PL1.1
How next generation sequencing changes the practice of medicine

***H. Brunner**;*
Deptartment of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands.

Now that massively parallel (or next generation; NGS) sequencing has become a reality, it is time to ask the question whether this technology will change the way we practice medicine in the clinic. While true costs that include personnel, bioinformatics support and equipment will be considerably higher, we may expect that the costs for sequencing 50-150 genes should not exceed 1000 Euro. This will allow the creation of diagnostic panels of for many clinical situations (muscular dystrophy; neurodegenerative disorders; blindness, deafness, cardiomyopathy; long QT syndrome; Noonan and related conditions etc). This will largely replace the testing of single genes, or of several genes in succession as is now customary. The projected cost of consumables for sequencing all 21000 human genes (the exome) using the SOLID platform is 2000 Euros. This could be used to test for instance to detect ***de novo*** changes in mental retardation patients. We may predict the following:

• Diagnostic testing of genes will move to the front end of the diagnostic process in many clinical situations. When a patient is seen in the outpatient clinic, an exome may already be done.

• Clinical geneticists should themselves aim to be involved in the diagnostic process from the start. This argues for multidisciplinary diagnostic clinics

• Clinical diagnostic skills (in dysmorphology, or other) will become less important and understanding genes and their functions in terms of the human organism becomes a critical skill.

• Numerous patients will be diagnosed with unique (new) genetic conditions. This calls for geneticists to participate and perhaps organize specialist clinics for (very) rare diseases. Geneticists should develop skills that allow them to feel comfortable in their role as the ultimate expert on a subset of these very rare conditions.

• Clinical geneticists should consider setting up services for the public that deal with incidental and minor findings on exome analysis. This may well be in the shape of e-consults rather than of formal outpatient clinics.

• The counseling element of clinical genetics (what am I to do with my life given my genetic profile and risks) remains essentially unchanged.

PL2.1*
De novo balanced chromosomal rearrangements have high risk of neurodevelopmental and psychiatric disorders.

***C. Halgren**[1], I. Bache[1], N. M. Nielsen[2], S. Kjaergaard[3], K. Brøndum-Nielsen[4], P. K. A. Jensen[5], C. Fagerberg[6], L. N. Krogh[7], M. Frisch[2], J. Hansen[5], T. Bryndorf[8], N. Tommerup[1];*
[1]University of Copenhagen, Copenhagen, Denmark, [2]Statens Serum Institut, Copenhagen, Denmark, [3]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [4]Kennedy Center, Glostrup, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Vejle Hospital, Vejle, Denmark, [7]Odense University Hospital, Odense, Denmark, [8]Hvidovre University Hospital, Hvidovre, Denmark.

Carriers of prenatally detected *de novo* balanced reciprocal translocations or inversions are believed to have 6-9% risk of congenital malformations and/or developmental delay. However, systematic data regarding late-onset disorders are lacking.

A cohort (N=41) of unselected carriers, that were detected prenatally in the period 1970-2008, was identified in the Danish Cytogenetic Central Register. Using information from national medical registries, we compared morbidity in the cohort to that of a 5:1 matched control group (N=205). Carriers were offered clinical re-examination, analysis with Affymetrix SNP 6.0 Array, and breakpoint mapping with Next Generation Sequencing (NGS) Mate-pair Analysis.

We observed no serious congenital malformations in the cohort. However, the risk of neurodevelopmental and/or psychiatric disorders, including mental retardation, learning disabilities, attention and/or behavioral disorders, autism spectrum disorders, and mood disorders, was significantly elevated (19.5% vs. 8.3% among the controls, p=0.04). Analysis for copy number variants >100 kb did not provide prognostic information about late-onset disorders. So far Mate-pair sequencing indicate that many affected carriers have complex rearrangements and/or rearrangements that truncate brain expressed genes, including genes known to be involved in neurodevelopmental disorders.

Our study demonstrated that prenatally detected *de novo* balanced chromosomal rearrangements have high risk of late-onset neurodevelopmental and/or psychiatric disorders but are not associated with congenital malformations. The breakpoint mapping, which will be completed in March 2011, will reveal whether NGS can improve the counseling dilemma associated with prenatally detected apparently balanced *de novo* chromosomal rearrangements.

PL2.2
Development and validation of non-invasive prenatal diagnostic test for trisomy 21

*E. A. Papageorgiou[1], A. Karagrigoriou[2], E. Tsaliki[1], V. Velissariou[3], N. P. Carter[4], **P. C. Patsalis**[1];*
[1]Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]University of Cyprus, Nicosia, Cyprus, [3]Mitera Hospital, Athens, Greece, [4]The Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

The development of a Non-Invasive Prenatal Diagnostic (NIPD) test for Down syndrome (Trisomy 21) has become one of the most interesting fields in the prenatal world of the last decade. Extensive investigation of epigenetic differences between the mother and the fetus has led to the identification of Differentially Methylated Regions (DMRs) which have the potential to be used in the development of NIPD test for Trisomy 21 (Papageorgiou et al., AJP, 2009).In this study, we have been using a subset of our previously identified DMRs to develop a non-invasive prenatal diagnostic test for Trisomy 21 using the Methylated DNA Immunoprecipitation (MeDIP) methodology in combination with Real-time qPCR. The statistical significance of the 12 selected DMRs was evaluated using the Mann-Witney U test and selection of the best DMRs was followed.

We hereby present a strategy to achieve non-invasive fetal chromosome dosage assessment through the analysis of fetal specific DMRs. We achieved non-invasive prenatal detection of Trisomy 21 by determining the methylation ratio of normal and Trisomy 21 cases for each tested fetal specific DMR present in maternal peripheral blood, followed by further statistical analysis. The application of the above fetal specific methylation ratio approach provided with 100% accuracy the correct diagnosis of 66 normal and 34 Trisomy 21 pregnancies.

We present in this study the successful development and validation of a low cost, fast, sensitive and universal, non-invasive prenatal diagnostic test for Trisomy 21 which can be potentially implemented in diagnostic laboratories.

PL2.3*
mRNA-Seq analysis of monozygotic twins discordant for Trisomy 21 reveals large chromosomal domains of gene expression dysregulation

***A. Letourneau**[1], S. B. Montgomery[1], D. Gonzalez[2], C. Borel[1], D. Robyr[1], E. Migliavacca[1,3], Y. Hibaoui[4], L. Farinelli[5], M. Gagnebin[1], E. Falconnet[1], S. Deutsch[1], S. Dahoun-Hadorn[4], J. L. Blouin[1,4], A. Feki[4], R. Guigo[2], E. T. Dermitzakis[1], S. E. Antonarakis[1,4];*

[5]FASTERIS SA, Plan-les-Ouates, Switzerland.
Trisomy 21 (T21) is the most widely studied model of aneuploidy. It is likely that the majority of the phenotypes are related to alterations of gene expression. In this study, we investigated the perturbations of gene expression in fibroblasts derived from a pair of monozygotic twins discordant for T21. The use of these samples eliminates the bias of genome variability and most of transcriptome differences observed are likely to be related to the supernumerary chromosome 21.
The transcriptome was studied by mRNA-Seq; more than 200 million 100bp paired-end reads were generated and mapped using MAQ and GEM (Ribeca et al, unpublished). The expression level of 15'000 protein-coding genes was compared between the discordant twins. On average, we found that 4% of the genes are differentially expressed. Surprisingly, for most of the chromosomes, we identified large chromosomal regions that are either up- or downregulated in the trisomic twin. This raised the hypothesis that differential expression may be organized in domains throughout the genome. The same domains of gene expression dysregulation have also been found when we compared the transcriptomes of induced pluripotent stem (iPS) cells derived from the same twins fibroblasts, indicating that iPS cells retain a specific memory of their origin. Control comparisons of fibroblasts between normal monozygotic twins showed some transcriptional differences likely due to the contribution of stochastic, technical and environmental factors.
Our study reveals a unique finding in genome regulation of T21 nuclei and may be important for the molecular pathogenesis of whole and partial chromosome aneuploidies.

PL2.4
Next-generation sequencing in >240 families with X-linked intellectual disability

X-linked intellectual disability (XLID) is a clinically and genetically heterogeneous condition. It accounts for 10% of all forms of intellectual disability. To date, mutations in >90 genes have been implicated in this disorder, yet in the majority of families, the underlying molecular cause is still unknown. We performed Next Generation Sequencing (NGS) for mutation detection in >240 XLID families that had been recruited by the European MRX Consortium and associated groups. In total, we detected potentially XLID causing mutations in up to 45% of our cohort. Only 28% of the families carried mutations in the >90 established XLID genes, which may be due to the fact that prior to NGS, many of the families had undergone pre-screening for mutations in known XLID genes. Unique truncating and/or novel perfectly co-segregating, functionally plausible missense mutations with high pathogenicity scores were detected in 20 genes that had not been implicated in XLID before. Numerous of these novel genes play a role in the regulation of transcription, while others are involved in ubiquitin-mediated protein degradation or in synaptic function, and many interact with ID genes that are already known. To our knowledge, this is the largest study ever into the molecular causes of XLID and the first one employing NGS to elucidate monogenic disorders in a systematic manner. It illustrates that in spite of a previous, Sanger-sequencing-based 'drain the pond' screening effort (Tarpey et al, Nature Genetics, 2009), the pond of unknown XLID genes is not empty yet.
Supported by BMBF, Max-Planck-Society, EU.

PL2.5*
Identification of the gene underlying Congenital Short Bowel Syndrome, pointing to its major role in intestinal development

Congenital Short Bowel Syndrome is an autosomal recessive disorder characterized by substantial shortening of the small intestine and by intestinal malrotation. Until recently, nothing was known about the genetic cause. Homozygosity mapping was performed using 610K SNP arrays of Illumina on five patients of four different families, including one consanguineous family with two affected siblings and one unaffected child. We found an overlapping homozygous region in four of the five patients. In this region a homozygous deletion concerning one exon of a gene encoding a tight-junction protein, was detected in one of the patients. Furthermore, a homozygous deletion in the first intron was detected in the affected siblings of the consanguineous family, this deletion co-segregates with the disease phenotype in this family. Sequencing of the gene in three other patients resulted in the identification of additional mutations: one patient proved to have a heterozygous frameshift mutation and a heterozygous splice site mutation, whereas two other patients were

homozygous for a nonsense mutation and a missense mutation, respectively. The gene is expressed in the intestine of human embryos throughout development. The missense mutation abrogated the normal localization of the encoded protein at the cell membrane. Knock-down experiments in zebrafish resulted in general developmental defects, including shortening of the intestine and absence of goblet cells, which are characteristic for the mid-intestine. Therefore, loss-of-function of the identified gene leads to Congenital Short Bowel Syndrome, likely by interfering with tight-junction formation, with intestinal development and with gut length determination.

Kevin Park, Liverpool, United Kingdom.*

Carbamazepine (CBZ) is the most commonly prescribed anti-epileptic drug. However its use can cause various forms of subcutaneous adverse reactions ranging from maculopapular exanthema (MPE) to Stevens-Johnson syndrome (SJS), a life-threatening skin reaction. A strong correlation has been demonstrated between CBZ-induced SJS and HLA-B*1502 in Asian populations however as HLA-B*1502 is largely absent in European populations, the test is not applicable in Europeans.

We investigated whether genetic variants, particularly within the HLA locus, play a role in susceptibility to CBZ-induced adverse reactions. We performed a genome-wide association study of 22 participants with CBZ-induced hypersensitivity syndrome (HSS), 43 participants with CBZ-induced MPE and 3958 population controls, all of European descent. We replicated the study with an independent set of participants (n=145) with CBZ-induced MPE and SJS.

HLA-A*3101 strongly associated with both HSS (3.5x10-8) and MPE (1.1x10-6) in two independent association studies. Follow-up genotyping of HLA-A*3101 in additional cases and controls confirmed HLA-A*3101 as a risk factor for HSS (OR 12.4; 95% CI 1.3 to 120.4), MPE (OR 8.3; 95% CI 3.6 to 19.4), and SJS (OR 25.9; 95% CI 4.9 to 116.2).

We report for the first time in participants of European ancestry, a strong association between HLA-A*3101 and CBZ-induced hypersensitivity. This finding has immediate clinical relevance in the care of epilepsy patients. The presence of HLA-A*3101 increases the probability of developing hypersensitivity from 5% to 26%, while its absence reduces the risk to 3.8%. This work provides the foundation for genetic testing of HLA-A*3101 for all prospective CBZ users.

PL3.1

The personal genomes of individuals with extreme phenotypes: Cardiac repolarization & sudden cardiac death

A. Chakravarti;

McKusick - Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Although the genome (actually, two genomes) of specific individuals are now being sequenced there is great uncertainty regarding what phenotypic predictions we can make from the sequence itself. Accurate phenotypic predictions may be impossible unless we are more educated about the genetic architecture of human disease and the contributions of epigenetic and environmental effects. One exception to this expectation is perhaps phenotypic prediction in individuals with a rare susceptibility allele or an excess of common susceptibility variants.

Sudden cardiac death, arising from dysregulated cardiac repolarization, is a hallmark of the long QT syndrome and extreme elevations of the QT interval. A variety of human genetic studies by many investigators, including us, have identified over 30 genes contributing to inter-individual variation in the QT interval. We will summarize the current genetic and genomic knowledge in this area, and the study of families and population cohorts, to evaluate whether phenotypic prediction of sudden cardiac death is possible at least for a defined segment of the population.

PL3.3

The genetics of type 2 diabetes: crossing the translational bridge.

M. McCarthy[1,2];

[1]*Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), Churchill Hospital, Oxford, United Kingdom,* [2]*Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.*

Until recently, progress in identification of the genetic variants influencing predisposition to common forms of diabetes and obesity has been slow. However, advances have transformed the situation, with researchers now able to undertake well-powered surveys of genetic variation across the genome.

For T2D, genome-wide association studies have extended the number of loci harbouring common variants implicated in diabetes-susceptibility beyond 40. Most of these seem to impact on beta-cell function and there is evidence that cell cycle regulation pathways are overrepresented. However, even in combination, these variants account for only around 10% of the genetic predisposition to T2D.

Genetic diagnostics plays an increasingly important role in the diagnosis of relatively rare monogenic forms of diabetes and obesity and provides a molecular basis for accurate prognostication and therapeutic optimisation. In contrast, the modest effect of the common variants thus far implicated in common forms of diabetes and obesity has precluded similar clinical applications. Indeed, the principal translational justification for genetic discovery efforts lies in explaining the mysteries of disease pathogenesis: there have been numerous advances in this respect, though much more remains to be done.

The large proportion of heritability and familiality not explained by the GWA approach (which has surveyed only common SNP-based variation) raises questions about the basis of the "missing" genetic variance. The contribution to disease risk of low-frequency and rare variants is being enumerated through large-scale next-generation sequencing studies. Discovery of low frequency penetrant alleles influencing T2D risk (and/or risk of obesity and other metabolic and cardiovascular traits) will not only provide important insights into disease pathogenesis, but also powerful reagents to support functional and physiological studies.

S01.1
Controlling gene expression by the regulation of chromatin compaction in the nucleus

***W. Bickmore**;*
MRC Human Genetics Unit, Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom.

It is widely appreciated that histone modifications correlate to gene expression states and can, in some cases, directly impact on gene expression and repression. But, our understanding of chromatin states beyond the level of the nucleosome itself is rudimentary and so there has been little exploration of how these levels of chromatin structure might contribute to the regulation of gene expression.
Important and well studied regulators of gene expression during development are the polycomb repressive complexes (PRCs). These complexes have also been implicated in human cancers and their histone modifying activities have been studied extensively. However, we show that polycomb repressive complexes act at the level of chromatin compaction in the nucleus and we go on to demonstrate that the ability of the PRC1 complex to compact chromatin, and to repress gene expression is not dependent on its histone ubiquitination activity.

S01.3
Topography of nuclear functions studied by high-resolution microscopy

***T. Cremer**[1], M. Cremer[1], Y. Markaki[1], B. Hübner[1], K. Austen[1], D. Smets[1], J. Rouquette[1], M. Gunkel[2], S. Beichmanis[2], R. Kaufmann[2], H. Leonhardt[1], L. Schermelleh[1], S. Fakan[1], C. Cremer[2];*
[1]LMU Biocenter, Department of Biology II, Ludwig Maximilian University of Munich (LMU), Martinsried, Germany, [2]Kirchhoff-Institute for Physics and BioQuant Center, University of Heidelberg, Heidelberg, Germany.

Recent developments of light optical nanoscopy with resolution beyond the classical Abbe limit (1) have supplemented electron microscopic approaches (2,3) to study the structure of individual CTs in space and time and their spatial relationships to non-chromatin domains (4). The results of these studies support the chromosome territory-interchromatin compartment (CT-IC) model of nuclear architecture (5): CTs are built up from a network of interconnected chromatin domains with a DNA-content in the order of 1 Mb (~1Mb CDs) . Their structure has not yet been resolved, but we argue that these domains are built up from a series of more or less compacted chromatin loop domains with a DNA content in the order of 100 kb (~100 kb CDs). Moreover, several ~1Mb CDs may form larger chromatin clusters. The IC forms a 3D network of channels and larger, DNA free IC-lacunas (width > 400 nm). It starts at the nuclear pores and pervades the nuclear interior expanding both between CTs and within CTs. Accordingly, CTs may be compared with sponges built up from 3D interconnected chromatin domains and the pervading IC channels. A layer of decondensed chromatin, termed the perichromatin region (PR), covers the more compact interior of ~1 Mb-CDs and constitutes the nuclear compartment for transcription and DNA-replication (1, 3).

S02.2
Modeling rare blood diseases with induced pluripotent stem cells

***S. Agarwal**[1,2];*
[1]Children's Hospital Boston, Boston, MA, United States, [2]Harvard Medical School, Boston, MA, United States.

Genetic mutations associated with blood diseases are being discovered at an unprecedented rate. To develop new treatments, we must determine how these mutations cause defects in hematopoietic development and cell function. The advent of "direct reprogramming" technology allows us to revert a patient's skin or blood cells to an embryonic state, yielding "induced pluripotent stem" (iPS) cells. iPS cells carrying patient mutations can in turn be differentiated into numerous specific tissue types to examine pathogenesis in a developmental context. iPS technology is well suited for modeling human genetic blood disorders (e.g. dyskeratosis congenita, Pearson marrow pancreas syndrome, Shwachman Diamond syndrome) that have been a challenge to study using engineered mice or primary patient cells. Work-to-date creating iPS cells from patients with bone marrow failure syndromes is providing insights into disease mechanisms and stem cell biology, and prospects for therapy.

S02.3
Induction of Pluripotency

***H. Schöler**[1,2];*
[1]Department of Cell and Developmental Biology, Max Planck Institute of Molecular Biomedicine, Muenster, Germany, [2]Medical Faculty, University of Muenster, Muenster, Germany.

The mammalian germline comprises two principal parts: the inner cell mass and epiblast, containing pluripotent cells, and the germ cell lineage, hosting unipotent cells. Several pluripotent stem cell types have been derived from the first part. Embryonic stem (ES) cells, derived from preimplantation embryos, comprise at least two populations of cells with divergent states of pluripotency. In addition, epiblast stem cells (EpiSCs), derived from postimplantantion embryos, also do not comprise a uniform cellular population, as we've shown the presence of at least two EpiSC types: one resembling epiblast tissue of early and the other of late pregastrulation embryos.
A current aim in cell and developmental biology is to program cells at will. The first step in converting a given cell into another cell is through achievement of a pluripotent stem cell state that resembles that of ES cells. To date, somatic cells need to be pushed to a pluripotent state by the introduction of exogenous factors, mostly transcription factors. Reprogramming of mouse and human somatic cells into pluripotent stem cells, designated as induced pluripotent stem (iPS) cells, was first described in 2006 using fibroblasts as the somatic cell source and initially requiring introduction of the virally-expressed transcription factor quartet of Oct4, Sox2, c-Myc, and Klf4. As we have recently shown, induced EpiSCs (iEpiSCs) can be obtained by directly reprogramming somatic cells with the quartet under EpiSC culture conditions. We previously reported that Oct4 alone is sufficient to directly reprogram adult mouse and human fetal neural stem cells (NSCs) into iPS cells, thus highlighting the crucial role played by Oct4 in the process of reprogramming.
In contrast to the recent reprogramming of somatic cells, induction of pluripotency in primordial germ cells (PGCs) was accomplished 20 years ago by the mere modulation of the culture conditions. Recently, we converted adult germline stem cells (GSCs) into germline-derived pluripotent stem (gPS) cells. GSCs are unipotent cells of the testis that are capable of not only self-renewing, but also giving rise to sperm. Like ES cells, GSCs exhibit significant levels of Oct4 and Klf4, but low endogenous expression Sox2 and c-Myc. To better understand the reprogramming process, we sought to identify factors that mediate reprogramming at higher efficiency. We established an assay based on *Oct4* reactivation to screen nuclear fractions from extracts of pluripotent cells. **BAF chromatin remodeling complexes containing the Brg1 protein have been shown to be not only** essential for early embryonic development, but also, as we have previously shown, paramount in enhancing the efficiency of reprogramming somatic cells to pluripotency mediated by the quartett. As knockdown of Brg1 leads to differentiation of ES cells, we investigated the early effect of Brg1 knockdown by assessing the impact of RNA interference on the expression levels of key pluripotency factors. We show that Brg1

knockdown leads to an immediate alteration in *Oct4, Sox2*, and *Nanog* expression. More specifically, *Sox2* expression is downregulated, while *Nanog* expression is upregulated. *Oct4* expression is immediately upregulated, perhaps triggering ES cell differentiation. Our data suggest that Brg1 plays an important role in regulating Oct4 expression, which is instrumental in maintaining cells in a pluripotent state.

S03.1
Dissecting regulatory variation in human genomes using RNA sequencing

S. Montgomery;
Development and Genetic Medicine, University of Geneva, Geneva, Switzerland.

Our ability to understand and predict complex human traits is being enhanced by our ability to uncover the effects of genetic variation on cellular state. Specifically, by identifying the genetic variants which influence the expression of particular genes it is likely we are also uncovering those variants which inform various human conditions. Now, with advances in RNA sequencing (RNA-Seq), we can better interrogate transcriptome complexity; this provides us with the ability to better understand the repertoire and abundance of transcripts in multiple cell types. Furthermore, with the increasing availability of individual genomes we have the resolution to integrate rare and common as well as small and large variants into a more complete model of association with the aim of pinpointing specific causal variants. I will discuss what we are learning and how genetic studies of gene expression are evolving using RNA-Seq and population genome sequencing.

S03.2
Exploring the invisible world using metagenomics: systemic analysis of the ecosystem ‚human gut'

P. Bork;
Structural and Computational Biology, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany.

Environmental sequencing (metagenomics) is uncovering genomic parts lists of various microbial communities, but our understanding of their functioning remains limited. I will briefly discuss the status of this young field (Raes and Bork, 2008), in which due to utilization of NGS data and ambitions increase exponentially. I will illustrate the developments using the example of the human gut, where recently NGS has been demonstrated to provide an entry a new dimension in analysis (Qin et al., Nature 2010). New biological discoveries, like the identification of a stratification of microbial communities in the human population dubbed enterotypes (Arumugam et al., 2011) come along with big hopes for microbial markers in various diseases with considerable diagnostic potential.

S03.3
Sequencing Thousands of Human Genomes

G. Abecasis;
Center for Statistical Genetics, Department of Biostatistics, University of Michigan, Ann Arbor, MI, United States.

Identifying and characterizing the genetic variants that affect human traits is one of the central objectives of human genetics. Ultimately, this aim will be achieved by examining the relationship between interesting traits and the whole genome sequences of many individuals. Whole genome re-sequencing of thousands of individuals is not yet feasible, but advances in laboratory methods (for example, to enable the genotyping of thousands of individuals at hundreds of thousands of SNP sites) and in statistical methodology (for example, to enable accurate correction for population stratification and genotype imputation) have resulted in substantial progress in our understanding of complex disease biology.

Here, we discuss practical study designs for the first generation of whole genome sequencing studies. These will enable the examination of 1,000s of individuals at >15 million of polymorphic sites. These studies will be enabled by continuing advances in laboratory technology and statistical methods and should further refine our understanding of complex disease genetics. I illustrate the possibilities both with simulation and with results from ongoing studies.

S04.1
Joubert Syndrome: impaired cilia and Shh dependent cerebellar development

N. Spassky;
Inst. Nat. de la Santé et de la Recherche Méd. U1024, Inst. de Biol. de l'Ecole Norm. Sup. (IBENS), Paris, France.

Joubert Syndrome (JS) is a multisystemic disorder characterized by a complex cerebellum/brainstem malformation where the most striking feature is a severe cerebellar vermis defect ranging from hypoplasia to complete aplasia. JS belong to a group of rare genetically heterogeneous diseases recently reclassified as ciliopathies, where causative genes encode ciliary or basal body proteins and the function and/or the structure of cilia, sensory organelles, are abnormal. One of the most intriguing JS genes is CEP290 as it has the widest phenotypic spectrum ranging from isolated blindness to in utero lethal Meckel-Grüber syndrome and mutations of this gene are responsible for 50% of JS with renal and ocular involvement (CORS). It is totally unknown how CEP290 and ciliary loss of function impair human cerebellar growth giving rise to the drastic vermis malformation characteristic of JS. Here we show that Shh dependent growth of human cerebellum, supported by the granule cells progenitors (CGP) proliferation, starts around 15 gw, that GCP possess a primary cilium and that CEP290 is localized at its base. We find that GCP proliferation and response to SHH is severely impaired in JS cases bearing mutations in genes including CEP290 or MKS3, as well as in a Jeune syndrome ciliopathy case and a Thanatophoric dysplasia case, a putative ciliopathy. Finally, we show that in JS cases, GCP proliferation and response to SHH are impaired not only in the vermis but also, and to the same extent, in the hemispheres. These results add a feature to the already described JS defects and rule out impaired GCP expansion as the origin of vermis hypo/aplasia. Our results show that Shh dependent GCP proliferation and consecutive cerebellar growth starts around 15 gw in the human cerebellum and is impaired in JS whole cerebellum. They also suggest that this could be a common feature to several ciliopathies.

