primary causes of iron overload were excluded. All exons and 5'UTR region of SLC40A1 gene were analyzed by dHPLC and DNA sequencing. Phylogenetic analysis, prediction analysis (Polyphen) and homology modeling study (Swiss Prot) were performed for the novel detected variants.
Results and Conclusions. We detected the novel heterozygous missense variant c.524C>A (p.A175D) in three subjects of one Italian family. The mutation co-segregated with the affected family members and it was absent in 322 normal chromosomes. Interspecies comparison of ferroportin protein sequence showed that alanine 175 is strongly conserved. Software prediction and molecular modeling analysis indicate that its substitution with the negative charged aspartic acid 175 could modify the channel charge distribution, impairing the iron outing. This results indicate that the A175D is a novel loss of function mutation in SLC40A1 gene associated with ferroportin disease. A functional study for investigating in vitro the mutated iron exporter efficiency is underway.

P13.18
Hereditary Hemochromatosis in Russian children

N. Averiyanova[1], *S. Polykova*[1], *N. Jourkova*[1], *O. Kondakova*[1], *A. Asanov*[1,2], *V. Pinelis*[1];
[1]*Scientific Center for Children's Health, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

Hereditary Hemochromatosis type 1 (HH-1) is an inherited disorder of iron metabolism that results of mutations in the HFE gene. The most common mutations in HFE gene are C282Y, H63D and S65C. Since allele and genotype frequencies of these three variants of the HFE gene vary in different population, the determination of their prevalence in Russian children is important because genetic diagnostic in early stage can help to prevent the development of serious complications in these patients. There are two groups of children: 63 patients with biochemical signs of iron overload (BSIO, iron level was more 23,6 mkmol/l and transferrin saturation higher 40%) and 43 patients with somatic diseases without iron overload. All samples of DNA were genotyped by PCR followed by RFLP analysis. The H63D homozygote was identified in 14.2%, compound heterozygotes H63D/C282Y and H63D/S65C in 4.8% and 3.2% of patients with BSIO. The frequency of H63D heterozygote was in 3.5 times higher, than in control group (P=0,0004). We did not find patients with homozygote of mutations C282Y and S65C. However the frequencies of heterozygote mutations of C282Y and S65C in patients with BSIO were higher than in control group. Thus our data have shown that the main genotypes were homozygote H63D/H63D and compound heterozygotes H63D/C282Y and H63D/S65C in children with syndrome of iron overload. Taking in account that biochemical signs of iron overload syndrome could be observed in children with different somatic diseases therefore molecular-genetic study is necessary to confirm HH-1.

P13.19
Polymorphisms of interleukin-8 (rs2227543, rs4073) and -18 (rs1946518, rs187238) genes and diabetic retinopathy

I. Cilenšek[1], *A. Hercegovac*[2], *R. Terzić*[2], *M. Globočnik Petrovič*[3], *D. Petrovič*[1];
[1]*Institute of Histology and Embryology, Medical faculty, Ljubljana, Slovenia,* [2]*Department of Biology and Human Genetics, Tuzla, Bosnia and Herzegovina,* [3]*Eye Clinic, University Medical Centre Ljubljana, Ljubljana, Slovenia.*

Diabetic retinopathy (DR) is caused by alterations of the retinal microvasculature leading to the breakdown of the blood-retina barrier and pathological angiogenesis. In DR and other angiogenesis-associated diseases, increased levels of cytokines, inflammatory cells, growth factors, and angiogenic factors are present. DR is one of the primary causes of visual loss worldwide.We evaluated possible roles of interleukin-8 gene polymorphisms (1633T/C-rs2227543, 251A/T-rs4073) and interleukin-18 gene polymorphisms (-607C/A-rs1946518, -137G/C-rs187238) in the development of DR in Caucasians with type 2 diabetes. 271 patients with DR and 113 without DR were enrolled in this cross-sectional study. We did not observe an association between either interleukin-8 gene polymorphisms (rs2227543, rs4073) or interleukin-18 gene polymorphisms(rs1946518, rs187238) and DR in Caucasians with type 2 diabetes. We did not find statistically significant differences in interleukin-8 serum levels between diabetics with the TT and AA genotype and those with other genotypes. The interleukin-18 serum levels between diabetics with the CC genotype of the rs1946518 polymorphism and those with other genotypes (AA, AC) were not significantly different. Moreover, we did not observe a statistically significant effect of the tested polymorphisms of either interleukin-8 or interleukin-18 genes on serum levels in diabetics. In conclusion, our study indicates that the examined polymorphisms of interleukin-8 (rs2227543, rs4073) and interleukin-18 (rs1946518, rs187238) genes are not genetic risk factors for diabetic retinopathy. Therefore, they may not be used as genetic markers for diabetic retinopathy in Caucasians with type 2 diabetes.

P13.20
Lesch-Nyhan syndrome in Russian patients

E. Y. Zakharova, *G. E. Rudenskaya, L. A. Bessonova;*
Medical Genetics Research Centre, Moscow, Russian Federation.

Lesch-Nyhan syndrome (LNS) is an X-linked error of purine metabolism: hypoxanthine-guanine phosphoribosiltransferase (HPRT) deficiency produced by numerous *HPRT1* gene mutations.

The disease is associated with uric acid overproduction leading to early gout with renal and/or articular symptoms and neurological manifestations depending on the degree of enzymatic deficiency. In total HPRT absence classic LNS with severe movement disorders and self-injurious behavior develops. Partial HPRT deficiency, or Kelly-Seegmiller syndrome (KSS) produces phenotypes with less severe or no CNS involvement. While somatic symptoms are treated with allopurinol, there is no treatment for neurological symptoms. Mutations *de novo* make up 30 per cent of cases, most of patient's mothers are heterozygous carriers. Enzymatic and molecular diagnostics are in current use the latter being more reliable for carrier and prenatal testing. First Russian DNA-confirmed cases, three SLN and one KSS, are presented. In SLN patients age 3, 5 and 8 years three novel *HPRT1* mutations, Gly179Arg, c.606+1insT and IVS1+5G-A, were detected. Mutation Gly15Ser found in a 14-year-old boy with somatic KSS was described earlier with the same phenotype. All mothers and two patients' sisters proved to be carriers; in one family prenatal DNA testing was performed. Despite typical presentation, the diagnosis in all patients was significantly delayed, SLN was considered cerebral palsy and KSS was regarded as juvenile arthritis. That is, the disease is underestimated in practice. All boys with severe motor delay and hyperkinesias, even without self-injurious behavior, should be screened for hyperuricemia. Juvenile gout in males also needs testing for HPRT deficiency.

P13.21
Unravelling the leukodystrophies: clinical, biochemical and molecular aspects of sixty Brazilian patients with white matter abnormalities

*C. M. Lourenco[1], C. Funayama[1], M. Turcato[1], C. Sobreira[1], G. Simao[1], A. Santos[1], A. Pessoa[2], A. Weinmann[3], L. Giuliani[3], M. Wajner[4], R. Giugliani[4], **W. Marques Jr**[1];*

[1]University of Sao Paulo, Ribeirao Preto, Brazil, [2]Albert Sabin Hospital, Fortaleza, Brazil, [3]Federal University of Mato Grosso do Sul, Mato Grosso do Sul, Brazil, [4]Medical Genetics Service, Clinics Hospital of Porto Alegre, Federal University of Rio Grande do Sul, Porto Alegre, Brazil.

INTRODUCTION Leukodystrophies are a group of rare, heterogenous genetic diseases, which affect myelin, the major constituent of brain and spinal cord white matter.

AIMS Describe the clinical findings of sixty patients diagnosed with a genetic disorder of cerebral white matter and the approaches for the diagnosis.

METHODS/PATIENTS All the patients were evaluated in the neurogenetics clinics by geneticists and neurologists. Clinical anamnesis, physical exam, neuroimaging studies (CT scan and brain MRI with spectroscopy), ophtalmological and auditory evaluations, neurophysiological studies (EEG, ERG, BAER and EMG/NCV), hormone and biochemical tests, muscle biopsy with respiratory chain mitochondrial analysis, screening for inborn errors of metabolism (lysosomal enzymatic studies, peroxisomal and sterol panels, cholestanol dosage, organic acids, sulfatides and aminoacids chromatography, GAGs analysis) and, when indicated, nerve/skin biopsy for EM studies, karyotype and molecular tests were performed in the course the of investigation.

RESULTS Diagnoses in our patient population are summarized in Table 1

Disease group	Specific diagnoses (n)
Inborn errors of metabolism	X-linked adrenoleukodystrophy (4), MLD (3), Krabbe disease (2), infantile Refsum disease (1), α-methylacyl-CoA racemase deficiency (1), Niemann-Pick disease type C (4), Aicardi-Goutières syndrome (1), Canavan disease (1), neuronal ceroid lipofuscinosis (2), holocarboxylase synthetase deficiency (1), cerebrotendinous xanthomatosis (1).
Hypomyelination disorders	VWM disease (7; ovarioleukodystrophy, 1), Van der Knaap disease (1), 4H syndrome (1)
Mitochondrial disorders	MNGEopathy (1), Leigh syndrome (2).
Other disorders	Cockayne syndrome (1), leukoencephalopathy with brainstem and spinal cord involvment and lactate elevation (1), ARSAL syndrome (1), 18q deletion syndrome (1)

CONCLUSIONS About 50% of patients with white matter abnormalities remains without diagnosis even in a reference center after an exhausting investigation, therefore a specific protocol for studying and categorizing these patients is crucial not only for an academic or scientific purpose but it is mandatory for any clinician who wants to offer for such patients the correct therapeutics when it is available.

P13.22
Against All Odds: Treating Niemann-Pick type C in Brazil

C. M. Lourenco[1], *V. Van der Linden[2], E. Ribeiro[3], R. Boy[4], M. Santos[5], W. Marques Jr[1];*

[1]University of Sao Paulo, Ribeirao Preto, Brazil, [2]Hospital Barão de Lucena, Recife, Brazil, [3]Albert Einstein Hospital, Fortaleza,, Brazil, [4]State University of Rio de Janeiro, Rio de Janeiro, Brazil, [5]Pequeno Principe Hospital, Curitiba, Brazil.

BACKGROUND: Niemann-Pick type C disease (NPC) is a rentless neurodenerative disorder characterized by a defect in cholesterol esterification causing lipid storage; Substrate Reduction Therapy (SRT) has been proposed as a treatment for NPC and other neurolipidoses based on the effects of iminosugars in the brain. OBJECTIVE: To report the follow-up of a cohort of Brazilian NPC patients treated with SRT for a period of 3 years

MATERIAL/METHODS: 28 patients with clinical, biochemical and/or molecular diagnosis of NPC were evaluated with a clinical protocol/ physical examination and complementary exams (abdominal ultrasound, brain MRI,EEG,NCV/EMG) during 3 years of treatment with the iminosugar N-butyldeoxynojirimycin (NB-DNJ)

RESULTS: All patients but two had started on NB-DNJ after the onset of the neurological symptons. Most of the patients have the classical childhood presentation of NPC disease, but there were 4 patients with perinatal presentation. Stabilization of mental deterioration was seen in 18 patients with neurological symptons - although in the remaining 8 patients NB-DNJ appeared to slow the neurological progression of the disease, further neurological deterioration could be seen. Electrophysiological studies did not demonstrate any peripheral neuropathy. NB-DNJ was only discontinued in two patients for different reasons (worsening of tremor and difficulty to manage the diarrhea episodes, respectively).

CONCLUSIONS: SRT seems to be a reasonable and safe approach to treat NPC patients. Nevertheless, there are patients that seem to have a poor response, regardless of the age of starting the treatment, so it is necessary to develop better biomarkers to follow treatment responses in NPC patients.

P13.23
Analysis of RNase P in MHBD deficiency

A. J. Deutschmann[1], *K. Rauschenberger[2], P. Traunfellner[1], H. Steinbeisser[2], A. Amberger[1], J. Zschocke[1];*

[1]Division of Human Genetics, Innsbruck, Austria, [2]Institute of Human Genetics, Heidelberg, Germany.

Loss of function of the mitochondrial enzyme 17β-hydroxysteroid dehydrogenase type 10 (HSD10, MHBD) causes an organic aciduria with a neurodegenerative course and evidence of mitochondrial dysfunction. Several mutations in the *HSD17B10* gene have been identified. Interestingly, disease severity is not correlated to the dehydrogenase activity. Recently HSD10 was found to be part of the ribonuclease P (RNase P) protein complex in mitochondria. RNase P is an endonuclease consisting of three proteins (MRPP1, HSD10, MRPP3) and is responsible for the 5`-maturation of precursor transfer RNAs (pre-tRNAs) required for mitochondrial protein translation.

We now analyzed whether HSD10 mutations found in patients interfere with mtRNase P assembly or function. Quantitative RT-PCR analysis of different pre-tRNAs sequences in HSD10 knock-down cells caused accumulation of tRNA precursors. Western blot analyses of the three mtRNase P subunits in protein extracts from patient fibroblasts as well as HSD10 knock-down HEK and HeLa cells compared to control cells showed markedly reduced expression of both HSD10 and MRPP1. Expression of MRPP3 was not affected. On RNA level MRPP1 expression levels were comparable to controls, indicating that HSD10 mutations cause reduced MRPP1 protein stability. Surprisingly, pre-tRNA levels in patients` fibroblasts did not differ from control cells.

Taken together our results indicate that HSD10 mutations found in patients interfere with RNase P production, but this is not reflected in impaired mitochondrial tRNA processing in cultivated fibroblasts. It is possible that additional factors contribute to mitochondrial dysfunction in HSD10 (MHBD) deficiency.

P13.24
An APEX-based genotyping microarray for the screening of mutations in the LDLR gene

R. Taslerová[1], *L. Kuntová*[1], *L. Tichý*[1], *P. Zapletalová*[1], *L. Kopečková*[1], *L. Dušková*[1], *T. Freiberger*[2], *L. Fajkusová*[1];

[1]*University Hospital Brno, Centre of Molecular Biology and Gene Therapy, Brno, Czech Republic,* [2]*Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic.*

Familial Hypercholesterolemia (FH) is an autosomal dominant inborn disease of lipid metabolism resulting in accelerated atherosclerosis and premature coronary heart disease. The early identification and treatment of FH patients is extremely important. FH is associated predominantly with mutations in the genes encoding the low-density lipoprotein receptor (LDLR) and its ligand apolipoprotein B (*APOB*). So far, more than 1000 sequence variants of the LDLR gene have been described. However, only one *APOB* mutation is prevalent in Europe.

Owing to time consuming and expensive classical DNA analysis of the whole LDLR gene (DNA sequencing), we have proposed a new diagnostic tool, an APEX (Arrayed Primer EXtension)-based genotyping DNA microarray called FH chip. The FH chip enables detection of 167 mutations in the LDLR gene and 1 mutation in the APOB gene simultaneously containing point mutations and small DNA rearrangements detected in Czech FH patients and other European and Asian FH populations.

To date, more than 300 FH suspected patients were analysed by using FH chip. In approximately 25 % of all cases a mutation was found, which corresponds to results obtained by DNA sequencing of the LDLR gene.

The FH chip is a rapid, reproducible, specific and cost-effective tool for genotyping and in combination with MLPA (Multiple Ligation-dependent Probe Amplification) represents a reliable molecular genetic protocol for the large-scale screening of FH mutations in the Czech population.

This work was supported by grants MSMT 2B08060 and LC06023.

P13.25
Exome sequencing, an efficient diagnostic tool for mitochondrial disorders

H. Prokisch[1,2], *T. Haack*[1], *K. Danhauser*[1], *B. Haberberger*[1], *S. Eck*[2], *P. Freisinger*[3];

[1]*Technical University of Munich, Institute of Human Genetics, München, Germany,* [2]*Helmholtz Zentrum München, Institute of Human Genetics, Munich, Germany,* [3]*Technical University of Munich,, München, Germany.*

Faulty energy supply due to defective oxidative phosphorylation is the biochemical signature of mitochondrial disorders a genetically heterogenous group of rare, severe and highly invalidating human conditions. Due to it's clinical and genetic heterogeneity the diagnosis of mitochondriopathies is challenging and usually relies on biochemical analysis of biopsy material. Therefore, the majority of patients lack a molecular diagnosis and there is an urgent need for new strategies to close the gap between biochemical definition and molecular genetic correlate.

Next generation sequencing strategies are currently revolutionizing mutation detection both for the routine diagnosis of known mutations and the identification of new genes for rare disorders.

We demonstrate the efficacy of exome sequencing in combination with a cellular rescue-assay to elucidate the genetic basis in biochemically defined mitochondrial disorders. We report the identification of mutations in known disease genes and the discovery of causative mutations in ACAD9, a member of the acyl-CoA dehydrogenase (ACAD) protein family. The pathogenic role of novel variants was established by the correction of the biochemical defect on expression of the wild-type protein in patient's fibroblasts. ACAD9 screening of 120 patients identified two additional index cases.

Riboflavin, the vitamin precursor of the FAD moiety, which is the catalytic cofactor of ACADs, is known to foster their assembly and stability. Riboflavin treatment of mutant cell lines for 3 days resulted in a significant increase of complex I activity. Notably, recent publications and our own clinical observations support beneficial effects of a high dosage riboflavin regimen in ACAD9 patients.

Screening for mitochondrial deafness mutations in Hungarian patients: experience of 7 years

K. Komlósi[1], *A. Maász*[1], *K. Hadzsiev*[1], *P. Kisfali*[1], *J. Bene*[1], *K. Németh*[2], *G. Fekete*[2], *B. Melegh*[1];

[1]*Department of Medical Genetics, University of Pécs, Pécs, Hungary,* [2]*2nd Department of Pediatrics, Semmelweis University, Budapest, Hungary.*

Sensorineural hearing loss is the most common phenotype of mitochondrial diseases. Although in most cases interfamilial and intrafamilial phenotypic variation is observed, the clinical presentation can be specific for a certain mutation. The mutations reported so far affect mitochondrial tRNA and 12S rRNA genes. Our department performs mitochondrial DNA analysis since 1999 and mutation screening of nuclear and mitochondrial deafness-genes since 2003. Among 60 Hungarian patients affected by hearing loss we identified one common syndromic deafness mutation and two rare Ser^{UCN}-tRNA mutations in two families with non-syndromic hearing impairment. In a 12-year-old boy with seizures, bilateral hearing loss and ragged red fibers the A3243G heteroplasmic mutation was detected. In a 10 year-old boy and his family with bilateral hearing loss but no palmoplantar keratoderma we identified the A7445G Ser^{UCN}-tRNA mutation in homo- and heteroplasmic forms independently of the hearing status, delineating our case from other pedigrees. Haplotype analysis revealed a rare variant of the U4b haplogroup. In a 5-year old boy and three generations with bilateral hearing loss analysis revealed the T7510C Ser^{UCN}-tRNA mutation in homoplasmic form, reported only in 3 Caucasian families previously.

According to the incidence of mitochondrial diseases the role of mtDNA mutations in hearing loss is expected to be higher as verified. Among 60 patients we found two rare mutations both affecting the Ser^{UCN}-tRNA. Since in some families maternal inheritance is not clearly revealed, screening for mitochondrial mutations should always be considered in any family in which paternal transmission of the hearing impairment can be excluded.

P13.27**
Mutations in TTC19 cause mitochondrial complex III deficiency and neurological impairment in humans and flies.

D. Ghezzi[1], *P. Arzuffi*[1], *D. Diodato*[1], *C. Lamperti*[1], *M. Zordan*[2], *P. D'Adamo*[3], *R. Costa*[2], *M. Zeviani*[1];

[1]*The Foundation "Carlo Besta" Institute of Neurology, Milan, Italy,* [2]*Dept. of Biology, University of Padova, Padua, Italy,* [3]*IRCCS "Burlo Garofolo", University of Trieste, Trieste, Italy.*

Deficiencies of Mitochondrial Respiratory Chain complex III (cIII) are rare and can be caused by mutations in mtDNA-cytochrome b or in nuclear BCS1L genes; nevertheless most of cIII-defective cases remain genetically undefined.

We identified a homozygous non-sense mutation in the tetratricopeptide 19 (*TTC19*)-encoding gene in patients from two families, affected by progressive encephalopathy associated with profound cIII deficiency and accumulation of cIII-specific assembly intermediates. A second homozygous nonsense mutation was later found in a fourth unrelated patient. We experimentally demonstrated that the wild-type TTC19 protein is targeted to, and embedded in, the inner mitochondrial membrane. We then showed that TTC19 is part of two high-molecular weight complexes, one of which co-migrates with cIII. Physical interaction between TTC19 and cIII was then demonstrated by co-immunoprecipitation.

By in silico data mining, TTC19-like protein sequences were found throughout the Metazoan radiation. We investigated a *Drosophila melanogaster* knockout model for TTC19 that showed low fertility, strong bang sensitivity, severely reduced spontaneous motor activity, and impaired optomotor test, associated with cIII deficiency. Importantly, the cIII deficiency found in the KO adult flies was not present in mutant larvae, that developed normally into adult individuals, suggesting the existence of an alternative cIII assembly process in the developing stages of the fly.

In conclusion we provide evidence that TTC19 is a putative cIII

assembly factor in animals, and its absence determines severe neurological abnormalities in both human and flies.

P13.28
Novel mutation in *MPV17* gene in two sisters with hepatocerebral mitochondrial depletion syndrome.