S04.2
Ciliary control of feeding behavior and body weight

N. F. Berbari, R. C. Pasek, E. B. Malarkey, R. A. Kesterson, T. R. Nagy, ***B. K. Yoder***;
University of Alabama at Birmingham, Birmingham, AL, United States.

Primary cilia have essential functions in regulating signaling pathways during mammalian development. In adults, cilia are also important as evidenced by the spectrum of phenotypes observed in mouse models and human patients with ciliary defects (ciliopathies); however, their roles in tissue physiology are poorly understood and the mechanisms underlying most ciliopathies remain enigmatic. We are addressing this issue using conditional tissue-specific cilia mouse mutants and show that disruption of cilia in the hypothalamus results in hyperphagia and obesity. A similar obesity phenotype was reported in mouse models of Bardet-Biedl Syndrome (BBS). BBS mutants have defects in receptor transport into the cilium and are thought to be unable to sense the anorexigenic peptide leptin. Here we assess the leptin signaling axis in cilia mutants and demonstrate they are sensitive to leptin prior to becoming obese, are leptin insensitive when obese, and then regain leptin sensitivity after caloric restriction to bring mutants back to wild type body weight. Thus leptin resistance is a secondary consequence of the obesity and not causal indicating that pathways other than the leptin-melanocortin axis are involved. Data indicate that one of these pathways could be the melanin concentrating hormone (MCH) axis. Previous data indicate that MCH receptor localizes in the cilium of control but not of BBS mutants. Further, we show that MCH binds MCHR1 in the cilium and that in the absence of the cilium, the MCH signaling pathway is altered. Pharmacological and genetic studies are being conducted to assess whether defects in MCH signaling are directly associated with the obesity phenotype in cilia mutants. This work will provide novel insights into how dysfunction of the cilium contributes to the onset of obesity and more generally the importance of the cilium in regulating normal neuronal activity and energy balance.

S04.3
Joubert syndrome

***J. Gleeson**;*
Howard Hughes Medical Institute, University of California, San Diego, CA, United States.

Joubert syndrome is characterized by congenital ataxia, oculomotor apraxia and metal retardation and the pathognomonic Molar Tooth Sign on brain MRI (MTI). Joubert syndrome and related disorders (JSRD) refers to a multiorgan class of conditions displaying the MTI as well as frequent retinal blindness, nephronophthisis, hepatic fibrosis and polydactytly. JS and more broadly JSRD are caused by mutations in at least 10 different genes that are unified by the finding that the encoded proteins localize at or near the cellular primary cilium. Up until recently, neurons were not generally regarded to have primary cilia, but with better cilia visualization tools we now know that the most or all neurons in the developing and adult brain display primary cilia. Furthermore, mutations in these genes frequently result in altered structure of the primary cilium. Two competing models have emerged to explain the genotype-phenotype correlations: 1] These genes determine the structure of the primary cilium, alterations of which result in disease. 2] These genes modulate the efficiency of signaling of the many pathways linked to the primary cilium including Platelet derived growth factor, Sonic hedgehog and Wnt signaling.
The genes mutated in Joubert syndrome suggest that altered structure and/or function of the primary cilium underlie this complex phenotype, but many important questions remain: 1] What can the genes identified to date tell us about the basis of this class of disease? 2] What type of genetic modifiers can explain the widely variable expressivity in this disease? 3] What types of treatment options will emerge from the molecular characterization of this disease?

S05.1
Mechanisms and evolution in mammalian transcriptional regulation

***D. T. Odom**[1,2];*
[1]Cancer Research UK Cambridge Research Inst., Li Ka Shing Centre, Regulatory Systems Biology Lab., Cambridge, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom.

My laboratory investigates the complex relationships among tissue-specific transcription, genetic sequence, and evolution using high-throughput methodologies. We have demonstrated the remarkable divergence in tissue-specific transcriptional regulation that has occurred among mammals. We found that a set of liver-specific transcription factors whose function, amino acid sequence, and targeted binding motif are highly conserved throughout mammals changes both their potentially targeted genes and also their precise binding locations globally. An outstanding mechanistic question arose from the discovery of the rapid divergence of transcription factor binding: what directs these transcription factor binding changes? Is it genetic sequence, epigenetic state, organismal development, or some combination of these?
We showed that an aneuploid mouse line carrying a human chromosome could isolate genetic sequence as an independent variable in directing transcriptional regulation. Remarkably, mouse-encoded transcription factors bound the human chromosome in mouse liver almost precisely as do human-genome-encoded transcription factors in human liver. We found that the mouse nucleus could also accurately re-create the epigenetic landscape and even mRNA regulation across the entirely of this human chromosome. Thus, it is almost entirely genetic sequence variation that is responsible for interspecies differences in transcriptional regulation.
I will be discussing other current projects, including the evolution and conservation of CTCF binding events across multiple mammalian orders, and the manner that RNA polymerase III maintains its conserved transcriptome in the face of rapid remodeling of its transcribed tRNAs.

RNAi-based therapeutic strategies for inflammation and metabolic disease

***M. Czech**[1], M. Aouadi[1], G. J. Tesz[1], S. M. Nicoloro[2], M. Prot[1], S. Amano[1], G. R. Ostroff[1];*
[1]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, United States, [2]University of Massachusetts Worcester Campus, Worcester, MA, United States.

Infiltration of macrophages into adipose tissue in animal models of obesity increases expression and secretion of many factors which could potentially regulate lipogenesis and sequestration of fat in adipocytes. Recently our laboratory reported that human omental adipose tissue was more highly infiltrated with macrophages in obese, insulin resistant subjects, even when matched to equally obese human subjects that were insulin sensitive. We have initiated strategies to target macrophages with siRNA to suppress expression of genes that promote adipose dysfunction and metabolic disease. We have silenced TNF-α as well as other genes that promote inflammation using siRNA encapsulated within hollow shells of β, 1-3 D-glucan prepared from yeast cell walls (denoted GeRPs, for Glucan-encapsulated RNAi particles). Both oral and intraperitoneal administration routes have been tested in mice with GeRPs loaded with siRNA anchored between cationic (polyethyleneimine) and anionic (tRNA and siRNA) layers that also contain an amphipathic peptide. We have now developed simplified versions of these formulations with fewer components in order to enhance reproducibility of manufacture, promote siRNA release from GeRPs after phagocytosis and increase gene silencing potency. The newly developed GeRPs have achieved significant gene silencing in mice targeting Map4k4, a protein kinase that controls inflammation in marcrophages, as well as the cell surface proteins F4/80 CD40, CD80 and CD86 analyzed by FACS. The simplified GeRP system consists of glucan shells loaded in a step-wise procedure under various pH conditions with only an amphipathic peptide, Endo-porter, and siRNA. Current experiments are devoted to testing whether gene silencing in macrophages in vivo by these simplified GeRP formulations can alleviate insulin resistance in obese mouse models and in other animal models of inflammation.

S07.1
Causes and consequences of microRNA dysregulation in cancer

***C. M. Croce**;*
Comprehensive Cancer Center, Wiseman Hall, Ohio State University, Columbus, OH, United States.

During the past several years it has become clear that alterations in the expression of microRNA genes contribute to the pathogenesis of most, perhaps all, human malignancies. These alterations can be caused by a variety of mechanisms, including deletions, amplifications or mutations involving microRNA loci, by epigenetic silencing or by dysregulation of transcription factors targeting specific microRNAs. Since malignant cells show dependence on the dysregulated expression of microRNA genes, which in turn control or are controlled by dysregulation of multiple protein coding oncogenes or tumor suppressor genes, these small RNAs provide important opportunities for development of future microRNA based therapies.

S07.2
Evolution of the Cancer Genome

***M. R. Stratton**;*
Wellcome Trust Sanger Institute, Cancer Genome Project, Hinxton, Cambridge, United Kingdom.

All cancers carry somatically acquired changes in their genomes. Some, termed “driver” mutations, are causally implicated in cancer development. The remainder are “passengers”, and bear the imprints of mutational processes operative during cancer development. Following the advent of second generation sequencing technologies the provision of whole cancer genome sequences has become a reality. These sequences generate comprehensive catalogues of somatic mutations, including point mutations, rearrangements and copy number changes and provide insights into the evolutionary processes underlying the development of individual human cancers including the factors generating variation and the forces of selection. These insights will form the foundation of our understanding of cancer causation, prevention and treatment in the future.

S07.3
Roles of Chromatin ubiquitylation in DNA Double Strand Break Repair and Tumor Suppression

***R. A. Greenberg**;*
School of Medicine, University of Pennsylvania, Philadelphia, PA, United States.

Germline mutations to the Breast Cancer Early Onset 1 gene (BRCA1) confer a strong predisposition to breast and ovarian epithelial cancers. BRCA1 maintains genomic integrity by activating cell cycle checkpoints and error-free mechanisms of DNA double strand break (DSB) repair. Cancer causing mutations disrupt these activities primarily by impairing BRCA1 recognition and retention at DSBs. We have discovered that BRCA1 is targeted to DSBs via an interaction with the ubiquitin interacting protein, RAP80 (Sobhian et al. *Science* 2007). RAP80 provides a DNA damage recognition element by specifically binding lysine^{63}-linked ubiquitinated (K63-Ub) structures on chromatin adjacent to DSBs for a complex consisting of BRCA1 and several other proteins (Shao et al. *Genes & Development* 2009; Shao et al. *PNAS* 2009). These results imply that ubiquitin recognition is required for genome integrity and suppression of malignancy. Related to this hypothesis, new insights into the roles of this complex in DNA repair and tumor suppression will be presented. Recent findings from my laboratory have revealed that DSB associated ubiquitin also enables communication between DNA damage responses and transcriptional processes that occur on chromatin in cis to the site of damage (Shanbhag et al. *Cell* 2010). Using a novel assay that we have developed for single cell analysis, we have observed an ATM dependent process that silences transcription for multiple kilobases in cis to DSBs. New mechanistic insights into this ATM dependent DSB silencing pathway will be presented along with its implications to DSB repair, epigenetic inheritence, carcinogenesis, and viral latency.

S08.1
Mitochondrial quality control and neurodegeneration

***T. Langer**[1,2];*
[1]Institute for Genetics, University of Cologne, Cologne, Germany, [2]Max-Planck-Institute for Biology of Aging, Cologne, Germany.

Dysfunction of mitochondria has severe cellular consequences and is linked to aging and neurodegeneration in human. Several surveillance mechanisms have evolved which prevent the accumulation of non-functional mitochondria and ensure cellular integrity. Whereas irreversibly damaged mitochondria can be selectively removed by autophagy, various intraorganellar proteases degrade non-native mitochondrial proteins and limit mitochondrial damage. These include hexameric m-AAA proteases, ATP-dependent proteases in the inner membrane of mitochondria, mutations of which are associated with hereditary spastic paraplegia and spinocerebellar ataxia (SCA28). m-AAA proteases are part of large supercomplexes with prohibitin scaffolds in the inner membrane. Recent experiments link the function of this protein complex to mitochondrial fusion and the processing of the dynamin-like GTPase OPA1, which is emerging as a central mechanism to monitor mitochondrial integrity. A dysfunction of mitochondria as well as the loss of prohibitins or m-AAA proteases induces the proteolytic breakdown of OPA1 isoforms by the OMA1 peptidase triggering mitochondrial fragmentation. Recent experiments on the role of this mitochondrial quality control mechanism for neuronal survival will be discussed.

S08.2
Insights into human neurodegenerative disease from Drosophila genetics

***N. Bonini**;*
306 Leidy Laboratories, Department of Biology, University of Pennsylvania, Philadelphia, PA, United States.

The causes of amyotrophic lateral sclerosis (ALS) are poorly understood, although TDP-43 has been suggested to play a critical role. We found that ataxin 2, a polyglutamine (polyQ) protein mutated in spinocerebellar ataxia type 2 (SCA2), is a potent modifier of TDP-43 toxicity in yeast and Drosophila (Elden et al., 2010). Moreover, the proteins physically associate in an RNA-dependent manner, and ataxin 2 is abnormally localized in spinal cord neurons of ALS patients. Given these findings, we assessed the role of mutations in the gene encoding ataxin 2 (*ATXN2*) in ALS. Ataxin 2 bears a polyQ repeat which is normally 22 or 23 Qs, but becomes expanded to ≥34Qs in SCA2. We therefore considered that polyQ expansions greater than normal, but below the threshold for SCA2, may be associated with ALS. Analysis of 915 ALS patients revealed that intermediate-length polyQ expansions (27-33 Qs) in the *ATXN2* gene are significantly associated with ALS (4.7% of ALS cases vs 1.4% in controls).

The *ATXN2* gene presents additional interesting features because the polyQ expansions associated with SCA2 are typically pure CAG repeats. However, similar expansions that are interrupted with other codons in analysis to date present atypically with parkinsonism. Given the association of *ATXN2* with ALS, we determined the sequence of the *ATXN2* expansions in our ALS patients (Yu et al., 2011). These data indicate that expanded alleles associated with increased risk for ALS all bear at least one CAA interruption. These data suggest that the nature of the repeat sequence, as well as the length of the polyQ expansion, may play a role in neurological effects conferred by polyQ repeat expansions in the *ATXN2* gene.

S08.3
When does neurodegeneration start in Huntington‘s disease: study of pre-symptomatic phase

***S. Tabrizi**;*
Neurodegenerative Disease, UCL Institute of Neurology, MRC Prion Unit, London, United Kingdom.

Huntington’s disease is a neurodegenerative condition characterised by deterioration of motor and cognitive function as well as neuropsychiatric disturbance. The mean age of onset is 40 years, and progression is slow and inexorable, with death occurring typically 15-20 years later. It is inherited in an autosomal dominant manner. Currently there are no treatments available that modify disease progression. However, novel

therapeutic agents specifically targeting HD pathology are now on the horizon.
As Huntington's disease has a 100% sensitive and specific genetic test, it allows us to study at-risk subjects who carry the HD gene many years before symptom onset. The optimal point at which to introduce neuroprotective agents in the hope of delaying symptom onset and slowing the rate of disease progression is likely to be in the premanifest stage before the onset of rapid neuronal degeneration and emergence of clinical symptoms. Data from a conditional Huntington's disease mouse model suggests the potential reversibility of this neuronal dysfunction leading to full recovery when expression of the mutant gene is halted.
Studies such as TRACK-HD and PREDICT-HD have advanced our understanding of the clinical manifestations and underlying pathobiology of HD in the earliest phase of the neurodegenerative disease process, such that we are now better equipped to enter disease- modifying clinical trials and offer hope to the families affected by this devastating disease. In TRACK- HD, which is a large multi-national observational study, we are investigating a range of potential measures and biomarkers in premanifest HD gene carriers and early HD subjects which will have utility in clinical trials, and also help us understand the neurobiology of the premanifest and early phase of Huntington's disease.
In this talk I will summarise the state of the art in understanding the presymptomatic phase of neurodegeneration in Huntington's disease.

S09.1
Old men and selfish spermatogonia: how much do they contribute to the mutation burden?

A. O. M. Wilkie[1], *J. Lim*[1], *G. McVean*[2], *G. Turner*[3], *G. K. Jacobsen*[4], *E. Rajpert-DeMeyts*[5], *A. Goriely*[1];
[1]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [2]Dept of Statistics, University of Oxford, Oxford, United Kingdom, [3]Dept of Pathology, Oxford Radcliffe Hospitals NHS Trust,, Oxford, United Kingdom, [4]Dept of Pathology, Rigshospitalet, Copenhagen, Denmark, [5]Dept of Growth & Reproduction, Rigshospitalet, Copenhagen, Denmark.
Gain-of-function mutations in 5 genes (RET, FGFR2, FGFR3, PTPN11 and HRAS) that cause congenital malformations exhibit the collective properties of very high apparent rates of germline base substitution, near-exclusive paternal origin, and increased average age of the father from whom the mutation has arisen (paternal age effect, PAE). Somatic mutations in these same genes have been described in various human cancers.
We have developed methods to quantify several of these mutations in human sperm and have also identified FGFR3 and HRAS mutations in spermatocytic seminoma, a rare type of testicular tumour. The combined evidence suggests that these mutations, although occurring rarely, provide a selective growth advantage to the mutant spermatogonial cell, resulting in clonal expansion over time, accounting for the PAE. To date, all examples of these "selfish" spermatogonial mutations locate within a single signalling pathway, the growth factor receptor-RAS pathway, which is a key determinant of spermatogonial stem cell proliferation and renewal. Our recent immunohistochemical analysis of normal testes shows features consistent with the occurrence of mutational microclones; a variety of patterns of antigen positivity are observed, consistent with different underlying driver mutations.
Regulation of cell turnover is important in many disease contexts, for example neurogenesis and neoplasia, so the consequences of mutations that hijack this process within the testis are potentially far reaching. Depending on the spectrum of average PAE mutations levels, they may contribute significantly to the 'dark matter' in human heritability, currently speculated to be explained by uncommon alleles of moderate effect. Hence this mechanism is likely to be important in the origins of common complex diseases such certain cancers and psychiatric disorders, as well as in congenital malformations.

S09.3
DNA damage and its implications for the aging epigenome

P. Oberdoerffer;
Mouse Cancer Genetics Program, Epigenetics of DNA Repair and Aging Section, NCI-Frederick, Frederick, MD, United States.
Changes in chromatin structure are a conserved hallmark of aging and age-related diseases. The mechanisms driving these changes as well as their functional significance are heavily investigated. Over the past few years, it has become evident that DNA damage is a major contributor to a wide range of direct (genomic) and indirect (epigenomic) changes observed in aged nuclei, placing it at the crossroads of age-associated nuclear defects and functional decline. Recently, we were able to show that DNA damage associated epigenomic changes can be caused by the redistribution of the chromatin modifier SIRT1 from promoters and repetitive DNA to sites of DNA breaks, resulting in gene expression changes at ostensibly undamaged genomic loci. This SIRT1-associated gene deregulation correlated with a significant, albeit small fraction of age-related epigenetic changes. Preliminary data from our lab now implicate numerous other chromatin modifiers in DNA double-strand break (DSB) repair, suggesting a more general role for DNA damage-induced epigenomic reorganization in the aging process. Specifically, our data indicate that a repressive chromatin structure may be a critical and novel aspect of DSB repair, involving a significant nuclear reorganization of factors associated with age-related heterochromatin formation. Unlike DNA damage itself, damage-associated epigenetic changes are, at least theoretically, reversible and may, thus, provide a unique means to interfere with age-related nuclear reorganization and concomitant tissue dysfunction.

S10.1
Using custom arrays to improve the understanding of metabolic disorder

B. F. Voight;
Broad Institute of Harvard and MIT, Cambridge, MA, United States.
Establishing the statistical significance of novel associations from genome-wide studies through replication as well as the fine-mapping of established loci to identify causal alleles are both crucial activities for understanding the genetics of complex traits in humans. As our understanding of human traits has increased over the past several years, new technologies are required to continue the accelerated pace of genetic discovery in performing both replication and fine mapping experiments. Each of these experiments requires hundreds of thousands of SNPs to be genotyped in thousands of samples and, until very recently, comprehensive application of these experiments has been cost prohibitive. To overcome this challenge, I describe the approach to the design, as well as the features, of a custom genotyping assay, the Metabochip, tailored to interrogate high priority genetic loci implicated in metabolic disorder and clinically important anthropometric measurements. After a brief characterization of the properties of the array, I will focus on insights gained from extensive replication studies for type-2 diabetes: namely, (1) how the array provides clues to the extent of polygenicity of this trait, and (2) how the depth of replication results can be used to extract new biological insight, using text-based mining approaches or protein-protein interaction networks. The Metabochip, and other similarly designed custom genotyping technologies like it, offer a practical and powerful experiment to advance the understanding of complex traits in humans.

S10.2
Ankylosing Spondylitis

M. A. Brown, *Wellcome Trust Case-Control Consortium 2, Australo-Anglo-American Spondyloarthritis Consortium (TASC), The Spondyloarthritis Research Consortium of Canada (SPARCC);*
MBBS, MD, FRACP, Autoimmunity Division, University of Queensland, Brisbane, Australia.
Ankylosing spondylitis (AS) is an inflammatory arthropathy affecting primarily the spine and pelvis, with a disease prevalence of 0.4% in white Europeans. Susceptibility to AS is known to be highly heritable (h2>90%), and the major gene for the condition, HLA-B27, has been known since 1972. However, only 1-5% of HLA-B27-carriers develop AS, and 10-20% of cases do not carry the gene, suggesting that other genes must be involved. Genetic studies of AS have made rapid progress over the past 5 years, with associations with novel genes

and genetic loci providing insights into the disease pathogenesis, stimulating much follow-up functional research and therapeutic development.
In order to identify further genetic variants predisposing to AS, a gwas was performed involving 1782 British and Australian cases fulfilling modified New York Criteria, and 5167 historical controls from the Wellcome Trust Case Control Consortium 2 (WTCCC2). The study was combined with existing results from the Australo-Anglo-American AS Consortium (TASC) consortium, and replication of the most significant findings performed in 2109 cases and 4410 controls from Australia, Britain, and the Canadian SPARCC consortium. As well as confirming known associations at *HLA*, *IL23R*, *ERAP1*, *KIF21B, 2p15* and *21q22,* we identified and subsequently replicated risk predisposing variants in *RUNX3*, *IL12B*, and *LTBR*, and found suggestive association at *ANTXR2*, *PTGER4*, *CARD9*, *TRADD* and *TBKBP1-TBX21*.
Additionally, we identified a single SNP within the MHC, rs4349859, which lies near the gene *MICA* and tags HLA-B27 with near perfect sensitivity (98%) and specificity (99%). Studies in cases and controls carrying different HLA-B27-subtypes, some AS-associated and some not, indicate that rs4349859 is not itself AS causative, and further reduce the likelihood that an *HLA-B*27*-linked gene is responsible for the association of B27 with AS. This SNP is far cheaper and easier to genotype than *HLA-B*27*-itself, and can be used as an alternative to *HLA-B*27*-typing, at least in European populations.
In most common diseases the proposed genetic model involves interaction between loci, but to date no convincing examples of such interaction have been demonstrated. We identified an interaction between *HLA-B*27* and variants within *ERAP1* in the WTCCC2 (p=0.02), TASC (p=0.014) and replication datasets (p=0.0019). Specifically, risk variants in *ERAP1* increased odds of disease in *HLA-B*27*-positive, but not *HLA-B*27*-negative, cases (combined $P=7.3x10^{-6}$). In contrast, SNPs at other AS-loci, including *IL23R, KIF21B, IL12B* and the intergenic regions 2p15 and 21q22, were AS associated in both *HLA-B*27*+ve and *HLA-B*27*-ve disease. This result indicates that *HLA-B*27*+ve and *HLA-B*27*-ve forms of disease have substantially different but overlapping aetiologies. Interestingly, in a separate WTCCC2 study, we have demonstrated that *ERAP1*is associated with psoriasis, and that the association is restricted to cases carrying the HLA Class I protein HLA-Cw6. The findings support mechanisms of association of *HLA-B*27* and *ERAP1* with AS that involve peptide presentation, and that ERAP1 contributes to disease risk through its action in trimming peptides prior to loading into nascent HLA class I molecules, rather than by cleaving pro-inflammatory cytokine receptors on the cell membrane.
Many further genes are likely to be identified over the coming years. The International Genetics of Ankylosing Spondylitis Consortium will perform what will likely be the definitive SNP genotyping study of AS, involving over 12,000 cases and 20,000 healthy controls genotyped for 200,000 markers targeting immunogenetically relevant genes using the 'Immunochip'. This study will bring new findings including new genes, fine-mapping of known genes, data about the value of genetic risk prediction in different world populations, and even pharmacogenetic data regarding TNF-antagonist response and intolerance.
These findings provide substantial material for the functional biology community to research, with the promise of early translation in both therapeutics and improved diagnostic tests.

Dog: how comparative genetics inform human diseases

***K. Lindblad-Toh**;*
Scientific Director of Vertebrate Genome Biology, Broad Institute, Cambridge, MA, United States.

No abstract received as per date of production. Please see www.eshg.org/eshg2011 for possible updates.

S11.2
Drosophila: Parkinson's disease

***A. J. Whitworth**;*
MRC Centre for Developmental and Biomedical Genetics, Dept of Biomedical Science, University of Sheffield, Sheffield, United Kingdom.

Neurodegenerative diseases present an increasing challenge to biomedical science. Our understanding of the cause and nature of diseases is greatly informed by study of models organisms that recapitulate features of the disease. One model system that has proven surprisingly tractable for these diseases is the fruit fly, *Drosophila melanogaster*. In my lab we are principally focussing on understanding the function of genes linked to Parkinson's disease (PD). PD is the second most prevalent neurodegenerative disorder principally affecting the dopaminergic neurons of the substantia nigra. The pathogenic mechanisms are unknown and there is currently no cure or disease-modifying therapies. Genetic studies have begun to identify single-gene mutations responsible for rare heritable forms of PD and define genetic risk factors contributing to disease prevalence in sporadic cases. These findings provide an opportunity to gain insight into the molecular mechanisms of this disorder through the creation and analysis of appropriate genetic models. Analysis of a number of Drosophila models of PD has revealed some profound and sometimes surprising insights into PD pathogenesis. Moreover, these models can be used to investigate potential therapeutic strategies that may be effective in vivo, and tests have highlighted the efficacy of a number of neuroprotective compounds. I will discuss the methodologies employed in developing the various Drosophila models, and the recent advances that these models in particular have contributed to our understanding of the mechanisms that underlie PD pathogenesis and possible treatment strategies.

S11.3
Modeling Parkinson's disease in zebrafish

***O. Bandmann**;*
Sheffield Institute of Translational Neuroscience, Dept. of Neuroscience, University of Sheffield, Sheffield, United Kingdom.

Parkinson's Disease (PD) is the second most common neurodegenerative disease after Alzheimer's Disease. The pathological hallmark of PD is loss of dopaminergic neurons in the substantia nigra (SN). Currently, only symptomatic treatment is available. The identification of monogenically inherited subtypes of PD has provided us with crucial new insight into the pathogenesis of this disorder, but not led to better therapy as such. Mitochondrial dysfunction is of crucial importance in the pathogenesis of both sporadic and familial PD.
Zebrafish (*Danio rerio*) are emerging as a new animal model for human disease. They are vertebrates and therefore more closely related to humans than other model systems such as *c. elegans* or *drosophila*. There is very high sequence homology of many PD genes between humans and zebrafish. The embryos develop externally and are transparent. The dopaminergic nervous system in zebrafish is well characterized.
We will use PD as an example how zebrafish can be used to study human disease. Knockdown of *parkin* (an autosomal recessively inherited PD gene, leading to the disease due to loss of function) leads to loss of dopaminergic neurons and mitochondrial dysfunction with specific lowering of complex I activity, mirroring both the biochemical and pathological abnormalities observed in human PD patients with *parkin* mutations. A STOP mutation in *PINK1*, a further autosomal recessively inherited, loss of function PD gene also results in mitochondrial dysfunction and loss of dopaminergic neurons. In addition, *PINK1* mutant zebrafish larvae display a behavioural phenotype compatible with the abnormalities observed in human patients.

S12.1
PGD - 21 years on

***J. Harper**;*
UCL Centre for PG & D, EGA Institute for Womens Health, University College London, London, United Kingdom.

Preimplantation genetic diagnosis (PGD) was developed in 1989 as an alternative to prenatal diagnosis to help couples at risk of transmitting a genetic disease to have a healthy family. To achieve this patients go through in vitro fertilisation (IVF) procedures. Cells are removed from the embryo at one of three stages; polar bodies from the oocyte/

zygote, blastomeres from cleavage stages or trophectoderm from blastocysts. During the last 21 years, the majority of cycles have been performed using cleavage stage biopsy. The diagnosis has mainly been performed using the polymerase chain reaction (PCR) for monogenic disorders and fluorescent in situ hybridisation (FISH) for chromosome analysis.

This technology has also been used as an adjunct to IVF to help choose the 'best' embryo for transfer by testing for as many chromosomes as possible; preimplantation genetic screening (PGS). PGS has been a controversial procedure as thousands of cycles have been performed, but eleven randomised controlled trials (RCT) have shown that it does not increase IVF delivery rates for certain indications.

The European Society of Human Reproduction and Embryology (ESHRE) set up an international PGD consortium in 1997 to monitor PGD and collect data on PGD cycles worldwide. We have collected data on over 33,000 cycles of PGD/PGS, produced four guidelines on PGD/PGS and have five working groups.

Recent advances in the field of PGD/PGS have been the exploration of polar body biopsy (for those countries where embryo biopsy is not allowed) and blastocyst biopsy. Improvements in embryo freezing by using vitrification have resulted in an increase in pregnancies from biopsied embryos. The use of array-comparative genomic hybridisation (a-CGH) or single nucleotide polymorphism arrays (SNP-arrays) is rapidly entering the PGD/PGS arena. Many groups are performing blastocyst biopsy, vitrifying the embryos, and using array technology to perform the diagnosis. The embryos are replaced in a future cycle. For PGS, the new technology needs to be shown to improve delivery rates by performing RCTs.

Controversially, PGD has been used for social sexing, the diagnosis of late onset disorders and HLA matching. Treatment of these indications has caused many ethical discussions and the use of whole genome scanning will bring more debate.

S12.2
Use of aCGH in Prenatal Diagnosis

***A. L. Beaudet**;*

Department of Molecular and Human Genetics, Houston, TX, United States.

Array comparative genomic hybridization (aCGH) is currently being offered as a rapid and reliable method of prenatal testing for the detection of structural and numerical chromosome abnormalities. aCGH can survey the entire genome for submicroscopic deletions and duplications, aneuploidy and other unbalanced chromosomal abnormalities and is being increasingly applied to prenatal diagnosis, where it is already making significant impact. Inclusive of our reported experience with 300 prenatal cases (PMID 19012303), we now have aCGH data on 841 clinical prenatal samples, 545 (65%) of which were direct amniotic fluid or direct CVS specimens, allowing for a turnaround time far superior to that of cultured cells. Copy number changes were detected in 166 (20%) of the total 841 cases. Of these, 94 (11%) were CNVs that were interpreted as likely benign either because they were inherited from a phenotypically normal parent (90) or they were *de novo* (4) but had been previously observed in our aCGH database of over 26,000 clinical cases and phenotypically normal individuals. Of the 63/841 (7.5%) cases in which clinically significant genomic imbalances were detected, 23/841 total cases (2.7%) or 23/63 abnormal cases (36.5%) would not have been detected by conventional G-banded prenatal chromosome studies alone. These data demonstrate the superior diagnostic power of aCGH compared to conventional karyotype analysis, with a relatively small number of findings of uncertain significance (1% or less), most of which can be resolved by analyzing parents or by using data from ever-growing experience with diagnostic aCGH. It is noteworthy that we have now analyzed more than 400 prenatal samples on high-resolution oligo arrays and the frequency of findings of uncertain significance has remained at approximately 1%. Furthermore, the increasing availability and decreasing cost of prenatal aCGH will likely lead to its universal acceptance as a first-line prenatal diagnostic test for fetal chromosomal abnormalities in the near future. Furthermore, we have successfully optimized aCGH technology to achieve detection of copy-number imbalances of 1 Mb from single cells; with improving technology for fetal cell or fetal DNA enrichment, this may open up new avenues for non-invasive prenatal diagnosis.

S12.3
Non-invasive prenatal diagnosis using circulating fetal DNA: state of the art

***Y. M. D. Lo**;*

Li Ka Shing Institute of Health Sciences and Department of Chemical Pathology, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong.

The discovery of the presence of cell-free fetal DNA in maternal plasma in 1997 has opened up new possibilities for non-invasive prenatal diagnosis. Early work had focused on the detection of paternally-inherited targets in maternal plasma, e.g. Y chromosomal markers. Recently, the development of technologies for analyzing single DNA molecules, e.g. digital PCR and next-generation sequencing, has greatly enhanced our ability to exploit the diagnostic capabilities of circulating nucleic acids. Hence, using next-generation sequencing, fetal trisomy 21 can be detected with high sensitivity and specificity from maternal plasma (Chiu et al. BMJ 2011; 342: c7401). Furthermore, it has been demonstrated in a proof-of-concept study that the entire fetal genome can be scanned non-invasively by maternal plasma DNA sequencing (Lo et al. Sci Transl Med 2010; 2: 61ra91). It is envisioned that plasma DNA analysis will play an increasingly important in prenatal diagnosis and monitoring.

S13.1
Genomic imprinting: an epigenetic gene regulatory model

***D. P. Barlow**;*

Research Center for Molecular Medicine of the Austrian Academy of Science, Vienna, Austria.

Genomic imprinting is an epigenetic process leading to parental-specific expression of 1-2% of mammalian genes that offers one of the best model systems for a molecular analysis of epigenetic regulation in development and disease. In the twenty years since the first imprinted gene was identified, this model has had a significant impact on decoding epigenetic information in mammals. So far it has led to the discovery of long-range *cis*-acting control elements whose epigenetic state regulates small clusters of genes, of unusual macro ncRNAs that directly repress genes *in cis* and critically, it has demonstrated that one biological role of DNA methylation is to allow expression of genes normally repressed by default. Here we describe our progress in understanding how imprinted protein-coding genes are silenced, in particular, focussing on the role of macro (or long) ncRNAs that have broad relevance as a potential new layer of regulatory information in the mammalian genome. The *Airn* macro ncRNA silences the *Igf2r* protein-coding gene on the paternally inherited copy of mouse chromosome 17. We have previously established an *in vitro* model in differentiating ES cells that emulates the developmental onset of imprinted expression of *Igf2r* and *Airn* (Latos et al., 2009). The ES cell model was used to determine the functional length of *Airn.* Several ES lines carrying different *Airn* truncations were generated and tested for their ability to direct imprinted *Igf2r* expression and to change the physical characteristics of the *Airn* ncRNA itself. The data show the *Airn* ncRNA sequence and structure do not play a role in *Igf2r* repression. Since the *Airn* transcript overlaps the *Igf2r* promoter, we next tested if transcriptional overlap was sufficient to repress *Igf2r* by moving the *Airn* promoter directly in front of the *Igf2r* promoter. Together, the results do not support a functional role for the *Airn* ncRNA but, instead, indicate that transcriptional overlap by the *Airn* ncRNA is sufficient to repress *Igf2r* in cis.

S13.2
How epigenetics disconnects the ability to learn with increasing age

***R. M. Stilling**, A. Fischer;*

European Neuroscience Institute Göttingen, Göttingen, Germany.

Aging is a major issue in modern societies since it is the main risk factor for dementia, especially Alzheimer's disease. It has been shown across various species including humans, monkeys and rodents that age-associated memory impairment (AAMI) correlates with deregulated gene expression in certain brain regions such as the hippocampus. During the last years it became increasingly evident that genome-environment interactions have a significant impact on cognitive functions and that these GxE interactions are mediated by epigenetic mechanisms like DNA methylation and post-translational

histone modifications.
Recent findings in our laboratory raise the possibility that acetylation on Lysine 12 of Histone 4 (H4K12ac) is an important regulator in dynamic transcription of learning associated genes. H4K12ac was the only of several investigated acetylation sites on H4 and H3 that did not respond to a learning stimulus in the fear-conditioning paradigm in a mouse model of early aging (16-month-old mice). The finding that H4K12ac seems to be especially important for transcriptional elongation links this modification to the almost complete loss of transcriptome plasticity in 16-month-old mice. H4K12 acetylation as well as memory performance could be reinstated by intrahippocampal injection of an HDAC inhibitor in old individuals.
Furthermore, we employed 24-month-old mice that represent a model for advanced aging. The 24-month old mice showed significant impairment in the novel object recognition (NOR) learning paradigm. By employing a combination of ChIP-seq and DNA microarray we were able to define the epigenetic landscape of H4K12 acetylation and the hippocampal transcriptome of these mice. We observed elevated genome-wide levels of H4K12ac, which corresponded to a high degree of differential gene expression in the aged hippocampus. In summary, histone acetylation-mediated GxE interactions seem to be an essential regulator of stimulus-driven transcription and a hallmark of age-associated deficits and diseases.

S13.3
Towards epigenome-wide association studies (EWAS)

***S. Beck**;*
UCL Cancer Institute, University College London, London, United Kingdom.

What determines a phenotype is one of the fundamental questions in biology and medicine. In addition to genetic factors, epigenetic factors such as DNA methylation have been shown to play important roles. To understand the rules governing DNA methylation and their functional consequences requires genome-wide analysis of methylome dynamics. I will present our efforts using array- and sequencing-based platforms for high-throughput methylome analysis, discuss some of the lessons learnt and give an outlook on how this approach may be used for epigenome-wide association studies (EWAS) to analyse and better understand phenotypic plasticity in health and disease.

Genomics of blood pressure and hypertension

***A. F. Dominiczak**;*
School of Medicine, Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom.

The presentation will describe the initial difficulties experienced in early genome wide association studies of blood pressure and hypertension as well as strategic developments including large meta-analyses and sampling from the extremes of blood pressure distribution. Published and in press successes, which include more than 20 SNPs/loci associated with blood pressure and hypertension, will be described together with the future directions such as exome sequencing as well as clever functional studies leading to clinically useful applications.

S15.1
Jewish population structure

***M. Metspalu**;*
Inst. of Molecular and Cell Biology, Dept. of Evolutionary Biol., Univ. of Tartu – Eston. Biocentre, Tartu, Estonia.

I shall give a brief overview of the genetic studies that have addressed Jewish origins including studies focusing on uniparentally and biparentally inherited markers but will focus on genome-wide patterns of variation across the vast geographic span of Jewish Diaspora communities and their respective neighbours.
We have used Illumina 6X0 bead arrays to genotype individuals from 20 Jewish Diaspora communities, including in addition to the European communities those from Northern Africa, India and Central Asia, and compare these patterns of genome-wide diversity within the context of the genetic landscape of the Old World. We have also improved the sampling of the host populations and those from the historically suggested region of Jewish origins in the Middle East.
Principal component and structure-like analyses show that most Jewish samples shear genetic ancestry signals and form a sub-cluster that overlies with some Levantine populations but not the paired Diaspora host populations. Nevertheless, in line with the history of the different Jewish communities, different levels of admixture with the host populations can be identified. In the extreme, Ethiopian Jews (Beta Israel) and Indian Jews (Bene Israel and Cochini) cluster with neighbouring autochthonous populations in Ethiopia and western India, respectively, despite a clear paternal link between the Bene Israel and the Levant.
Overall these results point to the genetic origins of most Jewish Diaspora communities in the Levant and exemplify how genetic information may be utilized to address questions of demographic history where historical evidence is weaker or inexistent.

S15.3
Genome diversity in Asia

M. Seielstad[1,2]*, The Pan-Asian SNP Initiative;*
[1]Genome Institute of Singapore, Singapore, Singapore, [2]University of California San Francisco, San Francisco, CA, United States.

Asia harbors substantial cultural and linguistic diversity, but the geographic structure of genetic variation across the continent remains enigmatic. Here we report a large-scale survey of autosomal variation from a broad geographic sample of Asian human populations. Our results show that genetic ancestry is strongly correlated with linguistic affiliations as well as geography. Most populations show relatedness within ethnic/linguistic groups, despite prevalent gene flow among populations. More than 90% of East Asian (EA) haplotypes could be found in either Southeast Asian (SEA) or Central-South Asian (CSA) populations and show clinal structure with haplotype diversity decreasing from south to north. Furthermore, 50% of EA haplotypes were found in SEA only and 5% were found in CSA only, indicating that SEA was a major geographic source of EA populations.

S16.1
Research Governance - So…Last Century?

J. Kaye*;*
Department of Public Health, Centre for Law, Health and Emerging Technologies, University of Oxford, Oxford, United Kingdom.

Since the advent of the Human Genome Project, we have seen significant changes in the way that research is carried out. Samples and data are now shared widely on a global level by researchers in international consortia and biobanking networks. The problem is that our research governance systems are nationally based, following national legal requirements and guidelines, and relying on the expertise of research ethics committees for oversight. In this paper I will argue that our current national research governance systems are inadequate for the task of international data sharing and that radical new approaches are needed to bring our research governance systems into the 21st century.

S16.2
Feedback of individual genetic results to research participants: in favor of a qualified disclosure policy

A. L. Bredenoord*;*
University Medical Center Utrecht, Julius Center, dept Medical Ethics, Utrecht, Netherlands.

In recent years, a debate evolved regarding the question whether researchers have a duty to return individual genetic research results to research participants. This unsettled debate has rapidly gained in urgency in view of the emergence of biobanks and the advances in next-generation sequencing technology, which has the potential to generate unequalled amounts of genetic data. This implies that the generation of many known and unknown genetic variants in individual participants of genetics/genomics research as intentionally or collaterally obtained by-products is unavoidable.

In both the scientific debate and in international guidelines, the extreme positions of full disclosure and no disclosure whatsoever are seldom defended. A duty to warn when this may save the life of a research participant is apparently recognized widely. As no disclosure is unethical because it fails to adhere to the so-called rule of rescue and full disclosure nonsensical (at best) as it could imply disclosure of all raw sequencing data, any disclosure policy in between means we have to consider how and by whom a selection should be made about which results are eligible for disclosure.

In this presentation, a qualified disclosure policy is proposed. This policy contains a standard default package, possibly supplemented with three additional packages. Whereas the default package, containing life-saving information of immediate clinical utility, should be offered routinely and mandatory to all research participants, offering (one of) the three additional packages is context-specific. Such a qualified disclosure policy in our opinion best balances the potential benefits of disclosure with the potential risks for research participants and the harms of unduly hindering biomedical research.

ES1.1
Mitochondrial diseases

***P. F. Chinnery**;*
Mitochondrial Research Group & Institute for Genetic Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom.

The first pathogenic mutations of mitochondrial DNA (mtDNA) were identified over 20 years ago, paving the way for two decades of clinical and molecular research, and opening up the new field of mitochondrial medicine. Pathogenic mutations of mtDNA have been found in > 1 in 200 of the general population, and cause mitochondrial disease in > 1 in 5000. The spectrum of mitochondrial disorders continues to increase, both at the molecular and clinical level, presenting new challenges for diagnosis and treatment.

This presentation will provide the basic biochemical and molecular knowledge required to understand mitochondrial disorders in a clinical context, describe novel phenotypes that present in adult life, discuss the complex interplay between the nuclear genome and the mitochondrial genome in human disease, and describe new treatments under development for these disorders.

ES1.2
Neonatal screening for inherited diseases

***U. von Döbeln**[1,2];*
[1]Centre for Inherited Metabol. Dis. (CMMS), Karolinska Universitetssjukhuset, Stockholm, Sweden, [2]Department of laboaroty medicine, Karolinska Institute, Stockholm, Sweden.

Mass screening of newborn infants by analysis of blood samples dried on filter paper (DBS) is performed all over the world. The aim is to find infants with treatable inborn diseases in order to improve the long term outcome by early institution of treatment.

Neonatal screening started with the autosomal recessive disorder phenylketonuria (PKU) in the early sixties by the pioneering work of Robert Guthrie. He developed a bacterial assay on DBS that could detect infants with this serious disorder before it had given symptoms. Patients with PKU born before the start of screening are mentally retarded while those treated since the neonatal period become completely normal.

New disorders (eg galactosemia, congenital hypothyroidism, congenital adrenal hyperplasia, cystic fibrosis) have been added one by one when analytical methods for the screening of them have been developed. Screening for congenital hypothyroidism is the most widely spread over the world. This disorder has a fairly high incidence (1:3000) and is easy to treat at a low cost with one pill of thyroxin a day.

In the early nineties a new era for neonatal screening started with the introduction of LC-MS-MS. With this equipment the concentration of more than a hundred metabolites can be quantified simultaneously in a 3 mm diameter punch of dried blood on filter paper at an analysis time of 2 min per sample. New technologies for DNA analyses will certainly also contribute to the development of neonatal mass screening.

LC-MS-MS has meant a technological break through but has also led to ethical and economical dilemmas with respect to choice of disorders to include in the screening panel.

This is well illustrated by the differences between countries. In the USA the panel comprises more than 54 disorders whilst at the other extreme Great Britain is screening for four.

ES2.1
Lynch syndrome (HNPCC)

***E. Mangold**;*
Institute of Human Genetics, University of Bonn, Bonn, Germany.

Hereditary non-polyposis colon cancer (HNPCC), also called Lynch syndrome, is an autosomal-dominant predisposition to colon cancer and other malignancies (e.g., endometrium, urinary tract, small bowel, biliary tract, ovary, stomach cancer). Lynch syndrome patients and their first degree relatives are recommended lifelong surveillance for colorectal cancer and other Lynch syndrome malignancies starting in their 20s and 30s. The diagnosis can be made based on clinical data and family history (Amsterdam criteria) and/or when a causative germ line mutation has been detected. To date, private mutations in mismatch-repair genes MSH2, MLH1, MSH6, PMS2 or deletions of EPCAM leading to epigenetic silencing of MSH2, are known as molecular causes of Lynch syndrome. The identification of a causative mutation is important, as it allows predictive testing in healthy family members.

Not all Lynch syndrome patients meet the Amsterdam criteria for Lynch syndrome. The diagnosis of HNPCC should also be considered when the patient's individual history and family history meet one or more of the less stringent criteria (revised Bethesda guidelines). Among these patients an examination of tumor tissue for Lynch syndrome characteristics is able to detect those, who have a high probability for Lynch syndrome and therefore should undergo surveillance and mutation screening. A high microsatellite instability and loss of DNA mismatch repair protein expression are characteristic for Lynch syndrome tumors. However, a loss of MLH1 and PMS2 expression is also observed in a considerable portion of sporadic cancers.

This educational will focus on diagnostic approaches in patients diagnosed with or suspected of Lynch syndrome and point out possible pitfalls.

ES2.2
BRCA1 and *BRCA2* genes cancer susceptibility: from bench to bedside

***D. Stoppa-Lyonnet**[1,2];*
[1]Genetics Department, Institut Curie, Paris, France, [2]University Paris Descartes, Paris, France.

The chromosomal mapping of the *BRCA1* gene by Mary-Claire King twenty years ago has opened the field of breast cancer genetics, and paved the way to the personalized management of women at-risk because of their breast cancer family history.

The first application of the identification of the *BRCA1* and *BRCA2* genes was indeed genetic testing. Yet, 20 years latter, *BRCA1/2* genetic testing remains complex because of the large size of the coding sequences, of the broad allelic heterogeneity - disease-predisposing mutations being different from a family to another in most cases -, and of the vast number of rare variants with unknown significance (VUS). The international ENIGMA consortium (Evidence based Network for the Interpretation of Germline Mutant Alleles) has been recently created to classify these VUS by using multiple approaches including family cosegregation data.

Tumour risk estimate is also a major concern. Numerous factors, both genetic and non-genetic, are influencing risks. Their identification, still ongoing, is of the utmost importance for the individualised management of at-risk women, and for opening new ways of prevention and treatment. Two international consortia, now associated, play a major role on their identification namely the IBCCS (International *BRCA1/2* Carrier Cohort Study) and CIMBA (Consortium of Investigators of Modifiers of *BRCA1* and *BRCA2*) consortia, for non-genetic and genetic factors respectively.

The discovery of the involvement of the BRCA1 and BRCA2 proteins in the Double-Strand Break DNA repair pathway has lead to specific clinical trials testing molecules increasing the tumour genomic instability such as alkylating agents and Base Excision Repair inhibitors (PARPi). Their first results are promising and, importantly, could also have an impact on non-*BRCA1/2* related breast tumours, some of them showing DSB repair defects as well.

Thus, in this particular field, may be more than in any other genetic medicine areas, it is fascinating to see how much, in so few years, the distance between bench and bedside has shortened, at-risk women and researchers now walking next to each other.

Design, analysis and interpretation of genome-wide association studies

***C. A. Anderson**;*
Statistical Genetics, Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Genome-wide associations studies (GWAS) have revolutionised the field of human genetics and have directly led to the identification of over a thousand loci associated with complex traits and disease. In this presentation I will begin by outlining the rationale behind genome-wide association studies and the technological advances that were necessary to make them a reality. I will go on to discuss how to design a successful GWAS and outline some of the steps that should be undertaken to reduce false-positive and false-negative findings. I will then review GWAS replication studies and meta-analysis. Throughout the presentation I will draw on examples from the GWAS literature. I will finish by summarising the major lessons learnt from GWAS and discussing the 'next-generation' of genome-wide association studies.

Cutaneous mosaicism 2011: understanding the patterns and mechanisms

***R. Happle**;*
Department of Dermatology, University of Freiburg, Germany, Freiburg, Germany.

All nevi reflect mosaicism. Such skin lesions show a remarkable divergency of archetypical patterns. Some unusual types are the "Ruggieri pattern"of pigmentary disturbances, and the hypopigmented macules of Pallister-Killian syndrome. - Epigenetic cutaneous mosaicism can today explain the hereditary patterns of lyonization as well as hereditary autosomal pigmentary disturbances arranged along Blaschko's lines. - Genomic mosaicism: Such mosaics can usually not be transmitted to the next generation. A new possible example of a lethal mutation surviving by mosaicism is papular nevus spilus syndrome that is characterized by ipsilateral neurologic defects, especially in the form of segmental hyperhidrosis. Phylloid hypomelanosis is a novel neurocutaneous phenotype that reflects mosaic trisomy 13q. - The concept of type 2 segmental manifestation of autosomal dominant skin disorders, reflecting early LOH, has been confirmed by molecular analysis in six different skin disorders including NF1, Hailey-Hailey disease, Darier disease and rhodoid nevus syndrome ("capillary malformation-arteriovenous malformation"). - Conversely, in autosomal recessive epidermolysis bullosa, postzygotic loss of homozygosity may cause revertant mosaicism in the form of mosaic patches of healthy skin. Similarly, ichthyosis variegata (ichthyosis in confetti) reflects thousands of revertant clones involving the *KRT10* locus. - The concept of didymosis (twin spotting) explains the coexistence of two different mosaic patches such as capillary didymosis, cutis tricolor, or phacomatosis spilorosea. - Superimposed segmental manifestation of polygenic skin disorders: Clinical examples now include psoriasis, atopic eczema, lichen planus, systemic lupus erythematosus, dermatomyositis, pemphigus vulgaris, vitiligo, graft-versus-host disease, granuloma annulare, drug eruption, and multiple melanocytic nevi. This new genetic concept offers an explanation why in polygenic skin disorders "mixed" cases of both segmental and nonsegmental involvement may occur; why the segmental manifestation is rather severe, tends to occur early in life and is rather difficult to treat; and why family members may show the same disorder in a nonsegmental form.

ES6.1
Marfan syndrome: evolving nosology, evolving pathophysiology and evolving treatment with improved survival

***C. Boileau**[1,2,3];*
[1]Inserm U698, Paris, France, [2]University Versailles SQY, Versailles, France, [3]Ambroise Paré University Hospital, Boulogne, France.