D. Piekutowska-Abramczuk[1], *A. Węglewska-Jurkiewicz*[1], *M. Pronicki*[1], *K. Tońska*[2], *M. Kaliszewska*[2], *E. Ciara*[1], *D. Jurkiewicz*[1], *S. Łuczak*[1], *P. Kowalski*[1], *M. Borucka-Mankiewicz*[1], *A. Tańska*[1], *J. Trubicka*[1], *M. Pelc*[1], *J. Sykut-Cegielska*[1], *M. Krajewska-Walasek*[1], *E. Pronicka*[1];
[1]*Children's Memorial Health Institute, Warsaw, Poland,* [2]*Institute of Genetics and Biotechnology, University of Warsaw, Warsaw, Poland.*

Mitochondrial DNA depletion syndromes (MDSs) are autosomal recessive disorders characterized by tissue-specific reduction of mtDNA copy number leading to dysfunction of affected organs. They usually develop in infants and small children, and are clinically classified as myopathic, encephalomyopathic and hepatocerebral forms. The cases, where liver was the most or the only affected organ, usually die of severe liver failure before 1 year of life. At least 10 nuclear genes are known to be involved in the pathogenesis of particular MDS form.
Here we describe two sisters presented with progressive liver failure (cholestasis, jaundice, elevated liver enzymes, hepatomegaly, iron accumulation), encephalopathy (hypotonia, nystagmus, periodical stridor), poor feeding and lactic acidosis started from a very beginning after birth, died in 12th and 7th month of life.
Histological picture of liver biopsy of an older sister and autopsy in the younger one was characteristic for hepatocerebral MDS. Severe mtDNA depletion was detected in liver (89%) and muscle tissue (83%) of the younger girl, but was not so evident in muscle sample of the older one (60%, liver-NA).
Molecular analysis of selected genes associated with hepatocerebral MDS (*DGUOK, MPV17, POLG1*) revealed a novel mutation c.191C>G (p.Pro64Arg) on two *MPV17* alleles in both sisters confirming clinical diagnosis of hepatocerebral MDS. We consider this molecular variant to be pathogenic as it is located in conserved transmembrane domain of the protein.
It is the first report of mitochondrial depletion associated with *MPV17* dysfunction in Polish patients.
The study was supported by MNiSW grant No.2857/B/P01/2010/39 and CMHI No.S111/08

P13.29
The clinical variability of mitochondrial encephalomyopathy due to mutation in SCO2 gene

J. Pilch[1], *E. Jamroz*[1], *M. Kajor*[2], *D. Piekutowska-Abramczuk*[3], *P. Kowalski*[3];
[1]*Department of Child Neurology, Medical University of Silesia, Katowice, Poland,* [2]*Department of Anatomopathology, Medical University of Silesia, Katowice, Poland,* [3]*Department of Genetics, The Children's Memorial Health Institute,, Warsaw, Poland.*

The cytochrome C oxidase (COX) - complex IV of the respiratory chain consists of 13 protein subunits encoded by mitochondrial (3) and nuclear (10) DNA. The low activity of complex IV is caused not only by mutations in genes coding particular subunits but also by mutations in other genes of both mitochondrial and nuclear DNA. One of them is SCO2 gene. Mutations in this gene resulting in a defect in COX assembly, lead to a lethal infantile cardioencephalomyopathy. In the clinical picture dominate: muscular hypotonia leading with time to respiratory failure, limitation in extraocular movements, hypertrophic cardiomyopathy, lactic acidosis, decrease of COX activity in muscle biopsy.
The authors analyze clinical features in three infants with the mutation in SCO2 gene. As the first symptom all the children had muscular hypotonia with hypo/areflexia. Progress of clinical symptoms leading to respiratory insufficiency was observed. At one of the children in the following stage of the disease laryngeal stridor and symptoms of laryngomalacia were dominating. Cardiomyopathy appeared in the final stage of the disease suggesting mitochondrial myopathy. As for the other two children in the initial stage, both clinical symptoms and neurogenic pattern in EMG suggested spinal muscular atrophy. The following symptoms: hyperlactatemia, ptosis, and changes in MRI in one of them, suggested mitochondrial cytopathy without cardiomyopathy. For all the children mutation in SMN1 gene was excluded and next neurogenic atrophy in muscle biopsy was stated. Molecular study of SCO2 gene revealed the same homozygous p.1541G->A mutation and allowed the final diagnosis.

P13.30
A novel mitochondrial ATP6 frameshift mutation causing isolated complex V deficiency, ataxia and encephalomyopathy

A. Schaller[1], *D. Hahn*[2], *B. Schröter*[3], *B. Steiner*[3], *A. Häberli*[2], *J. M. Nuoffer*[2], *S. Gallati*[1];
[1]*Division of Human Genetics, Bern, Switzerland,* [2]*Institute for Clinical Chemistry, Bern, Switzerland,* [3]*Division of Neuropediatrics, Luzern, Switzerland.*

Background: The process of ATP production by mitochondrial ATPase (F1F0-ATP synthase, complex V) is a rotary process driven by an electrochemical proton gradient across the inner mitochondrial membrane. F0 that couples the proton gradient to ATP synthesis by F1, contains among others the subunits ATP6 and ATP8 that are encoded by mitochondrial DNA. Dysfunction of mitochondrial ATPase due to missense mutations in ATP6 is a frequent cause of severe mitochondrial encephalomyopathies.
Purpose: To identify the biochemical and molecular defect in a 4 year old girl with ataxia, microcephaly, developmental delay, mental retardation and elevated lactate suspected for a mitochondriopathy.
Methods: OXPHOS measurements were performed in patient's skeletal muscle and skin fibroblasts. BN-PAGE with subsequent immunoblotting was applied to study complex V assembly. Relevant parts of the mitochondrial genome were sequenced. The function of the respiratory chain was analysed by high resolution respirometry.
Results: We found an isolated reduced complex V activity in the patient's muscle tissue and fibroblasts. Immunoblotting after 1D BN-PAGE revealed in addition to the complex V holocomplex increasing amounts of mitochondrial ATPase subcomplexes. Oxygen consumption studies in patients fibroblasts demonstrated reduced ADP-stimulated respiration with pyruvate/malate or succinate as substrates. A heteroplasmic frameshift mutation was found in the ATP6 gene in patient's muscle tissue and blood. The mutation was not detectable in the mother's DNA extracted from blood and buccal cells.
Conclusion: We describe a novel pathogenic frameshift mutation in ATP6 associated with ataxia and encephalomyopathy resulting in incomplete assembly and reduced activity of the complex V holoenzyme.

P13.31
A family case of Leigh syndrome caused by a novel mutation in mtDNA

Y. Itkis[1], *P. Tsygankova*[1], *E. Zakharova*[1], *S. Mikhailova*[2], *G. Rudenskaya*[1];
[1]*Research Center for Medical Genetics, Moscow, Russian Federation,* [2]*Russian Clinical Child Hospital, Moscow, Russian Federation.*

A family case of Leigh syndrome with atypical manifestation caused by a novel mtDNA mutation is presented. The family consists of a mother and her two sons: 7-year-old and 4-year-old boys. The delivery of both brothers passed with no serious complications. Early motor development was normal. At age of 2.5 years, against the absolute health, in both children a restrain of right hand was noticed. Since that time the disease has an undulating course with progressive hyperkinesis, dystonia, dextral hemiparesis and dysarthria. Speech and mental development is delayed and worsenes. Expressive language is poor but receptive language is satisfactory. There were no seizures, vision or hearing problems. MRI of elder brother showed symmetric lesion of basal ganglia, but MRI of junior brother revealed the same damage only on the left side. MRI of mother showed similar damage on the right side, however she has only moderate sinistral hemiparesis since the age of 5 years, when a clumsy left hand was noticed.
Leigh disease was supposed. After *SURF1* gene mutations were excluded, a search of mtDNA mutations in blood cells was performed. A novel substitution m.3945 C>A in ND1 gene was detected in children in homopasmic state and in heteropasmic state in the mother.
A nucleotide replacement leads to substitution of aminoacid Ile to Met. In 212 control DNA samples the same substitution was not found. We proposed this substitution being pathogenic.
Thus, this case demonstrates the clinical variability of Leigh syndrome and proves the necessity of mtDNA sequencing.

P13.32
Clinical diagnosis and management of patients with mucopolysaccharidosis type II in Belarus

A. Kulpanovich, *I. Naumchik;*
National Medical Center «Mother and child», Minsk, Belarus.

Mucopolysaccharidosis type II (MPS II, Hunter syndrome) is a multisystem, multiorgan X-linked recessive disorder with a variable age of onset and variable rate of progression caused by deficiency of the lysosomal enzyme iduronate-2-sulphatase.

Aims: To summarize the clinical features of patients with MPS II in Belarus and to characterise the dynamic of the disease progression for the improvement of the clinical diagnosis.

Methods: We present the clinical observation of Hunter syndrome cases which were confirmed by laboratory biochemical methods. The clinical study includes the analysis of 139 phenotype features: facial abnormalities, neurologic, ophthalmologic, auditory, cardiovascular, respiratory, gastrointestinal, musculoskeletal symptoms etc.

Results: 18 patients (males) with MPS II from 14 unrelated families were studied. Median age at diagnosis was 5 years 1 month (range: 1-23,5 years), median age at onset of symptoms was 3 months (range: at birth â€“ 2,5 year). Interval from symptom onset to disease diagnosis was 4 years 1 month (range: 1,9â€“23,3 years). Four patients were died, two of them at the first decade and two another at second decade of life, median age of death was 12 years 1 month (range: 7â€“19,4 years). Basing on the analysis of facial abnormalities, neurologic, ophthalmologic, auditory, cardiovascular, respiratory, gastrointestinal, musculoskeletal symptoms we defined the most significant phenotypic markers and pattern of early clinical diagnostics and developed management of this disorder in Belarus.

P13.33
Prenatal cerebral cysts: presentation of the first prenatally diagnosed Molybdenum cofactor deficiency (MOCD)

S. N. van der Crabben[1], *F. C. Hofstede*[1], *L. S. de Vries*[1], *L. Pistorius*[1], *M. M. C. Wamelink*[2], *M. G. M. de Sain- van der Velden*[1], *P. G. J. Nikkels*[1], *K. D. Lichtenbelt*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*VU University Medical Center, Amsterdam, Netherlands.*

Molybdenum Cofactor Deficiency (MOCD) is a rare autosomal recessive metabolic disorder, caused by a disrupted function of sulfite oxidase (SO) that requires MOC for proper functioning.

Case 1

After a full term pregnancy of healthy Caucasian non-consanguineous parents, a girl was born by emergency caesarean section. Amniotic fluid contained thick meconium . Six hours postpartum she developed seizures. Care was withdrawn five days after birth because of severe brain damage. The microscopic abnormalities in the brain were compatible with severe peripartum asphyxia.

Case2

Ultrasound examination in the second pregnancy at 34 weeks of gestation showed bilateral cerebral cysts, ventriculomegaly and cerebellar hypoplasia. On suspicion of a SO deficiency or MOCD an amniocentesis was performed, showing high S-Sulfocysteine in the amniotic fluid. Delivery was induced and a macrosomic girl was born with full cheeks and deep-set eyes. MOCD was confirmed in urine, plasma and amniocytes postnatally. Beyond the neonatal period she developed seizures. Brain MRI showed progressive cerebral atrophy. She died at the age of 3 ½ months.

Sequence analysis of MOCS1 showed a homozygous splice site mutation (c.418+1 G>A) in both cases and heterozygosity in their parents.

Conclusion

These sibs display the variable expression of MOCD, ranging from severe asphyxia with neonatal convulsions to extensive cerebral deformations. Metabolic work-up, including measurement of S-sulfocysteine, should be performed in a fetus with prenatal brain cysts and newborns with unexplained asphyxia or brain damage to make a timely diagnosis and offer parents the opportunity of prenatal diagnosis or PGD in a future pregnancy.

P13.34
Clinical and molecular data of 24 patients with mucopolysaccharidosis type VI from Poland, Baltic States and Belarus

A. Jurecka[1,2], *L. Cimbalistiene*[3], *N. Gusina*[4], *K. Õunap*[5], *A. Rozdzynska*[6], *J. Marucha*[1], *V. Opoka-Winiarska*[7], *B. Czartoryska*[8], *A. Tylki-Szymanska*[1];
[1]*Department of Metabolic Diseases, Endocrinology and Diabetology, The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Molecular Biology, University of Gdansk, Gdansk, Poland,* [3]*Center for Medical Genetics, Vilnius University Hospital, Santariskiu Klinikos, Vilnius, Lithuania,* [4]*Center "Mother and Child", Minsk, Belarus,* [5]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [6]*Anthropometry Laboratory, The Children's Memorial Health Institute, Warsaw, Poland,* [7]*Department of Paediatric Pulmonology and Rheumatology, Medical University of Lublin, Lublin, Poland,* [8]*Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland.*

Background. Mucopolysaccharidosis type VI (MPS VI; Maroteaux-Lamy syndrome) is a rare autosomal recessive disorder caused by a deficiency of N-acetylgalactosamine-4-sulfatase (ARSB).

Aim. We aimed to analyze the natural history and the spectrum of mutations responsible for the disorder in Central and Eastern Europe.

Material and Methods. We studied 20 unrelated MPS VI families (4 Polish, 6 Lithuanian, 2 Estonian and 8 Belarussian), in whom clinical diagnosis was biochemically confirmed by demonstrating abnormal excretion of dermatan sulphate in urine and deficient activity of ARSB in plasma or fibroblasts.

Results. Clinical heterogeneity was observed among our patients and three major clinical phenotypes of the disease can be distinguished: severe (n = 6, 25%), attenuated (n = 9, 37.5%) and intermediate (n = 9, 37.5%). A remarkably large number of patients in our cohort showed an attenuated phenotype of the Maroteaux-Lamy syndrome, with regression later in life and prolonged survival. We identified 97.5% of the ARSB mutant alleles, 6 of them novel (c.31091insCCTGAAG+delATACT, Q88X, T92K, W57C, G167R and 161_166insT). We also report 5 previously described mutations (R152W, Y210C, Y266S, G302R, Q97X) as well as 2 non-pathogenic polymorphisms (A33V, S384N).

Conclusions. 1. Three major clinical phenotypes of the disease could be distinguished among our patients: severe, attenuated and intermediate. 2. When compared with data published in the literature, a larger number of patients in our study presented with an attenuated phenotype. 3. The relatively attenuated phenotype may be associated with the R152W mutation, which suggests a specific genotype-phenotype correlation.

P13.35
Molecular analysis of most common mutations in Phenylalanine hydroxylase gene in Iranian population

S. Zare karizi[1], *M. Hosseini Mazinani*[2];
[1]*Islamic Azad University Science and Research Campus, Tehran, Islamic Republic of Iran,* [2]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.*

Phenylketonuria (PKU) is the most prevalent disorder of amino acid metabolism. It is one of the most important preventable causes of mental retardation. Incidence of PKU in Iran has been estimated at 1 in 3627 births. The aim of this study is to assess the prevalence of PKU mutations in Iranian population. For this purpose, 150 unrelated patients with classic PKU (300 alleles) were screened for 10 mutations (IVS10-11g>a, R252W, R261X, R261Q, IVS11nt1, R408W, R408Q, L333F, 364delG and S67P) using polymerase chain reaction-restriction fragment length polymorphism. The predominant mutations in this population sample are IVS10-11g>a, R261Q, IVS11nt1 and R252W with the frequency 21.7%, 9%, 6.7% and 4.7% respectively. In addition, 6 other mutations have been identified at relatively low frequencies (R261X (4%), 364delG (3.7%), L333F (2%), R408W, R408Q and S67P (0.33%)).

These informations provide a good basis for direct DNA diagnosis of PKU in this population.

P13.36
Osteoclasts derived from patients with NF1 display in vitro tolerance to zoledronate

E. Heerva[1], *S. Peltonen*[2], *J. Peltonen*[1];
[1]*University of Turku, Turku, Finland,* [2]*Turku University Hospital, Department of Dermatology, Turku, Finland.*

Neurofibromatosis type 1 (NF1) is an autosomal dominant neuro-cutaneous-skeletal syndrome with an incidence of about 1/3000. Up to half of patients with NF1 have osteoporosis. Bisphosphonate drugs are used in osteoporosis, and the drug results in reduced small GTPase activity (including Ras) in osteoclasts, ultimately leading to slower bone remodeling. As NF1 is associated with hyperactive Ras, our aim was to evaluate in vitro effects of zoledronate in NF1 osteoclasts. Bone mineral density (BMD) of 16 patients with NF1 was measured and their osteoclast progenitors were isolated from peripheral blood. Control osteoclasts were obtained from 16 age- & sex-matched control persons.

Osteoclast progenitors were differentiated into osteoclasts in vitro, and were treated with 10E-6, 10E-7 and 10E-8 zoledronate. NF1-osteoclasts demonstrated a dose-dependent tolerance to zoledronate compared to control osteoclasts. Three patients were taking bisphosphonates at time of the study, but no differences in their cell culture results were found. The in vitro results may reflect to long-term effects of bisphosphonates in osteoporotic patients with NF1.

P13.37
Second tier testing by tandem mass spectrometry reduces the false positive rate in newborn screening (NBS)

G. Dimitar*, D. Matern, D. Oglesbee, K. Raymond, S. Tortorelli, P. Rinaldo; Biochemical Genetics Laboratory, Department of Laboratory Medicine and Pathology, Mayo Clinic School of Medicine, Mayo Clinic, Rochester, MN, United States.*

The primary goal of newborn screening is the early diagnosis of asymptomatic newborns affected with treatable conditions. The desire for the highest possible sensitivity has the innate risk of compromising specificity thus not only adding to the cost of management of the patients but also potentially increasing the risk of dysfunctional parent-child relationships. Approaches to reduce false positive results include: 1) utilization of as many as possible analytes and informative ratios; 2) Definition of clinically validated cutoff target ranges; 3) Implementation of second-tier tests (performed on the same specimen without further patient contact).

In recent years our laboratory has introduced in routine clinical practice the following second-tier tests: 1) profiling of methylcitric acid, methylmalonic acid and homocysteine for disorders of propionate and methionine metabolism; 2) succinylacetone for Tyrosinemia type I (now incorporated in the primary screening); 3) alloisoleucine for maple syrup urine disease; 4) steroid profiling for congenital adrenal hyperplasia (CAH); 5) Ethylmalonic acid, glutaric acid, 3-hydroxyglutaric acid and 2-hydroxyglutaric acid for Glutaric acidemia type I and Type II.

Utilization of these methods has impacted our practice in three ways: First, the false positive rate of screening by MS/MS has declined to 0.05 % with a positive predictive value of 64 % (2010 metrics); Second, problematic cut-off values have been optimized to reduce the risk of false negative results; Third, we are able to screen for new groups of disorders, not previously included in the screening panel such as remethylation disorders and different types of CAH.

P13.38
Niemann-Pick disease, type C: phenotypes and *NPC1* mutations in Russian patients

G. E. Rudenskaya[1], *T. M. Bukina*[1], *S. V. Mikhailova*[2], *E. Y. Zakharova*[1];
[1]*Medical Genetics Research Centre, Moscow, Russian Federation,* [2]*Russian Children's State Hospital, Moscow, Russian Federation.*

Niemann-Pick disease type C (NPC) is an autosomal recessive neurovisceral metabolic disease, one of sphingolipidoses. NPC is heterogeneous genetically and clinically. About 95% of cases are caused by numerous mutations of *NPC1* gene. Juvenile NPC manifesting in 4-14 years, usually before 10 years, makes up about 65% of cases; infantile, early childhood and adult forms are infrequent. Genotype-phenotype correlations exist. Along with DNA testing detection of non-etherified cholesterol in skin fibroblast lysosomes is in current use, but it is more complicated and less reliable for prenatal testing. Recently pathogenetic treatment with miglustat was proposed which makes early diagnostics vital. We diagnosed NPC in five unrelated patients, in one of them the diagnosis was verified biochemically, in four others by DNA testing (in two cases only one of allelic mutations was detected). Four children age 5-9 years, three of Russian and one of Azerbaijan ethnicity, had severe juvenile NPC with dementia and multiple neurologic signs in all and evident visceromegaly in two. Adult NPC in a 18-year-old Byelorussian girl presented mostly with dementia and psychiatric signs including acute psychosis while neurologic signs and splenomegaly were mild and transient which, along with normal MRI, hampered diagnostics. The genotypes were: p.Pro1007Ala/?, p.Ser954Leu/c.3614delC, p.Ser954Leu/? (in Azerbaijan patient) and p.Ser954Leu/c.326dupT (in adult NPC). Mutation p.Pro1007Ala is relatively common in European populations (along with p.Ile1061Thr); mutation p.Ser954Leu was described previously in German and Canadian patients in heterozygous or compound heterozygous state like in ours; mutations c.3614delC and c.326dupT are novel.

P13.39
Correlation between lipid profile / cardiovascular risk and type of mutation in Portuguese patients with familial hypercholesterolemia

A. C. Alves, A. M. Medeiros, ***M. Bourbon****;
Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal.*

Familial Hypercholesterolemia (FH) is characterized by high levels of LDLc in plasma, accelerated atherosclerosis and increased risk of premature coronary heart disease. FH results from mutations in three genes involved in lipid metabolism: LDLR, APOB, PCSK9. It is known that FH patients' phenotype is heterogeneous varying with different conditions.

The aim of this study was to analyse the biochemical profile of patients with genetically diagnosed FH in accordance with the mutations in different genes and the different types of mutations identified in the LDLR gene to identify whether there is a correlation between these variables in Portuguese patients.

Biochemical parameters, total cholesterol (TC), LDLc, HDLc, triglycerides, ApoB and ApoA of 325 patients with FH were analyzed by SPSS using ANOVA and Tukey.

Patients with mutations in the PCSK9 have LDLc and TC levels significantly higher than patients with mutations in the remaining two genes. There is no significant difference in these parameters between patients with mutations in LDLR and APOB genes, although all values are higher in patients with mutations in the LDLR. Patients with nonsense mutations in the LDLR gene present values of TC, LDL and ApoB statistically higher than in patients with missense mutations. The comparison between the other categories showed no significant changes in biochemical parameters. Patients with mutations in the PCSK9 have a more severe phenotype than patients with mutations in LDLR and APOB genes.

The type of mutation (in different genes or different mutations in LDLR) is important in determining cardiovascular risk in FH patients.

P13.40
Susceptibility genes of metabolic syndrome and its symptoms in children and adolescents with obesity

O. S. Glotov[1], *I. A. Makchrova*[2], *E. U. Marochkina*[1], *M. A. Glebova*[3], *A. S. Glotov*[1], *T. E. Ivashchenko*[1], *V. S. Baranov*[1];
[1]*Ott's Institute of Obstetrics and Gynecology RAMS, St-Petersburg, Russian Federation,* [2]*Saint-Petersburg State Pediatric Academy, St-Petersburg, Russian Federation,* [3]*Saint-Petersburg State University, St-Petersburg, Russian Federation.*

The prevalence of metabolic syndrome (MS) in developed countries, particularly in children, continuously grows. The aim of our study was to assess frequency of occurrence of polymorphisms of candidate genes TCF7L2, APOE, APOC3, LPL, REN, ADRB1, ADRB2, AGTR2, ACE, AGT, BKR2, NOS3, MTHFR in children with metabolic syndrome and control group.304 children were enrolled in this study: 160-main group (patients with obesity) and 144-control group in the age of 5-17 years (mean age was 12±0,18). MS was diagnosed in accordance with criteria, proposed by IDF in 2007. All polymorphisms were determined by PCR-RFLP and PCR-biochip methods. MS was diagnosed in 28

(17,5%) children in the age of 11-17 years. We observed an increase of TCF7L2 C/T and T/T genotype frequency (58,2% and 33,0%; p<0,001) in children with obesity, in comparison to healthy children. Significant differences were found in ADRB2 C/G and G/G genotype distribution (52,5% and 18,6%; p=0,003) between obese patients and control group. Children with obesity possessed significantly higher AGTR2 A/A genotype frequency (37,3%; p=0,019) in comparison to healthy children, besides higher A/A genotype frequency was observed among boys (69,0%; p<0,001). NOS3 T/T genotype was more frequent in girls than in boys (55,1%; p=0,031). ACE D/D genotype was more frequent in boys (57,0%; p<0,05). REN A/A and A/G genotypes were more frequent in boys (11,1 and 26,7%; p=0,021). During the selection of risk groups MS for children with obesity it is expedient to analyses for a patient polymorphism of genes of TCF7L2, ADRB2, AGTR2.

P13.41
Variation in DNA methylation influences metabolic syndrome-related phenotypes

M. A. Carless, *J. Neary, T. D. Dyer, D. L. Rainwater, A. G. Comuzzie, M. C. Mahaney, J. Blangero;*
Texas Biomedical Research Institute, San Antonio, TX, United States.

Metabolic syndrome is a complex disorder that is reaching pandemic proportions and is a strong predictor of diabetes and cardiovascular disease. Currently little is known about the importance of epigenetic variation in disease risk. We performed preliminary analysis quantifying relative DNA methylation in 190 Mexican Americans, within the San Antonio Family Heart Study, at 1,505 gene-centric CpG sites using an Illumina GoldenGate assay to identify epigenetic correlates with metabolic syndrome-related phenotypes. Linear models were used to identify a number of consistent correlations across multiple dimensions of metabolic syndrome for many CpG sites in highly relevant genes. For example, CpG methylation within *POMC* was correlated with fasting (p=0.031) and 2 hour (p=0.020) insulin, high density lipoprotein cholesterol (HDL-C; p=0.002) and triglycerides (p=0.009) as well as with NCEP:ATPIII defined metabolic syndrome (p=0.011). Deficiencies in *POMC* are strongly correlated with obesity and it is possible that methylation reflects another mechanism by which decreased expression influences body weight. Methylation of CpG sites in other candidate genes such as *RYK*, *RUNX1T1* and *TGFBR3* were also correlated with various metabolic syndrome phenotypes including fasting and 2 hour glucose, fasting and 2 hour insulin, body mass index, waist circumference, HDL-C, triglycerides and metabolic syndrome. Of interest is the fact that methylation at each of these sites was associated with a more detrimental profile of phenotypes. We are currently employing next-generation sequencing technologies and large-scale methylation arrays to look for genome-wide alterations in DNA methylation that might contribute to metabolic syndrome in a larger cohort of 1,200 individuals.

P13.42
Identification of a new thyrotropin receptor germline mutations in children with congenital hypothyroidism

E. Parshkova[1], *E. Khusnutdinova*[1], *O. Malievskiy*[2], *A. Kiyaev*[3], *M. Bermisheva*[1];
[1]*Institute of Biochemistry and Genetics, Russian Academy of Sciences., ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation,* [3]*Ural State Medical Academy, Regional Child Clinical Hospital, Ekaterinburg, Russian Federation.*

The TSH receptor gene (*TSHR*) encodes a transmembrane receptor , present on the surface of follicular cells which mediates the effects of TSH secreted by the anterior pituitary. Is critical for the development and function of the thyroid gland. It belongs to a subfamily of heptahelical G protein coupled receptors that have a common structure consisting of seven transmembrane segments, three extracellular and three intracellular loops, an extracellular amino terminal domain, and an intracytoplasmic carboxyl terminal tail.

Congenital hypothyroidism (CH) affects 1 in 3000 - 4000 newborns. In Bashkortostan the incidence is 1 in 3800 births. We examined the frequency of *TSHR* mutations among patients with permanent primary congenital hypothyroidism and in the general population of Republic Bashkortostan (Russia).

In total, 82 children aged 8 months to 17.2 years with CH diagnosed by neonatal screening were investigated. All patients had markedly elevated TSH levels concomitant with low peripheral thyroid hormone levels. A reduced thyroid volume or absence of the thyroid gland was determined by ultrasonography or/and scintigraphy. This constellation of clinical findings warranted the diagnosis of congenital hypothyroidism.

We found 4 patients with moderate to severe CH who had monoallelic mutations in TSHR. Observed mutations included one previously characterized mutation (R450H) and three uncharacterized mutations (L653F, L440I, and R531W).

The results demonstrate that mutations in the *TSHR* gene can be responsible for clinical manifestation of congenital hypothyroidism in a relatively small subset of children. So, additional investigations are needed for conformation of pathogenecy for this novel sequence variations.

P13.43
MicroRNA Expression Profiling in Patients with Tyrosinemia Type I

M. Ozen[1,2], *S. Sevli*[1], *E. Soyucen*[3], *E. Karaca*[1], *A. Yuksel*[4];

Tyrosinemia type I is a tyrosine catabolism disease causing tyrosine accumulation resulting from deficiency of the enzyme fumarylacetoacetate hydrolase (FAH), due to mutations in the *FAH* gene. It usually presents with severe liver involvement in young infants. MicroRNAs are small regulatory RNAs that function in post-transcriptional gene expression. miRNA deregulation was observed in the variety of pathologic conditions but their role in the metabolic diseases are not known yet.

We have studied 20 patients with clinical features of failure to thrive, hepatomegaly, liver failure, proximal renal tubular dysfunction, and tyrosinemia which are classical phenotypes of Tyrosinemia Type I. All patients showed either very low or deficient FAH enzyme activity. In order to identify possible miRNAs targeting *FAH* gene transcripts, microRNA expression profiling is performed in Agilent microarray platform representing 723 human and 76 human viral miRNAs in the fibroblasts of these patients. MicroRNA expressions were compared in the fibroblasts, leukocytes and sera of the Tyrosinemia patients. Computational algorithms are also used for prediction of putative mRNA-miRNA interactions. Among them, hsa-miR-768-3p, hsa-miR-513a-5p, and hsa-miR-525-5p are most probable microRNAs targeting the non-conserved sites on FAH mRNA. Verifications of alterations of the expression levels of the selected miRNAs are in progress.

Our data might suggest an active role for miRNAs in the tyrosine catabolism pathway and characterizing miRNA profile in the tyrosinemia patients might help to delineate microRNAs having distinctive role in the disease pathogenesis and also promising targets for future therapeutic studies.

P13.44
Analysis of *UDP 1A9* gene in Polish population using pyrosequencing

O. Zakerska[1,2], *M. Skrzypczak-Zielińska*[2], *B. Malengowska*[2,3], *A. Mikstacki*[4], *B. Tamowicz*[4], *M. Szalata*[2,3], *R. Słomski*[2,3];

Interindividual diversity in anaesthetic drug metabolism is a major cause of adverse effects, in most cases correlated with the genetic defect in the biotransformation pathway enzymes or receptors. One of the widely used anaesthetics is propofol. Interindividual variability in propofol pharmacokinetics and pharmacodynamics may influence on the anaesthetic function of this drug. Over 99% of this anaesthetic is biotransformated in the liver to several metabolites. The major pathway of metabolism is glucuronidation, catalysed by the microsomal enzyme UDP-glucuronosyltransferase, particularly the isozyme 1A9 (UGT1A9), which belong to the superfamily of enzymes

encoded by the UGT1A gene complex on chromosome 2q37. Several polymorphisms and mutations in this gene have been described. The three crucial of UGT1A9 alleles, UGT1A9 *3 (p.Met33Thr), *4 (p.Tyr242X), *5 (p.Asp256Asn) are associated with decreased or absence of enzyme activity, what determine increased risk of toxic effect. The aim of our study was to optimize a genotyping method to identify the most important in propofol toxicity UGT1A9 variants, and to analyze the frequency of them in Polish population. 100 Polish patients under propofol anaesthesia were examined. The strategy used to identify polymorphisms in the UGT1A9 gene was nested PCR amplification of exon 1 fragments including codon 33, 242 and 256, followed by pyrosequencing. We found a UGT1A9*3 allele frequency of 5%, however the UGT1A9*4 and *5 alleles was not identified, while in others European, Asian and Afro-American populations this variants have been detected.

P13.45
Dysregulation of epicardial, pericardial and subcutaneous adipokines in obesity and coronary artery disease

F. Atalar[1], *S. Gormez*[2], *B. Caynak*[3], *D. Gunay*[4], *B. Akpinar*[5], *U. Ozbek*[6], *A. Buyukdevrim*[7];

[1]*Istanbul University, Istanbul Medical Faculty, Child Health Institute, Growth-Development and Pediatric Endocrinology Department, Istanbul, Turkey,* [2]*Acibadem Hospital, Cardiology Dept, Istanbul, Turkey,* [3]*Istanbul Bilim University, Faculty of Medicine, Dept. of Cardiovascular Surgery and Florence Nightingale Hospital, Istanbul, Turkey,* [4]*Florence Nightingale Hospital, Biochemistry Laboratory, Istanbul, Turkey,* [5]*Istanbul Bilim University, Faculty of medicine, Dept of Cardiovascular Surgery and Florence Nightingale Hospital, Istanbul, Turkey,* [6]*Istanbul University, Experimental Medical Research Institute, Dept of Genetics, Istanbul, Turkey,* [7]*Emeritus, Istanbul University, Istanbul Medical School, Dept of Internal Medicine, Section of Diabetes, Istanbul, Turkey.*

Epicardial adipose tissue (EAT), pericardial adipose tissue (PAT) and subcutaneous adipose tissue (SAT) are mediators of obesity and may also be involved in the pathogenesis of coronary artery disease (CAD). We aimed to investigate the association of EAT, PAT; as intra-thoracic visceral fat and SAT with obesity and CAD by the gene and protein expression analysis of related adipokines.

In patients with CAD(n=32) and without CAD(control group) (n=27) subdivided by body mass index of <or=27 and >27kg/m^2, the gene expression of seventeen adipokines were studied by qRT-PCR and the serum level of the most abundant adipokines were analyzed by ELISA.

Gene expression analysis revealed the aberrant mRNA levels of angiotensin,FABP-4,CD68, leptin (LEP),leptin receptor(LEPR),VEGF,TNF-α,Il-6,Il-18,STAMP-2 in EAT,PAT and SAT of patients with CAD and patients with CAD and obesity while the expression of RBP-4 and adiponectin were higher in controls.11β-HSD1 expression was increased in patients with CAD and obesity in EAT,PAT and SAT. In PAT of patients with CAD and patients with CAD and obesity,the expression of angiotensin2 receptor,PAI-1 and C3 were higher than EAT and SAT.The expression of glucocoticoid receptor(GR) was higher in PAT and SAT of patients with CAD and obesity.Leptin serum level was significantly correlated with leptin gene expression in PAT (r=0.539;p=0.01),abdominal fat volume(r=0.484;p=0.03) and subcutaneous fat volume(r=0.605;p=0.005)of patients with CAD.A strong correlation was determined between 11β-HSD1 and LEPR,GR andCD68 genes in EAT,PAT and SAT(p<0.05,respectively).

EAT,PAT and SAT adipokines exhibit a dysregulated mRNA profile in both obesity and CAD.

P13.46
Altered expression of genes associated with atherosclerosis in peripheral blood of subjects with hypertension and subjects with type 2 diabetes mellitus.

N. A. Stoynev[1], *B. Rukova*[2], *I. Dimova*[2], *S. Hadjidekova*[2], *D. Nikolova*[2], *D. Toncheva*[2], *T. Tankova*[1];

[1]*Department of Diabetology, Clinical Center of Endocrinology, Medical University, Sofia, Bulgaria,* [2]*Department of Medical Genetics, Medical University, Sofia, Bulgaria.*

The aim was to identify atherosclerosis related genes specifically associated with type 2 diabetes and with hypertension.

The study includes 36 subjects (23 males and 13 females), divided in 4 age-matched groups: 9 subjects with type 2 diabetes mellitus and hypertension (group 1), 9 subjects with type 2 diabetes mellitus without hypertension (group 2), 9 subjects with hypertension without diabetes (group 3) and 9 healthy subjects as a control group.

Gene expression analysis was performed by Human Atherosclerosis RT^2 Profiler PCR Array. It includes 84 genes related to the formation of atherosclerotic plaques, 5 housekeeping genes and 3 control RNA fragments. Statistically significant up- or down-regulation is accepted as at least 4-fold difference in expression as compared to the control group.

Altered expression of 27 genes was observed in all studied groups as compared to the control group - 23 up-regulated, 4 down-regulated. It was accepted as non-specific.

In subjects with diabetes mellitus, 10 genes matched the criteria for increased expression: APOE, BAX, BCL2L1, LDLR, MMP3, MSR1, NFKB1, PDGFB, SPP1 and TGFB2. No genes with decreased expression were found.

In subjects with hypertension increased expression was found for FAS. Decreased expression in hypertensive subjects was observed for SERPINB2.

Conclusions: Subjects with hypertension and type 2 diabetes mellitus appear to present with non-specific changes in the expression of some atherosclerosis-associated genes in peripheral blood.

The presence of type 2 diabetes increases the expression of 10 genes. The presence of hypertension increases the expression of FAS and decreases the expression of SERPINB2.

P13.47
Enteropeptidase: a gene associated with a starvation human phenotype as a novel target for the treatment obesity and type II diabetes

I. Harosh, *S. Braud;*

ObeTherapy, Evry, France.

Many obesity related genes have been proposed as targets for the treatment of obesity. However, these obesity genes did not provide efficient drug therapy for obesity treatment. This is mainly due to the redundancy of the biochemical pathway involved in obesity and the lack of specificity of the gene targets. It is therefore a challenge to identify crucial gene(s) targets involved in energy metabolism associated with “lean or starvation phenotype”.

Congenital Enteropeptidase defficiency is an extremly rare pathology which answer to all these criteria. Enteropeptidase catalyzes the conversion of inactive trypsinogen into active trypsin *via* the cleavage of the acidic propeptide from trypsinogen

We have generated knock out transgenic mice for enteropeptidase which shows the same phenotype like in human. These data and in vivo preclinical data using per os small molecule for long term treatment (9 weeks) will be presented.

P13.48
Lack of association of a fatty acid amide hydrolase (FAAH) gene variant to weight loss in a one-year intervention for obese children and adolescents (Obeldicks)

N. Knoll[1], *A. Volckmar*[1], *A. Scherag*[2], *C. Pütter*[2], *M. Kleber*[3], *J. Hebebrand*[1], *A. Hinney*[1], *T. Reinehr*[3];

[1]*Department of Child and Adolescent Psychiatry and Psychotherapy, University of Duisburg-Essen, Essen, Germany,* [2]*Institute of Medical Informatics, Biometry and Epidemiology, University of Duisburg-Essen, Essen, Germany,* [3]*Vestische Hospital for Children and Adolescents, University of Witten/Herdecke, Datteln, Germany.*

Introduction: Recently, it was shown that obese carriers of the A allele of SNP rs324420 in FAAH lost more weight and improved associated phenotypes better than non-carriers during an intervention. We tried to replicate this finding in obese children and adolescents undergoing a one year lifestyle intervention (Obeldicks progam).

Subjects and methods: 453 overweight and obese children and adolescents (10.8 ± 2.6 years, BMI-SDS 2.4 ± 0.5; 55% girls) were genotyped for rs324420 (C/A) by restriction fragment length polymorphism (RFLP) analysis. Participants received a balanced diet, containing 55 En% carbohydrates, 30 En% fat and 15 En% proteins. Moreover, they took part in an exercise therapy once a week. Blood was

taken at baseline and after one year of intervention. Anthropometric (height, weight, BMI and BMI-SDS) and plasma parameters (total cholesterol, LDL-cholesterol, HDL-cholesterol, triacylglycerides, glucose, insulin and HOMA) as well as blood pressure were measured.
Results: Both BMI and BMI-SDS improved significantly among all subjects. The mean systolic blood pressure was also lowered and concentrations of HDL-cholesterol increased significantly. However, none of the measured parameters were associated with FAAH rs324420 genotypes.
Conclusion: We did not detect association of FAAH genotypes with weight reduction in overweight and obese children and adolescents. Hence, the previous finding in adults could not be confirmed. As the length (1 year to 3 month) and the set up (hypo caloric diet in adults versus physical activity plus balanced meals) of the interventions differed, these parameters might have influenced the different results.

P13.49
Maturity Onset Diabetes of the Young (MODY) in an Italian family associated to a mutation disrupting the HNF-1 binding site at P2 promoter of HNF4A gene

E. Marasco[1], *P. Fici*[1], *G. Storci*[1], *A. Di Rocco*[1], *G. Cavallari*[2], *M. Seri*[3], *M. Bonafè*[4], *V. Mantovani*[1,3];
[1]*Center for Applied Biomedical Research (CRBA), S.Orsola-Malpighi Hospital, Bologna, Italy,* [2]*Dep. General Surgery and Organ Transplants Bologna University, Bologna, Italy,* [3]*Unit of Medical Genetics, S.Orsola-Malpighi Hospital, Bologna, Italy,* [4]*Department of Experimental Pathology, Bologna University, Bologna, Italy.*

Backgroud: Maturity-onset diabetes of the young (MODY) is a heterogeneous group of disorders characterized by early onset of non-insulin-dependent diabetes and autosomal dominant inheritance. At least 9 MODY-causing genes have been identified.
Aims and Methods: we aimed to investigate the promoter P2 of HNF4A gene in 97 families with suspected MODY, that were negative for mutation in coding sequence of the most common MODY genes GCK, HNF1A and HNF4A. The proximal P2 promoter was screened from -365 using dHPLC and sequencing.
Results: the -169 C>T was detected in a female patient (diabetes at age 8) and her brother (diabetes at age 11), both displaying phenotype of HNF4A/MODY1. The variant was absent in 214 normal chromosomes. The substitution lies within a known binding site for HNF-1alpha in a conserved nucleotide position. Evidence for the pathogenicity of this mutation was obtained in transient plasmid transfection assays with mutated and wild-type P2 promoter. Luciferase activity assay revealed a markedly decreased activity of the mutant allele compared to the wild type in cancer cell lines and in freshly isolated rat primary pancreatic islets.
Conclusion: our results indicate that the -169C>T mutation at the HNF4A P2 promoter gene plays a causative role in MODY, due to an impairment of the HNF-1alpha-dependent activation of HNF-4alpha in adult beta-cell. This is the first time that the P2 promoter activity is investigated in freshly isolated primary rat pancreatic islets. Our finding highlights the need to include the P2 promoter in the molecular screening of HNF4A gene.

P13.50
Mutation screening of *PAH* gene in Slovak Pku patients using high-resolution melting

E. Polak[1], *J. Radvansky*[1,2], *L. Kadasi*[1,2];
[1]*Faculty of Natural Sciences, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics, Slovak Academy of Science, Bratislava, Slovakia.*

Phenylketonuria (PKU) is an autosomal recessive inherited disorder arising from a deficiency of phenylalanine hydroxylase (PAH), which catalyses the essential conversion of phenylalanine (Phe) to tyrosine (Tyr). In the majority of cases, PKU is caused by mutations in the *PAH* gene, and it presents with different phenotypes which are classified according to Phe tolerance. More than 500 mutations have been described world-wide and the PAH enzyme has been fully characterized. The incidence of the disease in the Slovak population had been estimated to be 1:10 000 newborn. In our previous studies complete mutation spectrum among Slovak PKU patients has been characterized. So far we are able to detect approximately 95% of mutant alleles with direct sequencing and MLPA analysis. In this work we present high-resolution melting (HRM) as an effective, sensitive and cheap method for mutation screening of the *PAH* gene. PCR conditions for all 13 exons of the gene were optimized for HRM analysis. Melt profiles were acquired on a 96 well LightScanner instrument (Idaho Technology) and melt data were normalized and temperature shifted. All of the known mutations within amplicons were detected by shifted melting curves, what indicates high sensitivity of the method. However, some polymorphisms in the ends of amplicons were not detected. Details of our work will be presented on poster.

P13.51
Mutational analysis of phenylalanine hydroxylase gene in Slovenian patients with phenylketonuria: five novel mutations

U. Groselj[1], *T. Hovnik*[1], *J. Kovac*[1], *M. Zerjav Tansek*[1], *T. Battelino*[1,2];
[1]*University Children's Hospital, Ljubljana, Slovenia,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.*

Phenylkatonuria (PKU, OMIM 261600) is an autosomal recessive metabolic disorder arising from the deficiency of hepatic enzyme phenylalanine hydroxylase (PAH). In the majority of all cases PKU is caused by missense mutations in the PAH gene, which maps to chromosome 12, region 12q23.2.
The average birth incidence of PKU in Slovenia is approximately one in 8000. Currently, Slovenian national PKU register contains around 130 patients, 107 of them were included into our mutational analysis of PAH gene. The entire coding region of the PAH gene spanning 13 exons was PCR amplified and analyzed with denaturing high-performance liquid chromatography (dHPLC). On all the identified PCR fragments we subsequently performed an automated sequencing analysis.
The cumulative mutation detection rate in this group of patients was 95%. We have identified 32 different disease-causing mutations, five of them novel: p.L15GfsX24, p.V45A, p.L62P, p.R157S and c.56_60delACAGG. Twelve patients were found to be homozygous (two for the p.R158Q mutation and the rest for the p.R408W), all the other patients were compound heterozygotes. The single most frequent mutation in Slovenian PKU population is p.R408W in exon 12 (34%), which is in concordance with previous European and regional studies of PAH gene. 30-40 patients are likely to be BH4 responsive.
dHPLC proved to be a fast and sensitive method for mutational screening of the PAH gene. In combination with sequencing method, it represents a reliable and cost-effective diagnostic tool for detection and identification of unknown molecular defects in patients with PKU.