Marfan syndrome (MFS), the prototypical heritable connective tissue disorder, has been known for its pleiotropy since Victor McKusick's founding monograph in 1955. Through the years, clinical pleiotropy has led to an evolving nosology (Berlin, 1986: Gent I, 1996; and Ghent II, 2010) that illustrates the difficulty of the diagnosis of MFS. Twenty years ago the syndrome was found to be due essentially to mutations within the *FBN1* gene that encodes fibrillin 1, the major component of 10 nm diameter microfibrils, matrix structures found as isolated aggregates or closely associated with elastin. Careful clinical investigations and the identification of molecular defects located in new genes (*TGFBR2* and *TGFBR1*) have lead to the recognition of overlapping syndromic entities: Marfan syndrome type 2 and the Loeys-Dietz syndrome. Conversely, *FBN1* gene mutations have been identified in familial diseases affecting mainly one organ system (isolated ectopia lentis, familial thoracic aortic aneurysm and dissection, Marfanoid habitus), thus showing that they are allelic to MFS. This molecular complexity of human diseases has benefited the understanding of pathogenic mechanisms underlying MFS since it opened avenues of research not only in the field of connective tissue remodelling, but also in alteration of TGF β signalling. Historically, MFS was thought to result from structural weakness of connective tissue. This was confirmed with the indentification of mutations (either missense or nonsense) in the *FBN1* gene associated with a dominant negative or haploinsuffisiency effect, respectively. Mutations could reasonably well explain the altered mechanical properties of the zonules (ocular ligaments containing high levels of isolated microfibrillar aggregates) and the aortic media (containing elastin lamellae closely bordered with microfibrils) in MFS. However, no clear genotype/phenotype correlation could be established between *FBN1* mutations and various forms of MFS but for the identification of an association between mutations in exons 24-32 and the neonatal MFS as well as the tendency to a more severe phenotype in adults. Further insight into pathophysiology has been gained through the study first of the transgenic *Fbn1* $^{mg\Delta}$ and subsequently the KI *Fbn1* ^{C1039G} mice strains, the latter providing a model more analogous to the situation in affected humans. The mice strains have led to the identification of increased TGF β signalling within disease tissues. This finding is in agreement with an additional role for fibrillin 1: matrix sequestration of inactive TGF β and regulation of TGF β activation by targeting and concentrating TGF β at specific locations through its interaction with latent TGF-β-binding proteins (LTBPs). The identification of altered TGF β signalling has led to several clinical trials worldwide to test the efficacy of Losartan on blunting the overstimulation of the signalling and thus on the aortic disease. The scientific challenge is now the identification of genetic modifiers that could lead to the identification of prognostic factors and new therapeutic targets.

ES6.2
The Ehlers-Danlos syndrome: a disorder with many faces

***A. de Paepe**;*
Centre for Medical Genetics, Ghent University Hospital, Ghent, Belgium.

The Ehlers-Danlos Syndromes (EDS) comprise a heterogeneous group of diseases which are characterized by fragility of the soft connective tissues and widespread manifestations in skin, ligaments and joints, blood vessels and internal organs. The clinical spectrum varies from mild skin and joint hyperlaxity to severe physical disability and life-threatening vascular complications. Current classification (Villefranche Nosology) recognizes 6 genetic subtypes, most of which are linked to mutations in one of the genes encoding fibrillar collagen proteins or enzymes involved in post-translational modification of these proteins. Mutations in type V and type III collagen cause classic or vascular EDS respectively while mutations involving the synthesis or processing of type I collagen are involved in the kyphoscoliosis, arthrochalasis and dermatosparaxis type of EDS. Establishing the correct EDS subtype has important implications for genetic counselling and management and is supported by specific biochemical and molecular investigations. Over the last years, several new EDS variants have been characterized which call for a refinement of the Villefranche classification. Moreover, the study of these diseases has brought new insights into the molecular pathogenesis of EDS by implicating genetic defects in the biosynthesis of other extracellular matrix molecules, such as proteoglycans and tenascin, or genetic defects in molecules involved in intracellular trafficking, secretion and assembly of extracellular matrix proteins.

No causal therapy is available for EDS, but a series of "preventive" guidelines are applicable to all forms of EDS. Key-aspects of management include cardiovascular work-up, physiotherapy, pain management and psychological support. Recently, a clinical trial has shown promising results for a betablocker, Celiprolol, in the prevention of vascular catastrophies in patients with vascular EDS.

ES7.2
Neurofibromatosis

***E. Legius**;*
Center for Human Genetics, Laboratory for Neurofibromatosis Research, K.U. Leuven, Leuven, Belgium.

RAS proteins play key roles in normal cell growth, malignant transformation, learning and memory. Somatic mutations in *RAS* genes and several of their upstream and downstream molecules play an important role in different human malignancies.

Neurofibromatosis type 1 is caused by heterozygous mutations in the *NF1* tumor suppressor gene coding for neurofibromin. Neurofibromin functions as a GTP-ase activating protein towards RAS and neurofibromatosis type 1 was the first human inherited disorder to be associated with an increased signalling through the RAS-Mitogen Activated Protein Kinase (MAPK) pathway.

Most features of NF1 are the result of tissue specific inactivation of the normal *NF1* allele. "Second hits" in the *NF1* gene have been observed in NF1 related tumors such as neurofibromas, gastrointestinal stromal tumors, pheochromocytomas, brain tumors, and glomus tumors of the digits. "Second hits" were also seen in melanocytes from café-au-lait spots, and pseudarthrosis tissue. In addition patients with NF1 have an increased risk of malignant peripheral nerve sheath tumors.

These "second hits" in *NF1* result in a deficiency of RAS signalling down regulation with subsequent overactivity of the RAS pathway. Cognitive difficulties in NF1 patients and *Nf1* heterozygous mice have been attributed to haploinsufficiency for *NF1(Nf1)*. Pharmacological down regulation of RAS activity is capable of correcting learning and memory deficits in adult mice. Clinical trials in humans with NF1 trying to pharmacologically correct the learning disabilities are running at this moment.

Legius syndrome is a more recently described entity resembling neurofibromatosis type 1. It is caused by heterozygous mutations in *SPRED1*, a negative regulator of RAF activation by RAS-GTP. Legius syndrome patients show the same multiple café-au-lait spots as patients with NF1 but without Lisch nodules, neurofibromas, optic pathway gliomas and NF1 related bone abnormalities. Melanocytes from café-au-lait spots in Legius syndrome patients show a "second hit" in the *SPRED1* gene. Legius syndrome is associated with mild learning problems and the *Spred1* knockout mouse model shows similar learning and memory deficits as the *Nf1* mouse model.

These findings point to important roles for the evolutionary conserved RAS-MAPK pathway not only in oncogenesis but also in cognition, growth and development.

In recent years germline mutations in genes coding for other components of the RAS signalling cascade have been recognized in a group of phenotypically overlapping disorders, referred to as the neuro-cardio-facial-cutaneous syndromes or Ras-o-pathies. These disorders are characterized by variable degrees of cognitive impairment, cardiac abnormalities, facial dysmorphism, short stature, skin abnormalities and a variable cancer risk.

ES9.1
Arrays in daily practice

***C. M. A. van Ravenswaaij-Arts**;*
University Medical Centre Groningen, Department of Genetics, University of Groningen, Groningen, Netherlands.

This presentation will focus on the interpretation of array results in a routine diagnostics setting from a cytogenetic and clinical point of view. The main take-home messages will be:

1. Know your diagnostic limits. Within these limits, data should be of high quality, accurate and reproducible.
2. Define thresholds that are realistic for the array platform used and are manageable without losing too much information.
3. Be aware of the relationship of the array result with the underlying cytogenetic abnormality and with the possible mechanism of formation. This is important for the follow-up studies that should be recommended (e.g. karyotyping, FISH or array) and for counselling (e.g. recurrence risk).
4. Recognise the importance of clinical information and the use of databases.
5. Know when not to use arrays, and ensure you answer the physician's question.
6. Be aware of the increasing number of CNVs that are "risk factors" for MR/MCA, but which, on their own, may not be sufficient to cause a phenotype. This also implies that inheriting a CNV from a non-affected parent may mean it can still make a contribution to the child's phenotype.
7. Be aware that for CNVs, "*de novo*" does not automatically mean "pathogenic".
8. Be aware of unexpected findings. Pre-test counselling on the possibility of unexpected findings is important. If no national guidelines are available, local guidelines should be set up.

I will give illustrative examples for all these take-home messages.

ES9.2
Deciphering Developmental Disorders

***N. P. Carter**;*
Molecular Cytogenetics, Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Improved diagnosis for children with developmental disorders requires the integration of several important elements. These include accurate and detailed phenotyping, reproducible and consistent application of new genomic methodologies, a comprehensive database to inform diagnosis and genetic counselling, open data sharing for additional research opportunities and a comprehensive collection of patient and parental DNAs to facilitate further disease-gene discovery. We are bringing all these elements together by direct collaboration between the 23 UK Regional Genetics Services and the Wellcome Trust Sanger Institute in the Deciphering Developmental Disorders (DDD) project (http://www.ddduk.org). The main aim of the DDD project is to improve diagnosis for children with developmental disorders within a 5-year period. This will be achieved by the systematic application of the latest microarray and sequencing methods to 12,000 children with developmental disorders and their parents from the UK recruited through the Regional Genetics Services. The new technologies will raise ethical challenges that we will address by a programme of

ethics and sociological research, working with patients and the UK genetics community. The high-resolution genomic and phenotypic data collected on this unparalleled scale will deliver accurate diagnosis for 1000s of families; a knowledge base for clinical interpretation of results from new technologies; the design of cost effective, efficient diagnostic assays; standards of good practice addressing ethical issues raised by new genomic technologies; and the opportunity for major UK research into diagnostic applications based on next generation sequencing.In his educational session, I will describe how the current DECIPHER database (https://decipher@sanger.ac.uk) can be used to inform diagnosis of developmental disorders and how the database has been adapted to provide informatics support for patient recruitment and clinical reporting of significant findings for the DDD project. Furthermore, I will describe the pragmatic approach we are taking to filtering the research findings to maximise the feedback of pertinent findings to the clinical teams while minimising the risk of feeding back incidental findings that might cause psychological harm to the patient or family.

C01.1

Landscape of somatic structural alterations in chronic lymphocytic leukemia (CLL) detected by whole-genome sequencing

L. Bassaganyas[*1], J. M. C. Tubio*[*1], G. Escaramis[1], C. Tornador[1], S. Bea[2], X. S. Puente[3], D. Gonzalez-Knowles[1], R. Guigo[1], I. Gut[4], C. Lopez-Otin[3], E. Campo[2], **X. Estivill**[1,5];*

[1]Center for Genomic Regulation (CRG), Barcelona, Catalonia, Spain, [2]Hematopathology Unit, Hospital Clinic, Barcelona, Catalonia, Spain, [3]Departamento de Bioquimica y Biologia Molecular, Universidad de Oviedo, Oviedo, Spain, [4]Centro Nacional de Analisis Genomicos, Barcelona, Catalonia, Spain, [5]Pompeu Fabra University, Barcelona, Spain.

Cancer is driven by somatically genetic mutations that can be acquired gradually overtime or by single catastrophic events. Chronic lymphocytic leukemia (CLL) is one of the most frequent cancers in western countries, representing 35% of all cases of leukemia. Different genetic alterations have been identified in CLL, including chromosomal aberrations detected by cytogenetic analysis, FISH and aCGH. The limitations of these techniques do not allow the identification of the full set of somatic structural variation at molecular level. Our understanding of oncogenesis has benefited greatly from next-generation sequencing technology. Massively sequencing, in combination with computational approaches, offers the potential to carry out genome-wide screening of all sort of chromosomal rearrangements. Using a toolkit (PeSVFisher) that includes several algorithms to identify structural variations in genomic sequencing, we have analyzed whole-genome sequencing, whole-exome sequencing and SNP/CGH arrays data, to annotate the entire complement of genomic rearrangements in ten patients with CLL. By identifying read pairs that did not align correctly with respect to each other on the reference genome, we have catalogued hundreds of somatic rearrangements. Moreover, depth of coverage of whole-genome sequencing and whole-exome sequencing data provides a comprehensive catalogue of copy number variations. The analysis of these first ten CLL cases represents the first step in a comprehensive characterization of the genomic alterations at the structural level, coupled with functional analysis, of CLL in the framework of the CLL genome project to decode the genetic changes that are responsible for the development and progression of CLL.

C01.2

Exome sequencing in the identification of breast cancer predisposition genes

K. M. Snape[1], *E. Ruark[1], S. Hanks[1], P. Tarpey[2], S. Seal[1], A. Renwick[1], G. Bowden[1], D. Hughes[1], C. Turnbull[1], J. Douglas[1], M. R. Stratton[2], N. Rahman[1];*

[1]Institute of Cancer Research, Sutton, United Kingdom, [2]The Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

High, intermediate and low penetrance genetic variants predisposing to breast cancer have been identified but account for <30% of estimated disease heritability. Our systematic resequencing of candidate genes previously identified the predisposition genes, *CHEK2, ATM, BRIP1* and *PALB2*. These genes are characterized by rare, inactivating, primarily truncating mutations that confer a relative risk of breast cancer of 2-4. It is highly plausible that there exist additional genes acting in a similar fashion and whole exome sequencing should allow their identification. However, there are significant scientific and cost constraints on such experiments.

To explore the utility of exome sequencing in gene identification in breast cancer susceptibility we have sequenced 50 familial breast cancer exomes using the Agilent whole-exome pulldown, Illumina Genome IIx sequencing and NextGENe software for data analysis. We first identified rare (<5% frequency) mutations resulting in premature protein truncation, as these have the highest likelihood of being associated with disease. Each sample contained ≥ 15 such mutations. Five were in known genes (*CHEK2* (n=3) *ATM* (n=1) and *BRCA2* (n=1)) and therefore likely to be causative. However, without prior knowledge of their role in breast cancer predisposition, recognition of these as pathogenic mutations would have been challenging. Amongst the remaining 45 samples were some interesting genes, including some with two truncating mutations which we are following up.

Our data demonstrates that exome sequencing in familial breast cancer can identify predisposition genes but that there are significant challenges in using this approach in an agnostic fashion to discover new genes.

C01.3*

The role of germline allele-specific expression of TGFBR1 in colorectal cancer predisposition

N. Segui[1], *K. N. Stevens[2], E. Guino[3], L. S. Rozek[4], V. R. Moreno[3], G. Rennert[5], G. Capellà[1], S. B. Gruber[2], L. Valle[1];*

[1]Translational Research Laboratory, Catalan Institute of Oncology - IDIBELL, Barcelona, Spain, [2]Department of Epidemiology, Department of Internal Medicine, and Department of Human Genetics, University of Michigan, Ann Arbor, MI, United States, [3]Bioinformatics and Biostatistics Unit, Catalan Institute of Oncology - IDIBELL, Barcelona, Spain, [4]Environmental Health Science, School of Public Health, University of Michigan Medical School, Ann Arbor, MI, United States, [5]CHS National Israeli Cancer Control Center and Carmel Medical Center, Haifa, Israel.

A previous report suggested that allele-specific expression (ASE) of *TGFBR1* confers an increased risk of colorectal cancer (CRC)[1]. Subsequent studies showed contradictory results[2-5]. Considering its potential use in the clinical evaluation of CRC susceptibility we herein perform a validation study.

While in the original study ASE was measured using SNaPshot, here we use pyrosequencing. We show that this technology is a more powerful and robust method for allelic imbalance assessment, showing reproducible and consistent results when using different allelic markers, even when high-quality RNA is not available. Blood lymphocytes and normal colon mucosae were used as source of non-tumoral biological material.

Two different populations were analyzed: 433 healthy controls and 426 CRC patients of Ashkenazi Jewish descent, and 178 CRC cases from a Caucasian-dominated population. In the Ashkenazi cohort, 26% controls and 27% patients were informative. ASE values ranged from 0.67 to 1.39 (median: 1.00) for controls and from 0.76 to 1.67 (median: 1.00) for cases (median difference -0.003; 95%CI -0.032 to 0.025; p=0.81). 50% of the Caucasian cases resulted informative. Their ASE values ranged from 0.68 to 1.40 (median: 1.01), and no significant differences were identified neither when compared with the Ashkenazi controls or with the cases. Only 25-50% of all individuals are informative for analysis, so novel approaches may be required to comprehensively determine the role of allele-specific expression of TGFBR1 in colorectal cancer.

Our results suggest that ASE of *TGFBR1* does not confer an increased risk of CRC.

C01.4*

Chromosomal, epigenetic and microRna-mediated inactivation of LRP1B, a modulator of the extracellular environment of thyroid cancer cells

H. Prazeres[1], *J. Torres[1], F. Rodrigues[2], M. Teixeira-Pinto[1], M. Sobrinho-Simões[1], P. Soares[1];*

[1]IPATIMUP, Porto, Portugal, [2]IPO Coimbra, FG, EPE, Coimbra, Portugal.

The Low density lipoprotein receptor Related Protein (LRP1B), encoding an endocytic LDLfamily receptor, is amongst the 10 most significantly deleted genes across 3,312 human cancer specimens. We undertook the present study to elucidate the mechanisms of LRP1B inactivation in cancer cells and to investigate the key roles of this lipoprotein receptor in the carcinogenesis. Here we show that LRP1B inactivation (by chromosomal, epigenetic and microRNA-mediated mechanisms) modulates the tumor microenvironment to confer cancer cells an increased invasive capacity. LRP1B displays frequent DNA copy number loss and CpG-island methylation resulting in mRNA under-expression. By using CpG-island reporters methylated *in vitro*, we found that DNA methylation disrupts a functional binding site for the histone-acetyltransferase p300 located at intron 1. We identified and validated a microRNA targeting LRP1B (miR-548a-5p) which is overexpressed in cancer cell lines as a result of 8q22 DNA gains. Restoration of LRP1B impaired *in vitro* and *in vivo* tumor growth, inhibited cell invasion and led to a reduction of soluble growth factors, cytokines and matrix metalloproteinases in the extracellular medium. These findings link DNA copy-number changes, an epigenetic transcription factor and a specific microRNA with the modulation of the extracellular medium, through LRP1B (de)regulation.

C01.5
Chromosomal instability in cancer: How does p53 guard the genome?

***P. H. G. Duijf**, J. M. Schvartzman, R. Sotillo, C. Coker, R. Benezra;*
Memorial Sloan-Kettering Cancer Center, New York, NY, United States.

Chromosomal instability, a high rate of chromosome missegregation during mitosis, is a hallmark of many human cancers and a major driving force for solid tumor progression. The mitotic checkpoint, a key surveillance mechanism to safeguard against chromosomal instability, is frequently hyperactivated in tumor cells. While we know that p53 protects against varies forms of genomic instability, how aberrant p53 signaling leads to chromosomal instability through mitotic checkpoint hyperactivation has thus far remained elusive. We find that, via induction of p21 expression and inhibition of cyclin-dependent kinase activity, crosstalk to the Retinoblastoma (Rb) pathway is critically important to prevent overexpression of the E2F target gene *Mad2*. Mad2 is a mitotic checkpoint protein whose overexpression is sufficient to hyperactivate the checkpoint and initiate aneuploid tumor formation *in vivo*. We show here that its overexpression is required to mediate the chromosomal instability phenotypes of impaired p53 and Rb pathways. In the context of aberrant Rb pathway signaling, Mad2 overexpression is required for the acquisition of chromosomal instability and anaplastic mammary tumor formation. Additionally, in a p53 mutant knock-in mouse model that develops tumors with stable, diploid genomes, the Mad2 upregulation and chromosomal instability that is caused by p21 loss can be rescued by genetic reduction of Mad2 levels. These results demonstrate that Mad2 overexpression is an essential mediator of the chromosomal instability and tumor phenotypes observed upon inactivation of the two tumor suppressor pathways that are most frequently impaired in human cancer.

C01.6
Germline gain-of-function mutations of *ALK* disrupt central nervous system development

*C. Gordon[1], L. de Pontual[1,2], D. Kettaneh[1], M. Oufadem[1], N. Boddaert[3], M. Lees[4], J. Mollet[5], A. Munnich[6,1], L. Brugière[7], O. Delattre[5], M. Vekemans[6,1], S. Lyonnet[6,1], I. Janoueix-Lerosey[5], **J. Amiel**[6,1];*
[1]Université Paris Descartes, INSERM U-781, Paris, France, [2]Service de Pédiatrie, Hôpital Jean Verdier, AP-HP, Bondy, France, [3]Service de Radiologie Pédiatrique, INSERM U-1000, Hôpital Necker-Enfants Malades, AP-HP, Paris, France, [4]Department of Clinical Genetics, Great-Ormond Street Hospital for Children, London, United Kingdom, [5]INSERM U-830, Institut Curie, Paris, France, [6]Département de Génétique, Faculté de Médecine ; AP-HP, Hôpital Necker-Enfants Malades, Paris, France, [7]Service d'Oncologie Pédiatrique, Institut Gustave Roussy, Villejuif, France.

Neuroblastoma (NB) is a frequent embryonal tumour of sympathetic ganglia and adrenals with extremely variable outcome. Recently, somatic amplification and gain-of-function mutations of the anaplastic lymphoma receptor tyrosine kinase (*ALK,* MIM 105590) gene, either somatic or germline, were identified in a significant proportion of NB cases.

Here we report a novel syndromic presentation associating congenital NB with severe encephalopathy and abnormal shape of the brainstem on brain MRI in two unrelated sporadic cases harbouring *de novo*, germline, heterozygous *ALK* gene mutations. Both mutations are gain-of-function mutations that have been reported in NB and NB cell lines only. Electroporation of the neural tube of embryonic day 1.5 chicken embryos with a mutant *ALK* construction results in spreading of neural progenitors beyond the ventricular zone at two days post-electroporation; this phenotype is not observed when wild-type *ALK* is over-expressed. This supports the hypothesis that activating mutations in ALK disrupt neurogenesis in the central nervous system. These observations further illustrate the role of oncogenes in both tumour predisposition and normal development, and shed light on the pleiotropic and activity-dependent role of ALK in humans. More generally, missing germline mutations relative to the spectrum of somatic mutations reported for a given oncogene may be a reflection of severe effects during embryonic development, and may have to be looked for in patients with extreme phenotypes.

C02.1
Clinical and molecular findings in 91 patients with the clinical diagnosis of Cornelia de Lange Syndrome

***I. Stefanova**[1], A. Dalski[1], S. Vogt[2], D. Braunholz[1], F. J. Kaiser[1], G. Gillessen-Kaesbach[1];*
[1]Institut für Humangenetik, Lübeck, Germany, [2]Institut für Humangenetik, Bonn, Germany.

Cornelia de Lange Syndrome(CdLS) is characterized by dysmorphic features, growth and cognitive impairment, limb malformations and other features. Mutations in the genes NIPBL,SMC1A and SMC3 are known to cause CdLS.

91 patients were referred to us for molecular analysis of NIPBL and SMC1A.

In 64 patients we found no mutations.In 30 of them we support the clinical diagnosis CdLS, in 13 we suggest a different condition. For 21 patients insufficient clinical information was supplied.

In 27/91patients we found probably pathogenic mutations, 25 in NIPBL and 2 in SMC1A. 21 are novel mutations. 13/27patients have a mild, three an intermediate whereas six patients have a severe CdLS phenotype. In 5/27patients the clinical data was insufficient.

95% of the patients with NIPBL or SMC1A mutation show typical facial features for CdLS.All patients have mental retardation(59% mild,18% moderate,23% severe). 18% have severe malformations of the upper limbs and other 36% show typical X-ray findings. For 72% intrauterine growth retardation was reported and 67% have short stature at present. 75%of the patients are dystrophic and 94% have microcephaly. Further features are feeding difficulties(76%), cleft palate(24%), congenital heart defects(40%), kidney anomalies(12%), gastrooesophageal reflux and hearing loss.

It is of note that one SMC1A mutation is familial. The patient´s mother also shows features of CdLS.

In addition we report a case of gonadal mosaicism with two affected sibs and parents not carrying the pathogenic NIPBL mutation.

We discuss the clinical and molecular findings of 91patients with suspected clinical diagnosis CdLS and compare them with the literature.

C02.2*
Advances in phenotype-genotype correlations in Holoprosencephaly: about a European series of 645 probands.

***S. Mercier**[1,2,3], C. Dubourg[2,3], M. Belleguic[1], I. Gicquel[3], L. Rochard[3], L. Ratié[3], L. Pasquier[1], C. Bendavid[2,3], P. Loget[4], N. Garcelon[5], B. Campillo-Gimenez[5], S. Jaillard[3], C. Quélin[1], V. Dupé[3], V. David[2,3], S. Odent[1,3];*
[1]Service de Génétique clinique, CHU, Rennes, France, [2]Laboratoire de Génétique Moléculaire, CHU Hôpital Pontchaillou, Rennes, France, [3]Institut de Génétique et Développement, UMR 6061 CNRS, Université Rennes1, Rennes, France, [4]Service d'Anatomie Pathologique, CHU Hôpital Pontchaillou, Rennes, France, [5]Département d'Informatique Médicale, CHU Hôpital Pontchaillou, Rennes, France.

Holoprosencephaly (HPE) is the most common malformation of the human forebrain resulting from incomplete midline division of the prosencephalon. Three ranges of increasing severity are described: lobar, semi-lobar and alobar HPE. Other milder subtypes are part of the HPE phenotypic spectrum: Middle Interhemispheric Variant (MIH or syntelencephaly), septo-optic dysplasia and microforms that consist in facial midline defects without any HPE typical brain malformation.

Since 1996, a European network was organized from Rennes, France: data of 645 HPE probands and 699 relatives were analyzed and DNA prospectively collected.

Here we report the clinical and molecular data of the largest European series in HPE. Our cohort encompasses 51% of foetuses and 49% of children with a sex ratio (female/male) of 1,2. Facial defects, brain associated malformations, neural tube defects, extra-brain associated malformations are detailed. Mutations in the four main genes implicated in HPE (SHH, ZIC2, SIX3 and TGIF) were identified in 26% of cases. They are inherited in more than 70% of cases in SHH, SIX3, and TGIF. Instead of the other genes, they arise de novo in 70% of cases for ZIC2. Moreover rearrangements were detected in further 4% of cases by subtelomeric MLPA analysis and in further 22% in 260 HPE patients screened by array-CGH. Interestingly some probands have both a microrearrangement and a mutation in another HPE gene which adds additional support to «multiple-hit process» in HPE.

Based on statistical analyses we report new phenotype-genotype

correlations that may help define molecular analysis strategy and genetic counseling.