P13.52
Mutation analysis of phenylketonuria (PKU) in south western of Iran

N. Ajami[1], *A. Foroughmand*[1], *S. Kazeminezhad*[1], *M. Aminzadeh*[2];
[1]*shahid chamran university, Ahvaz, Islamic Republic of Iran,* [2]*Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran.*

Introduction: Deficiency in hepatic phenylalanine hydroxylase (PAH) causes phenylketnouria that is an autosomal recessive and heterogeneous metabolic disorder. Molecular basis of this most prevalent disorder is frequent mutations in phenylalanine hydroxylase gene. PAH require tetrahydrobiopterin as a cofactor for conversion of phenylalanine to tyrosine. Loss of PAH activity results in accumulation of phenylalanine in tissues and biological fluids that cause the formation of secondary neurotoxic metabolites. To date more than 600 mutations in the *PAH* gene have been identified and submitted to the *PAH* and HGMD databases. The prevalence of phenylketonuria In Europe or among the general Caucasian populations is about 1 in 10,000. In Iran the incidence of PKU might be about 1.6 in 10,000.
Methods: This study enrolled 40 Iranian southwestern residents. DNA extraction from peripheral blood leukocytes performed by Diatom DNA prep 100 kit. Using manually designed primers, PCR amplification accomplished for the exons 6, 7, 10 and 11 of *PAH* gene. Then we used direct sequencing of amplified fragments for identification of mutations. Analysis of DNA sequences performed by Mutation Surveyor software.
Results: In this study, we observed eleven mutations, I224T, S231P, R176X, c.592_613del22, R243X, R252W, R261Q, Y356X, IVS10-11G>A, IVS11+1G>C and Q375R. The Q375R is a new mutation in exon 11. V245V, Q232Q and L385L were three detected silent mutations with high frequency.

Discussion: Khuzestan population comprises a heterogeneous ethnic group in southwestern of Iran. With mutation detection rate equal to 46.25%, 40% of patients were homozygous and 10% were heterozygous that indicate high consanguinity.

P13.53
Long-chain-3-hydroxyacil-CoA dehydrogenase deficiency - the most frequent fatty acid oxidation disorder in Latvia: 7 cases

***Z. Krumina**, Z. Daneberga, M. Kreile, R. Lugovska;*
Children's University Hospital, Riga, Latvia.

Background: Long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency is one of the defects of mitochondrial β-oxidation and the only one of all fatty acid disorders diagnosed in Latvia during the last 13 years.
Objectives: To characterize clinical, biochemical and molecular data in 7 patients with LCHAD deficiency, found by selective screening in Latvia.
Methods: Retrospective analysis of clinical and laboratory findings in our patients.
Results: Five patients presented during early infancy (2.5 months - 6.5 months) with vomiting, poor feeding, lethargy, hepatopathy and nonketotic hypoglycemia. Three of them developed coma and seizures. One patient presented at the age of 21 months with hypoglycemic coma and seizures, psychomotor retardation and one patient was diagnosed before clinical symptoms. Two patients were born preterm with severe intrauterine growth retardation. During metabolic crisis all patients had typical acylcarnitine profile, increased level of 3 - hydroxydicarboxylic acids in urine, elevated liver enzymes, moderate lactic acidemia and hyperammonemia. All patients had homozygous mutation 1528G>C in *HADHA* gene. Acute hepatopathy during prenancy was reported in three cases. After infancy progressive retinopathy occurred in three patients, two patients had episodes of severe muscle pain and rhabdomyolisis during intensive physical activities or illnesses.
One patient died at the age of 6.5 months before diagnosis was made, other died at the age of 10 years during acute gastroenterocolitis.
Conclusion: LCHAD deficiency is frequent fatty acid oxidation disorder in Latvian population. Newborn screening would be important for early detection of all patients.

P13.54
Neurodegeneration in Cobalamin A Deficiency

***R. Gavrilova**;*
Mayo Clinic, Rochester, MN, United States.

Cobalamin (Cbl) A deficiency is rare cause of Cbl-responsive methylmalonic academia. It results from defect in mitochondrial Cbl reductase, encoded by *MMAA*. Treatment with B12 reduces the amount of MMA. Liver or stem cell transplantation has been applied in some cases. Despite therapy patients suffer progressive neurodegenerative course resulting in significant disability. The metabolic defect underlying nerve degeneration is unknown but some authors propose synergistic toxic effect of methylcitrate, malonic acid, propionyl-CoA on respiratory chain and tricarboxylic acid cycle resulting in brain damage.
An 11year old boy born to consanguineous marriage developed normally until 3 years of age when he suffered a metabolic stroke during an intercurrent viral illness. Brain MRI showed bilateral stroke-like lesions in the globus pallidus. He was diagnosed with Cbl A deficiency based on elevated MMA responsive to vitamin B12 challenge and was found to have homozygous c.1034delT frameshift mutation in *MMAA*. Despite cyan-cbl carnitine and metronidazole therapies, protein restriction and stem cell transplant within 1.5 years after his acute presentation he lost ability to walk and his speech output decreased due to severe dystonia that started in left upper extremity but progressively generalized. Dystonia improved with deep brain stimulation at 11 years.
Standard treatment of Cbl-responsive MMA has improved survival but has not modified neurodevelopmental outcome. Stem cell transplantation did not alter disabling neurological deterioration in our patient but DBS improved dystonia. The mechanism underlying progressive brain damage is uncertain but new therapies targeting proposed secondary mitochondrial respiratory chain dysfunction and antioxidants should be investigated.

P13.55
Mutation in the *OTC* promoter may cause symptoms of ornithine carbamoyltransferase deficiency

***O. Luksan**[1], M. Jirsa[1], M. Hřebíček[2], L. Dvořáková[2];*
[1]IKEM, Institute for Clinical and Experimental Medicine, Praha, Czech Republic, [2]Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University in Prague, and General University Hospital in Prague, Praha, Czech Republic.

Ornithine carbamoyltransferase deficiency (OTCD; OMIM311250) is the most common inherited defect of the urea cycle. Mutation analysis of the coding regions of *OTC*, the enzyme catalyzing the synthesis of citrulline in the liver, fails in 20-25% of patients manifesting OTCD. In such cases, the disease may be caused by gross gene rearrangements or defects in regulatory regions of the gene.
In our study we examined the 5'UTR, identified and functionally characterized *OTC* regulatory elements and estimated the pathogenicity of a promoter variation c.-366A>G found in a female patient with mild symptoms of OTCD.
Three alternative transcription start sites located 95, 119 and 169 bp upstream the iniciation codon were determined within the *OTC* 5' UTR. The human *OTC* promoter and enhancer elements were predicted from the homology with rat and mouse and functional functionaly characterized using dual lucisferase reporter assay. Functional studies revealed a moderate transcriptional activity of the promoter in both liver and kidney derived cells. Significantly higher and liver specific *OTC* expression was observed when promoter interacted with the distal enhancer. The promoter variation c.-366A>G did not affect the function of the promoter alone but it disrupted the interaction of the promoter with the enhancer, which was observed as 50% decrease of the transcriptional activity.
Our data indicate that full transcriptional activity of human *OTC* promoter depends on an upstream enhancer. The promoter - enhancer interaction contribute to tissue specific expression of *OTC* in the liver and the disruption can lead to the manifestation of OTCD.

P13.56
'Full-blown' Lowe syndrome without congenital cataracts in a patient with an *OCRL* p.Gln199X mutation and a silent variant, p.Arg35Arg.

***M. Ludwig**[1], M. Refke[2], M. Draaken[2,3], S. Pasternack[2], R. C. Betz[2], H. Reutter[2,4];*
[1]Dept. of Clinical Biochemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany, [2]Institute of Human Genetics, University of Bonn, Bonn, Germany, [3]Department of Genomics, Life & Brain Center, Bonn, Germany, [4]Dept. of Neonatalogy, University of Bonn, Bonn, Germany.

The oculo-cerebrorenal syndrome of Lowe is an X-linked recessive disorder characterized by the triad of congenital cataracts, mental retardation and incomplete renal Fanconi syndrome. Additionally, various neurological signs may be present such as developmental delay, seizures, hypotonia, areflexia or behavioural disturbances. Patients show progressive growth retardation and may develop a debilitating arthropathy. Although phenotype might vary, congenital cataracts have been assumed the first and obligatory sign.
We report a 13 year old patient showing the complete phenotypic spectrum of Lowe syndrome who was not classified as having the disease due to the absence of any ocular involvement. *OCRL* gene analysis revealed a Gln199X (c.760T; according to ENST00000371113) mutation and a silent variant (c.G270A; p.Arg35Arg) in the patient. We suggested that the synonymous substitution might effect correct splicing, however an *in vitro* model revealed only normally spliced transcripts. Moreover, RNA obtained from the patients' EBV transformed lymphocytes showed presence of both transcripts due to alternative splicing of exon 18a.
Taken together, the silent variant provided no clue for the milder phenotype in the context of a classic Lowe mutation (p.Gln199X). This finding extends the phenotypic spectrum caused by *OCRL* mutations and illustrates that even in the absence of congenital cataracts Lowe syndrome has to be assumed, if all other features are present.

Mitochondrial complex I deficiency is the most common OXPHOS defect. Mutations have been detected in mitochondrial and nuclear genes, but many patients remain unresolved and new genes are likely involved. In a consanguineous family, patients presented since early childhood with easy fatigability, exercise intolerance and lactic acidosis in blood. In muscle, subsarcolemmal mitochondrial proliferation and a severe complex I deficiency were observed. Exercise intolerance and complex I activity improved by supplementation with a high dosage of riboflavin. Homozygosity mapping revealed a candidate region on chromosome three containing six mitochondria-related genes. Four genes were screened for mutations and a homozygous substitution was identified in ACAD9 (c.1594C>T), changing the highly conserved arginine-532 into tryptophan. This mutation was absent in 188 ethnically matched controls. Protein modelling suggested a functional effect due to loss of a stabilizing hydrogen bond in an α-helix and a local flexibility change. To test whether the ACAD9 mutation caused the complex I deficiency, we transduced fibroblasts of patients with wild type and mutant ACAD9. Wild type ACAD9, but not mutant ACAD9, restored complex I activity. An unrelated patient with the same phenotype was compound heterozygous for c.380G>A and c.1405C>T, changing arginine-127 into glutamine and arginine-469 into tryptophan respectively. These amino acids were highly conserved and the substitutions were not present in controls, making them very likely pathogenic. Our data support a new function for ACAD9 in complex I function, making this gene an important new candidate for patients with complex I deficiency, which could be improved by riboflavin treatment.

P13.58

The E670G SNP in the PCSK9 gene in polish population with acute myocardial infarction

A. Banaszewska[1], *M. Piechota*[1], *J. Dudziak*[2], *K. Ziemnicki*[1], *M. Slomczynski*[2], *R. Plewa*[1];

[1]*Department of Animal Physiology and Development, Adam Mickiewicz University, Poznan, Poland,* [2]*J. Strus Hospital, Department of Cardiology, Poznan, Poland.*

The SNP at E670G within exon 12 is one of the main genetic alteration determining plasma low density lipoprotein cholesterol (LDL-C) level in human.

The aim of the study was to determine the incidence of the E670G SNP polymorphism in PCSK9 in polish population with acute myocardial infarction and investigate the contributions of this genetic variant to differences in plasma levels of LDL-C.

The investigated group consisted of 72 individuals with a mean age of 62 years, and with a mean plasma LDL-C level of 137 mg/dl. For the determination of the frequency of the E670G polymorphism a genomic DNA was amplified by standard PCR with primers specific for 12 exon. Each product was sequenced on an CEQ 8000 (Beckman Coulter).

Analysis of exon 12 sequence shows homozygous AA genotype in 62 individuals and heterozygous AG in 10 subjects. Additionally, the G allele of the E670G SNP in the PCSK9 gene was present at an increased frequency in participating men in comparison to women. LDL-C level was non-significantly higher in those with the AG in comparison to the AA genotypes (mean 165 mg/dl and 133 mg/dl respectively, p=0,09).

Neverthelater identification of another PCSK9 gene variants affecting LDL receptors density on cell surface and LDL-C level could provide a wider insight into a pathogenesis of atherosclerosis.

P13.59

Molecular diagnostic in patients with hepatocerebral mitochondrial encephalomyopathies

P. Tsygankova[1], *E. Zakharova*[1], *S. Mikhailova*[2], *L. Kolpakchi*[2];

[1]*Research center for medical genetics, RAMS, Moscow, Russian Federation,* [2]*Russian children clinical hospital, Moscow, Russian Federation.*

We present the results of molecular genetic investigations in a group of 13 children with Alpers syndrome (A.S.) and mitochondrial hepatocerebral syndrome (MHS). We performed sequence analysis of POLG in patients with strong suggestion of AS. In one AS patient only one mutant allele revealed. Two infant patients with MHS phenotype also had mutations in POLG gene (in heterozygous state). Depletion of mtDNA was detected in blood only in patients with DGUOK and MPV17 genes mutations. Anatomopathological issue in the patient with POLG mutations (A467T/ G268A) showed necrosis lesions in basal ganglia and brain stem (typical for Leigh syndrome phenotype). Our data confirm that test for POLG gene mutations is very important in patients with mitochondrial hepatopathy and not only in AS phenotype. Complicating factors are search for a second mutant allele and helpless use of blood DNA for mtDNA depletion detection.

phenotypes and genotypes in patients with AS and MHS

phenotype	mutant gene	1st mutant allele	2nd mutant allele	mtDNA depletion in blood

Assessment of three various screening tests for easy detection/ exclusion of common SCO2 mutation among patients with cytochrome c oxidase deficiency

S. Łuczak[1], *D. Piekutowska-Abramczuk*[1], *M. Małkowska*[2], *J. Trubicka*[1], *E. Ciara*[1], *P. Kowalski*[1], *M. Borucka-Mankiewicz*[1], *D. Jurkiewicz*[1], *A. Tańska*[1], *M. Pelc*[1], *M. Krajewska-Walasek*[1], *E. Pronicka*[1];

[1]*The Children's Memorial Health Institute, Warsaw, Poland,* [2]*The Institute of Genetics and Biotechnology, University of Warsaw, Warsaw, Poland.*

SCO2 is one of the ancillary proteins necessary for correct assembling and functioning of cytochrome c oxidase (COX). It is involved in the transport and incorporation of the copper ions to the CuA enzymatic site on COXII subunit of the enzyme. Mutations in the *SCO2* gene (22q13) lead to serious damage of the protein resulting in severe COX deficiency observed mainly in muscles, heart and brain. The common substitution is g.1541G>A (p.E140K), which was identified at least on one allele in all so far reported patients.

The aim of this study was to optimize conditions to determine the best method for screening of g.1541G>A mutation in COX-deficient patients.

In the study were selected three molecular techniques; two - based

on Real Time equipment (TaqMan probes and HRM), and one - on gel electrophoresis (SSCP). In HRM method, melting curve analysis is used for identification of mutations. Genotyping with Taqman's probe enables identification of specific mutation. SSCP identifies changed samples by comparison their electrophoretic mobility to control samples in polyacrylamide gel.
Preliminary studies provided reliable results from all mentioned methods.
Advantages and disadvantages of every method will be evaluated, which will allow to choose the best of them.
Determination of the rapid genetic screening test for COX deficiency caused by mutations in the *SCO2* gene let confirm a final diagnosis and will enable establishment of treatment decisions in affected children.
The study was supported by the project no. N N407 115440.

P13.61
Spastic paraplegia due to CYP7B1 mutations (SPG5) : what can we learn about 27-hydroxycholesterol metabolism?

F. Mochel[1,2,3], *F. Lamari*[3,4], *D. Rinaldi*[3], *C. Goizet*[5,6], *V. Ratziu*[7], *A. Durr*[1,2];
[1]*INSERM UMR S975, Institut du Cerveau et de la Moelle, Hôpital de La Salpêtrière, Paris, France,* [2]*AP-HP, Département de Génétique, Hôpital de La Salpêtrière, Paris, France,* [3]*Unité Fonctionnelle Neurométabolique, Hôpital de La Salpêtrière, Paris, France,* [4]*AP-HP, Unité Fonctionnelle de Biochimie Métabolique, Hôpital de La Salpêtrière, Paris, France,* [5]*Département de Génétique Médical, CHU de Bordeaux, Hôpital Pellegrin, Bordeaux, France,* [6]*Université Victor Segalen Bordeaux 2, CHU de Bordeaux, Hôpital Pellegrin, Bordeaux, France,* [7]*AP-HP, Service d'Hépato-Gastroentérologie, Hôpital de La Salpêtrière, Paris, France.*

Hereditary spastic paraplegias (HSP) constitute a clinically and genetically heterogeneous group characterized by a progressive 'dying back' degeneration of the cortico-spinal tracts. Mutations in CYP7B1 were identified in SPG5 families presenting with a pure form of HSP (Tsaousidou et al, 2008; Goizet et al, 2009). CYP7B1 encodes the cytochrome P450 7α-hydroxylase implicated in cholesterol metabolism, and plays a role in the alternate/acidic pathway for primary bile acid production. Increased levels of oxysterols, 27- and 25-hydroxycholesterol were recently identified in the plasma of 4 SPG5 patients (Schüle et al, 2010). Besides the potential consequences on hepatobiliary functions of altered bile acids synthesis in SPG5, in vitro studies suggest that 27-hydroxycholesterol - an endogenous selective estrogen receptor modulator - may decrease bone mineral density, inhibit the cardiovascular protective effects of estrogens and increase oxidative stress in retinal pigment epithelial cells. Therefore, we investigated 9 SPG5 patients from 6 families in order (i) to confirm that plasma oxysterols can be used as biomarkers in HSP due to CYP7B1 mutations, and (ii) to explore the non-neurological manifestations that may result from the altered oxysterols metabolism in SPG5 patients - i.e. bone homeostasis, hepatobiliary and cardiovascular functions, retinal trophicity. Preliminary data suggest that the elevation of plasma 27-and 25-hydroxycholesterol in our SPG5 cohort is associated with systemic complications, and in particular reduced bone density. Better delineating the non-neurological manifestations that may occur in SPG5 should also shed light on the best therapeutic approaches aiming at lowering 27-hydroxycholesterol levels.

P13.62
Molecular characterization in Japanese patients with classical xanthinuria.

K. Ichida[1,2];
[1]*Department of Pathophysiology, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan,* [2]*Division of Kidney and Hypertension, Jikei University School of Medicine, Tokyo, Japan.*

Classical xanthinuria (OMIM #278300) is an inherited metabolic disorder caused by a deficiency of xanthine dehydrogenase (XDH), resulting in hypouricemia. Classical xanthinuria frequently presents with renal calculi and occasionally leads to renal failure. Classical xanthinuria is classified into two categories. Classical xanthinuria type I lacks only XDH activity by XDH gene mutations, while the type II results from dual deficiency of XDH and aldehyde oxidase due to mutations in the molybdenum cofactor sulfurase (MOCOS) gene. Classical xanthinuria is easily differentiated by means of the allopurinol loading test. As allopurinol is converted to oxypurinol by both XDH and aldehyde oxidase, oxypurinol is detected in urine and serum of subjects with classical xanthinuria type I upon administering allopurinol.
We studied fifteen Japanese hypouricemic subjects with classical xanthinuria from fourteen different families at Jikei University School of Medicine. We report the spectrum of mutations identified to data. Eleven subjects were xanthinuria type I, while three subjects were xanthinuria type II. We could not verify a causative mutation of XDH and MOCOS genes in one subject with xanthinuria. The percentage of xanthinuria type I in xanthinuria was 78.6 %. In xanthinuria type I, mutation C2567Del was identified most in eight alleles out of thirty alleles, while C682T, leading to R228Ter, was identified in five alleles out of thirty alleles. In xanthinuria type II, most frequent C1255T, leading to R419Ter, is identified in four alleles out of six alleles. Any mutations did not dominate in XDH mutations of xanthinuria type I.

J13.01
Glycogen-Storage Disease Type I b - Case Report

I. I. Kavecan, *J. Jovanovic Privrodski, M. Obrenovic, N. Konstantinidis, J. Tomic, D. Jojkic Pavkov;*
Institute for Children and Youth Health Care Vojvodina, Novi Sad, Serbia.

Glycogen Storage Disease type 1b due to glucose-6-phosphatase deficiency, is a type of glycogenosis due to glucose-6-phosphate deficiency. Glycogen-storage disease type Ib is autosomal recessive genetic trait caused by mutations at loci 11q23. The incidence was estimated at 1: 100,000.
This male patient was first-born child. This was controlled and non-complicated pregnancy. Parents are not consanguineous. The baby was born on term. Growth parameters were weight=3750 g; length= 54 cm, head circumference 34 cm. Apgar score was 8/9. The proband developed hypoglycemia and sepsis very soon after birth. He developed hepatomegaly and splenomegaly confirmed with ultrasound. His growth and development were delayed and he had repeated episodes of pyogenic infection.
Physical examination in the second year of life revealed growth retardation, microcephaly, rounded "doll's face" appearance, abnormal earlobes, divergent strabismus, gothic palate, long eyelashes, small mouth, thin lips, hypertelorism and abnormal sole creases. He had a distended abdomen with an enlarged liver over 7 cm below the costal margin and enlarged spleen below 5 cm the costal margin. He had cryptorchismus. His motor and mental development were retarded, he had hypotonia. Laboratory findings revealed neutropenia, hypoglycemia, hyperlactatemia, hypertriglyceridemia, hyperuricemia.
Regular administration of G-CSF improved his health and decreased his hospital stay.
Diagnosis of GSD Ib was confirmed after detection of homozygous mutation c.1042_1043delCT on his SLC37A4 gene.

J13.02
Glut1 deficiency syndrome: clinical, biological and therapeutic aspects

S. Dumitriu, *M. Puiu;*
University of Medicine and Pharmacy, Timisoara, Romania.

The medical and personal history of a 5 year old boy in observation since he was 2 proves for the good communication between family and specialists. Glucose transporter type 1 deficiency syndrome (Glut1-DS) characterized by infantile seizures refractory to anticonvulsants, is associated with head growth, mental and motor development delays, spasticity, ataxia, dysarthria, opsoclonus and other paroxysmal neurologic symptoms, often prior to meals. Andrei had been considered normal at birth. Birth weight and Apgar scores were normal. His first seizure occurred at age 3 as myoclonic jerking of shoulders and arms, nodding of the head, eyes rolling, hypotonia, impaired consciousness. Seizures prevailed every morning. The delay was mainly in language and motor coordination. MRI showed moderate frontal atrophy. Fasting EEG revealed mild to moderate slowing of background activity and multifocal and generalized high-amplitude irregular spikes and spike-and-waves; most of discharges were clinically silent, occasionally they were accompanied by myoclonic jerks of shoulders and arms or nodding of the head. EEG recording 1 h after breakfast showed disappearance or marked reduction of epileptic activity. Specific investigations confirming Glut-1DS like erythrocyte glucose uptake and mutation analysis of GLUT-1 are time consuming and expensive.

Starting from mother observations we performed pre- and postprandial EEG recordings in a boy with seizures aggravated by fasting and ameliorated by i.v. Glucose administration. This simple examination provides a powerful tool to identify patients with possible Glut-1 DS.

Metabolic biomarkers in Children with Autism Spectrum Disorders

s. farshidi[1], *H. pouretemad*[2], *e. pishyareh*[3], *s. gafari*[1];
[1]*hope gene fundation metabolic screening and research center, tehran, Islamic Republic of Iran,* [2]*psychiatric department -Shahied Beheshti UMHSH, tehran, Islamic Republic of Iran,* [3]*psychiatric departmen- Welfare & social sciences UMHSH, tehran, Islamic Republic of Iran.*

Autism is a complex neurodevelopmental disorder and thought to be influenced by genetic factors. the prevalence of inherited metabolic disorders are very high in Iranian (1/1000 birth) ,and their symptoms may miss by wrong diagnosis .
Objective: Evaluate plasma concentrations of abnormal metabolites of amino acids & acylcarnitine by HPLC chromatography (blood - urine) and MS/MS methodes in children diagnosed with autism Spectrum Disorders.
Criteria:
Inclusion :
- Diagnosis of autism spectrum disorder based on clinical evaluation
- Age ≥ 24 months -
- gender: both
Exclusion :
Acquired developmental disability or cerebral palsy.
children with deafness, dysmorphism, congenital malformations, short stature, birth defects.
Method : Seventy two autistic children, 60 boys and 12 girl, between the ages of 2-7 years (2008-2010), and satisfying the DSM-III-R criteria (American Psychiatric Association, 1987) for the diagnosis of autism, were selected to participate in this study.
Plasma concentrations of aminoacids & acytylcarnitine were measured in 72 children with autism and in 80 control children.
• Results:
male:female ratio 5:1
9 patient had positive metabolic evaluation (confirmed by urine organic acids , molecular genetics tests
18% positive family history and in 70% consanguinity marriage.
• The most frequent diagnoses were fatty acid oxidation disorders and organic acid disorders
Conclusions: These results are similar to those of the comparison studies, although the overall prevalence IEM is higher in this study. This is probably due to the effects of ethnicity and consanguinity and increasing ascertainment.

J13.04
Cystic fibrosis and bronchic responsivity

L. Pop[1], *I. Popa*[1], *Z. Popa*[2], *L. Tamas*[3], *I. M. Ciuca*[1];
[1]*Pediatric II Department, UMF V Babes, Timisoara, Romania,* [2]*Cystic Fibrosis National Center, Timisoara, Romania,* [3]*Biochemistry Department, UMF V Babes, Timisoara, Romania.*

Background: The aim: the evaluation of bronhic responsivity (BR) in cystic fibrosis (CF) patients. Methods: Patients with CF (11 cases) and patients with CF and bronchial asthma (4 cases), patients with CF and allergic bronchopulmonary aspergillosis (ABPA) - 2 cases . Spiromery tests used: metacholin (if FEV1≥ 80 %) and β2 agonist (if FEV1≤ 80 %) of predicted value. Tests were considered positive: decrease of FEV1 with 20 % comparative to the control value ($PC_{20\%}$ FEV1) for methacoline test, respectively increase of FEV1 ≥ 15 %(in beta mimetic). In patients with asthma we effectuated prick tests and specific IgE antibody for *Aspergillus fumigatus*. Results: In the group with CF, 7 patients presented mixed moderate or severe ventilator dysfunction; 4 of them had positive BD test and 3 had negative test. Four patients of the same group had normal basal ventilometric parameters. Two of them presented positive test with metacholin for medium BR. In the group of the CF and asthma two presented moderate BR, one had normal ventilometric indexes and one presented mild obstructive ventilator dysfunction with positive bronchodilatator (BD) test. In these patients prick tests and the specific IgE antibody were negative. ABPA was confirmed through cultures and IgE specific. The evolution of these cases was towards severe mixed ventilator dysfunction with positive BD test. Conclusion: Bronchial hyperresponsivity is a common phenomenon in CF, with variations from one patient to another, increases in time and was present at all clinical situations from our study.

J13.05
Absence of ambiguous genitalia in a girl with salt wasting form of 21-hydroxylase deficiency

N. Mahdieh[1], *B. Rabbani*[2], *A. Rabbani*[3], *M. Haghi Ashtiani*[4];
[1]*Ilam University of Medical Sciences, Ilam, Islamic Republic of Iran,* [2]*Growth and development Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Children's Medical Center, Pediatric Center of Excellence, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Children's Medical Center, Pediatric center of Excellence, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Congenital adrenal hyperplasia (CAH) is a group of autosomal recessive disorders, mainly known by causing ambiguous genitalia in girls. It is caused by mutations in cortisol biosynthesis enzymes. 90-95% of the cases are occurred due to mutations in CYP21A2 gene. There is a range of phenotypic variability because of different mutations of the gene.
Method and case presentation: We report here a newborn girl with no ambiguous genitalia but 21 hydroxylase deficiency.
Results: Biochemical assays of the patient showed high level of 17 hydroxyprogesterone. She enrolled to the hospital with no sign of virilization. CYP21A2 gene mutations were determined by direct sequencing.
Discussion: There is a need for detailed examination of newborns for CAH at diagnosis and pediatricians should be aware of the cases with salt wasting crisis with no ambiguous genitalia. Molecular genetic analysis would confirm the mutation for the diagnosis. Genotype-phenotype discrepancy could be interpreted by the effect of modifying factors during pregnancy.

J13.06
Congenital adrenal hyperplasia and mutation detection in Iran

B. Rabbani[1], *N. Mahdieh*[2], *A. Rabbani*[3], *R. Bagheri*[4], *E. Zaridust*[5], *F. Sayarifar*[5], *M. Akbari*[1];
[1]*Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [2]*Ilam University of Medical Sciences, Ilam, Islamic Republic of Iran,* [3]*Growth and development research center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Growth and development Research center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Children's Medical Center, Pediatric Center of Excellence, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Background: Congenital adrenal hyperplasia (CAH) accounts for one of the important causes of ambiguous genitalia in girls. 90-95% of the causes around the world are due to CYP21A2 gene mutations.
Methods: CYP21A2 gene is examined in patients affected with CAH with allele specific PCR and multiple ligation probe amplification (MLPA) methods. Direct sequencing is performed for those with rare and novel mutations.
Results: To date, deletion and chimers include about 30% of the CYP21A2 gene. IVS2-13A/C > G, Q318X, R356W, I172N, E6 Cluster, 707_714del8 mutations defined the rest of deleterious mutations, respectively.
Conclusion: Congenital adrenal hyperplasia (CAH) is one of the common causes of ambiguous genitalia in Iran. Newborn screening programs should be used since there are lots of consanguineous marriages in the country. Carrier detection and prenatal diagnosis is performed in the country.

J13.07
Familial hypocalciuric hypercalcemia - a case report

A. V. Popoiu, *G. Doros, C. M. Popoiu, V. L. David, E. S. Boia;*
Emergency Children Hospital Louis Turcanu, Timisoara, Romania.

Introduction: Familial Hypocalciuric Hypercalcemia (FHH) is a rare form of asymptomatic hypercalcemia. The vast majority of FHH is caused by autosomal dominant loss-of-function mutations in the gene CASR, which codes for the calcium-sensing receptor (CASR).

Loss-of-function mutations in CASR impair the feedback inhibition of parathyroid hormone secretion in response to a rise in the blood calcium concentration. Thus, higher than normal blood calcium levels are necessary to inhibit release of parathyroid hormone, resulting in hypercalcemia associated with normal or mildly elevated levels of parathyroid hormone. Material: We report the case of a 11 month old female baby, admitted for the closure of a large persistent ductus arteriosus, who was accidentally discovered with a high blood calcium level of 2,99 mmol/l (normal values 2,10 -2,60), ionized calcium 1,38 mmol/l (1,03 - 1,30), normal phosphatemia, having actually no symptoms of hypercalcemia. The child presented moderate hypotrophy and dyspneea due to a large left-to-right shunt. The renalfuntion was normal. The calciuria was decreased 1,25 mmol/24h (1,75 -7,5 mmol/l). Urinary creatinine was low 0,45 mmol/24h (5 - 18). Parathormon levels were moderately increased 108 pg/ml (10 - 70 pg/ml). No genetic testing was possible in that child. The child had an unevenfull closure of ductus arteriosus, and thrive well now. Conclusions: The benign course of the disease require no medication for lowering the calcium levels, nor is parathyroidectomy indicated.

J13.08
Analysis of SMPD1 gene in an Iranian patient affected by Niemann Pick disease type B

H. Aryan, *O. Aryani, M. Houshmand, E. Khalili, G. Aryan;*
Special Medical Center, Tehran, Islamic Republic of Iran.

Niemann-Pick disease, an inborn error of sphingomyelin catabolism, results from the deficient activity of the lysosomal hydrolase, acid sphingomyelinase (sphingomyelin phosphodiesterase; E.C.3.1.4.12). Two allelic forms of this autosomal recessive disorder have been delineated based on their distinct phenotypes. Type A Niemann-Pick disease is a severe neurodegenerative disorder of infancy characterized by progressive psychomotor retardation, hepatosplenomegaly, and death by three years of age. In contrast, Type B Niemann-Pick disease is a nonneuronopathic disorder characterized by hepatosplenomegaly, respiratory involvement, and survival into adulthood. The clinical course of patients with Type A disease is quite uniform, whereas the severity among Type B patients is more variable. In fact, some mildly affected Type B patients may survive into the sixth decade of life. Our case was a 6-year-old girl characterized by hepatosplenomegaly, respiratory involvement, hyperlipidemia and thrombocytopenia who affected by Niemann Pick type B. Enzyme activity in peripheral blood lymphocytes for this patient was less than 10% of controls. Whole SMPD1 gene sequencing analysis of this proband depicted a homozygote mutation in codon 36 which changes codon Valine to Alanin in exon 1. For confirmation of the mentioned mutation, we analyzed exon 1 of SMPD1 gene for her parents. Sequencing analysis showed heterozygote state for this alteration

MnSOD Val16Ala polymorphism in Romanian patients with Type 1 Diabetes and Retinopathy

*A. Pop[1], **N. M. Panduru**[1], M. Ioana[2], E. Mota[2], M. Mota[2], D. A. Ion[3], M. Anghel[4], S. Radu[4], A. Cimpoeru[5], G. Pop[1], C. Graunteanu[2], D. Clenciu[2], C. Cozma[1], E. Cioboata[2], I. Duta[4], O. Tudose[4], R. Ionica[4], M. Truica[4], C. Serafinceanu[1], R. Lichiardopol[1], D. M. Cheta[1];*
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Craiova University of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, BucharestT, Romania, [4]IDNBM N. C. Paulescu, Bucharest, Romania, [5]Craiova University of Medicine and Pharmacy, Bucharest, Romania.

Diabetic retinopathy (DR) is one of the leading causes of blindness and has an unclarified pathogenesis in which genetic predisposition may play a role. Hyperglycemia increases oxidative stress which may trigger the development of DR. SOD2 is a key enzyme which protects cells from oxidative damage. Functional polymorphisms in SOD2 gene may result in predisposition to DR. The aim of this study was to evaluate the possible association between Val16Ala polymorphism (rs4880) in SOD2 gene and DR, in type 1 diabetes.

We enrolled 189 unrelated Caucasian patients with type 1 diabetes divided into a group A - patients with diabetes duration over 15 years without DR (n=70) and group B - patients with DR (n=119). Genotyping was achieved by Taqman. Statistical analysis was performed using DeFineti software and Cochran-Armitage correction was applied.

Genotype spread analysis indicated that ValVal genotype is more frequent in the DR group (22.68%) compared with controls (17.14%). There was a significant deviation from Hardy-Weinberg equilibrium in the control group (X2=8.22,F=0.343). Presence of homozygous 16Val allele seem to increase the risk for DR (OR=1.333), while the 16Ala allele seems to be protective (OR=0.750), but he results are not statistically significant (p=0.55). Corrected OR for both alleles are not reaching statistical significance.

This is the first study of Val16Ala polymorphism in DR from Romanian population. Although this is a small study that suggests there is no association between Val16Ala polymorphism and DR, further studies are necessary in order to clarify the role of SOD2 gene in DR.

J13.10
Clinical, Enzymatic, and Molecular Diagnosis of Mucopolysaccharidoses in Iran, a Five Years Experience

Y. Shafeghati[1,2], *F. Hadipour*[2], *Z. Hadipour*[2];
[1]Genetics Research Center, Tehran, Islamic Republic of Iran, [2]Medical Genetics Department, Sarem Women Hospital, Tehran, Islamic Republic of Iran.

Mucopolysacchridoses are prevalent in our population, constitute a very important health problem and burden in this community. High rate of consanguineuous marriages, one of the important predisposing factors. They are “Enzymopathies” and the result of homozygous or compound heterozygous mutations in different genes which are responsible to encode specific enzymes inside the cells. Each enzyme catalyzes one of the different metabolic reactions that is necessary to degrade intra-lysosomic glycosaminoglycans. Result of the mutation in a coding gene may cause severe enzyme deficiency, intra-lysosomal accumulation of glycosaminoglycan macromolecules, and a specific phenotype. Typical sequence of symptoms may include progressive neurodevelopmental delay or regression, behaviour abnormality, progressive dysmorphic-course facies, corneal clouding, hearing loss, visceromegaly, skeletal dysplasia, and dysostosis multiplex congenita. We have studied 72 families in the past 5 years, that were referred for evaluation and diagnosis of a dysmorphic, neurodevelopmental regressive disorders with the MPS phenotype. The diagnosis in the index cases (after a detailed clinical, biochemical, radiological, imaging studies) confirmed by enzyme assay and in a few of the cases by molecular analysis.

We also determined to use Enzyme Replacement Therapy in some of our patients with type I, type II, and type VI, and also performed BMT, in a few of them.

The result of this experience on clinical, enzyme assay, and molecular analysis would be presented in the congress.

Keywords: MPSs, Mucopolysaccharidosis, Macromolecular Enzymopathies, Iran Experience

Methylmalonic aciduria and Homocystinuria detected by joint NMR and chromatography techniques: A Case Report.

N. Usurelu[1], *A. Nicolescu*[2,3], *S. Garaeva*[4], *V. Burgoci*[1], *V. Sacara*[1], *G. Postolati*[4], *G. Redcozubova*[4], *N. Simionescu*[2,5], *V. Ciochina*[4], *O. Toma*[5], *C. Deleanu*[2,3];
[1]The National Centre of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of, [2]”Petru Poni” Institute of Macromolecular Chemistry, Iasi, Romania, [3]”Costin D. Nenitescu” Institute of Organic Chemsitry, Bucharest, Romania, [4]The Institute of Physiology and Sanocreatology of Academy of Science, Chisinau, Moldova, Republic of, [5]”Alexadru I. Cuza” University, Faculty of Biology, Iasi, Romania.

Methylmalonic aciduria is a genetically heterogeneous metabolic disorder due to abnormal activity of methylmalonyl-CoA mutase.

We report on an 11 months boy, hospitalized for the second time in intensive therapy with recurrent vomiting, dehydration, ketonuria, metabolic acidosis accentuated after high protein intake. The parents are not consanguineous, their older boy died from unidentified similar metabolic conditions, age 10 months.

The blood and urine amino acids were examined by liquid chromatography. The elevated level of homocysteine (Hcy) [17.8µmol/l], cysteine, ethanolamine and ammonia in blood and only of Hcy in urine had been detected. High concentration of Methylmalonic acid (MMA) in urine[1631.4 mmol/mol creatinine] was detected by NMR spectroscopy of urine. In addition, CT scanning showed spina bifida aperta L5-S5.

The serum concentration of Hcy is elevated in both folate and cobalamin deficiencies, whereas MMA in serum or urine is a specific marker of cobalamin function. No mutation in MTHFR 677C-T in this patient was detected. The therapy with vitamin B_{12}[1mg/day], folic acid [5mg/day] along the restricted protein diet reduced the level of MMA in urine [to180.0 mmol/mol creatinine], of Hcy in blood and urine and improved the development of the child.
Further actions: Tests for mutations in MTHFR/1298A, MTRR, MTR, MMAA genes will be performed for this family. The NMR spectroscopy for both urine and amniotic fluid of the mother may be proposed for prenatal diagnosis. NMR spectroscopy of body fluids provided more analytic information in this case and may be used as screening method for diagnosis of inborn metabolic errors.

Discussions over a case of congenital diaphragmatic hernia

E. S. Boia[1], *M. C. Popoiu*[1], *V. L. David*[2], *M. Boia*[1], *O. Adam*[2], *P. Fuicu*[1], *A. V. Popoiu*[1], *M. Puiu*[1];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*Emergency Children's Hospital "Louis Turcanu", Timisoara, Romania.*

Background: Congenital diaphragmatic hernia (CDH) is a birth defect associated with high mortality and morbidity during neonatal period. It has become increasingly apparent that genetic factors like retinoid-related genes may be involved in the pathogenesis of the disease. The need to increase the survival has pushed the limits of therapy to fetal surgery and endoscopic interventions. In severe cases, it is preferred nowadays to perform a temporary fetal endoscopic tracheal occlusion in order to stimulate lung development. Case report: We present a case of a male preterm child with right CDH. The CDH was diagnosed at 19 weeks of gestation and at 28 weeks a fetal endoscopic tracheal occlusion was performed. He was born by C-section at 32 weeks, birth weight of 3000 g. Even from birth the child suffered from severe hypoxia and pulmonary hypertension necessitating tracheal intubation and mechanical ventilation. During the first 24 hours of life the SaO2 remains under 80% despite the aggressive resuscitation, inotropic support, 100% O2, surfactant and Ilomedin administration. The patient died 36 hours after delivery because of severe pulmonary hypoplasia and pulmonary hypertension. Conclusion: Despite the modern and sometimes heroically treatment methods for CDH the final negative outcome is sometimes inevitable. Accurate medical lung development assessment is mandatory, before any attempt of surgical therapy. Sometimes pregnancy interruption should be considered as the best way to avoid sufferance.

P14.02
Combined strategies using airway clearence games and physical exercise in young pacients with cystic fibrosis

B. Almajan Guta[1], *C. Avram*[2], *A. Rusu*[3], *O. Cluci*[3], *V. Almajan-Guta*[1], *M. Oravitan*[2], *L. Pop*[4];
[1]*University "Politehnica" Timisoara, Timisoara, Romania,* [2]*West University Timisoara, Timisoara, Romania,* [3]*Speranta Special Care Center Timisoara, Timisoara, Romania,* [4]*University of Medicine and Pharmacy Timisoara, Timisoara, Romania.*

Physiotherapy in cystic fibrosis techniques are often frustrating and exhausting for the child.
This study is aiming to demonstrate the need of respiratory clearance games and the importance of adapting these techniques to the CF children in order to increase compliance to therapy and quality of life.
Methods
We conducted a 12 months prospective study on 20 patients with CF aged between 4 and 12 years, from Romanian National Cystic Fibrosis Centre. They followed the protocol consisting in airway clearance games (flow-ball, TrainAir) and aerobic activities five times a week for 40 minutes. Children have been tested at inclusion and at the end of the study using the Questionnaire of life quality in CF. For data analysis we used Spearman's rho.
Results
After one year we observed an increase in sleep quality in 20% of cases and 30% of them enhanced the nutritional status. The majority of patients increased the level of fitness during ADL. Moderate fatigue in effort decreased from 60% to 50 % .Initially 40% of them followed constant educational activities compared to 60 % finally. Hospitalizations due to exacerbations decreased from 60% to 45% compared to the last year. Good correlation (at the 0.01 level) was observed between mucus quantity and fatigue during ADL, educational activities and sleep quality.
Conclusions:
Combined airway clearance games and physical exercises are a very good choice to optimize the quality of life in children with cystic fibrosis.

P14.03
A pharmacogenetic analysis of Fabry patient responses to pharmacological chaperone treatment with AT1001 (GR181413A, Migalastat Hydrochloride)

E. R. Benjamin[1], *X. Wu*[1], *C. Della Valle*[1], *E. Katz*[1], *R. Schiffmann*[2], *J. P. Castelli*[1], *P. Boudes*[1], *D. J. Lockhart*[1], *K. J. Valenzano*[1];
[1]*Amicus Therapeutics, Cranbury, NJ, United States,* [2]*Baylor Research Institute, Dallas, TX, United States.*

Fabry disease is an X-linked lysosomal storage disorder caused by mutations in *GLA*, the gene that encodes α-galactosidase A (α-Gal A). The pharmacological chaperone AT1001 (GR181413A, migalastat hydrochloride, 1-deoxygalactonojirimycin) is currently in Phase 3 clinical development as a potential therapy for Fabry disease. AT1001 selectively binds and stabilizes α-Gal A, increasing total cellular levels and activity for some mutant forms (defined as "responsive"). Responsive mutant forms can be determined readily in male Fabry patients; however, this is more challenging in female patients due to the expression of wild-type and mutant forms of α-Gal A. We assessed whether pharmacogenetic information could aid in the identification of Fabry patients with responsive mutant forms of α-Gal A. Fabry disease-associated mutant forms (473 in total) were individually expressed in HEK-293 cells; ~60% responded to AT1001 incubation. *GLA* mutations from the subset of mutant forms that responded to a clinically-relevant concentration of AT1001 (10 μM) were categorized as 'eligible'; others were considered 'ineligible'. Phase 2 clinical trial results were then retrospectively analyzed by grouping subjects, based on genotype, into these two categories. Oral administration of AT1001 increased α-Gal A more frequently in males with 'eligible' (13/14) versus 'ineligible' (0/3) mutations. Importantly, AT1001 treatment decreased kidney interstitial capillary globotriaosylceramide by ≥50% more frequently in male and female subjects with 'eligible' (7/10) versus 'ineligible' (2/7) mutations. Thus, the α-Gal A response measured *in vitro* for each mutant form may identify Fabry patients who can respond to AT1001 and are more likely to benefit from AT1001 therapy.