Microcephaly with simplified gyration, West syndrome and infantile diabetes linked to inappropriate apoptosis of neural progenitors

C. J. Poulton[1], *R. Schot*[1], *S. Kheradmand Kia*[1], *M. Y. de Wit*[1], *M. Jones*[2], *H. Venselaar*[1], *G. Vriend*[3], *E. de Graaf*[1], *A. M. Bertoli-Avella*[1], *G. M. S. Mancini*[1];
[1]Erasmus MC, Rotterdam, Netherlands, [2]La Plata, La Plata, Argentina, [3]CMBI, Neijmegen, Netherlands.

We describe the causative gene defect in a new syndrome with primary microcephaly, infantile spasms epilepsy, diabetes and early death. Microcephaly with simplified gyration (MSG) is a rare malformation of cortical development, not always associated with severe epilepsy. Infantile onset permanent diabetes is caused by inappropriate apoptosis of pancreatic beta cells, e.g. Wolcott-Rallison syndrome (WRS).We have previously described a WRS patient with MSG suggesting abnormal apoptosis as a common mechanism. Additional families exhibiting this combination have been collected.

Genomic linkage revealed a region on chromosome 18 with a LOD score of 4.3.This corresponded to an area of overlapping homozygosity on SNP array.

Two homozygous non-conservative missense mutations in a novel gene were found in patients from two unrelated consanguineous families, but not in 300 matched controls, and were predicted as pathogenic by Poliphen-2, SIFT programs and the HOPE project. The gene involved is highly expressed in ventricular and subventricular zone of the fetal brain cortex and pancreas and is presumably implicated in regulation of apoptosis. Patient fibroblasts and cells treated with specific siRNA showed an increased susceptibility to apoptosis under stress conditions. Autopsy specimen from one patient showed increased apoptosis in the cerebral cortex. qRT-PCR revealed dysregulation of other genes in the apoptotic control system.in patient cells.

We have identified a new syndrome with MSG, epilepsy and infantile diabetes caused by novel mutation pointing to apoptosis of neural progenitors in the developing cortex as the causal mechanism. This work sheds light on the mechanisms of brain development and West syndrome.

C02.4*

Ageing in Prader-Willi syndrome: Twelve persons over the age of 50 years

M. Sinnema[1,2], *C. T. R. M. Schrander-Stumpel*[1], *M. A. Maaskant*[2,3,4], *L. M. G. Curfs*[1,2];
[1]Department of Clinical Genetics, MUMC, Maastricht, Netherlands, [2]Governor Kremers Centre, MUMC, Maastricht, Netherlands, [3]Department of Health Care and Nursing Science, Maastricht University, Maastricht, Netherlands, [4]Stichting Pergamijn, Echt, Netherlands.

Introduction: The life expectancy of persons with Prader-Willi syndrome (PWS) has increased in recent years. Because of the paucity of reports on older persons with PWS, the natural history, the onset and type of age related problems are not well known. We will present data on physical, behavioural, psychiatric and ageing characteristics in the first cohort of individuals with PWS aged over 50 years.

Method: Twelve persons with a genetically confirmed diagnosis of PWS aged over 50 years are described (4 deletion; 8 mUPD). Data were collected through semi-structured interviews with the individuals with PWS and their main carers.

Results: Cardiovascular diseases, diabetes, dermatological and orthopedic problems were common physical complaints in elderly with PWS. Function in ADL, psychological functioning, physical functions and care dependence were substantially worse in elderly (50+) compared to the control group (18-49 yrs). 7/8 persons with mUPD had a history of psychiatric illness. Behavioural and food related problems were not less prevalent in the older individuals compared to the control group.

Discussion: Given the combination of age related physical morbidity, physical appearance, behavioural and psychiatric problems and functional decline in our cohort, we hypothesize premature ageing in elderly with PWS. Healthy ageing in PWS requires a lifespan approach that recognizes the presence, progression and consequences of specific morbidity. The knowledge of the PWS specific age related health risk factors will be used to adjust guidelines for preventive management.

C02.5

Craniofacial characteristics of Fragile X syndrome identified by dense surface and signature graph analyses

P. Hammond[1], *M. J. Suttie*[1], *I. Heulens*[2], *F. Faravelli*[3], *F. Forzano*[3], *C. S. Perrotta*[4], *T. Mattina*[4], *R. F. Kooy*[2];
[1]UCL Institute of Child Health, London, United Kingdom, [2]Department of Medical Genetics, University of Antwerp, Antwerp, Belgium, [3]E.O. Ospedali Galliera, Genova, Italy, [4]Department of Pediatrics, University of Catania, Catania, Italy.

For a disorder as common as fragile X syndrome, a hereditary form of cognitive impairment, the facial features are relatively ill defined. An elongated face and prominent ears are the most commonly accepted dysmorphic hallmarks. We analysed 3D photographs of 50 males with full FMR1 mutations using dense surface modelling (DSM) techniques and a new method that forms a directed graph with normalised faces as nodes and edges linking faces showing closest dysmorphism. We identified as yet unrecorded facial characteristics such as infra-orbital proptosis, hyperplasticity of the nasal bone-cartilage interface, mid-facial hyperplasia and increased supra-orbital height. Subsequently, we began analysis of micro-CT images of the fragile X mouse model. Results indicated reduced inter-parietal bone length and reduced length and width of the inner skull. We also found reduced lateral separation of condylar surfaces and increased mandibular height due to altered orientation of condyle, coronal and angle tip, and increased depth at anterior molars.

Thus, we have refined the facial characteristics of fragile X syndrome and have obtained a 95% discrimination rate between affected and control males. Some of the abnormalities, e.g., nasal cartilage deficiencies in patients and mid-facial effects in the mouse model, correspond in both species and suggest a common mechanism. This supports reports that FMR1, the gene silenced in the disorder, influences eye and cranial cartilage development through effects on neural crest cells and is consistent with a previous study of Bardet-Biedl syndrome where similar nasal bone and mid-facial abnormalities were linked to adverse neural crest cell behaviour.

C02.6

Epigenetic modification of the FMR1 gene in fragile X syndrome is associated with differential response to the mGluR5 antagonist AFQ056.

Fragile X syndrome (FXS) is caused by expansion of a CGG repeat in the 5' untranslated region of the fragile X mental retardation 1 (FMR1) gene. This mutation is associated with hypermethylation

at the FMR1 promoter and subsequent transcriptional silencing. The absence of FMRP (FMR1 protein) at the synapse has many consequences, including up-regulation of metabotropic glutamate receptor 5 (mGluR5)-mediated signaling. It has been postulated that this increased mGluR5 signal may be responsible for many of the clinical manifestations observed in fragile X syndrome. mGluR5 receptor antagonists have shown promise in preclinical FXS models and in one small open-label study of FXS. We examined whether a receptor subtype-selective inhibitor of mGluR5, AFQ056, improves the behavioral symptoms of FXS in a randomized, double-blind, two-treatment, two-period, crossover study of 30 male FXS patients aged 18 to 35 years. We detected no significant effects of treatment on the primary outcome measure, the Aberrant Behavior Checklist-Community Edition (ABC-C) score, at day 19 or 20 of treatment. In an exploratory analysis, however the patients with full FMR1 promoter methylation and no detectable FMR1 messenger RNA improved, as measured with the ABC-C, significantly more after AFQ056 treatment than with placebo ($P < 0.001$). If confirmed in larger and longer-term studies, these results suggest that blockade of the mGluR5 receptor in patients with full methylation at the FMR1 promoter may show improvement in the behavioral attributes of FXS.

Microcephalic primordial dwarfism is an autosomal recessive group of conditions with extreme growth failure, characterised by intrauterine growth retardation, short stature and microcephaly. Several genes involved in fundamental cellular processes have been identified for these disorders: PCNT in MOPD II ; ATR , CEP152 in Seckel syndrome; but none previously for Meier-Gorlin syndrome.

Here, we report the identification of five further genes encoding components of the pre-replication complex. Homozygosity mapping in a Saudi Arabian family with an uncategorised form of microcephalic primordial dwarfism established a novel locus at 1p32.3. Subsequent sequencing identified biallelic missense ORC1 mutations in 4 families with microcephalic dwarfism from a cohort of 170 cases. We found that replication licensing was impaired in Orc1 patient cell lines and cell cycle progression slowed, in keeping with ORC1's role, (along with ORC2-6, CDC6 and CDT1), as a component of the Pre-Replication Complex that licenses replication initiation. Furthermore, developmentally, Orc1 depletion substantially impaired zebrafish embryo growth.

Extending our studies to patients with Meier-Gorlin syndrome, in which primordial dwarfism is accompanied by absent or hypoplastic patellae and microtia, we then identified biallelic missense/truncating mutations in ORC1, and through further sequencing multiple mutations in other preRC complex components, ORC4, ORC6, CDT1 and CDC6. We therefore implicate the pre-replication complex as a whole in the developmental regulation of human growth, and surprisingly show that disruption of its function is associated with a distinct and broad spectrum of developmental abnormalities.

Hajdu-Cheney syndrome is a rare skeletal disorder characterized by the association of facial anomalies, radiological findings (acro-osteolysis, general osteoporosis, insufficient ossification of the skull) and periodontal disease (premature loss of permanent teeth). Although most cases are sporadic, transmission in a few families suggests autosomal dominant inheritance. We sequenced the exomes of six unrelated patients and identified nonsense and frameshift heterozygous mutations in *NOTCH2* for five of them. The five mutations are invariably located within the last 3' coding exon of *NOTCH2*, distal to the ankyrin repeats and NLS necessary for the transcriptional activity of Notch2 intracellular domain, while deleting the PEST domain. These results suggest that mutant mRNA products escape nonsense-mediated decay and that truncated *NOTCH2* proteins act in a gain-of-function manner. This mutational mechanism also suggests that decreasing Notch2 signaling using selective gamma-secretase inhibitors may have therapeutic interest in this severe and progressive disease. Finally, our findings establish an important role for Notch2 signaling in bone homeostasis that may notably be relevant to better understanding of mechanisms leading to osteoporosis.

Osteogenesis imperfecta (OI) is a heterogeneous genetic disorder characterized by bone fragility and susceptibility to fractures after minimal trauma. After mutations in all known OI genes had been excluded by Sanger sequencing, we applied next-generation sequencing to analyze the exome of a single individual with a severe form of the disease whose parents are second cousins. A total of 26,922 variations from the human reference genome sequence were subjected to several filtering steps. In addition, we extracted the genotypes of all dbSNP130-annotated SNPs from the exome sequencing data and used these 299,494 genotypes as markers for the genome-wide identification of homozygous regions. A single homozygous truncating mutation, affecting SERPINF1 on chromosome 17p13.3, remained that was embedded into a homozygous stretch of 2.99 Mb. The mutation was also homozygous in the affected brother of the index patient. Subsequently, we identified homozygosity for two different truncating SERPINF1 mutations in two unrelated patients with OI and

parental consanguinity. All four individuals with SERPINF1 mutations have severe OI. Fractures of long bones and severe vertebral compression fractures with resulting deformities were observed as early as in their first year of life. Collagen analyses with cultured dermal fibroblasts displayed no evidence for impaired collagen folding, posttranslational modification, or secretion. SERPINF1 encodes pigment epithelium-derived factor (PEDF), a secreted glycoprotein of the serpin superfamily. PEDF is a multifunctional protein and one of the strongest inhibitors of angiogenesis currently known in humans. Our data provide genetic evidence for an involvement of PEDF in human bone homeostasis.

3MC syndrome has been proposed as a unifying term encompassing the overlapping Carnevale, Mingarelli, Malpuech and Michels syndromes. These rare autosomal recessive disorders exhibit a spectrum of developmental features, including characteristic facial dysmorphism, cleft lip and/or palate, craniosynostosis, learning disability and genital, limb and vesicorenal anomalies. Here we studied eleven families with 3MC syndrome and identified two mutated genes, COLEC11 and MASP1, both of which encode proteins in the lectin complement pathway (collectin kidney 1 (CL-K1) and MASP-1 and MASP-3, respectively). CL-K1 is highly expressed in embryonic murine craniofacial cartilage, heart, bronchi, kidney and vertebral bodies. Zebrafish morphants for either gene develop pigmentary defects and severe craniofacial abnormalities. Finally, we show that CL-K1 serves as a guidance cue for neural crest cell migration. Together, these findings demonstrate a role for complement pathway factors in fundamental developmental processes and in the etiology of 3MC syndrome.

Vertebral and metaphyseal chondrodysplasia, spasticity with cerebral calcifications, and strong predisposition to autoimmune diseases such as systemic lupus erythematosus and autoimmune cytopenias are the hallmarks of the genetic disorder Spondyloenchondrodysplasia (SPENCD; MIM 271550). We mapped a locus to chromosome 19p13 and identified ten different mutations in the ACP5 gene in 14 patients aged from 3 to 63 years.

ACP5 encodes tartrate-resistant phosphatase (TRAP), a lysosomal enzyme that is expressed predominantly in macrophages, osteoclasts and dendritic cells. The mutations abolish enzyme function in the serum and cells of affected individuals. Phosphorylated osteopontin (p-OPN), a protein involved in bone reabsorption and in immune regulation, accumulates in serum, urine and cells cultured from TRAP-deficient individuals. Patient-derived dendritic cells exhibit an altered cytokine profile and are more potent than matched control cells in stimulating allogeneic T cell proliferation in mixed lymphocyte reactions. Thus, TRAP deficiency leads to (1) a defect in bone remodeling, particularly at growth plates, and (2) accumulation of phosphorylated osteopontin, a potent pro-inflammatory cytokine, leading to interferon release and autoimmunity.

The discovery of TRAP deficiency as the basis of SPENCD discloses new therapeutic options such as hematopoietic stem cell transplantation, enzyme replacement therapy, or pharmacologic modulation of the OPN-IFN axis. The findings also shed new light on the role of osteopontin and its regulation by tartrate-resistant acid phosphatase in the pathogenesis of common autoimmune disorders.

Bohring syndrome is characterized by severe intellectual disability, distinctive facial features and multiple congenital malformations. Whole exome sequencing and follow-up by Sanger sequencing revealed heterozygous de novo nonsense mutations in the additional sex combs like 1 gene (ASXL1) in seven patients with Bohring syndrome. ASXL1 belongs to the Polycomb group (PcG) and trithorax complexes family. This family of genes is required for maintenance of both activation and silencing of Hox genes, which determine segmental identity in the developing embryo. Somatic mutations in ASXL1 have previously been reported with leukemia and myelodysplactic syndrome. Thus, our findings suggest a new link between severe developmental disorders and cancer.

Facioscapulohumeral muscular dystrophy (FSHD) is characterized by progressive and often asymmetric weakness and wasting of facial, shoulder girdle and upper arm muscles. FSHD is most often caused by contraction of the D4Z4 macrosatellite repeat array, but only when the repeat array is localized on a specific permissive genetic background of chromosome 4q. Repeat contractions non-permissive 4q or 10q chromosomes do not cause FSHD. D4Z4 repeat contractions are associated with local chromatin relaxation and transcriptional upregulation of the retrotransposed gene *DUX4* in FSHD myotubes only.

We performed detailed D4Z4 sequencing in permissive and non-permissive haplotypes and identified specific single nucleotide polymorphisms (SNPs) in the polyadenylation signal of *DUX4*. While permissive chromosomes carry a typical polyadenylation signal for *DUX4*, non-permissive chromosomes have sequence variants that would predict the *DUX4* polyA signal to be non-functional. Indeed, transfection studies revealed that *DUX4* transcripts are efficiently polyadenylated and more stable when expressed from permissive chromosomes. These findings suggest that FSHD arises through a toxic gain of function attributable to the stabilized *DUX4* transcript. In addition to the SNPs affecting the polyadenlyation signal other SNPs are currently being investigated for their role in *DUX4* mRNA processing and stability. In controls *DUX4* is highly expressed in the germ line and then is epigenetically silenced in somatic tissues. In FSHD, the combination of inefficient D4Z4 chromatin silencing and stabilization of *DUX4* mRNAs results in inappropriate DUX4 protein expression in muscle cells. Therefore, FSHD represents the first human disease caused by the inefficient repression of a retrogene array.

C04.2*

High-resolution breakpoint mapping of 10 regulatory and 32 *FOXL2* encompassing deletions in BPES using targeted microarrays

H. Verdin[1], *B. D'haene*[1], *Y. Novikova*[1], *J. Nevado*[2], *P. Lapunzina*[2], *B. Menten*[1], *E. De Baere*[1];

[1]*Ghent University Hospital, Ghent, Belgium,* [2]*Instituto de Genética Médica Y Molecular (INGEMM), Universidad Autónoma de Madrid, Madrid, Spain.*

Blepharophimosis syndrome (BPES) is a rare autosomal dominant developmental disorder characterized by a complex eyelid malformation associated or not with ovarian dysfunction. Deletions encompassing the *FOXL2* gene and regulatory deletions located outside its transcription unit represent 12% and 5% of molecular defects respectively. In total we identified 32 *FOXL2* encompassing and 10 regulatory deletions. The deletion size and breakpoint locations are highly variable, suggesting absence of a recombination hotspot. To unravel the mechanisms underlying these rearrangements, we aimed to determine the precise locations of the breakpoints. A second purpose was to identify genotype-phenotype correlations for extra-ocular features. We used high-resolution tiling arrays to fine-map the breakpoints. For 27 deletions, both breakpoints could be fine-mapped, allowing junction PCRs. Of these, six deletions could be delineated at the nucleotide level so far. At least two out of six deletions are caused by a recombination-based mechanism using LINE and *Alu* elements as recombination substrates. With regard to genotype-phenotype correlations, an *ATR* encompassing deletion was found in five of eight BPES patients with reported microcephaly. Interestingly, in two patients with joint abnormalities the *SOX14* gene was located within the deletion, potentially implicating this gene in the pathogenesis of this extra-ocular feature. In the largest series of *FOXL2* encompassing and regulatory deletions in reported, high-resolution breakpoint mapping was used to gain more insights into the mechanisms underlying the deletions, and to correlate deletion size and breakpoint location to extra-ocular features.

C04.3

Non-coding, regulatory mutation implicates the HCFC1 gene in non-syndromic intellectual disability.

J. Gecz[1,2], *L. Huang*[1,3], *S. Willis-Owen*[1,4], *M. Field*[5], *A. Hackett*[5], *M. Shaw*[1], *A. Gardner*[1], *C. Shoubridge*[1], *M. Corbett*[1];

Recent systematic X chromosome exon re-sequencing and high resolution copy number profiling on a set of 208 families resolved only ~50% of these. In one unresolved family, known as MRX3 (J Med Genet, 28, 372-7; 1991), we excluded the presence of a mutation in 99.5% of the coding sequence in the linkage interval by massively parallel (MPS) and Sanger sequencing. We postulated a non-coding mutation might be disease causing and from 15 such (unique) variants we investigated one, chrX(hg18) 152890455 A>G, in further detail. We show, that this intergenic nucleotide change unidirectionally affects the expression of the HCFC1 gene. This variant occurs in one of six consensus binding sites of the YY1 transcription factor. We examine its effect by EMSA and luciferase reporter assays and show that YY1 binding is abolished. HCFC1 forms a complex (among others) with the MLL family of H3K4 methyltransferases that is important in cell cycle regulation. We also show further downstream effect of HCFC1 de-regulation on the E2F1 transcription factor and as such putatively linking HCFC1 de-regulation to p53 regulated neurogenesis. Interestingly, YY1 itself has recently been found mutated in a sporadic case with ID (Nat Genet, 42(12):1109-12, 2010). Our data show that patients with MECP2 (and also HCFC1) duplications do not have their HCFC1 mRNA up regulated. Currently ~86% of all disease causing mutations are in protein coding regions, however, this may represent ascertainment bias, which can now be addressed at least partly by the application of MPS technology.

C04.4

Distinct effects of allelic NFI-X mutations on nonsense-mediated mRNA decay engender either a Sotos-like or a Marshall-Smith syndrome

Using a combination of array comparative genomic hybridization and a candidate gene approach, we identified nuclear factor I/X (NFI-X) deletions or nonsense mutations in three sporadic cases of a Sotos-like overgrowth syndrome with advanced bone age, macrocephaly, developmental delay, scoliosis and unusual facies. Unlike the aforementioned human syndrome, Nfi-x-deficient mice are unable to gain weight and die in the first three postnatal weeks, while they also present with a spinal deformation and decreased bone mineralisation. These features prompted us to consider NFI-X as a candidate gene for Marshall-Smith syndrome (MSS), a severe malformation syndrome characterized by failure to thrive, respiratory insufficiency, accelerated osseous maturation, kyphoscoliosis, osteopenia and unusual facies. Distinct frameshift and splice NFI-X mutations creating premature translation termination codons that escaped nonsense-mediated mRNA decay (NMD) were identified in nine MSS subjects. NFI-X belongs to the Nuclear factor one (NFI) family of transcription factors, but its specific function is presently unknown. We demonstrate that NFI-X is normally expressed prenatally during human brain development and skeletogenesis. These findings demonstrate that allelic NFI-X mutations trigger distinct phenotypes, depending specifically on their impact on NMD.

C04.5*

Revertant somatic mosaicism in Dyskeratosis Congenita by mitotic recombination.

[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Queen Mary University of London, London, United Kingdom.

Somatic mosaicism due to reversion of a pathogenic allele to wild type is an intriguing phenomenon. We have observed reversion by mitotic recombination of a mutation in *TERC* (telomerase RNA component) in a family affected by Dyskeratosis Congenita (DC). DC is a disorder of telomere biology and is characterized by mucocutaneous abnormalities and dystrophic nails. Persons affected by DC are at risk for bone marrow failure, cancer and lung fibrosis.

We identified a deletion in *TERC* in the proband of a family with autosomal dominant DC. Segregation of the mutation was confirmed in all affected relatives by sequence analysis on peripheral blood DNA. In two affected brothers, discrepancies in the peak heights suggested overrepresentation of the wild-type allele, whereas the mutation had remained heterozygous in tissues other than blood. Therefore, this mosaicism in peripheral blood must result from somatic reversion of the mutated allele to normal. Neither one of these patients developed bone marrow failure. SNP array analysis on blood DNA from the brothers showed acquired uniparental disomy of chromosome 3q, including *TERC*. In one of these two patients, two independent events of mitotic recombination on chromosome 3 were observed, which were both present in different blood cell lineages of this person. Therefore, the reversion events must have occurred in non-lineage specific haematopoietic precursor cells.

In conclusion, we have found recurrent revertant mosaicism in a family with DC. This finding is important for improving diagnostic testing and understanding the variable phenotype of DC.

C04.6

Mutations in RAD21 as a cause of a new cohesinopathy

F. J. Kaiser[1], *D. Braunholz*[1], *J. Wilde*[2], *C. Gil-Rodriguez*[3,1], *M. Albrecht*[1], *D. Clark*[2], *A. Rampuria*[2], *W. Xu*[1], *I. D. Krantz*[2,4], *G. Gillessen-Kaesbach*[1], *J. A. Horsfield*[5], *M. A. Deardorff*[2,4];

Cornelia de Lange syndrome (CdLS) is a dominantly inherited multisystem developmental disorder that includes distinctive facial features, growth retardation, limb defects and variable cognitive delay. Mutations in *NIPBL* have been identified in approximately 75% of patients with severe classical CdLS but have been found in a far lower percentage of patients with mild or atypical features. NIPBL is required for the establishment of sister chromatid cohesion through the loading of Cohesin, a multimer consisting of SMC1 and SMC3 and the clasp proteins, RAD21 and STAG. Following the identification of *NIPBL*, mutations in *SMC1A* and *SMC3* were detected in a small percent of patients. These patients have a milder phenotype without major structural anomalies, although all have significant mental retardation. By mutation-screening of several genes encoding cohesins or associated proteins in a cohort of 180 mutation-negative individuals, two *de-novo RAD21*-mutations in patients with features that diverge from classical CdLS were identified. We have measured the expression and activity of these missense-mutations in protein-interaction, DNA-damage and zebrafish developmental-assays. In short, one of these RAD21-mutations which increases binding to STAG2, appears to function in a dominant-negative manner and results in a more severe phenotype than the other loss-of-function mutation, which alters binding to SMC1. Cohesinopathies comprise a broadening spectrum of pediatric developmental disorders. We will discuss the current understanding of mechanisms by which Cohesin mutations may alter transcriptional profiles to result in multiple variant developmental phenotypes and speculate on clinical features that appear to be unique and common between different "disorders of Cohesin".

C05.1

Novel Method to Estimate the Phenotypic Variation Explained by Genome Wide Association Studies Reveals Large Fraction of the Missing Heritability

Z. Kutalik[1,2], *J. Whittaker*[3], *D. Waterworth*[4], *J. S. Beckmann*[1], *S. Bergmann*[1];

[1]Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland, Lausanne, Switzerland, [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland, [3]GlaxoSmithKline, Medicines Research Centre, Stevenage, United Kingdom, [4]Medical Genetics, GlaxoSmithKline, Philadelphia, PA, United States.

Genome-wide association studies (GWAS) are conducted with the promise to discover novel genetic variants associated with diverse traits. For most traits, associated markers individually explain just a modest fraction of the phenotypic variation, but their number can well be in the hundreds. We developed a maximum likelihood method that allows us to infer the distribution of associated variants even when many of them were missed by chance. Compared to previous approaches, the novelty of our method is that it (a) does not require having an independent (unbiased) estimate of the effect sizes; (b) makes use of the complete distribution of P values while allowing for the false discovery rate; (c) takes into account allelic heterogeneity and the SNP pruning strategy. We then applied our method to the latest GWAS meta-analysis results of the GIANT consortium. It revealed that while the explained variance of genome-wide (GW) significant SNPs is around 1% for waist-hip ratio (WHR), the observed P values provide evidence for the existence of variants explaining 10% (CI=[8.5%-11.5%]) of the phenotypic variance in total. Similarly, the total explained variance likely to exists for height is estimated to be 29% (CI=[28%-30%]), three times higher than what the observed GW significant SNPs give rise to. This methodology also enables us to predict the benefit of future GWA studies that aim to reveal more associated genetic markers via increased sample size.

C05.2

Accurate prediction of a minimal region around a genetic association signal that contains the causal variant

Z. Bochdanovits[1], *J. Simón-Sánchez*[1], *M. Jonker*[2], *W. Hoogendijk*[1], *A. van der Vaart*[2], *P. Heutink*[1];

[1]VU Medical Center, Amsterdam, Netherlands, [2]Vrije Universiteit, Amsterdam, Netherlands.

In recent years, genome wide association studies have been very successful in identifying loci for complex traits. However, typically these findings involve noncoding and/or intergenic SNPs without a clear functional effect that do not directly point to a specific gene. Hence, the next challenge is to identify the causal variant responsible for the association signal. Typically the first step is to identify all genetic variation in the locus region by, for example, resequencing a large number of case chromosomes. Once all variants are identified, the causal one needs to be ascertained in further functional studies. Because the experimental follow up can be laborious, restricting the number of variants to be scrutinized would yield a great advantage. Therefore, an objective method for choosing the size of the region to be followed up would be highly valuable. Here we propose a simple method to call the minimal region around a significant association peak that is very likely to contain the causal variant. We model Linkage Disequilibrium (LD) in cases from the observed single SNP association signals and predict the location of the causal variant by quantifying how well this relationship fits the data. Simulations showed that our approach identifies genomic regions of on average ~50 kb with up to 90% probability to contain the causal variant. We apply our method to two genome-wide association datasets and localize both the functional variant REP1 in the α-synuclein gene that conveys susceptibility to Parkinson's Disease and the APOE gene involved in susceptibility to Alzheimer's Disease.

C05.3*

Anaylsis of 150 exomes using an automated analysis pipeline

S. H. Eck[1], *T. Wieland*[2], *E. Graf*[2], *A. Benet-Pagès*[1], *T. Meitinger*[2], *T. M. Strom*[2];

[1]Helmholtz Zentrum München, Munich, Germany, [2]Helmholtz Zentrum München, Human Genetics, Munich, Germany.

Enrichment techniques for targeted sequencing of coding regions are currently applied to identify rare variants. We developed a pipeline to analyze exome sequencing data. The pipeline is a combination of

Perl scripts and public available software packages (BWA, SAMtools). It calculates quality metrics and performs read alignment to the reference sequence, variant calling, variant annotation and selection of candidate variants according to the genetic model. Variants are stored in a database, which allows user queries through a web interface and enables pedigree or gene based searches. Exomes deposited in the database can be used as controls.
We applied the analysis pipeline to ~150 exomes. From an average of ~7-10 GB of aligned sequence, the pipeline calls ~16,000-20,000 coding variants. Approximately 7,500-8,500 of these are non-synonymous variants of which ~700-800 not present in dbSNP (version 132). Depending on the number of affected individuals investigated and the underlying inheritance model, we are able to confine this list to 1-10 putatively disease causing variants.
We compared our results with known disease causing recessive mutations in 438 genes obtained from the Human Gene Mutation Database (HGMD). We quantified the amount of new, putatively deleterious variants and assessed the frequency of literature-annotated disease mutations. We identified 16 new heterozygous nonsense variants. 174 of HGMD annotated mutations (~0.85%) had a frequency of >5% in our samples. After subtracting these mutations with an unlikely high frequency, the carrier burden of recessive mutations from HGMD in these genes is between 0 and 9 per individual (average 3.12).

C05.4*

Identity-By-Descent Filtering of Exome Sequence data for Disease-Gene Identification in Autosomal Recessive and X-Linked Disorders

P. M. Krawitz[1], *C. Rödelsperger*[1], *S. Bauer*[1], *J. Hecht*[1], *M. R. Schweiger*[2], *P. N. Robinson*[1];
[1]*Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany.*

Next-Generation Sequencing (NGS) and exome-capture technologies are currently revolutionizing the way geneticists screen for disease-causing mutations in rare Mendelian disorders. Current analysis strategies involve intersection filtering, restriction of candidates to sequence variants predicted to be deleterious, searching for de novo mutations in trios, and using linkage analysis to filter out exome sequences from chromosomal regions that do not demonstrate linkage. None of the above mentioned analysis strategies are well suited for identification of disease genes in small families segregating autosomal recessive (AR) or X-linked (XL) diseases.
Here, we present an algorithm that can be used to narrow down the candidate regions in exome sequences of affected siblings of consanguineous or non-consanguineous parents in AR disorders. Our algorithm uses a non-homogeneous hidden Markov model (HMM) that employs local recombination rates to identify chromosomal regions that are identical by descent (IBD=2) in children of consanguineous or non-consanguineous parents solely based on genotype data of siblings derived from high-throughput sequencing platforms. Using simulated and real exome sequence data, we show that our algorithm is able to reduce the search space for the causative disease gene to a fifth or a tenth of the entire exome. We have used our algorithm successively on real data to identify disease genes including the PIGV gene as the cause of Mabry syndrome (Krawitz et al., Nat Genet. 2010,42:827-9). Here, we will present the algorithm as well as a recent modification of the algorithm for XL diseases.

C05.5

Genome-Wide Association Meta-Analysis of Total Brain Volume: Results from the ENIGMA Consortium

A. Arias-Vásquez[1], *.. The ENIGMA Consortium*[2];
[1]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands,* [2]*http://enigma.loni.ucla.edu/publications/ohbm2011/, Los Angeles, CA, United States.*

There is evidence that differences of brain volume, either global or regional, are related to their specific functioning and to more global cognitive processes. Our overall aim is to identify common genetic variants that modify the risk for psychiatric disorders based on the identification of genetic variants involved in the variance of the volume of brain structures in healthy individuals. Mean total brain volume was automatically segmented in T1-weighted MRI scan using FreeSurfer. 16 groups worldwide have now pooled their imaging genomics data from a total of >7000 subjects. Genetic homogeneity of the samples was assessed and genotypes were imputed using the HapMap III reference panel, and associations were tested via dosage of each imputed SNP (accounting for kinship in family-based samples). After quality control, results files and summary statistics were pooled for meta-analysis. By February 2011, 16 groups had uploaded GWAS results in >7000 subjects. Association conducted at ~1.3 million autosomal SNPs showed that none of the individual sites contained genome-wide significant GWAS results (p<10^-8). Conversely, meta-analysis of the data from the 16 studies yielded genome-wide significant p-values for total brain volume. To date, neuroimaging genetics has largely employed candidate gene, GWAS, or image-wide GWAS analyses in samples < 1000 subjects. This leads to a lack of power to detect significant effects while controlling the false positive rate. Our collaborative ENIGMA pilot project on total brain volume shows the utility of data sharing and meta-analysis, and the value of large sample sizes for genetic analysis of brain measures.

C05.6*

The influence of genetic variations on regulatory modules in the liver.

A. Kreimer[1], *I. Pe'er*[2];
[1]*Department of Biomedical Informatics, Columbia University, New York, NY, United States,* [2]*Department of Computer Science, Columbia University., New York, NY, United States.*

Deciphering the influence of genetic variants on regulatory modules, and the correlation between such regulatory variants and phenotype (e.g. disease) has been the subject of extensive research in recent years. Here, we present a novel approach to this problem, which entails analyzing modules of genes, rather than studying SNP-gene connections independently. First, we search pair-wise connections between transcripts whose levels are co-associated to the same SNP. Second, we combine these pairs into modules that share a regulating SNP. Third, we assign a confidence score to each module. Finally, we split the samples in each module according to the genotype of the main SNP and find the best allele specific SNPs that explain the expression of the largest group of genes in each subset of samples. We applied our method to data on genetic and gene expression in the liver across 371 samples by Merck. We detect 129,109 pairs of transcripts that are jointly associated to the same SNP as their most significant regulator. These make up 10,354 modules, 518 including 10 transcripts or more. These are significantly more and larger modules than in permuted data (2,322+-208, 220+-42 of size 10 or more). We quantified the confidence in a module as a likelihood score, and prune a subset of 114 modules with FDR<0.02. We observe similar annotations of modules from two sources of information: the enrichment of a module in gene subsets and locus annotation of the genetic variants. This provides a validation of our methodology.

C06.1

Identification of recent admixture in an Indian population of African ancestry: prospects for complex disease mapping

A. Basu[1], *A. Narang*[2], *P. Kumar*[2], *A. Mukhopadhyay*[2], *D. Dash*[2], *M. Mukherjee*[2];
[1]*National Institute of BioMedical Genomics, Kalyani, India,* [2]*IGIB, New Delhi, India.*

Identification and study of genetic variation in recently admixed populations not only provides insight into historical population events but is also a powerful approach for mapping disease genes. We studied a population of African-Indian(AI) origin which is believed to be the descendants from the Bantu speaking parts of Africa and have been residing in the western part of India for nearly >500years. We have carried out this study using a common set of 18534 autosomal markers; common between 26 Indian populations (50 K Affymetrix array), populations in the Human Genome Diversity Project (HGDP) and HapMap populations. Principal component analysis clearly revealed that the African-Indian population derives its ancestry from West-African as well as Indo-European speaking Northern and North-West Indian population(s). STRUCTURE and ADMIXTURE analysis revealed that, overall the AI population derive 58.7% of their genomic ancestry from their African past with very little inter-individual ancestry variation (8.4%). The extent of linkage-disequilibrium also reveals that the admixture event has been recent. Functional annotation of genes encompassing the ancestry informative markers revealed

significant enrichment of biological processes related to ion channel activity from the Indian ancestry. We briefly examine the implications of determining the genetic diversity of this population which could provide opportunities for possible studies using admixture mapping.

The dog population is composed of more than 400 breeds; each one is a genetic isolate with unique phenotypic characteristics. Dogs tend to suffer from the same range of diseases as humans, but the genetic complexity of these diseases within a breed is reduced as a consequence of intense selection and inbreeding.

In this study, we performed a comprehensive analysis using multiple test statistics to identify regions under strong selection in 518 dogs from 46 diverse breeds using a newly developed high-density genotyping canine array consisting of >170,000 evenly spaced SNPs. We first identified 44 genomic regions exhibiting extreme differentiation across multiple breeds. Genetic variation in these regions correlates with variation in several phenotypic traits that vary between breeds, and we identify novel associations with both morphological and behavioural traits. We next scanned the genome for signatures of selective sweeps in single breeds. These scans identify hundreds of regions strongly enriched for developmental genes and genes implicated in diseases. We characterised one highly differentiated region associated with body size and ear morphology, using high-throughput sequencing to provide a list of variants that may directly affect these traits.

In this study, we provide a detailed description of genomic regions under strong selection in the canine genome, including many linked to extreme phenotypic variation. We hypothesize that some of these regions will also contain canine disease genes of comparative relevance to human health.

C06.3
Increased number of microRNA target sites in genes encoded in CNV regions. Evidence for an evolutionary genomic interaction?

K. N. Felekkis[1], *K. Voskarides*[2], *H. Dweep*[3], *C. Sticht*[3], *N. Gretz*[3], *C. Deltas*[3];
[1]*University of Nicosia, Nicosia, Cyprus,* [2]*University of Cyprus, Nicosia, Cyprus,* [3]*University of Heidelberg, Mannheim, Germany.*

MicroRNAs (miRNAs) and Copy Number Variations (CNVs) are two newly discovered genetic elements that have revolutionised the field of molecular biology and genetics. By performing *in silico* whole genome analysis we demonstrate that both the number of miRNAs that target genes found in CNV regions as well as the number of miRNA binding sites are significantly higher than those of genes found in non-CNV regions. Analysis of human and chimpanzee genome demonstrates that the number of microRNAs targeting a gene, increase after the formation of CNVs since genes in CNVs formed in human lineage are targeted by a significantly higher number of microRNAs than the genes found within CNVs in chimpanzee, for which data are available. Collectively these results suggest that miRNAs may have acted as equilibrators of gene expression during evolution, in an attempt to regulate aberrant gene expression and to increase the tolerance to genome plasticity.

C06.4
Loss and gain of function in human *SERPINB11:* an example of a gene under selection on standing variation, with implications for host-pathogen interactions

S. Seixas[1], *N. Ivanova*[1], *Z. Ferreira*[1,2], *J. Rocha*[1,2], *B. L. Victor*[3];
[1]*IPATIMUP, Porto, Portugal,* [2]*Faculty of Sciences University of Porto, Porto, Portugal,* [3]*ITQB, Oeiras, Portugal.*

Serine protease inhibitors (SERPINs) are crucial in the regulation of diverse biological processes including inflammation and immune response. *SERPINB11*, located in the 18q21 gene cluster, is a polymorphic gene/pseudogene coding for a non-inhibitory SERPIN. This study sought a better understanding of the evolutionary history of *SERPINB11*, with special focus on evaluating the adaptive signature identified in Africans in a genome-wide scan for selection. Our study comprised the resequencing of *SERPINB11* in 20 Yorubans and the analysis of primate orthologous sequences. We identified a full-length *SERPINB11* variant encoding a non-inhibitory SERPIN as the putative candidate of selection, probably driven to higher frequencies by an adaptive response using preexisting variation. In addition, we detected contrasting evolutionary features for *SERPINB11* in primates: While primate phylogeny as a whole is under purifying selection, the human lineage shows evidence for positive selection in a few codons, all associated with the active *SERPINB11*. According to comparative modeling studies, positively selected codons are suggested to reduce SERPINB11's ability to undergo the typical conformational changes of inhibitory SERPINs - suggesting that it is evolving towards a new function in humans. The recognition of significant correlations between *SERPINB11* variants and pathogen richness has led us to propose a selective advantage through host-pathogen interactions, which may be linked to an adaptive response combating the emergence of infectious diseases during the Neolithic. This work represents the first description of a resurrected gene in humans, and is likely to represent an example of selection on standing variation triggered by drastic ecological shifts.

C06.5
Remarkably little homozygosity in first generation mixed race individuals

J. F. Wilson[1,2], *C. O'Dushlaine*[3,4], *R. Fraser*[1], *R. McQuillan*[1];
[1]*University of Edinburgh, Edinburgh, United Kingdom,* [2]*EthnoAncestry Ltd, Edinburgh, United Kingdom,* [3]*Massachusetts General Hospital, Boston, MA, United States,* [4]*The Broad Institute of Harvard and MIT, Boston, MA, United States.*

Long runs of homozygosity (ROH) are ubiquitous features of human genomes. There is, however, wide variation in the number and length of ROH across individuals and populations due to their diverse demographic histories: sub-Saharan African populations are the least homozygous and Native South Americans the most. Using genomic analysis we here demonstrate the remarkable lack of homozygosity in mixed race individuals: first generation (F1) West African x European individuals are the least homozygous of all, with an order of magnitude fewer ROH than commonly observed in other populations. Their parents may not share ancestors after the Out of Africa movement, ~70,000 years ago. Populations may be ranked by increasing mean number of ROH: (1) F1 West African x European; (2) F1 Afro-Caribbean x European; (3) Afro-Caribbean; (4) sub-Saharan African (excluding hunter-gatherers), F1 European x East African, F1 European x East Asian, Mauritian and Seychellois; (5) F1 European x South Asian; (6) F2 Eurasian mixed race individuals; (7) other Eurasians; and (8) Native North Americans. Afro-Caribbeans have on average ~20% European ancestry, and these haplotypes generate ROH in offspring with Europeans. F1 European x East Asian individuals carry a similar complement of ROH to sub-Saharan Africans, emphasising the great genetic diversity in Africa. The variance in the number of ROH was highest for Native North Americans: NROH was strongly inversely correlated with the large and variable genomic estimates of European admixture. The reduction in genome-wide homozygosity in mixed race individuals will reduce their risk for diseases with a recessive genetic component.

C06.6*

Microsatellite choice and Y chromosome variation: attempting to select the best STRs to date human Y chromosome lineages

G. B. J. Busby, *C. Capelli;*
University of Oxford, Oxford, United Kingdom.

Recently the debate on the origins of the major European Y chromosome haplogroup R-M269 has reignited, and opinion has moved away from Paleolithic origins to the notion of a younger Neolithic spread of these chromosomes from the Near East. We investigate the young, STR-based Time to the Most Recent Common Ancestor estimates proposed so far for R-M269 related lineages and find evidence for an appreciable effect of microsatellite choice on age estimates. We further expand our analysis to include a worldwide dataset of over 60 STRs which differ in their molecular attributes. This analysis shows that by taking into account the intrinsic molecular characteristics of Y chromosome STRs, one can arrive at a more reliable estimate for the age of Y chromosome lineages. Subsequently, we suggest that most STR-based Y chromosome dates are likely to be underestimates due to the molecular characteristics of the markers commonly used, such as their mutation rate and the range of potential alleles that STR can take, which potentially leads to a loss of time-linearity. As a consequence, we update the STR-based age of important nodes in the Y chromosome tree, showing that credible estimates for the age of lineages can be made once these STR characteristics are taken into consideration. Finally we show that the STRs that are most commonly used to explore deep ancestry are not able to uncover ancient relationships, and we propose a set of STRs that should be used in these cases.

C07.1

Impact of mtDNA mutations on mtDNA segregation throughout human oogenesis

S. Monnot[1], *N. Gigarel*[1], *D. C. Samuels*[2], *P. Burlet*[1], *L. Hesters*[3], *N. Frydman*[3], *R. Frydman*[3], *V. Kerbrat*[3], *B. Funalot*[1], *A. Benachi*[4], *J. Feingold*[1], *A. Munnich*[1], *J. Bonnefont*[1], *J. Steffann*[1];
[1]*INSERM unit U781, Necker Hospital, and Paris-Descartes University, paris, France,* [2]*Center for Human Genetics Research, Department of Molecular Physiology and Biophysics, Vanderbilt University Medical Center, Nashville, TN, United States,* [3]*Reproductive Medicine Department, A Beclere Hospital, Clamart, France,* [4]*Gynaecology-Obstetrics Department, Necker Hospital, paris, France.*

Mitochondrial DNA (mtDNA) mutations cause a wide range of serious diseases with high transmission risk and maternal inheritance. Owing to the absence of therapy, couples at risk to transmit such disorders commonly ask for prenatal (PND) and preimplantation diagnosis (PGD). The lack of data regarding heteroplasmy distribution throughout oogenesis, however hampers these procedures.

We tracked the segregation of 5 mtDNA mutations, namely m.3243A>G, m.8344T>G m.8993T>G, m.9185T>C and m.10197G>A responsible for MELAS, MERRF, NARP or Leigh syndrome during oogenesis, by quantifying the corresponding mutant loads in 6 carriers, their 14 oocytes, 53 first polar bodies (PB1), and 65 early embryos thought to estimate of the mature oocyte mutant load.

Our data indicate that

1/ mtDNA segregation is governed by random genetic drift for m.3243A>G throughout the whole oogenesis.

2/ the size of the bottleneck operating during oogenesis i) is likely to depend on the mutation type, and ii) is individual-dependent for m.3243A>G.

3/ while the absence of mutation constantly correlates between PB1 and the corresponding oocyte/embryo, mutant load may vary significantly (+30%) between these 2 clonally-derived daughter cells, irrespective of the mutation type, contrary to the data drawn from mouse models.

4/ a selection event against high mutant load oocytes might occur during meiosis.

5/ there is no correlation between the PB mutant load and the rate of cleavage, suggesting that oocyte fertilization and early embryonic development are not markedly affected by mtDNA mutations.

These data have obvious consequences on genetic counseling and PND/PGD procedures in mtDNA inherited disorders.

C07.2

Pre-implantation genetic diagnosis offers a fair chance of having unaffected offspring for mitochondrial DNA disorders

D. Hellebrekers[1], *R. Wolfe*[2], *A. Hendrickx*[1], *R. de Coo*[3], *C. de Die*[1], *J. Geraedts*[1], *P. Chinnery*[4], *H. Smeets*[1];
[1]*Maastricht University Medical Center, Maastricht, Netherlands,* [2]*School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia,* [3]*Department of Pediatric Neurology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands,* [4]*Institute of Human Genetics, Newcastle University, Newcastle, United Kingdom.*

Oxidative phosphorylation disorders due to maternally inherited homoplasmic or heteroplasmic mtDNA mutations affect approximately 1/5,000 individuals. The mutation level of transmitted heteroplasmic mtDNA point mutations varies significantly between embryos due to a segregational bottleneck. Prenatal (PND) or pre-implantation genetic diagnosis (PGD) of mtDNA disorders is complicated by the inability to accurately predict the threshold of clinical expression for most heteroplasmic mtDNA mutations. Here we tried to define a minimal mutant level below which the chance for an embryo of being affected is acceptably low, irrespective of the exact mtDNA point mutation. A systematic review was performed on muscle mutant levels of 159 different heteroplasmic mtDNA point mutations derived from 327 unrelated patients or pedigrees, excluding three overrepresented mtDNA mutations. We generated a distribution of mutation levels of all affected individuals (n=195) and their unaffected maternal relatives (n=19) from 137 pedigrees with a familial mtDNA mutation, and predicted the risk of being affected given a varying mutant level. This prediction required an assumption of overall prevalence of affected status in familial pedigrees. For familial mutations, little difference in mean muscle mutant level was observed between probands and affected maternal relatives and between affected individuals with a tRNA-versus protein-coding mutation. The overall prevalence of affected status in familial pedigrees was estimated as 0.477. A 95% or higher chance of being unaffected was associated with a muscle mutant level of 18% or less. PGD provides carriers of heteroplasmic mtDNA point mutations the opportunity to substantially increase the chance of having healthy offspring.

C07.3

Multiplex massively parallel sequencing for noninvasive prenatal diagnosis

B. H. W. Faas, *L. E. L. M. Vissers, I. M. Janssen, J. de Ligt, A. Eggink, J. A. Veltman, A. Geurts van Kessel;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Blood plasma of pregnant women contains circulating fetal DNA, with great potential for non-invasive detection of fetal chromosomal aneuploidies. We have explored the possibility for multiplex massively parallel sequencing to detect such fetal chromosomal aneuploidies.

From three women, carrying euploid fetuses (46,XY [N=1], 46,XX [N=2]) blood samples were drawn prior to invasive procedures and from five women, carrying aneuploid fetuses (47,XX,+21; 47,XY,+21; 47,XXX; 47,XX,+13; 47,XY,+18) blood samples were drawn after invasive procedures. Samples were taken at various gestational ages, ranging from 12^{+4} to 19^{+6}. DNA was isolated from 3.5-8 mL of plasma using either a QIAamp DSP Mini Blood Kit or a QIAamp Circulating Nucleic Acid Kit. Sequencing libraries were prepared individually and DNA was multiplexed after ligation of an unique sequencing barcode. Sequencing was performed on a SOLiD™ 4 system. Next, the sequence reads were mapped to the human reference genome (hg19) and quantified according to their genomic location. Subsequently, ζ-scores per chromosome were calculated as described elsewhere. Thresholds for aneuploidy were set at ζ>+3.0 and ζ<-3.0 for over- or under-representation, respectively, of a chromosome.

All aneuploidies yielded ζ-scores >3.0 for the aberrant chromosomes (range +3.38 to +9.43), whereas all other chromosomes were detected as normal (range -2.27 to +2.31). Our data thus indicate that full-blown fetal aneuploidies can be reliably detected in maternal plasma using a multiplex massively parallel sequencing approach. Further improvements in the rate of multiplexing samples to reduce costs and increase efficiency are currently under investigation.

C07.4*

The Use Of Array CGH for Prenatal Diagnosis Of Fetuses With Congenital Malformations Detected By Ultrasound

P. D. Brady[1], *E. Mattheeuws*[2], *J. A. Deprest*[3], *J. P. Fryns*[2], *K. Devriendt*[1], *J. R. Vermeesch*[1];
[1]*Centre for Human Genetics, K.U. Leuven, Leuven, Belgium,* [2]*Centre for Human Genetics, U.Z. Leuven, Leuven, Belgium,* [3]*Fetal Medicine Unit, U.Z. Leuven, Leuven, Belgium.*

Karyotyping has remained the gold standard for the detection of numerical and structural chromosome rearrangements for prenatal genetic diagnosis. Molecular karyotyping by array CGH is now a widely used technique for postnatal genetic analysis providing genome-wide detection of genomic imbalances at a resolution far superior to conventional karyotyping. The use of array CGH is an attractive alternative in the prenatal diagnostic setting, given the ability to overcome the resolution & time limitations of conventional karyotyping or the locus-specific limitations of targeted analyses such as FISH & MLPA.

We have undertaken a prospective study into the use of a high resolution array for the prenatal diagnosis of pregnancies where fetal abnormalities were detected on ultrasound scan. Over 100 fetal samples have been analysed from amniotic fluid and chorionic villi, using both direct and cultured material. Since UZ Leuven is a specialist referral centre for fetuses with isolated congenital diaphragmatic hernia (CDH), a subset of our referrals are from this cohort.

We show that array CGH detects a number of causal submicroscopic imbalances in fetuses with ultrasound anomalies. Of particular interest, our results allow us to refine the minimal critical region associated with CDH on chromosome 15q26 to a single gene, NR2F2 (COUP-TFII). We demonstrate an average reporting time of 8 days for uncultured material. We shall present our results, and also discuss our approach to the interpretation and reporting of CNVs detected prenatally.

C07.5

Diagnostic utility of array-based comparative genomicv hybridization (aCGH) in a prenatal setting

I. Maya[1], *B. Davidov*[1], *Y. Zalzstein*[1], *E. Taub*[1], *M. Shohat*[1,2];
[1]*Raphael Recanati Genetic Institute, Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel,* [2]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Objective: Array-based comparative genomic hybridization (aCGH) is a technique for detecting submicroscopic deletions and duplications. There is limited information regarding its use in the prenatal setting. Here, we present our experience of 431 prenatal aCGHs between 2006 and 2011.

Materials and Methods: We reviewed the medical files of 431 prenatal cases seen in the Recanati Genetic Institute between 2006 and 2011 on whom prenatal aCGH was carried out.