In vivo quantification of cerebral $GABA_A$ receptors in fragile X patients using [^{11}C] flumazenil Positron Emission Tomography

I. Heulens[1], *C. D'Hulst*[1], *N. Van der Aa*[1,2], *H. Van Esch*[3], *M. Koole*[4], *K. Porke*[5], *M. Van De Velde*[6], *W. Van Paesschen*[7], *F. Kooy*[1], *K. Van Laere*[4];
[1]*Department of Medical Genetics, University of Antwerp, Antwerp, Belgium,* [2]*Antwerp University Hospital, Antwerp, Belgium,* [3]*Centre for Human Genetics, University Hospital Leuven, Leuven, Belgium,* [4]*Department of Nuclear Medicine, University Hospital Leuven, Leuven, Belgium,* [5]*Department of Neuropsychology, University Hospital Leuven, Leuven, Belgium,* [6]*Department of Anaesthesiology, University Hospital Leuven, Leuven, Belgium,* [7]*Department of Neurology, University Hospital Leuven, Leuven, Belgium.*

Fragile X syndrome is the most common form of inherited mental retardation. In the brain of fragile X animal models, we found a decreased mRNA expression of several subunits of the $GABA_A$ receptor. $GABA_A$ receptors are the major inhibitory neurotransmitter receptors in the mammalian brain. This ionotropic receptor plays a role in learning and memory, hyperactivity, insomnia, epilepsy, anxiety and depression; processes that are disturbed in fragile X patients. This indicates that a dysfunction of the $GABA_A$ receptor is involved in the behavioural problems observed in the fragile X syndrome. The $GABA_A$

receptor is therefore a target for rational treatment of the syndrome. In a set of experiments we already demonstrated that GABAergic drugs are able to correct some of the symptoms in fragile X mice. However, before therapy on patients can be initiated, it is required to validate GABAergic abnormalities in human. As post-mortem studies are not feasible, we set up a study to image and quantify the $GABA_A$ receptor distribution *in vivo*. Using positron emission tomography (PET) with [^{11}C]Flumazenil, a known $GABA_A$ receptor antagonist, as a radioligand we determined the amount of $GABA_A$ receptors in the brain. We found an overall significant decrease (6-17%) in $GABA_A$ receptor availability in fragile X patients. The decrease was most prominent in specific brain regions, including cortical regions. This confirms that the GABAergic system is involved in the pathophysiology of the fragile X syndrome and suggests that GABAergic drugs might ameliorate several symptoms of fragile X patients, improving their quality of life.

P14.05
Creb1 is required for hydroxyurea-mediated induction of gamma-globin expression in K562 cells

***M. Banan**, E. Esmailzadeh, Z. Deilami, S. Farashi;*
Genetics Research Center, Tehran, Islamic Republic of Iran.

Hydroxyurea (HU) can augment gamma-globin expression in K562 cells. However, the transcription factors that are required for this upregulation have not been identified. Similarities between the HU and sodium butyrate (SB) pathways suggest Creb1 as a potential candidate. Reports indicate that in K562 cells, both HU and SB (1) activate p38 MAPK and (2) selectively induce Ggamma gene expression. In the case of SB, this induction seems to be mediated through a Creb1 binding site present in the promoter region of the Ggamma (and not Agamma) gene. In this study, we have investigated the possible role of Creb1 in the HU pathway. We show that transient or stable knockdown of Creb1 blocks HU-mediated gamma-globin induction in K562 cells. However quantitative ARMS-PCR (Amplification Refractory Mutation System) experiments suggest that HU does not solely induce Ggamma expression in this cell line. Electrophoretic mobility shift assays (EMSAs) indicate that HU treatment leads to increased levels of Creb1 complexes binding to the Ggamma promoter. Collectively, these results suggest that Creb1 is necessary for gamma-globin induction by HU, a role which may in part be mediated through the Ggamma promoter Creb1 binding site.

P14.06
Hemangioma of infancy: treatment options

***M. C. Stanciulescu**[1], E. S. Boia[2], M. C. Popoiu[2], V. L. David[1], A. Goanta[1], C. Bota[1];*
[1]Emergency Children's Hospital, Timisoara, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Background: Hemangiomas of infancy (HOI) are the most common tumors in children. Even that HOI are not primarily genetic diseases, there are several genes and loci implicated in the pathogenesis of vascular malformations and hemangiomas whit major influence over the clinical characteristics and evolution of hemangiomas: RASA1, KRIT, TIE2/TEK, ENG, SMAD4/MADH4. Material and method: This study is an analysis of all the cases with the diagnostic of HOI admitted in our hospital from January 2008 to December 2010 Results: There were a total number of 134 patients with age ranging from 2 months to 8 years. In 54.3 % of the cases were localized on the neck and head, 22.7% on the torso, 13.86% on the limbs, 3, 24% on the genitals, and multiple in 5.9%. Surgical excision was the most common procedure followed by Aethoxysclerol injection. In 8 cases we used a new therapy: propranolol. The outcomes of treatment were good in the majority of the cases with no major complications, except one case of keloid formation after the excision of a very large hemangioma. Conclusions: The treatment of hemangioma varies according to affected area. In most of the cases surgical excision is sufficient. For large hemangioma and those located in esthetic areas the most promising treatment is now propranolol. Aethoxisclerol is used only when propranolol therapy has no results and the surgical excizion is prohibited. Feature research should be focused to correlate the treatment with the genetic factors influencing the clinical course of HOI.

P14.07
One year-treatment with a combination of pravastatin and zoledronate on six patients affected with Hutchinson-Gilford Progeria: safety and efficacy.

***A. De Sandre-Giovannoli**[1,2], S. Sigaudy[1], P. Bourgeois[1], P. Roll[1,2], E. Jouve[3], G. Gorincour[4], J. Gentet[5], N. André[5], J. Micallef[3], P. Cau[1,2], N. Lévy[1,2];*
[1]Département de Génétique Médicale et Biologie Cellulaire, Hôpital d'Enfants La Timone, Marseille, France, [2]Inserm UMR_S 910, « Génétique médicale et génomique fonctionnelle », Faculty of Medecine, Marseille, France, [3]Centre d'investigation clinique - Unité de Pharmacologie Clinique et d'Evaluations Thérapeutiques (CIC-UPCET), Hôpital La Timone, Marseille, France, [4]Service de Radiologie Pédiatrique, Hôpital d'Enfants La Timone, Marseille, France, [5]Service d'Oncologie Pédiatrique, Hôpital d'Enfants La Timone, Marseille, France.

Hutchinson-Gilford Progeria Syndrome (HGPS) is a rare and severe genetic disease, characterized by segmental premature aging and accelerated atherosclerosis. It invariably leads to death in the teenage, due in most cases to myocardial infarction. No validated treatment is available to date. A recurrent, *de novo,* dominant mutation of the *LMNA* gene, encoding Lamins A/C, causes most HGPS cases, through the activation of a cryptic pre-mRNA splice site leading to the production of a truncated Lamin A precursor called "progerin". Progerin cannot be fully post-translationally processed, remains aberrantly prenylated and accumulates in cells' nuclei, where it exerts several toxic effects. Preclinical studies *in vitro* on patients' cells and on animal models provided proof-of-principle that the combined use of pravastatin, a statin, and zoledronate, an aminobisphosphonate, could improve several disease parameters, including growth, bone density and survival. These data allowed us to launch a phase II, open-label, single arm clinical trial, conducted in Marseille, France, on 12 European children affected with Progeria. The trial aims to assess the safety and efficacy of a combination of pravastatin and zoledronate on several pathological parameters, including growth, bone density and turnover as well as cardiovascular risk. Data obtained in six children treated for one year showed that the association of pravastatin and zoledronate is safe and can induce clinical beneficial effects in the mid-term. We thus report the first therapeutic intervention that seems to favorably impact the natural course of this devastating disease, with potential wider impacts in the field of aging.

P14.08
Association of Estrogen receptor α -351 XbaI A>G and -397 PvuII T>C Polymorphisms with uterine leiomyoma in women from Chaharmahal va Bakhtiari province; Iran

***f. taghizade mortezai**, S. Miraj, E. Farrokhi, M. Hashemzade Chaleshtori, S. Khyri;*
Cellular and Molecular Research Center, Shahrekord Univ. of Med. Sci. Shahrekord Iran, shahrekord, Islamic Republic of Iran.

Background and Aims: uterine leiomyoma, or fibroid, is common estrogen-related gynaecological disease, and it is estimated that one in four women during reproductive period will develop this kind of benign neoplasia. We aimed to elucidate the association of estrogen receptor a (ERα)-351 A>G (XbaI) and -397 T>C (PvuII) gene polymorphisms with leiomyoma in a group of women from province in southwest of iran.

Methods: 156 women with clinically diagnosed uterine leiomyoma and 151 healthy,normal women were included in the study. Genomic DNA was obtained from peripheral leukocytes. ERα-351 A/G XbaI and -397 T/C PvuII polymorphisms were assayed by the method of PCR-RFLP.

Results: Genotypes and allelic frequencies in each group were compared. The genotype/allele frequencies of Era -351 A>G and -397 T/C polymorphisms in leiomyoma groups were not different from those of normal controls.

Conclusion: We concluded that ERα -351 XbaI A>G and -397 PvuII T>C related genotypes/alleles were not correlated with an increased risk of uterine leiomyoma in study population.

P14.09
Towards lentiviral gene therapy for the treatment of Pompe disease

M. Stok, *H. de Boer, T. P. Visser, A. J. J. Reuser, E. D. van Deel, D. J. Duncker, N. P. van Til, G. Wagemaker;*
Erasmus Medical Center, Rotterdam, Netherlands.

The lysosomal storage disorder Pompe disease is due to a deficiency of the acid alpha-glucosidase (GAA) gene, and characterized by progressive muscle weakness, in its most severe form lethal in the first year of life due to cardiac and respiratory failure. Enzyme replacement therapy is effective, but not beneficial to all patients and often results in antibody formation. We have used a hematopoietic stem cell *ex vivo* lentiviral gene therapy approach in the Pompe mouse model using the native or a codon-optimized GAA transgene driven by the spleen focus forming virus promoter.
Using this strategy, sustained levels of GAA were achieved in leukocytes and other affected tissues of Pompe mice. Using the native sequence, glycogen storage was reduced significantly in heart and diaphragm, with near normalization of heart morphology and function, but only to a limited extent in skeletal muscle. Challenge of the treated animals with the rhGAA protein demonstrated robust specific immune tolerance. The use of the codon-optimized GAA gene (GAAco) resulted in even higher levels of GAA activity in all affected tissues, including skeletal muscle and an almost complete reduction of glycogen storage. Using the GAAco construct, skeletal muscle function was maintained and initial results also indicate reduced glycogen levels in brain tissue.
Thus, *ex vivo* hematopoietic stem cell lentiviral vector mediated gene therapy results in correction of the Pompe phenotype in the mouse model and would be suitable for further clinical exploration.

P14.10
Increased T allele frequency in multidrug transporter ABCB1 (MDR1) gene in FMF patients of colchicine unresponsiveness

S. Atik[1], *F. Ozen*[2], *C. Silan*[3], *A. Uludag*[1], *F. Candan*[4], *F. Silan*[1], *S. Ozdemir*[5], *O. Ozdemir*[1];
[1]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [2]*Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [3]*Department of Pharmacology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [4]*Department of Internal Medicine, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [5]*Department of Nuclear Medicine, Faculty of Medicine, Cumhuriyet University, Canakkale, Turkey.*

The multidrug resistance gene-1 (MDR1, ATP-binding cassette transporter: ABCB1, P-glycoprotein: P-gp) encodes membrane proteins that playing a crucial role in protecting cells from xenobiotics, chemicals and drugs. The TT genotype of 3435 codon in exon 26 of MDR1 gene causes to over-expression gene activity and efflux many chemically diverse compounds across the plasma membrane. We studied the association between C3435T polymorphisms (SNP) of MDR1 gene and colchicine-resistant FMF patients. Total genomic DNA samples from 52 FMF patients of colchicine unresponsiveness were used for Familial Mediterranean Fever (MEFV) and MDR1 genes profile analyses. Target genes were genotyped by multiplex PCR based reverse hybridization stripAssay method. The preliminary current results showed that increased T allele frequency (60%) in FMF patients of colchicine unresponsiveness. The distributions of the CC, CT and TT genotypes in colchicine nonresponder FMF patients were 17%, 46%, and 37%, respectively. Our results indicate that C3435T polymorphism in exon 26 of MDR1 gene is associated with colchicine resistance in nonresponder FMF patients during the common therapy protocol.

P14.11
Development of the exon exchange method for repair of mutant nebulin transcripts

J. Laitila, *K. Pelin;*
Department of Biosciences, Division of Genetics, University of Helsinki, Finland, Helsinki, Finland.

The nebulin gene (*NEB*) has 183 exons encoding transcripts up to 26 kb in length. Mutations found in *NEB* are dispersed throughout the gene, i.e. no mutational hot spots are evident. Mutations cause autosomal recessive nemaline myopathy, distal nebulin myopathy and core-rod myopathy, for which no therapy is available. The size of *NEB* limits the options of gene therapy development. Thus, our research has focused on methods correcting the mutation carrying transcripts. Recent advances in RNA reprogramming technologies have raised the possibility to develop RNA therapies for correction of mutations in *NEB* at the pre-mRNA level. Spliceosome-mediated RNA *trans*-splicing (exon exchange), i.e. splicing between two separate pre-mRNA molecules, allows the replacement of mutant exons with wild type ones at the pre-mRNA level. Targeted exon exchange requires the spliceosome and a target pre-mRNA, both provided by the cell, and a pre-*trans*-splicing RNA-molecule (PTM) which is produced from an expression vector transfected into the cells. PTMs can be designed to carry out three forms of exon exchange: 3'-, 5'- or internal exon replacement. We have developed PTMs for *NEB* 3'- and internal exon replacement. PTMs designed carry one or several wild type *NEB* exons to replace exons from target pre-mRNAs produced from *NEB* minigene expression vectors in cell cultures. We have obtained successful results from our 3'exon exchange and first internal exon exchange experiments. We are now focusing on further development of the internal exon replacement method, which would be the most useful one for correction of mutations in *NEB* transcripts.

P14.12
Stem cell therapy of a genetic model of neurodegeneration with cerebellar ataxia: the Harlequin mouse

M. Kumar[1], *Z. Csaba*[1], *S. Peineau*[1], *S. Mani*[2], *P. Gressens*[1], *V. El Ghouzzi*[1];
[1]*inserm u676, Paris, France,* [2]*Center for Neuroscience IISc, Bangalore, India.*

The treatment of neurodegenerative disorders represents one of the critical goals of medical research today. Although progressive neurodegenerative diseases are commonly associated with ageing, they also affect children and young adults. Cerebellar ataxias are rare neurodegenerative disorders, which can be thought of as a syndrome, which has many different causes, genetic or environmental. These diseases are progressive and very serious illnesses with no treatment available so far. A common feature in the early stages of these diseases lies in mitochondrial dysfunction and oxidative stress induced by a deregulation of oxidative phosphorylation.
The Harlequin (Hq) mouse, where a spontaneous mutation in the AIF gene results in a drastic reduction of its expression, gradually develops a cerebellar ataxia associated with mitochondrial degeneration and a complex I deficiency. Although all cerebellar neurons finally die after 6 months, granule neurons are affected first with a gradual death starting around 2 months.
We have designed an in vitro protocol combining media and selective factors to push hES toward the neuronal lineage and make them differentiate into functional neurons expressing granular markers of the cerebellum. We have also produced granule neuron progenitors to attempt cell replacement in ataxic Hq mice. We show that progenitors implanted in the cerebellum can differentiate into mature human neurons and integrate into the adult mouse cerebellum. Motor coordination was improved in cell-treated animals up to three months after implantation. Our results bring a proof-of-principle that human embryonic stem cell-based therapies might be relevant for treating neurodegenerative disorders.

P14.13
Oxidative stress and sperm DNA quality in couples experiencing recurrent spontaneous abortions

M. B. Shamsi, *K. Yadav, K. Kumar, D. Deka, R. Dada;*
AIIMS, New Delhi, India.

Introduction: Sperm has dynamic and critical role in embryogenesis that extends clearly beyond fertilization. Supraphysiological Reactive Oxygen Species (ROS) levels damage both mitochondrial and nuclear genome. During embryonic development, nucleotide alterations if unrepaired are lethal to accurate transmission of genetic information and affect the embryonic viability and post natal health. Nicks/breaks and/or nucleotide modification caused by unregulated free radical concentration due to inefficient antioxidant machinery leads to sperm DNA damage. This study was planned to understand the association of seminal ROS, antioxidant capacity and sperm DNA damage in men of couples experiencing recurrent pregnancy loss following spontaneous conception.

Material and Methods: Male partners of 77 couples experiencing recurrent pregnancy loss and 41 fertile controls were included in study. Seminal ROS were measured by luminol induced chemiluminescence. Seminal total antioxidant capacity (TAC) was assessed by commercially available kit. Sperm DNA integrity was quantified by single cell gel electrophoresis (comet assay). Semen analysis was done according to WHO 2010 guidelines. Mann-Whittney test was applied for statistical significance.
Results: Significantly increased ROS and reduced seminal TAC was observed in patients (p=0.002; p=0.014 respectively) as compared to controls. In patient group the number of sperms with DNA damage was higher (p=0.024).
Discussion: Seminal oxidative stress is a major cause of sperm DNA damage. DNA damage leads to recurrent spontaneous abortions, childhood cancers, genetic and epigenetic defects in offspring. Oxidative stress and sperm DNA damage assessment have better diagnostic and prognostic capabilities and should be included in diagnostic workup of patients experiencing recurrent pregnancy loss.

P14.14
Strategies for rehabilitation in a case with Russel-Silver syndrome

M. Cevei[1], *D. Stoicanescu*[2];
[1]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [2]*University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisora, Romania.*

Russel-Silver syndrome is a genetically heterogeneous disorder, characterized by prenatal and postnatal growth retardation, characteristic facial appearance, slow regressive evolution, risk of delayed development and learning disabilities. We present the case of a 1.7 years old girl, born from healthy, unrelated parents, hospitalized for treatment and functional rehabilitation. The birth was premature, by caesarean section at 36 weeks, after a pregnancy with early and late dysgravidy, birth weight 1900g. Clinical and functional evaluation at admission revealed hypotrophy, moderate motor retardation, characteristic facies, delayed developmental milestones, axial hypotonia, dorso-lumbar kyphosis accentuated in sitting position, symmetric muscle hypotrophy, balance disturbance, standing and sitting only with help, walking only sustained with a broad base of support, stability problems, mental development within ranges of chronological age. Rehabilitation treatment was complex and involved coordination of several team members. The main goals of the treatment were increasing the muscle tonus of the limbs, obtaining independent standing, establishment of stability for ambulation, walking, motor skills acquisition, posture amelioration, increasing tonus of paravertebral, abdominal muscles, body alignment. Intensive rehabilitation program consisted of hydrotherapy and aquatic therapy in thermal water, electrotherapy, general tonifiant daily massage, physical, occupational and speech therapy. She showed significant improvement, after three weeks of intensive treatment walked a few steps independently, but falled frequently, improved appetite, gained weight, improved muscle tone, climbed stairs independently, with support. Treatment normally involves massive amounts of stimulation in order to improve muscle function and control. Assessment of these cases is best accomplished by a multidisciplinary team.

P14.15***
Cysteine quantity correction in CADASIL using antisense mediated exon-skipping.

S. A. J. Lesnik Oberstein, *J. G. Dauwerse, D. J. Peters, M. H. Breuning, G. J. van Ommen, A. Aartsma-Rus;*
Leiden University Medical Center, Leiden, Netherlands.

Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is the most prevalent type of hereditary vascular dementia and is recognized as an important cause of stroke and dementia in the young. CADASIL is caused by characteristic missense mutations of the *NOTCH3* gene which lead to an uneven number of cysteine residues in the protein's ectodomain. This causes misfolding of the protein which leads to aggregation of NOTCH3 at the surface of vascular smooth muscle cells, a key factor in CADASIL pathophysiology
We are currently testing a novel application for antisense-mediated protein modulation, named 'cysteine quantity correction', as a treatment strategy for CADASIL. In this approach we use antisense mediated exon-skipping to intervene in protein synthesis at the pre-mRNA level. By inducing the skipping of specific exons, we re-establish an even number of cysteine residues in the NOTCH3 protein's ectodomain. Our hypothesis is that by this modulation the protein maintains function, but loses toxicity. With this approach, we can target ca. 70% of CADASIL related mutations using the same set of antisense oligonucleotides.
Technically, we are able to induce the desired exon-skipping in our CADASIL cell models as shown by RT-PCR and sequencing analysis. Currently, we are evaluating whether the induced cysteine quantity correction reduces CADASIL associated NOTCH3 accumulation *in vitro*, using Western blot and immunocytofluorescence.
Our hypothesis and preliminary, but promising, *in vitro* results will be presented.

P14.16
Production of K562 cells stably expressing MBD2 shRNAs

S. Farashi, *M. Banan;*
Genetic Research Center, Tehran, Islamic Republic of Iran.

MBD2 (Methyl Binding Domain 2) has been shown to repress the human γ-globin gene in mouse models. We have previously shown that transient MBD2 knockdown (35%) using siRNAs results in induction of γ-globin expression (1.75 fold) in K562 cell line. In order to achieve higher levels of knockdown and possibly g-globin induction, a lentivirus system was used for shRNA delivery. First, functionality of the system was verified by using a lentiviral transfer vector containing a GFP expression-cassette. Next, five lentivirus transfer vectors containing MBD2 shRNAs were screened for target gene knockdown by qRT-PCR in HEK 293T transient transfection assays. The two most effective shRNAs gave >70% mRNA knockdown levels after normalization for transfection efficiency. These vectors were subsequently packaged and used to transduce K562 cells. Upon infection and antibiotic selection, a cell population stably expressing MBD2 shRNAs was obtained. The amount of MBD2 knockdown and γ-globin expression was assessed in these cells by relative qRT-PCR. In one cell line (shRNA-3), MBD2 was knocked down by 73% and g-globin was induced 5-fold. In the other (shRNA-5), MBD2 was down-regulated by 51% and g-globin increased by 11.75-fold. These results support those of the transient RNAi experiments. Moreover, these cell lines can now be used for delineating the mechanism of MBD2 repression.

P14.17
Enzyme replaced therapy in MPS II patients in Novosibirsk.

N. Fedoruk, *A. Shorina;*
Pediatric department, Urgent Children's Municipal Hospital №3, Novosibirsk, Russian Federation.

Intention: To demonstrate clinical changes and objective and subjective improvement in health status in patients with mucopolysaccharidosis II (MPS II) after enzyme replacement therapy (ERT).
Materials and methods: Four patients with MPS type II (16, 13, 6, and 5 years old) who had been treated with Elaprase intravenous infusion weekly over a 54-week period. The urinary GAG level decreased to the initial value. A multidisciplinary physicians checkup including 6-MWT, ECG, computed tomographic scanning, US of the abdominal cavity, echocardiography, respiratory function test, clinical blood and blood serum biochemistry was performed before and after the therapy.
Results: Two children aged 5-6 years showed a general improvement of movement abnormalities and lung function in contrast with adult patients. A progressive arthropathy temporarily remitted in the 16 year old patient; there was no effect in the 13 year old. Mitral and aortic regurgitation and/or stenosis commonly decreased after ERT. US of the abdominal cavity did not show significant decreased hepatosplenomegaly in the patient aged 13.
Idursulfase is generally well tolerated, although infusion reactions did occur.
Conclusion: The response to ERT appears to depend on the severity of the
individual's condition and the age at which the treatment begins. Infusion reactions were observed in the older patients despite allergic problems which all children had before Elaprase treatment. Our experience demonstrates the first sign of ERT efficacy in most young

patients and increases their ability to take part in normal daily activities.

P14.18
Expression of pdx1 promote derivation of beta cells from mesenchymal stem cells

S. Talebi[1], *A. Aleyasin*[2], *M. Soleimani*[3];
[1]*National institute of genetic engineering ang biotechnology, Tehran, Islamic Republic of Iran,* [2]*Natinal institute of genetic engineering and biotechnology, Tehran, Islamic Republic of Iran,* [3]*tarbiat modares university, Tehran, Islamic Republic of Iran.*

The Pancreatic cells transplantation is a promising approach for treatment of type1 diabetes that caused by insulin deficiency; however, lack of suitable donors limits the application. Differentiated mesenchymal stem cells (MSCs) can be therapeutic source for the cure of type 1 diabetes. The aim of current experiment is to explore the possibility of derivation of insulin producing cells from bone marrow MSCs by overexpression of pdx1 transcription factor. In this study rat MSCs were isolated and identified by flow cytometry. Then, MSCs were transduced by lentiviruses harboring pdx1 and pdx1-expressing cells selected by puromycin. The appropriate expression of exogenous pdx1 was confirmed in level of mRNA and protein using RT-PCR and immunofluorescent analyses. In addition to ectopic expression of pdx1, differentiating medium containing nicotinamid and betamercaptoethanol (Nico/betaME) used to efficient differentiation of MSCs into beta cells. Then, the expression of islet markers was investigated by quantitative RT-PCR. The immunoflurescent showed a nuclear localization of pdx1. Pdx1-expressing MSCs transcribed specific pancreatic endocrine markers such as endogenous Pdx1, Ngn3, Glucagon and insulin regardless to using Nico/betaME, but the quantitative RT-PCR showed a high increase in all markers except insulin, in Nico/betaME treated cells compared to non-treated cells. The beta cells derived from MSCs also expressed glucokinase and Glut2 indicating these cells have the glucose sensing ability. In contrast, treated MSCs didn't express P48; it implies these cells have been committed to endocrine linage. In conclusion, MSCs as an available resource can have impacted in cell based gene therapy of type1 diabetes.

P14.19
PTC124 incubation towards ribosomal readthrough of nonsense mediated termination codons in the SLC6A8 and GAMT genes.

O. T. Betsalel*, T. Veltkamp, W. Kanhai, C. Jakobs, G. Salomons;*
VU University Medical Center, Department of Clinical Chemistry, Metabolic Unit, Amsterdam, Netherlands.

A recently discovered chemical entity, PTC124 (Ataluren) was shown to selectively induce ribosomal readthrough of premature but not normal termination codons. In vitro experiments and subsequent treatment of mdx mice showed a promising improvement in the form of functional recovery (Welch et al. 2007). This led us to investigate the effect of PTC124 on nonsense mediated premature termination in two of the three cerebral creatine deficiency syndrome genes, namely the creatine transporter gene (SLC6A8) and the guanidinoacetate methyl-transferase gene (GAMT). We obtained PTC124 from Selleck Chemicals (Houston, Texas, USA) and incubated patient's cell-lines containing nonsense mutations with 17μM of PTC124 for 46 days (SLC6A8, n=2) and 14 days (GAMT, n=3) and collected cells every 7 days. We measured intra-cellular creatine content and formation of 2H3-13C2-creatine using a two-step derivatization procedure, followed by quantification with GC-MS. With all cell-lines we found no increase of function, indicated by low intra-cellular creatine content (SLC6A8) (Rosenberg et al. 2007) and no formed 2H3-13C2-creatine (GAMT) (Verhoeven et al. 2004) as compared to the wild-type cell-lines. This led us to conclude that PTC124 (Selleck Chemicals) cannot induce ribosomal readthrough of the five tested nonsense mediated termination codons in the SLC6A8 and GAMT gene. However, since we were unable to validate the obtained compound, these results could also have been caused by the initial inability of our PTC124 to function correctly.

P14.20
Inhibition of superoxide dismutase expression with progestins as a mechanism for the treatment of familial amyotrophic lateral sclerosis.

D. E. Benjamin*;*
Cenoxsys Corporation, Princeton, NJ, United States.

Familial amyotrophic lateral sclerosis (fALS) is a severe motoneuron disease, and mutations in superoxide dismutase (SOD1) are responsible for at least 20% of cases. fALS is inherited in an autosomal dominant manner and disease severity is mutant gene dose-dependent. Knockout of the SOD1 gene does not result in motoneuron disease in the mouse. Thus reduction of mutant SOD1 expression has been proposed as a mechanism for treatment of fALS. We aimed to identify compounds that selectively decrease cellular levels of SOD1. A library of known drug-like molecules was screened for the ability to decrease SOD1 levels in several cell lines including Hek-293 cells and HeLa cells. Cells were seeded into 96-well plates and test compounds were added 24 hours later. Several progestins (IC50: 100-300 nM) dose-dependently decreased SOD1 levels following 96 hours of incubation. Total cell number, cell morphology, and total protein level was not affected in the transformed cell lines. However, in HeLa cells, all progestins exhibited significant cytotoxicity, as expected based on the reported toxic effect of siRNA to SOD1 in specifically cancer-derived cells. Norethindrone, a progesterone analog, selectively decreased SOD1 cellular levels by 80% (IC50: 92 nM). The progesterone receptor antagonist mifepristone dose-dependently inhibited this effect, supporting a receptor mediated action. In the G93A mouse model of fALS, 7 days intraperitoneal administration of norethindrone (100 μg/Kg) decreased spinal cord levels of mutant human SOD1 in preliminary studies. Collectively, these results suggest that further investigation of progestins in the treatment of fALS is warranted.

P14.21
Differential response to VPA in SMA therapy: Did we catch the bad guy?

L. Garbes[1], *J. Schreml*[1], *L. Heesen*[1], *I. Hoelker*[1], *T. Bauer*[2], *C. Mueller*[2], *J. Dimos*[3], *R. Heller*[1], *B. Wirth*[1];
[1]*Institute of Human Genetics, Institute of Genetics and Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany,* [2]*Institute of Pharmacology, University of Cologne, Cologne, Germany,* [3]*iPierian Incorporated, South San Francisco, CA, United States.*

Proximal spinal muscular atrophy (SMA) is the number one genetic killer during early infancy. It is caused by functional loss of SMN1, resulting in progressive degeneration of spinal α-motor neurons. SMA severity is mainly determined by SMN2 copy number. Consequently, a number of therapeutic approaches has been developed directly targeting SMN2. We have shown that valproic acid (VPA), a short-chain fatty acid histone deacetylase inhibitor (HDACi), significantly increases SMN levels in vitro, ex vivo and in VPA-treated SMA patients. However, in a first pilot clinical trial with VPA only 1/3 of the patients exhibited markedly increased SMN levels, whereas the remaining were non-responders. To identify the crucial factors accounting for this observation, we established fibroblast lines from >30 SMA-patients undergoing VPA-therapy. Response to VPA was concordant between blood and fibroblasts in about 65% of cases. By microarray analysis we identified four significantly differentially expressed transcripts between both patient-groups. Strikingly, non-responders lacked any differences in expression between mock- and VPA-treated cells, suggesting a failure of HDAC inhibition. Indeed, the most differentially expressed gene is involved in fatty acid transport suggesting an altered VPA import/export. By employing different analytical and biochemical methods, we could identify striking differences in fatty acid uptake and metabolism, which most likely account for the observed differential response to VPA.

Our data sheds first light on the molecular mechanisms influencing VPA response and may not only have a major impact on the therapy of SMA but also on other diseases treated with VPA, like epilepsy or migraine.

P14.22
Genotoxicity biomarkers in thalassaemic patients

E. Ferro[1], *G. Visalli*[2], *B. Baluce*[2], *R. Civa*[3], *G. Randazzo Papa*[4], *M. A. La Rosa*[3], *D. G. D'Ascola*[5], *B. Piraino*[3], *L. Rigoli*[3], *C. Salpietro*[3], *A. Di Pietro*[2];
[1]*Department of Pediatrics, Department of Neuroscience, Hospital University, Messina, Italy,* [2]*Department of Hygiene, Hospital University, Messina, Italy,* [3]*Department of Pediatrics, Hospital University, Messina, Italy,* [4]*A.S.P. N.5, Messina, Italy,* [5]*Department of Thalassemia, Riuniti Hospital, Reggio Calabria, Italy.*

Introduction: Iron plays a role in carcinogenesis through the generation of oxygen free radicals. In thalassemic patients that do not receive transfusions, abnormal iron absorption produces an increase in the body iron. Regular blood transfusions lead to a greater iron accumulation, therefore it is essential an iron chelation therapy.
Purpose: To evaluate the efficiency of iron chelating therapy to prevent genotoxicity in polytransfused thalassemic patients, we analysed lymphocytic DNA damage by Micronucleus test (MNT) and Comet assay.
Methods: The study includes 77 transfusions-dependent β thalassemic patients and a control group of 20 no transfused subjects with thalassemia intermedia. The patients were divided in four therapy groups: 25 were treated with Deferasirox (ICL670), 23 with Deferoxamine (DFO), 10 with Deferiprone (L1) and 19 with combined therapy (DFO+L1).
Results: The results are summarized in Table 1. Micronuclei distribution is different in four groups (Kruskal-Wallis test, p=0.014). No significant differences were observed using the Comet assay for the high intra-group variability.
All groups showed a significant difference compared with the control group (Mann-Whitney U test, p<0.05) for MNT, except for the patients with ICL670 therapy.
Discussion: In the examined sample, ICL670 is the most effective, followed by the DFO and combined therapy.
The Deferiprone would seem the least effective but needs a more numerous patients group.

Table 1: The results for Micronucleus test and Comet assay

	NO Therapy	ICL670	DFO	L1	DFO+L1
MN	13.3 ± 6.4	14.5 ± 7.8	17 ± 6.2	24.1 ± 9.4	18.4 ± 15.2
Tail DNA %	11.4 ± 8.5	14 ± 12.7	11.9 ± 7.9	14.4 ± 12.3	14.2 ± 13.2

J14.01
Stem cell a new way in treatment hearing loss impairment.

M. Falah[1], *M. Houshmand*[2], *S. Kamrava*[1], *M. Falah*[1], *M. Farhadi*[1];
[1]*Department and Research Centre of ENT & Head and, Tehran, Islamic Republic of Iran,* [2]*National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran., Tehran, Islamic Republic of Iran.*

Deafness is a condition that has an enormous personal, social and economical impact.
The options available to treat are very limited, and represented by prosthetic devices such as hearing aids and cochlear implants. There is a clear need for a therapeutic breakthrough that will help the millions of people affected, so studies in stem cell technologies have been initiated in order to repair, regenerate or replace lost hair cells
The auditory organs appear to contain cell with stem cell properties that can differentiate to hair cells and neurons.
Embryonic stem cells are one potential source. Neural progenitors made from embryonic stem cells, transplanted into the inner ear, they differentiated in to cells that expressed neuronal markers. The re growth of these neurons suggests that it may be possible to replace audiotory neurons that have degenerated with neurons that restore auditory function.
Stem cell therapy to treat deafness is still some years in to the future because of; first, different cell types are potentially to be used, all of them having advantages and disadvantages. Second, in order to target such a small and secluded organ as the cochlea, difficult surgical techniques are to be used, some of which still need to be developed.
But we sure combination of stem cell, gene therapy and drug treatment in conjunction with technical devices, such as microprocessor-controlled cochlear-interface implants can start a new avenue for the development of strategies to restore hearing therefore they are offering a glimmer of hope for these afflictions.

Bacterial DNA interference with aged bone DNA amplification

A. Ghasemi[1,2], *M. Tavallaei*[3], *Z. Zafari*[1,4], *N. Mahdieh*[1], *A. Shirkavand*[1,5], *H. Bahmani*[3], *A. Mohammadi*[3], *M. S. Fallah*[1], *S. Zeinali*[1,6];
[1]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [2]*Azad University of Jahrom, Jahrom, Islamic Republic of Iran,* [3]*Human Genetic Research Center, Baqyatallah University, Tehran, Islamic Republic of Iran,* [4]*Khatam university, Tehran, Islamic Republic of Iran,* [5]*Biology Group, Faculty of Sciences, Razi University, Kermanshah, Islamic Republic of Iran,* [6]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*

Introduction: Molecular human identification of remnants of human body is of increasing usage in natural disasters, wars and forensic laboratories. Bone and teeth are major source for genomic DNA due to their higher stability. DNA degradation and also contamination with PCR inhibitors could interfere with DNA amplification and contamination with bacterial DNA might be a reason especially when we work with aged DNA (aDNA). Here we report effect of bacterial DNA contamination in DNA extracted from Iranian human remains from the war with amplification using real-time PCR.
Material and methods: DNA was extracted from aged bone (remained from 20-30 years before) and also E.coli. PCR based techniques were used to amplify both human and bacterial DNAs separately using different set of primers. aDNA was mixed with bacterial DNA and amplification was performed using both set of primers.
Result: Amplification of artificially contaminated aged bone DNA with E. coli DNA didn't showed any negative interference or inhibition by bacterial DNA. Even in some samples, amplification was performed just in the cases of mixture aDNA with bacterial DNA. We tested this with real-time PCR and conventional PCR results were confirmed by amplification of mixed DNA in 2-3 cycles before the aDNA.
Conclusion: It seems bacterial DNA does not inhibit amplification of human aDNA. Even in some instance it might act as a biological indicator for the presence or absence of PCR inhibitor.

P15.02
Validation of two commercially available kits for clinical Rapid Aneuploidy Detection

S. L. Hume, *B. Elyas, L. Podemski, S. Haase, K. Baptista-Wyatt, M. Hicks, M. J. Somerville, P. Scott;*
University of Alberta, Edmonton, AB, Canada.

Rapid aneuploidy detection (RAD), allows the rapid and efficient detection of the common aneuploidies in at-risk pregnancies. RAD, although widely used in Europe, is only beginning to emerge as a front-line prenatal test in North America. Our experience with 161 samples demonstrated that Aneufast™ v1 (Molgentix SL) required a high rate of reflex testing (10.2% of the chromosome pairs tested were non-informative or out-of-range representing 29% of all patient samples). In an effort to decrease cost and sample reporting time, we chose to validate Aneufast® v2, released in January 2011 and Elucigene's Q*STR*plus*V2 (Gen-Probe). A series of 48 samples were chosen: 24 with confirmed aneuploidies (karyotype and Aneufast™ v1), 2 normal controls, and 24 normal samples that required reflex with Aneufast™ v1. All samples were analyzed according to manufacturer's recommendations with 2 informative markers required for classification. Our results demonstrated that the amount of reflex testing in the validation dataset is dramatically reduced: 5.7% of chromosome pairs (20.8% of patient samples) for Aneufast® v.2 while Q*STR*plus*V2 required reflexing in 3.1% of chromosome pairs (12.5% of patient samples). The sensitivity and specificity of all three tests was identical (sensitivity = 95.5%, specificity = 100%). Importantly,

the Q*STR*plus*V2 kit, using the TAF9L microsatellite, determined the number of copies of the X chromosome present in the initial test while Aneufast® v2 required reflex to obtain the TAF9L ratio. Therefore, in our experience, the Q*STR*plus*V2 kit has a lower overall time to report and is more cost-effective.

P15.03
Twenty years of Molecular Genetics External Quality Assessment

Z. Deans[1], *S. Abbs*[2];
[1]*Scheme Organiser, UK NEQAS for Molecular Genetics, Institute of Human Genetics, Newcastle upon Tyne, United Kingdom,* [2]*Steering Committee Chairman, UK NEQAS for Molecular Genetics, GSTS Pathology, London, United Kingdom.*

UK National External Quality Assessment Scheme (UKNEQAS) for Molecular Genetics has been providing a measure of the standard of molecular laboratory services for the last twenty years. The scheme started in 1991 with a few laboratories participating in genotyping only external quality assessments (EQAs) for CF, HD and DMD. This has developed into a self-funding, not-for-profit organisation which now offers 29 separate EQAs to over 120 participating laboratories.

EQAs assess genotyping accuracy, result interpretation and clerical accuracy of the reports. Samples are distributed and participants are required to submit interpretative reports in the laboratory's standard format. This ensures that the whole process is assessed, from sample receipt to the issuing of the final report. Performance monitoring has identified errors in different steps of the process providing evidence that this assessment of the process is essential in measuring the standard of the laboratory. Web-based interpretative EQAs have been established for rarer diseases to reduce EQA costs for laboratories. Wherever professional Best Practice Guidelines are available these are used to establish the marking criteria for each EQA.

Six key areas are covered by these EQAs; core diseases, preimplantation genetic diagnosis, newborn screening, non-invasive prenatal diagnosis, molecular rapid aneuploidy testing (UKNEQAS for Cytogenetics collaboration) and molecular histopathology for *KRAS* and *EGFR* testing (UKNEQAS ICC collaboration).

Performance is high in well established EQAs but pilot EQAs identify a number of performance issues. As laboratories participate more regularly in EQAs then there is a marked improvement in performance and the standard of laboratory output.

P15.04
Measuring the improvement of the interpretation in cystic fibrosis laboratory reports

S. Berwouts[1], *E. Girodon*[2], *M. A. Morris*[3], *M. Schwarz*[4], *M. Stuhrmann*[5], *E. Dequeker*[1];
[1]*Katholieke Universiteit Leuven, Department of Human Genetics, Biomedical Quality Assurance Research Unit, Leuven, Belgium,* [2]*Groupe hospitalier Henri Mondor-Albert Chenevier, APHP, Service de Biochimie et Génétique, Créteil, France,* [3]*University Hospitals, Molecular Diagnostic Laboratory, Service of Genetic Medicine, Geneva, Switzerland,* [4]*St Mary's Hospital, Genetic Medicine, Manchester, United Kingdom,* [5]*Medizinische Hochschule, Institut für Humangenetik, Hannover, Germany.*

Interpretation of genetic test results in laboratory reports is an ISO and OECD requirement. It should be performed according to the indication for testing and considering that the recipient may not understand all implications of genetic test results. We assessed interpretation aspects for similar cases circulated through the Cystic Fibrosis (CF) External Quality Assessment (EQA) scheme in 2004 (n=232 laboratories), 2008 (n=202) and 2009 (n=203). The mock case described a newborn with meconium ileus at birth; a molecular analysis was requested to confirm the CF diagnosis. The presence of two mutations indeed confirmed the diagnosis. "Confirmation of diagnosis" was present in 90% of the reports in 2004, 95% in 2008 and 97% in 2009. "Recommendation for genetic counselling" was included in 85%, 90% and 89% of reports respectively. "Suggestion for prenatal or preimplantation diagnosis for subsequent pregnancies" was mentioned in 54%, 67% and 75% of reports respectively. The average interpretation score was 1.49/2.00 in 2004, 1.77/2.00 in 2008 and 1.85/2.00 in 2009. The score for laboratories that participated in the three years (n=132) evolved from 1.52/2.00 to 1.80/2.00 and 1.90/2.00. Those that participated only once scored 1.47/2.00 in 2004 (n=58), 1.67/2.00 in 2008 (n=15) and 1.51/2.00 in 2009 (n=18). In 2004, 22% of the participants obtained 2.00/2.00, compared to 66% in 2009. This study demonstrated that interpretation improved over the years, in particular regarding implications for all genetic counselling aspects, and that regular participation to EQA contributes to an improved quality of reporting.

P15.05
The Italian External Quality Assessment in classical cytogenetics: state of the art

G. Floridia, *F. Censi, F. Tosto, M. Marra, V. Falbo, D. Taruscio;*
Istituto Superiore di Sanità, Centro Nazionale Malattie Rare, Roma, Italy.