Results: The indications for testing were fetal anomalies on ultrasound (U/S) (43%), advanced maternal age (AMA)(20%), family history of a disorder of unknown etiology (15%), parental concern (13%), Abnormal routine karyotype (8%) and abnormal serum biochemical screening for common fetal aneuploidies (1%).

Of 34 cases with a known abnormal karyotype, 26 (75%) had a normal aCGH. This enabled us to reassure the families and the pregnancies were continued. The remaining 8 (25%) showed an abnormal aCGH, confirming the chromosomes were unbalanced, and were terminated. Of 397 cases with a normal karyotype, 7 had an abnormal aCGH and after genetic counseling they were terminated. Overall, new clinically relevant results were detected by aCGH in 41 cases, providing additional information for prenatal genetic counseling and risk assessment.**Conclusion:** Our results suggest that prenatal aCGH should be offered particularly in cases with abnormal U/S (detection rate was 1:46). We found the rate of detecting an abnormality by aCGH in low-risk pregnancies (normal fetal U/S) was 1:70, but larger studies will be needed to expand our knowledge and validate our conclusions.

C07.6

Prenatal diagnostic testing of the Noonan syndrome genes in fetuses with abnormal ultrasound findings

H. G. Yntema[1], *E. Croonen*[2], *W. Nillesen*[1], *L. Martens*[1], *M. Schepens*[1], *M. Ruiterkamp-Versteeg*[1], *H. Scheffer*[1], *B. Faas*[1], *I. van der Burgt*[1];
[1]*Department of Human Genetics, Nijmegen, Netherlands,* [2]*Department of Pediatrics, Nijmegen, Netherlands.*

Noonan syndrome is a genetically heterogeneous, autosomal dominant disorder characterized by short stature, congenital heart defects, distinctive facial features, and a variable degree of intellectual deficits. The *PTPN11* gene is involved in 50% of Noonan syndrome cases, but is also found to be mutated in 9% of fetuses with cystic hygroma and increased nuchal translucency (NT) (Lee *et al.* (Clin Genet 2009;75:190)). In our laboratory parallel testing of *PTPN11*and *KRAS* in fetuses with a normal karyotype and an increased NT showed a mutation frequency of 16% [Houweling *et al*. (2010) Prenat Diagn 30:284]. Until now, we have investigated the DNA of 76 fetuses for mutations in *PTPN11*, *KRAS*, *SOS1,* and *RAF1*. In 12 fetuses (15,8%) a *de novo* mutation has been identified in either *PTPN11* (n=8), *RAF1* (n=3), or *KRAS* (n=1).

In an anonymous study the DNA of 62 other fetuses with increased NT (>3.5 mm), cystic hygroma, hydrops fetalis or congenital heart disease - with or without ventricular megaly and/or renal abnormalities- and a normal karyotype, has been investigated for mutations in 10 genes of the RAS-MAPK pathway. Besides potentially causative mutations in *PTPN11* (n=1), *RAF1* (n-1), and *SOS1* (n=1), also unclassified variants in *BRAF* (n=1) and *MAP2K1* (n=1) have been identified. We conclude that prenatal testing for fetuses with an increased NT (>3.5 mm) should at least include *PTPN11*, *RAF1* and *KRAS* sequencing. If enough time and DNA is left, mutation analysis of *SOS1*, *BRAF* and *MAP2K1* should be considered.

C08.1*

A *de novo* paradigm for mental retardation

L. Vissers, *J. de Ligt, B. van Bon, C. Gilissen, M. Willemsen, I. Janssen, J. Schuurs-Hoeijmakers, M. Steehouwer, W. Nillesen, P. de Vries, K. van der Donk, B. van Lier, P. Arts, H. Scheffer, N. Wieskamp, M. del Rosario, A. de Brouwer, A. Hoischen, T. Kleefstra, B. de Vries, H. Brunner, J. Veltman; Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Recent studies have indicated that humans have an exceptionally high per-generation mutation rate of 7.6 x 10^{-9} to 2.2 x 10^{-8}. These spontaneous germ line mutations can have serious phenotypic consequences when affecting functionally relevant bases in the genome. In fact, their occurrence may explain why diseases with a severely reduced fecundity remain frequent in the human population, especially when the mutational target is large and comprised of many genes. This would explain a major paradox in the evolutionary genetic theory of cognitive disorders.

In this presentation, we will first describe our recent work on using a family-based exome sequencing approach to test this *de novo* mutation hypothesis in 10 patients with unexplained mental retardation[1]. Unique non-synonymous mutations were identified and validated in nine genes. Six of these, identified in different patients, were likely pathogenic based on gene function, evolutionary conservation and mutation impact. These findings provided a strong experimental support for a *de novo* paradigm for mental retardation.

The clinical relevance and ultimate proof for disease-causality of these novel genes lies in the identification of *de novo* mutations in additional patients of similar phenotype. As such, we are currently screening ~1,200 patients with unexplained mental retardation for mutations in *YY1*, representing one of these newly identified genes. Moreover, we are extending our family-based exome sequencing approach to 100 patients to establish the diagnostic yield for *de novo* mutations in patients with unexplained mental retardation.

[1]Vissers *et al*. A *de novo* paradigm for mental retardation. *Nature Genetics* **42**: 1109-1112 (2010).

C08.2

Homozygosity mapping, exon enrichment and next generation sequencing reveals single plausible gene defects in 72 consanguineous families with autosomal recessive intellectual disability

H. Najmabadi[1], *H. Hu*[2], *M. Garshasbi*[2], *T. Zemojtel*[3], *S. S. Abedini*[1], *W. Chen*[2,4], *M. Hosseini*[1], *F. Behjati*[1], *S. Haas*[3], *P. Jamali*[5], *A. Zecha*[2], *M. Kalscheuer*[2], *R. Ullmann*[2], *A. Kuss*[2], *A. Tzschach*[2], *K. Kahrizi*[1], *H. H. Ropers*[2];

[1]Genetics Research Centre, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]Max-Planck-Institute for Molecular Genetics, Department of Human Molecular Genetics, Berlin, Germany, [3]Max-Planck-Institute for Molecular Genetics, Department of Computational Molecular Biology, Berlin, Germany, [4]Max-Delbrueck-Centrum fuer Molekulare Medizin, Berlin, Germany, [5]Shahroud Welfare Organization, Semnan, Tehran, Islamic Republic of Iran, [6]Kariminejad-Najmabadi Pathology and Genetics Centre, Tehran, Islamic Republic of Iran, [7]Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany, [8]Kinderzentrum München, München, Germany, [9]Zentrum für Humangenetik und Laboratoriumsmedizin Dr. Klein und Dr. Rost, Martinsried, Germany, [10]Mashhad Welfare Organization, Mashhad, Islamic Republic of Iran, [11]Kinderneurologie und Sozialpädiatrie Vivantes.-Klinikum Neukölln, Berlin, Germany, [12]Yazd Welfare Organization, Yazd, Islamic Republic of Iran, [13]Genetics Unit, Ministry of Health, Directorate General of Health Affairs, Royal Hospital, Muscat, Oman, [14]Islamic Azad University of Kerman, Kerman, Islamic Republic of Iran.

Functional considerations and empirical data from animal models suggest that most gene defects are inherited as recessive traits. However, research into recessive disorders has lagged behind because in Western societies with their small-size families, most affected patients are isolated cases. Intellectual disability (ID) is a particularly important problem of health care world-wide, and most severe forms have a genetic etiology. Autosomal recessive forms of ID (ARID) are thought to be more frequent than X-linked ones, particularly in developing countries where parental consanguinity is common and the incidence of ID is significantly elevated.

Here we report on the first systematic attempt to shed more light on the molecular causes of ARID. By performing homozygosity mapping, exon enrichment and next generation sequencing (NGS), we have identified apparently causative gene defects in 72 out of 130 consanguineous families from Iran and elsewhere. In 26 families, causative changes were found in previously described disease genes. In three of these genes, i.e. AHI1, SRD5A3 and PRKCG, allelic mutations were found in more than one family. In 46 families, single apparently causative mutations were detected in genes not hitherto implicated in ID or related disorders such as autism, epilepsy or schizophrenia. Many of these genes are involved in (the regulation of) transcription and translation or other regulatory pathways known to be important for brain function, while others interact directly with known ID genes. Thus, the systematic identification of novel ID genes is also a potent strategy to unravel the pathways and pathogenetic mechanisms underlying cognitive disorders.

C08.3

Exome sequencing and ACAD9 mutation screening of patients with complex I deficiency

T. Haack[1,2], *K. Danhauser*[1], *B. Haberberger*[1], *P. Freisinger*[3], *S. Eck*[2], *M. Zeviani*[4], *T. Strom*[1,2], *T. Meitinger*[1,2], *H. Prokisch*[1,2];

[1]TU Munich, Institute of Human Genetics, Munich, Germany, [2]Helmholtz Zentrum München, Institute of Human Genetics, Munich, Germany, [3]Klinikum am Steinenberg, Reutlingen, Germany, [4]The Foundation 'Carlo Besta' Institute of Neurology, Milan, Italy.

Faulty energy supply due to defective oxidative phosphorylation is the biochemical signature of mitochondrial disorders, a genetically heterogenous group of rare, severe and highly invalidating human conditions. For a majority of patients, the molecular basis of the disorder remains unknown and there is an urgent need for new diagnostic strategies. We have recently used an exome sequencing strategy based on a single patient with a complex I deficiency to identify a pathogenic mutation in ADAD9, which codes for a member of the acyl-CoA dehydrogenase (ACAD) protein family. We had also shown that treatment of patient fibroblasts with riboflavin rescues the phenotype.

Here we demonstrate the efficacy of exome sequencing in combination with cellular assays in 12 additional unrelated complex I patients and the results of ACAD9 mutation screening in a group of 100 complex I patients. We found pathogenic variants in three known disease genes coding for mitochondrial proteins in four patients. In two instances, the pathogenic role of novel variants was established by the correction of the biochemical defect on expression of the wild-type protein in patient's fibroblasts. Fibroblasts of five patients with ACAD9 mutations were treated with riboflavin, the vitamin precursor of the FAD moiety, which is the catalytic cofactor of ACADs, is known to foster their assembly and stability. Riboflavin treatment of all five mutant cell lines resulted in a significant increase of complex I activity. This supports previous accounts of beneficial effects of a high dosage riboflavin regimen in ACAD9 patients.

C08.4

Next Generation diagnosis of Glycogen Storage Diseases

F. Smith[1], *T. Cullup*[1], *C. Deshpande*[2], *M. Champion*[2], *H. Mundy*[2], *K. Bhattacharya*[3], *S. Abbs*[1], *S. C. Yau*[1];

[1]GSTS Pathology, London, United Kingdom, [2]Guy's and St Thomas NHS Foundation Trust, London, United Kingdom, [3]Children's Hospital at Westmead, Sydney, Australia.

Glycogen storage diseases (GSD) are heterogeneous disorders caused by mutations in one of 18 genes encoding proteins of the glycogen metabolism pathway. Clinical and genetic heterogeneity between GSD subtypes makes diagnosis lengthy and costly, requiring numerous clinical assessments including muscle or liver biopsy, followed by sequencing for mutations in a sequential 'gene-by-gene' manner in some cases. We have developed a rapid and cost effective Next Generation diagnostic test to screen all 18 genes simultaneously. A bespoke Agilent SureSelect in-solution DNA array is used to capture ~1Mb genomic sequence from all 284 exons of the GSD genes. The captured material is sequenced on the Illumina GAIIx platform with up to 12 samples per lane, using index tagging to reduce costs. The massive capacity of such instruments ensures adequate sequencing coverage (>30x) of target exons +/- 50bp, to accurately detect heterozygous variants. Validation experiments have correctly detected homozygous and heterozygous single nucleotide sequence variants, deletions ranging from 1bp to 38bp, a complex indel of 27bp, and large CNVs. We have tested 16 patients diagnosed clinically with GSD and have detected pathogenic mutations in 14, in the AGL, PHKA2, PHKB, PHKG2, PYGL, PYGM and SLC37A4 genes. Compared with the current costly and lengthy investigation of these patients, including sequential gene sequencing in some cases, this comprehensive mutation screen for GSD provides cheaper and faster diagnosis within a number of weeks rather than months or even years. This Next Generation diagnosis changes the patient's investigative pathway, reducing the need for alternative invasive diagnostic procedures.

C08.5

High Throughput Genetic Analysis in Patients with Hereditary Retinal and Optic Nerve Diseases

S. Biskup[1], *B. Wissinger*[2], *T. Scheurenbrand*[3], *S. Kohl*[2], ***D. Boehm***[3];

[1]Herte Institute for Clinical Brain Research, Tübingen, Germany, [2]Molecular Genetics Laboratory, Institute for Ophthalmic Research Centre for Ophthalmology University Clinics Tuebingen, Tübingen, Germany, [3]CeGaT GmbH, Tübingen, Germany.

Hereditary retinal dystrophies (RDs) and optic nerve degenerations (ONDs) are amongst the genetically most complex and heterogenous conditions. Up to now more than 180 genes have been described to be implicated in RDs and ONDs. However it has been estimated that mutations in the known genes account for only ~ 50% of all affected subjects. Current genetic diagnostics based on mutation scanning techniques (e.g. HRM, dHPLC, SSCP) and Sanger sequencing on capillary sequencing machines frequently takes several month or years and is laborious and cost-intensive. Such considerations, as well as the demand to clarify the remaining 50% of unsolved cases, have resulted in an initiative to transfer hereditary ophthalmic disease diagnostics to the high-throughput sequencing (HTS) arena.

Methods: DNA is enriched for the coding and flanking intronic/UTR sequences of a panel of 190 genes known to be associated with RD and OND diseases using a custom designed Agilent SureSelect kit. Sequencing is performed using barcoded libraries on a single Oct on the SOLiD 4 platform. The basic data analysis is performed with Bioscope v1.2. All variants and putative deletions are re-sequenced by the gold standard Sanger sequencing or quantitative PCR, respectively.

Results: Here, we present the results of the high throughput analysis in 50 patients. We will demonstrate how so far genetically undiagnosed cases could be solved by our newly developed method. Most interestingly, we are able to detect different types of mutations including SNVs, as well as copy number variations ranging from small, large up to whole exon deletion.

C08.6
Multiplex Targeted High-Throughput Sequencing for mendelian cardiac disorders identified oligogenic inheritance

S. Fokstuen[1], *S. Nikolaev*[2], *D. Robyr*[2], *A. Munoz*[2], *L. Farinelli*[3], *C. Iseli*[4], *S. E. Antonarakis*[2,1], *J. Blouin*[1];
[1]*Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland,* [2]*Genetic Medicine, University of Geneva Medical School, Geneva, Switzerland,* [3]*Fasteris S.A., Plan-les-Ouates, Switzerland,* [4]*Ludwig Institute of Cancer Research and Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

Cardiomyopathies and arrhythmias are common, seemingly mendelian autosomal dominant cardiac disorders known as primary cause of sudden cardiac death in young adults. These diseases are characterized by a remarkable genetic heterogeneity, which makes it difficult to unravel the causative mutation in a diagnostic laboratory.
To circumvent these limitations, we explored targeted high-throughput sequencing of multiplexed indexed samples. Five patients suffering from different mendelian cardiac disorders were analysed. We designed a capture microarray with the total genomic length of 1 Mbp that includes all exons/splicing sites of 132 genes involved in cardiovascular mendelian disorders. In Patient 1 with arrythmogenic right ventricular dysplasia (ARVD) and a known PKP2 frameshift deletion, an additional novel nonsense variant was found in Sodium Channel V (SCN5A) gene (p.Lys991X). In Patient 2 with hypertrophic cardiomyopathy (HCM), a novel missense variant in Acid Alpha-Glucosidase (GAA) gene and a second novel missense variant in the desmoglein-2 (DSG2) gene were identified. In Patient 4 with long-QT syndrome (LQTS) two missense variants in two different channel genes (SCN5A and KCNQ) were found. Finally, in Patient 5 with LQTS, a novel missense variant in the Fibrillin (FBN1) gene (Marfan syndrome) was detected. We did not identify any pathogenic mutation in Patient 3 with HCM. To our knowledge, this is the first report of such common oligogenic inheritance in mendelian cardiac disorders. Multiplex targeted high-throughput resequencing holds considerable promises for molecular diagnosis of highly heterogeneous disorders in clinical practice and allows a better understanding of the complexity of mendelian disorders.

C09.1
Dystrophinopathies and X-inactivation pattern: about 26 symptomatic carriers at pediatric age

Aim: to define molecular basis underlying different clinical phenotypes of symptomatic DMD carriers at pediatric age.
Methods: 26 cases of early symptomatic DMD carriers followed in the french neuromuscular network were investigated. We report findings concerning clinical presentation, muscular histological analysis and type of gene mutation, as well as X-chromosome inactivation (XCI) patterns using DNA extracted from peripheral blood or muscle.
Results: The initial symptoms were significant weakness (88%) or exercise intolerance (27%). Clinical severity varied from a Duchenne-like progression to a very mild Becker-like phenotype. Cardiac dysfunction was present in 19% of the cases. Cognitive impairment was worthy of notice as 27% of the carriers are concerned. The muscular analysis was always contributive revealing muscular dystrophy (83%), mosaic in immunostaining (81%) and dystrophin abnormalities in Western Blot analysis (84%). 73% had exonic deletions or duplications and 27% had point mutations. XCI pattern was biased in 62% of the cases.
Interpretation: We report the largest series of manifesting DMD carriers and show that exercise intolerance and cognitive impairment may reveal symptomatic DMD carriers. The complete histological and immunohistological study of the muscle is the key of the diagnosis leading to the dystrophin gene analysis. Our study shows also that cognitive impairment in symptomatic DMD carriers is associated with mutations in the distal part of the DMD gene. XCI study does not fully explain the mechanisms as well as the wide spectrum of clinical phenotype, though a clear correlation between the severity of the phenotype and inactivation bias was observed.

C09.2
Development of systemic antisense treatment in dystrophic mouse models for Duchenne Muscular Dystrophy

A. Aartsma-Rus[1], *C. Tanganyika-de Winter*[1], *T. Karnaoek*[2], *J. C. T. van Deutekom*[2], *G. B. van Ommen*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Prosensa Therapeutics, Leiden, Netherlands.*

Antisense-mediated reading frame restoration is a promising therapeutic approache for Duchenne muscular dystrophy (DMD). It uses antisense oligonucleotides (AONs) to induce exon skipping to reframe mutated dystrophin transcripts, allowing synthesis of internally deleted, partly functional dystrophins. Proof of concept has been obtained in cultured cells and the mdx mouse model and this approach is currently tested in clinical trials by Prosensa/GSK (GSK2402968 and PRO044) and AVI Biopharma (AVI-4658).
The 2'-O-methyl phosphorothioate (2OMePS) chemistry used in the Prosensa/GSK trials has favorable pharmacokinetic properties, as it binds serum proteins, preventing clearance by the kidney and increasing serum half life. Uptake by healthy muscle is low, but is up to 10-fold higher in dystrophic muscle in animal models.
Here, we tested the safety and efficacy of high dose (200 mg/kg/week) AON treatment for up to 6 months in mouse models with varying levels of severity: mdx mice (mild phenotype) and mdx mice with one utrophin allele (mdx +/-; intermediate phenotype). This was well tolerated. Notably, in the more severely affected mdx +/- mice the therapeutic effect was larger: exon skipping and dystrophin levels were higher, the creatine kinase levels were more decreased and rotarod running time was more increased. Preliminary results suggest that AON levels in the muscles of the more severely dystrophic mdx +/- are higher than in those in mdx mice, confirming the hypothesis that AON uptake is aided by the disease pathology.
These results are encouraging for long term trials in patients, recently initiated by Prosensa Therapeutics/GSK.

C09.3*
A guideline for *CHD7* analysis

N. Janssen[1], *J. E. H. Bergman*[1], *R. M. W. Hofstra*[1], *L. H. Hoefsloot*[2], *C. M. A. van Ravenswaaij-Arts*[1];
[1]*Department of genetics, University Medical Center Groningen, Groningen, Netherlands,* [2]*Department of Human genetics, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands.*

CHARGE syndrome is a multiple congenital malformation syndrome. The causative gene, *CHD7*, was identified in 2004 and is a large gene comprising 37 coding exons. Not surprisingly, patients with a *CHD7*-mutation have a more variable phenotype than patients diagnosed with CHARGE syndrome based on the currently used clinical criteria. This raises the question whether CHARGE syndrome is a clinical or molecular diagnosis and in which patients *CHD7*-analysis should be done.
We explored the phenotypic spectrum of our cohort of 280 patients with a *CHD7*-mutation. The phenotype was highly variable, but external ear anomalies, cranial nerve dysfunction, semicircular canal hypoplasia and psychomotor delay were almost always present. In comparison with clinically diagnosed CHARGE patients cleft lip and/or palate and genital hypoplasia occurred more frequently and congenital heart defects less frequently in patients with a CHD7-mutation. In 5-10% of patients with typical CHARGE syndrome no *CHD7*-mutation could be identified. In these patients CHARGE syndrome remains a clinical diagnosis. In contrast, 14-17% of the patients with a *CHD7*-mutation do not fulfil the clinical criteria for CHARGE syndrome and in these patients *CHD7*-analysis can be helpful to establish the diagnosis. Confirming the diagnosis is important for the clinical surveillance of the patients. Moreover, finding a *CHD7*-mutation enables counselling of recurrence risk and reproductive options.
We propose a guideline for *CHD7*-analysis and indicate in which patients imaging of the semicircular canals is helpful. This guideline can help clinicians in their diagnostic work-up of patients suspected of CHARGE syndrome.

C09.4
The new Ghent criteria: What do they change?

L. Faivre[1], *G. Collod-Beroud*[2], *L. Ades*[3], *E. Arbustini*[4], *E. Arbustini*[5], *B. Loeys*[6], *C. Binquet*[7], *E. Gautier*[7], *K. Mayer*[8], *M. Arslan-Kirchner*[9], *M. Grasso*[4], *C. [1]*Departement de Genetique, Dijon, France,* [2]*INSERM U827, Montpellier, France,* [3]*Marfan research group, Sidney, Australia,* [4]*IRCCS, Pavia, Italy,* [5]*St George's hospital, London, United Kingdom,* [6]*Ghent University Hospital, Ghent, Belgium,* [7]*CIC-EC, Dijon, France,* [8]*Center for Human Genetics and Laboratory Medicine, Martinsried, Germany,* [9]*Institut für Humangenetik, Hannover, Germany,* [10]*Service de Genetique, Lyon, France,* [11]*Universitätsmedizin Charité, Berlin, Germany,* [12]*Center for Medical Genetics, Ghent, Belgium,* [13]*Center for medical genetics, Ghent, Belgium,* [14]*Departments of Genetics and Pediatrics, Stanford, CA, United States,* [15]*Centre de Référence Syndrome de Marfan, Paris, France,* [16]*Hôpital Ambroise Paré, Paris, France.*

The diagnosis of Marfan syndrome (MFS) is challenging, and international criteria have been proposed. New diagnostic criteria for Marfan syndrome were released in 2010, giving more weight to aortic root aneurysm and ectopia lentis. We aimed to compare the diagnosis reached by applying this new nosology vs. the 1996 Ghent nosology in a well-known series of 1,009 probands defined by the presence of an *FBN1* mutation. 83% of patients could be classified as MFS according to the new nosology as compared to 89% according to the 1996 Ghent criteria. For the remaining 17% of patients, insufficient criteria had been reported to make a diagnosis of MFS, and the patients would be classified as ectopia lentis syndrome (ELS), Myopia - mitral valve prolapse - Aortic root dilation - Skeletal findings - Striae syndrome (MASS), Mitral Valve Prolapse Syndrome (MVPS); or potential MFS in patients aged less than 20 years. The possibility has to be considered that these patients would go on to develop classic MFS with time. Although the number of patients for a given diagnosis differed only slightly, the new nosology led to a different diagnosis in 15% of cases: 10% of patients with a previous diagnosis of MFS were classified as ELS or MASS in the absence of aortic dilatation; conversely, 5% of patients could be reclassified as MFS according to the new nosology in the presence of aortic dilatation in his personal or familial history. Whatever is the diagnosis, aortic follow-up is mandatory in all patients.

Aortic aneurysms represent an important cause of cardiovascular morbidity and mortality. Thoracic aortic aneurysms and dissections are a main feature of some connective tissue disorders, such as Marfan syndrome and Loeys-Dietz syndrome.

We delineated a new syndrome presenting with aneurysms, dissections and tortuosity throughout the arterial tree in association with mild craniofacial features and skeletal and cutaneous anomalies. In contrast with other aneurysm syndromes, most of these affected individuals presented with early-onset osteoarthritis. We therefore propose to refer to this disorder as aneurysms-osteoarthritis syndrome (AOS). We recently mapped the genetic locus to chromosome 15q22.2-24.2. Subsequently, we identified mutations in *SMAD3*. This gene encodes a member of the TGF-β pathway that is essential for TGF-β signal transmission. *SMAD3* mutations lead to increased aortic expression of several key players in the TGF-β pathway, including SMAD3. We identified seven different mutations in unrelated families with AO syndrome. We present extensive clinical and molecular data from these patients among which a large family with 29 affected individuals.

Molecular diagnosis will allow early and reliable identification of cases and relatives at risk for major cardiovascular complications. Our findings provide models to study the development of both arterial wall anomalies and osteoarthritis and endorse the TGF-β signaling pathway as the primary pharmacological target for the development of new treatment strategies for aortic aneurysms and osteoarthritis.