The Italian External Quality Assessment (IEQA) in classical cytogenetics started in 2001 and is coordinated by the Istituto Superiore di Sanità, (ISS). The IEQA covers both prenatal and postnatal diagnosis, including cancer cytogenetics.

From 2001 to 2009 this activity has been funded by the Italian Ministry of Health through research projects and participation to the IEQA was free. Since 2010 laboratories pay a fee for each scheme and participation is not anymore restricted to public genetic services only (Gazzetta Ufficiale Serie Generale n.199-28th August 2009).

The IEQA is retrospective since laboratories submit images and reports of two cases they have already analysed; cases are selected according to a fixed schedule. In 2008 a web-based system was developed; all EQA phases are managed through three different sections dedicated to the Scheme Organizer, the participants and the assessors.

Assessment takes into account technical, analytical and interpretative performance and two different groups of assessors are involved in constitutional and cancer cytogenetics. A clear marking system has been established and agreed by the Scheme organiser and assessors in order to better identify the performance of laboratories. Following assessment each participant receives a summary letter and an individual report with scores and comments.

Results of the VIth (2008-2009) and VII th trial (2010) will be showed and discussed.

P15.06
European external quality assessment for the improvement of *KRAS* testing

E. Bellon[1], *M. Ligtenberg*[2], *G. De Hertogh*[3], *K. de Stricker*[4], *A. Edsjö*[5], *P. Laurent-Puig*[6], *J. C. Machado*[7], *E. Rouleau*[8], *P. Vandenberghe*[3], *S. Vander Borght*[3], *J. Van Krieken*[2], *E. Dequeker*[1];
[1]*Centre for Human Genetics, Biomedical Quality Assurance Research Unit, Katholieke Universiteit Leuven, Leuven, Belgium,* [2]*Department of Pathology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Centrum Moleculaire Diagnostiek, Leuven, Belgium,* [4]*Odense University Hospital, Odense, Denmark,* [5]*Clinical Pathology Malmö, Malmö, Sweden,* [6]*U775 Bases moléculaires de la réponse aux xénobiotiques, Paris, France,* [7]*IPATIMUP Diagnostics, Porto, Portugal,* [8]*Centre René Huguenin, St Cloud, France.*

KRAS mutational status in tumor cells has become an important determinant for the successful application of epidermal growth factor receptor targeting therapy in patients with colorectal cancer. In an effort to ensure optimal, uniform and reliable community based *KRAS* testing throughout Europe, a *KRAS* External Quality Assessment (EQA) scheme was set up. In total 76 laboratories from 14 different European countries participated and were divided among 6 regional schemes. For each scheme, one regional scheme organizer prepared and distributed the samples, in accordance with agreements on the mutational status. The samples included unstained sections of 10 invasive colorectal carcinomas with known *KRAS* genotype. The samples were centrally validated by a reference laboratory. From the 76 participating laboratories, 50 reported all 10 genotypes correctly (66%). Thirteen laboratories genotyped one out of 10 samples wrong and 3 laboratories genotyped two or more out of the 10 samples wrong. Ten laboratories reported a technical error (no result) for one or more samples. The average genotyping score for the *KRAS* EQA scheme is 9,49/10,00 (94,9%). There is an overall improvement in the score of laboratories that participated also in the *KRAS* EQA scheme of last year. Mistakes were made both in laboratories using commercial and "in-house" validated assays. In addition, we analysed tumor percentage analysis and written reports for educational purposes.

This EQA scheme is a useful tool to provide information about the performance of a given laboratory compared to others, and to stimulate optimalisation of lab procedures.

P15.07
Evaluation of tripled repeat primed (TP)-PCR assay and Sizing PCR assay of the FMR1 gene for the molecular diagnosis of the fragile X syndrome

I. De Clercq[1], *V. Debacker*[1], *K. Eycken*[2], *K. Claes*[1];
[1]*Ghent University Hospital, Gent, Belgium,* [2]*Abbott, Wavre, Belgium.*

Fragile X syndrome is caused by the abnormal expansion of the CGG repeat in the 5' untranslated region of the FMR1 (Fragile X Mental Retardation 1) gene. Routine molecular analysis includes a combination of PCR and Southern blot analysis. However, Southern blot analysis largely constrains throughput and efficiency and requires large amounts of high quality DNA.

This study aims to evaluate if in a routine diagnostic setting Southern blot can be replaced by PCR based assays. We evaluated the FMR1 TP (triplet repeat primed)-PCR assay (Abbott) for rapid distinction between normal and expanded FMR1 alleles and the FMR1 Sizing PCR assay (Abbott) for accurate sizing of alleles.

We evaluated assay performance using DNA from 4 cell lines and 53 archived samples (from 9 normal individuals, 1 case with a grey zone allele, 13 pre- and 31 full mutation carriers with repeat expansions ranging between 57-1300 CGG, 4 mosaic cases with alleles within the pre- and full mutation range). The TP-PCR assay accurately distinguished normal from expanded alleles. The Sizing PCR assay accurately sized premutation and full mutation alleles up to 335 CGG repeats. Interpretation of some mosaic cases was challenging with TP-PCR.

In conclusion, the assays evaluated allow efficient workflows in a diagnostic context and lead to a final conclusion for the large majority of the referred cases. A methylation-sensitive test is still required to unequivocally distinguish premutation from full mutation alleles with lengths in the transition zone (150-250 CGG), where correct interpretation depends on methylation status.

P15.08***
Discrepancies in reporting the CAG repeat lengths for Huntington's disease

O. W. Quarrell[1], *O. Handley*[2], *K. O'Donovan*[1], *C. Dumoulin*[3], *M. Ramos-Arroyo*[4], *I. Biunno*[5], *P. Bauer*[6], *M. Kline*[7], *B. Landwehrmeyer*[8];
[1]*Sheffield Children's Hospital, Sheffield, United Kingdom,* [2]*Institute of Neurology, London, United Kingdom,* [3]*Insitut du Pathologie et Genetique, Grosseleis, Belgium,* [4]*Dept. Medical Genetics, Complejo Hospitalario Pamplona, Pamplona, Spain,* [5]*ITB-CNR and BioRep, Milan, Italy,* [6]*Medizinische Genetik, University of Tübingen, Tubingen, Germany,* [7]*National Institute for Standards and Technology, Biochemical Science Division, Gaithersburg, MD, United States,* [8]*Dept of Neurology, University of Ulm, Ulm, Germany.*

Huntington's disease results from a CAG repeat expansion in the first exon of the *Huntingtin* gene; this is measured routinely in diagnostic laboratories. The European Huntington's Disease Network REGISTRY project centrally measures CAG repeat lengths from fresh blood samples; these were compared with the original results from 121 laboratories across 15 countries. We report on 1326 duplicate results: there was a discrepancy of reporting the upper allele in 51% of cases; this reduced to 13.3% if acceptable measurement errors proposed by the American College of Medical Genetics were applied. Duplicate results were available for 1250 lower alleles and discrepancies occurred in 40%. Clinically significant discrepancies occurred in 4.0% of cases with a potential unexplained mis-diagnosis rate of 0.3%. There was considerable variation in the discrepancy rate among 10 of the countries participating in this study. 348/1326 DNA samples were re-analysed by an accredited diagnostic laboratory based in Germany, with concordance rates of 93% and 94% for the upper and lower alleles respectively. This became 100% if the acceptable measurement errors were applied. The central laboratory correctly reported allele sizes for 6 standard reference samples, blind to the known result.

Our study differs from external quality assessment schemes in that these are duplicate results obtained from a large sample of patients across the whole diagnostic range. We strongly recommend that laboratories state an error rate for their measurement on the report; they should participate in external quality assessment schemes and use reference materials regularly to adjust their own internal standards.

P15.09
Efficiency of neurogenetic testing during a 10-year period

N. Teran, *H. Jaklič, B. Peterlin;*
Institute of Medical Genetics, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Neurogenetic disorders have low prevalence (<1/10000) in the general population. Specific genetic tests are used to help diagnose neurological diseases depending on the type of mutation. In this study we analysed the diagnostic yield and estimated the costs of negative results of neurogenetic testing.

We performed a retrospective review of the data in the database of the molecular genetic laboratory of the Institute of Medical Genetics, UMC Ljubljana, involving a 10-year period (2000-2010).

Overall, a mutation was identified in 30.9 % of the tested patients (n=443). In patients with muscle weakness (n=205) the mutation detection rate was 38.4 % with an estimated cost of 55,781.95 EUR per negative result. In patients with neuropathies (n=99) the mutation detection rate was 36.1 % with an estimated cost of 53,046.85 EUR per negative test. In patients with chorea (n=100) a positive result was obtained in 42.5 % (22,889.25 EUR per negative result). The diagnostic yield in patients with congenital malformations was 8.9 %; the estimated cost per negative result was 70,931.25 EUR. For ataxias (n=16) the mutation detection rate was 11.9 %; the estimated cost of negative result was 36,071.85 EUR.

The diagnostic yield and costs per negative results varied among the different diagnostic groups, reflecting utilization guidelines and selection criteria for neurogenetic testing. The results of this analysis may assist the clinician when weighing the decision whether to test or not. Guidelines including new testing strategies would contribute to appropriate and cost-effective use of molecular genetic testing in general.

P15.10
External quality assessment schemes for molecular testing on blood spots

A. Wittner, *Z. Deans;*
UKNEQAS Institute of Human Genetics, Newcastle upon Tyne, United Kingdom.

Newborn screening is performed in many countries by analysing dried blood spots to detect abnormal levels of chemicals as indicators of inherited blood and metabolic disorders. Confirmation of clinical diagnosis is often provided by molecular testing and DNA analysis is part of the cystic fibrosis (CF) and Medium chain acyl-CoA dehydrogenase deficiency (MCADD) screening protocols of several newborn screening programmes in Europe.

UK NEQAS for Molecular Genetics is an accredited, self-funding, not-for-profit organization providing external quality assessment schemes (EQAs) for a wide range of molecular disorders since 1991. The scheme has offered "CF molecular testing on blood spots EQA" for the last five years and introduced "MCADD molecular testing for the common ACADM mutation c.985A>G on blood spots EQA" in April 2010. Three blood spot samples are distributed 4 times a year and participants are required to analyse them according to their routine protocol and report the genotyping results. These are assessed for genotyping accuracy. To reflect the laboratory testing, the "MCADD extended mutation screening on blood spots pilot EQA" was introduced last year.

To further enhance these EQA schemes the development of artificial blood spots has been initiated. Using simulated EQA material will enable the distribution of samples with mutations/polymorphisms with the potential to cause interference during analysis or interpretation. The laboratories thereby would be provided with a measure of the robustness of their testing protocol and would be assured of the standard of their service.

P15.11
A quality management plan in a genetic testing laboratory in Romania

D. Vlad[1], *V. Dumitrascu*[2], *C. Gug*[3], *A. Cimporescu*[1], *A. Matusz*[4], *B. Barac*[2], *R. Olariu*[5], *F. Horhat*[6];
[1]*Emergency County Hospital, Timisoara, Romania,* [2]*Pharmacology Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [3]*Medical Genetics Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [4]*General Private Office, Timisoara, Romania,* [5]*Parasitology Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [6]*Microbiology Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.*

High quality genetic testing is very important for proper diagnosis and patient management.To provide the highest standard of analysis,strict laboratory assurance procedures must be followed.

In this study we developed a quality management plan that would enable us to assure the highest quality standards for genetic testing laboratories.We choosed ISO15189:2007 because it was the more appropriate standard according to our activities.

We nominated a member of the laboratory team to coordinate the plan,but involvement of all laboratory team to implement different parts of the standard for the laboratory is very important.A detailed quality management plan will allow identification of possible deficiencies in laboratory.

It is necessary that laboratory services include an effective labelling(so that the specimens are easily tracked) and adequate physical storage,in addition to the consideration of safety and ethics in genetic laboratory work.Laboratory technicians are responsible for the good quality of the patient's samples and sent for testing to laboratory.

The quality of the primary sample(s),to be collected using appropiate materials in a standardized way,represent the basic factor that affect the quality of performance and delivery of testing services,the adequacy of oversight and quality assurance mechanism.

The most significant percentage of errors that occurs in the laboratory takes place at the preanalytical phase.That phase encompasses test selection,ordering and specimen collection,processing,handling,and delivery to the testing site.

In conclusion,quality indicators reduces errors related to test selection and requests,specimen submission,test performance,and reporting and interpretation of results,leading to improved use of genetic laboratory services, including better health outcome for patients.

Chronic myeloid leukemia is characterized by neoplastic overproduction of myelocytes and neutrophils. Detection of cells carrying BCR/ABL fusion is extremely important in monitoring response to treatment, remission and relapse in CML patients. Among the molecular diagnostic techniques used amplification of BCR/ABL fusion transcript , RT-PCR is regarded to be most sensitive.

In this experimental study, we compared RT-PCR and NASBA techniques to determine quantitatively the number of bcr/abl transcripts. In order to make an accurate comparison, the sequences of primers and probes used in both techniques were the same. Fusion transcripts were synthesized and RNA was extracted from K562 leukemic cell line. A serial dilution of both fusion transcript and RNA was prepared; then sensitivity of both techniques was determined. RT-PCR and NASBA reaction products were labelled using equal ratios of DIG-11-dUTP and DIG-11-UTP respectively. Following denaturation , hybridization reactions were carried out with specific probes. The products were incubated in streptavidin coated microplates. Then, the plates were washed, anti-DIG conjugated to peroxidase added and using ATBS as substrate, enzymatic activity was determined by absorption at 405 nm. The our results showed that specificity between two techniques is equal but RT-PCR-ELISA sensitivity is about a 100-fold more than of NASBA-ELISA. Also, leukemia cell detection rate in sample by RT-PCR-ELISA and NASBA-ELISA is 4 and 400 cells, respectively.

Interpretation and Conclusions: Therefore, despite the NASBA technique have not need to thermal cycler PCR but have a low sensitivity than RT-PCR and it is not suitable method for quantitative assessment.

Thrombophilic gene mutations and pulmonary thromboembolism in Iranian patients

E. Sakhinia[1], *A. Poursadegh Zonouzi*[2], *A. Firoozi*[3], *N. Karimi Ansari*[3], *Y. Heshmat*[3], *A. Asghari Haghie*[3], *M. Ghaffari*[4], *K. Ansarin*[5];

Venous thromboembolism (VTE) is a common vascular disease that includes deep venous thrombosis and pulmonary thromboembolism. It is one of the leading causes of mortality across the world; with an annual incidence range from 1-5 cases per 1000 individuals. Various investigations examined the prevalence of thrombophilic gene mutations in patients who have suffered from a pulmonary thromboembolism. We aimed to determine the association of specific inherited thrombophilias with pulmonary thromboembolisms. A total of 85 subjects were included in this study: 53 patients who had been affected with a pulmonary thromboembolism and 32 healthy controls in the North West of Iran. Total genomic DNA was extracted from 2 ml EDTA anti-coagulated blood samples by a standard salting-out method and amplified by PCR using gene-specific primers. Amplification Refractory Mutation System (ARMS-PCR) method was used in the identification of PAI-1 (-675 I/D, 5G/4G), Factor XIII (Val34Leu), Beta-fibrinogen (-455G/A), Factor VII (Gln353Arg), Glycoprotein Ia (807C/T) and tPA (intron h D/I) gene mutations. Our data indicates that there were statistically significant differences in PTE patients compared with controls, when studying the frequency of these specific gene mutations. In conclusion, we propose that compound thromboplilic gene mutations rather than a specific gene mutation can be a risk factor for the occurrence of pulmonary thromboembolisms; however, further studies on a larger scale are required in order to gain a better understanding of the role of these gene mutations in pulmonary thromboembolisms.

Whole genome amplification in large biobanks

N. Klopp[1], *T. Illig*[1], *C. Korfhage*[2], *H. Wichmann*[1];
[1]*Helmholtz Zentrum München, Munich-Neuherberg, Germany,* [2]*QIAGEN GmbH, Hilden, Germany.*

Biobanks are a key resource for unravelling the molecular basis of diseases and the identification of new targets for disease therapy. One challenge of biobanks is to maintain huge collections of limited samples sizes for future studies. In consequence, there is need for a high quality amplification of limited amounts of nucleic acids. In this project we focused on the standardization and qualification tools of whole genome amplification (WGA) in the context of biobanks. A new simple quantitative PCR based test system was developed, which enables the standardization of the complete whole genome amplification process including (1) the quality and quantity of the template DNA and (2) the resulting WGA products. For validation of the performance, the system was tested in different laboratories using template DNAs of different quality. Consistent results could be achieved in the quality system test of the WGA products reflecting the amount and the fragmentation degree of the initial template DNA. The system was also implemented in the KORA-Biobank with SNP genotyping technology. The results of the WGA test system were correlated with the concordance of genome wide SNP genotypes from genomic template DNA and from

the corresponding WGA products. Based on this result, a general standardized protocol for WGA in biobanking will be developed.
Furthermore, the concept of this project is to make the WGA solution available to other national and international biobanks. The development of the proposed, innovative and specialized tools and customized solutions will help to expand and improve the used of biobanks.

Universidade de São Paulo, São Paulo, Brazil,* [3]*LIM 36, Universidade de São Paulo, São Paulo, Brazil,* [4]*Department of Pathology, LIM 03, Universidade de São Paulo, São Paulo, Brazil.*

Williams-Beuren syndrome (WBS; OMIM 194050) is caused by a hemizygous contiguous gene microdeletion at 7q11.23. Supravalvular aortic stenosis (SVAS), mental retardation, overfriendliness, and ocular and renal abnormalities comprise typical symptoms in WBS. Although fluorescence *in situ* hybridization (FISH) is considered the gold standard technique and the microsatellite DNA markers provide efficient confirmation, Multiplex ligation-dependent probe amplification (MLPA) could also be used. MLPA is a new technique for measuring sequence dosage, allowing large number of samples to be processed simultaneously and thus significantly reducing laboratory work. We assessed the performance of MLPA for the detection of microdeletions by comparing the results with those generated using microsatellite markers. We studied 77 patients with clinical diagnosis of WBS using five microsatellite markers: D7S1870, D7S489, D7S613, D7S2476, D7S489_A and commercial MLPA kit (SALSA P029). A total number of 77 patients were tested. Using five markers together, the result was informative in all patients. The microdeletion was present in 64 (83.1%) patients and absent in 13 (16.9%) patients. Maternal deletions were found in 56.3% of patients and paternal deletions in 43.7% of patients. The size of deletions was 1.55 Mb in 57/64 patients (89.1%) and 1.84 Mb in 7/64 patients (10.9%). Our results show a high degree of concordance between MLPA and markers assays for all samples tested. We conclude that even though the microsatellite markers were important for determine the parental origin, MLPA is a highly sensitive, quick and cost-effective alternative and can provide helpful information for clinical diagnose of WBS.

P15.16
A robust measure of workload for molecular diagnostic laboratories

S. A. R. Stenhouse[1], *R. Butler*[2], *A. Curtis*[3], *J. Deller*[4], *K. Kelly*[5], *G. Norbury*[6], *R. Mountford*[7];
[1]*UK Genetic Testing Network, Glasgow, United Kingdom,* [2]*Clinical Molecular Genetics Society, Cardiff, United Kingdom,* [3]*Clinical Molecular Genetics Society, Newcastle, United Kingdom,* [4]*UK Genetic Testing Network, London, United Kingdom,* [5]*Clinical Molecular Genetics Society, Aberdeen, United Kingdom,* [6]*Clinical Molecular Genetics Society, London, United Kingdom,* [7]*Clinical Molecular Genetics Society, Liverpool, United Kingdom.*

Recognising a longstanding need for a robust workload measure for diagnostic molecular genetics a group from the CMGS and UKGTN collaborated to devise such a system.
The initial premise for this work was that the measure should be transparent and flexible to allow comparisons between laboratories and to take account of developing technologies. The unit chosen for the measure was the final diagnostic report which is easily counted. As reports vary in complexity a weighting system was required. The unit chosen to weight the reports was ‘an amplicon’ which is again easily counted. The weights were then assigned to a band from A to G. The basic unit, Band A, is sample reception and DNA extraction with a weight of one. Band G has a weight of 40.
This system was piloted in 6 UK laboratories. The laboratories varied in size and testing repertoire to ensure a broad base for the trial.
Work is ongoing to align cytogenetic workload units with these molecular units and to validate the measure by comparing workload assigned to the external quality assessment schemes of UK NEQAS. This allows comparison of many laboratories testing the same cases. The mechanics of the system will be described in detail.

P15.17
Automated melting analysis for quality assessment of high resolution scanning data of multi-exon genes

M. Erali[1], *R. Palais*[2], *D. C. Pattison*[1], *N. H. Augustine*[3], *H. R. Hill*[1,3,4], *C. T. Wittwer*[1,3];
[1]*ARUP Institute for Clinical & Experimental Pathology, Salt Lake City, UT, United States,* [2]*Department of Mathematics, University of Utah, Salt Lake City, UT, United States,* [3]*Department of Pathology, University of Utah, Salt Lake City, UT, United States,* [4]*Department of Pediatrics and Medicine, University of Utah, Salt Lake City, UT, United States.*

High resolution melting analysis for scanning multi-exon genes is emerging as the most cost effective and rapid method to identify sequence variants. A microfluidic liquid handler was used to prepare pre-coated 96-well PCR plates with M13-tailed exon specific primers. PCR was done in 96-well plates followed by high resolution melting analysis on the LightScanner. However, analysis of the data can be a bottleneck in the process. Therefore, an automated analysis method for high resolution melting was developed to scan multiple exons of genes and assess the quality of the data generated. A custom program was developed to appropriately set normalization and overlay parameters, and calculate a Curve Spread value that provides an estimate of the degree of variability among clustered melting curves. The Curve Spread allows quality control of primer plates and master mix lots, and provides a standard metric to identify variant sequences as melting curves that do not cluster well with wild type samples. A higher Curve Spread value reveals a greater degree of variation and allows unknown samples containing variants to be easily identified. This software has been applied to the analysis of 70 clinical specimens suspected of having mutations in *CYBB*, variants of which are the major cause of X-linked chronic granulomatous disease. Standardized analysis eliminates user bias and automatically provides a Curve Spread value that can be used as a guide for judging the quality of amplification and to set decision criteria for reflex testing to identify the specific sequence of variants.