C09.6
Novel Ehlers-Danlos Syndrome caused by mutations in the *CHST14* gene - Expanding the Phenotype

R. Mendoza-Londono[1], *D. Chitayat*[1,2], *W. Kahr*[1], *A. Hinek*[1], *L. Dupuis*[1], *E. Goh*[1], *S. Blaser*[1], *A. Howard*[1], *L. Mittaz*[3], *A. Superti-Furga*[3], *S. Unger*[3], *G. Nishimura*[4], *L. Bonafe*[3];

Ehlers-Danlos Syndrome (EDS) is a heterogenous group of disorders characterized by varying degrees of connective tissue hyperextensibility. In 2010 a new type of EDS was described in patients of Japanese and of Turkish descent presenting with craniofacial characteristics, contractures and joint and skin laxity. All patients had mutations in the *CHST14* gene coding for the enzyme dermatan 4-O-sulfotransferase. We present the detailed clinical findings in 2 sisters of Afghani descent born to consanguineous parents. The patients presented with multiple contractures, progressive joint and skin laxity and hemorrhagic diathesis following minor trauma. Prenatal evaluation of patient 2 identified possible Dandy-Walker variant, prominent amnion-chorionic separation, bilateral club feet and clenched hands. Platelet aggregometry and electron microscopy revealed normal function and ultrastructure. Cultured fibroblasts produced normal amounts of fibronectin and elastin but demonstrated lack of collagen III production, lack of extracellular deposition of collagen 1 fibers and a peculiar intracellular retention of Collagen I. Both patients were found to be homozygous for a novel missense mutation in the *CHST14* gene.

The identification of two additional patients with this disorder raises awareness of the pan-ethnicity of the condition and expands our knowledge regarding its clinical manifestations. Our studies show that the condition has to be considered in cases presenting prenatally with clenched fists and amnion-chrion separation, that the facial features are characteristic regardless of ethnicity and the bleeding diathesis in these patients are not the result of thrombocytopathy. We also expand the knowledge regarding the collagen abnormalities in this condition.

C10.1
Exome sequencing reveals mutations in the retromer protein VPS35 as cause for Parkinson´s disease

Munich, Germany, [5]Department of Neurology, Medizinische Universität Innsbruck, Innsbruck, Austria, [6]Department of Neurology, Technische Universität München, Munich, Germany, [7]Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [8]Department of Neurology, Wilhelminenspital, Vienna, Austria, [9]Paracelsus-Elena Klinik, Kassel, Germany, [10]Department of Neurology, Sozialmedizinisches Zentrum Ost-Donauspital, Vienna, Austria, [11]Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, [12]Department of Clinical Neurophysiology, Georg-August-Universität Göttingen, Göttingen, Germany, [13]Institute of Human Genetics, Technische Universität München, Munich, Germany

Parkinson's disease is the second most common neurodegenerative disorder affecting 1%–2% of the population above the age of 60. It is characterized by degeneration of dopaminergic neurons in the nigrostriatal pathway and other monoaminergic cell groups in the brainstem leading to bradykinesia, resting tremor, muscular rigidity, and postural instability as well as non-motor symptoms. To identify rare causal variants in late-onset Parkinson's disease (PD), we investigated a family from Austria with 16 affected individuals by exome sequencing. We found a missense mutation, D620N, in the retromer protein VPS35 in all seven affected family members that are alive. By screening additional PD cases, we saw the same variant co-segregating with the disease in an autosomal dominant mode with high penetrance in two further families with five and ten affected members, respectively. Genotyping showed that the shared haplotype extends across 65 kilobases around VPS35. Screening the entire VPS35 coding sequence in additional 860 cases and 1014 controls revealed six further non-synonymous missense variants. Three were only present in cases, two only present in controls, and one present in cases and controls. D620N and a further variant detected in a PD case, R524W, were predicted to be damaging by sequence-based and molecular dynamics analysis. VPS35 is a component of the retromer complex which mediates retrograde transport between endosomes and the trans-Golgi network and which has recently been described to be involved in Alzheimer's disease.

C10.2*

Fine mapping of the celiac disease locus on 3q27-q28 harboring the LPP gene

***R. C. Almeida**[1,2], G. Trynka[2], J. Romanos[2], J. Gutierrez-Achury[2], C. Wijmenga[2];*
[1]University of Brasilia, School of Health Sciences, Brasilia, Brazil, [2]Department of Genetics, University Medical Centre Groningen and University of Groningen, Groningen, Netherlands.

Results from meta-analysis in genome-wide association studies (GWAS) revealed 26 loci to be associated with celiac disease, a common immune-mediated disease. The majority of the celiac loci also overlapped with results form GWAS conducted in other immune-mediated diseases, suggesting a shared genetic origin. One of the most strongly associated loci was found on 3q27-28 and this regions also seemed rather unique for celiac disease (rs1464510, p= 2.98 x 10^{-40}, OR=1.29). The region of association (18955-18960 Mb) is confined to within the LPP gene but to refine the region of association even further and to identify the haplotypes driving the association, we set out to fine-map the LPP region using different celiac populations, Dutch (803 cases and 846 controls), Finnish (647 cases and 1829 controls) and Italians (497 cases and 543 controls). We used genotype data from the celiac disease GWAS to look for others SNPs associated in this region in each population and also checked their linkage disequilibrium (LD) with rs1464510. We found different SNPs in each population with suggestive association and LD in Dutch (rs1559810, p=1.2 x 10^{-2}, r^2=0.8, D'= 0.9), Italian (rs6790359, p=7.8 x 10^{-4}, r^2 = 0.2, D'=0.9) and Finnish (rs9851967 p=2.1x10^{-4}, r^2=0.6, D'=0.8). Future analysis will focus on an imputated dataset, using IMPUTE 2 with HapMap III and 1000 Genomes Project as reference panels. To help to identify rare variants we plan to use additional European cohorts with high-density genotyping across the LPP region, including Spanish, UK, Pollish, and two non- European cohorts (Saharawi and Indian).

C10.3

A genome-wide association study identifies 2 loci associated with heart failure due to dilated cardiomyopathy

***E. VILLARD**[1], C. Perret[2], F. Gary[1], C. Proust[2], G. Dilanian[1], C. Hengstenberg[3], S. Cook[4], D. Tregouet[2], L. Tiret[2], R. Isnard[1], M. Komajda[1], P. Charron[1], f. Cambien[2];*
[1]INSERM UMR956, Paris, France, [2]INSERM UMR937, Paris, France, [3]Klinik und Poliklinik für Innere Medizin II, Regensburg, Germany, [4]Medical Research Council, Imperial College London, London, United Kingdom.

In this first genome-wide association study of heart failure due to dilated cardiomyopathy (DCM) with discovery and replication cohorts comprising overall 2344 cases and 2410 controls we identified two DCM-associated SNPs, rs10927875 and rs2234962 with respective P-values of 9.5 x 10-10 and 4.0 x 10-12 in the combined data set. The first SNP is located at a locus on 1p36.13 which exhibit a yin/yang haplotype structure encompassing several genes including HSPB7. The second SNP on 10q26.11 is located within BAG3 and is non-synonymous. Sequencing of BAG3 exons in patients with familial DCM identified several damaging mutations which were absent in healthy individuals, suggesting that they are causal for familial DCM. HSPB7 and BAG3 encode for non-structural proteins important for autophagy, which implicates perturbed protein processing as a new mechanism underlying DCM-associated heart failure.

C10.4*

Accumulation of common lipid variants influences atherosclerosis, and incident cardiovascular disease

***S. M. Willems**, A. Dehghan, A. Hofman, B. A. Oostra, J. Witteman, C. M. van Duijn, A. Isaacs;*
Erasmus MC, Rotterdam, Netherlands.

A recent genome-wide meta-analysis of >100,000 individuals identified multiple loci associated with LDL-C, HDL-C and TG. Risk scores computed from the top SNPs in those loci successfully discriminated low-lipid controls from individuals with extreme lipid values. These same scores were used to test the hypothesis that the cumulative effects of common SNPs are associated with sub-clinical atherosclerosis and incident coronary heart disease (CHD) in the Rotterdam Study (n=8131) and a Dutch family-based cohort, the Erasmus Rucphen Family Study (n=2081). Both included measurements of carotid intima media thickness (IMT) and plaques. The Rotterdam Study additionally included information on incident CHD (mean follow-up time≈11 years). Controlled for age and sex, the LDL-C risk score was associated with IMT (*P*=0.021) and strongly associated with plaque (*P*=1.7x10^{-8}). Cox proportional hazards models were used to assess MI and CHD incidence. For each standard deviation increase in the LDL-C score, the hazard ratio (HR[95%C.I.]) for MI was 1.14[1.04,1.25] (*P*=0.006) compared to the mean score. For CHD, the per SD increase in risk was HR[95%C.I.]=1.10[1.04,1.50] (*P*=0.003). Exclusion of prevalent cases and control for additional covariates minimally affected the point estimates. The HDL-C risk score was nominally associated with plaque (*P*=0.049). We found no associations with the TG risk score and clinical outcomes. In conclusion, an accumulation of common genetic variants with small effects on lipid levels, particularly LDL-C, can significantly impact sub-clinical and clinical outcomes. As our knowledge of genetic variation increases, pre-clinical genetic screening tools might enhance the prediction and prevention of clinical events.

C10.5

Lipidomic Profiles as Endophenotypes for Predicting Diabetes Progression in Mexican Americans

***J. E. Curran**[1], J. M. Weir[2], C. Bellis[1], M. A. Carless[1], J. B. Jowett[2], M. C. Mahaney[1], T. D. Dyer[1], H. H. H. Goring[1], A. G. Comuzzie[1], L. Almasy[1], P. J. Meikle[2], J. Blangero[1];*
[1]Texas Biomedical Research Institute, San Antonio, TX, United States, [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Lipids are a highly diverse class of molecule with essential roles in cellular structure, signaling, and energy storage. Dysregulation of lipid metabolism can lead to the development of various diseases including Alzheimer's, atherosclerosis, and diabetes. These lipid molecules may represent endophenotypes that are closer to gene action than classical lipid markers, and extremely valuable for genetic analysis. In a large-scale analysis of the human lipidome, we profiled 1,202 Mexican Americans from the San Antonio Family Heart Study, identifying and quantifying 356 different lipid species. We then performed quantitative genetic and genome-wide association analyses, using ~1,000,000 SNPs, to identify genetic factors influencing lipidomic profile variation. Most of the 356 lipid species are significantly heritable in our population. Results identified 128 lipid species that predict progression to diabetes in non-diabetics followed for ~10 years. The single best predictor of progression to diabetes is dhCer (dihydroceramide) 18:0, the biosynthetic precursor to ceramide 18:0. dhCer is significantly heritable (h^2=0.247; p=1.6×10^{-9}) and is markedly increased in diabetics (p=2.5×10^{-7}). In non-diabetics, those that progress to diabetes show higher dhCer 18:0 levels at baseline than non-progressors

($p=2.2\times10^{-8}$). This predictive relationship is maintained ($p = 1.2\times10^{-4}$) after accounting for baseline fasting glucose and insulin levels, indicating this lipid component may be an independent predictor of risk. A genome-wide association analysis reveals two rare SNPs on chromosome 3p22 (between *SNORA62* and *MOBP*) exhibiting significant association with dhCer 18:0 levels ($p=9\times10^{-8}$). Our results suggest that lipidomic profiles may represent endophenotypes that may help us identify genes involved in diabetes development.

C10.6*

Genetic association study of SNPs discovered from low coverage exome sequencing of 1000 phenotypically characterized Danish individuals

T. Sparso[1], *A. Albrechtsen*[2], *L. Skotte*[2], *N. Grarup*[1], *T. Jorgensen*[3], *Y. Li*[4], *J. Wang*[4], *R. Nielsen*[5], *T. Hansen*[6], *O. Pedersen*[1];

[1]*Marie Krogh Center for Metabolic Research, University of Copenhagen, Copenhagen, Denmark,* [2]*Department of Biology, University of Copenhagen, Copenhagen, Denmark,* [3]*Research Centre for Prevention and Health, Glostrup University Hospital, Glostrup, Denmark,* [4]*Beijing Genomics Institute, Shenzhen, China,* [5]*Departments of Integrative Biology and Statistics, UC Berkeley, Berkeley, CA, United States,* [6]*Hagedorn Research Institute, Copenhagen, Denmark.*

Background and hypothesis: Genome-wide association studies (GWAS) have driven the identification of multiple new loci contributing significantly to modulation of the fasting plasma glucose levels in humans. However, the explained heritability is still very modest.

We hypothesize that novel exome variation not captured by GWAS may contribute to the missing heritability of fasting plasma glucose levels.

Methods: Exome capturing of 1000 Danish individuals were performed on the Nimblegen 2.1M followed by next generation resequencing with a mean depth of x8. Within a 34Mb targeted region we identified 70,182 SNPs with a MAF>1%.

Any association between the identified SNPs and fasting plasma glucose level was evaluated directly from the sequencing data, by accounting for the uncertainty of the genotype rather than on the called genotypes. The tests are based on score statistics which require less numerical optimization than conventional likelihood ratio test.

Results: We find many novel and known variants with allelefrequency down to 1% that associate with fasting plasma glucose levels at the significance level of<10-3. However, we were not able to replicate any of the top 20 variants by direct genotyping in independent study populations of 9,893 individuals.

Conclusion: Low-coverage exome sequencing driven association studies yield many novel low frequency-and common variants; however; it seems that there are no single low-frequency variants in the examined exome with a large effect on the fasting plasma glucose levels on its own, suggesting the need for testing various burden tests to evaluate the cumulative impact of multiple variants within the same locus.

Seckel syndrome is a rare autosomal recessive disorder characterized by intrauterine growth retardation, short stature, severe microcephaly associated with mental retardation, and a typical “bird-headed” facial appearance. Using a genome-wide SNP homozygosity mapping strategy we identified a homozygous donor splice-site mutation in *CEP152* cosegregation with the disease in six Turkish families. Independently, we identified *CEP152* as causative gene in an additional Seckel patient born to consanguineous parents using an exome sequencing strategy. Furthermore, additional screening identified two other patients carrying compound heterozygous mutations in *CEP152*. *CEP152* encodes a 1654 amino acid protein that was originally identified in a proteomic screen of human centrosomes. We could show that CEP152 deficient fibroblasts show severe defects in mitosis and spindle organization resulting in cells with multiple centrosoms and abnormal nuclei pattern. In addition, Seckel cells showed an overall increased sensitivity to oxidative stress and responded with increased apoptosis. Furthermore, DNA-damage response was impaired in cells with mutated CEP152 confirming a functional link between centrosomal function and DNA repair responses. We could show that impaired CEP152 function leads to genomic instability via increased H2AX phosphorylation due to enhanced activation of ATM signaling pathways. These findings provide evidence for an important role of CEP152 in DNA damage response and genome maintenance. In summary, we identified the centrosomal protein CEP152 as a novel protein involved in the maintenance of genomic integrity and in the ability to respond to DNA damage, and show that that recessive loss-of-function mutations in *CEP152* can cause Seckel syndrome in humans.

Defects of ciliogenesis have been implicated in a wide range of human phenotypes and play a crucial role in different signal transduction pathways and cell cycle coordination. We thoroughly delineated the clinical, radiographic, and histological phenotype of the autosomal-recessive short-rib polydactyly syndrome Majewski type. Parametric multipoint linkage and haplotype structure analysis confirmed a linked interval with a maximum LOD score of 2.95 (17.36 Mb / 18.65 cM) on chromosome 4 encompassing 38 genes. Assuming an overlap of the phenotypic spectrum of our patients with other ciliopathies, we used known genes of the cilia proteome database and compared them with the genes in our candidate interval. The NIMA-related kinase 1 (*NEK1*) gene was highlighted as homozygous mutant mice show polycystic kidney disease, craniofacial anomalies, and growth reduction.

Sequencing of *NEK1* identified a homozygous nonsense and a

homozygous splice-site mutation in the affected persons of two consanguineous families as the underlying cause. *NEK1* encodes a serine/threonine kinase with proposed function in DNA double-strand repair, neuronal development, and coordination of cell cycle-associated ciliogenesis. With immunofluorescence analyses we confirmed that the absence of functional NEK1 significantly decreases the number of ciliated fibroblasts and alters the structural morphology of the primary cilium in vivo as well. Transmission electron microscopy indicated a defect in progression from stage I after vesicular accumulation of ciliogenesis to stage II and subsequent failure of axoneme growth. We further substantiate a proposed digenic diallelic inheritance of ciliopathies by identification of heterozygous mutations in *NEK1* and *DYNC2H1* in a further non-consanguineous family.

C11.3*

Whole Exome Sequencing Identifies The Genetic Cause Of A New Ciliopathy Syndrome

A. M. Waters[1], *F. Lescai*[2], *S. Christou*[1], *A. Brooks*[1], *E. Chanudet*[1], *D. Charu*[3], *R. Kleta*[4], *M. Hubank*[2], *E. Stupka*[2], *M. Winey*[5], *P. L. Beales*[1];

Gene identification in rare single-gene disorders significantly lends to the understanding of key developmental and physiological processes. As 85% of all disease-causing mutations are within coding exons, the recent application of massive parallel sequencing with exon capture has shown the efficacy of this technique in the rapid identification of mutations in Mendelian disorders. Herein, the genetic basis of a novel syndrome was sought in a non-consanguineous kindred consisting of 6 offspring where 4 exhibited mid-gestation intrauterine death. Dysmorphic features included cleft palate, high nasal bridge, short columella, micrognathia, wide mouth and low set ears. Systemic features included renal hypoplasia, duodenal atresia and cerebellar vermis hypoplasia with hydrocephalus, pre and post-axial polydactyly consistent with a predicted ciliopathy. Linked regions were identified on 1p31.1, 4q,19p13.3 and 20q13.13 using high density SNP arrays (Affymetrix 250k/sty and Illumina 550K). As the identified regions were large, whole exome capture (Nimblegen EZ Exome SR, v1) followed by massively parallel sequencing (Illumina GAIIx) was employed. A novel compound heterozygous loss of function mutation involving an essential splice site and a truncating change were found in an annotated gene which segregated with affected family members. Subcellular localization revealed a nuclear, centrosomal and basal body localization for this protein. Gene knockdown in zebrafish results in a ciliopathic phenotype consisting of curved body axis, U-shaped somites, microcrania, microphthalmia, cardiac oedema and renal cysts. Whole exome sequencing has identified compound heterozygous mutations in a new ciliopathy gene and supports its role in gene identification in rare and novel syndromes.

KIF7, the human ortholog of *Costal 2*, represents a key component of the Hedgehog (Hh) signaling pathway. Here we report mutations in *KIF7* in patients with Hydrolethalus and Acrocallosal syndromes (HLS and ACLS), two multiple malformation disorders with overlapping features such as polydactyly, mid-line brain abnormalities, and cleft palate. Consistent with a role of KIF7 in Hh signaling, we show a deregulation of most of the Gli transcription factor targets and impaired GLI3 processing in *KIF7* mutated patient tissue, as well as defects in primary cilia length in fibroblast cells. *KIF7* is also a likely contributor of alleles across the ciliopathy phenotypic spectrum; sequencing of a diverse patient cohort revealed several missense mutations which, upon *in vivo* testing were shown to be detrimental to protein function. Consistent with an epistatic role for such alleles, *in vivo* genetic interaction studies indicated that *KIF7* could exacerbate the phenotype induced by the loss of other ciliopathy transcripts. Our data demonstrate the role of KIF7 in the Sonic Hedgehog signaling pathway in humans through the regulation of Gli targets, its role in primary cilia function and expand the clinical spectrum of ciliopathies.

C11.5*

Sensenbrenner syndrome is caused by dysfunctional IFT-A mediated retrograde transport in the cilium

Sensenbrenner syndrome (a ciliopathy) is mainly characterized by skeletal and ectodermal anomalies, and can be accompanied by other features (e.g. chronic renal disease). We performed SNP array analysis and positional candidate gene sequence analysis in two siblings with Sensenbrenner syndrome of a consanguineous Moroccan family. Both patients suffered from nephronophthisis, and the youngest sibling had end-stage renal disease since the age of 3 years. We identified a homozygous mutation in the initiation codon of *C14ORF179* in both siblings. *C14ORF179* encodes IFT43, a subunit of the intraflagellar transport complex A (IFT-A) machinery of primary cilia. We show that the mutation disrupts translation; due to the mutation translation starts at an ATG in exon 2 instead of at the canonical initiation translation codon in exon 1. This results in a shortened N-terminally truncated IFT43 protein. The IFT-A protein complex (together with the dynein motor) drives retrograde axonemal transport in the cilium. We show that in fibroblasts of one of the affected siblings, disruption of IFT43 affects this transport from the tip of the cilium to its base. In fibroblasts of the patient with mutated *C14ORF179,* we found that IFT-B complex proteins aberrantly accumulate in the ciliary tips. Interestingly, we observed the same defect in fibroblasts from a Sensenbrenner syndrome patient with mutations in *WDR35/IFT121*, encoding another IFT-A subunit. Our results suggest that Sensenbrenner syndrome is caused by dysfunctional IFT-A mediated retrograde transport in the cilium.

C11.6*

CCDC39 is required for assembly of inner dynein arms and the dynein regulatory complex and for normal ciliary motility in humans and dogs

A. C. Merveille[1], *E. Davis*[2], *A. Becker-Heck*[3], *M. Legendre*[4], *M. Georges*[1], *A. Lequarré*[1], *N. Katsanis*[2], *H. Omran*[3], *S. Amselem*[4];

Primary ciliary dyskinesia (PCD) is an inherited disorder characterized by recurrent infections of the upper and lower respiratory tract, reduced fertility in males and *situs inversus* in about 50% of affected individuals (Kartagener syndrome). It is caused by motility defects in the respiratory cilia that are responsible for airway clearance, the

flagella that propel sperm cells and the nodal monocilia that determine left-right asymmetry. Recessive mutations that cause PCD have been identified in genes encoding components of the outer dynein arms, radial spokes and cytoplasmic pre-assembly factors of axonemal dyneins, but these mutations account for only about 50% of cases of PCD. We exploited the unique properties of dog populations to positionally clone a new PCD gene, *CCDC39*. We found that loss-of-function mutations in the human ortholog underlie a substantial fraction of PCD cases with axonemal disorganization and abnormal ciliary beating. Functional analyses indicated that CCDC39 localizes to ciliary axonemes and is essential for assembly of inner dynein arms and the dynein regulatory complex.

C12.1

A genome wide study reveals rare CNVs exclusive to Alzheimer Disease extreme phenotypes

A. Rovelet-Lecrux[1,2], *S. Legallic*[1,2], *D. Wallon*[1,3], *J. Flaman*[2], *T. Frebourg*[2], *D. Hannequin*[1,2], *D. Campion*[1,2,4];
[1]*CNR-MAJ, CMRR, Rouen University Hospital, Rouen, France,* [2]*Inserm U614, Faculty of Medicine, Rouen University, Institute for Biomedical Research and Innovation, Rouen, France,* [3]*Inserm U614, Faculty of Medicine, Rouen University, Institute for Biomedical Research, Rouen, France,* [4]*Research Department, CH du Rouvray, Sotteville les Rouen, France.*

Autosomal dominant early onset Alzheimer disease (ADEOAD) is a rare condition with a prevalence rate estimated to 5.3 per 100 000 persons at risk. Mutation screening of more than 150 ADEOAD families, ascertained in France by the National Centre for early-onset AD (CNR-MAJ) has shown that mutations of *APP*, *PSEN1* and *PSEN2* genes account for 85 % of ADEOAD families. We hypothesised that rare copy number variants (CNVs) could be involved in ADEOAD families without mutations in known genes. Using high resolution array CGH, we assessed the presence of rare copy number variants (CNVs) in two highly selected disease groups, 21 unrelated ADEOAD cases without alteration on *APP, PSEN1* and *PSEN2* genes and 12 isolated Alzheimer disease (AD) cases with age of onset before 55 years. This analysis revealed the presence of 7 singleton CNVs (4 in ADEOAD and 3 in isolated cases) not present in 1078 controls, thus yielding a nominal significance for association of every CNV with AD of p=0.019 in the ADEOAD group and p=0.011 in the isolated cases group, respectively. Strikingly, 4/7 rearrangements target genes encoded proteins that are tightly related to Amyloid β (Aβ) peptide metabolism or signalling. Although these variants are individually rare and restricted to particular subgroups of patients, their characteristics strongly support the causal role in human pathology of a set of genes coding for molecules suspected for a long time to modify Aβ metabolism or signalling and for which animal or cellular models had already been developed.

C12.2

Loss of Cav1.3 (CACNA1D) function in SANDD syndrome, a novel human channelopathy with bradycardia and congenital deafness

S. M. Baig[1], *A. Koschak*[2], *A. Lieb*[2], *M. Gebhart*[2], *C. Dafinger*[3], *G. Nürnberg*[4], *A. Ali*[1], *I. Ahmad*[1], *M. J. Sinnegger-Brauns*[2], *N. Brandt*[5,6], *J. Engel*[5,6], *M. E. Mangoni*[7], *M. Farooq*[1], *H. U. Khan*[8], *P. Nürnberg*[4,9], *J. Striessnig*[2], ***H. J. Bolz***[10,3];
[1]*Human Molecular Genetics Laboratory, Health Biotechnology Division, National Institute for Biotechnology and Genetic Engineering, Faisalabad, Pakistan,* [2]*Pharmacology and Toxicology, Institute of Pharmacy, Center for Molecular Biosciences, University of Innsbruck, Innsbruck, Austria,* [3]*Institute of Human Genetics, University Hospital of Cologne, Cologne, Germany,* [4]*Cologne Center for Genomics and Institute for Genetics, Cologne, Germany,* [5]*Institute of Physiology II and Tübingen Hearing Research Centre, University of Tübingen, Tübingen, Germany,* [6]*Department of Biophysics, Saarland University, Homburg/Saar, Germany,* [7]*CNRS, UMR 5203, INSERM U661, Université de Montpellier 1 et 2, Institut de Génomique Fonctionnelle, Département de Physiologie, Montpellier, France,* [8]*Department of Pathology, Khyber Teaching Hospital, Peshawar, Pakistan,* [9]*Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Cologne, Germany,* [10]*Center for Human Genetics, Bioscientia, Ingelheim, Germany.*

Hearing impairment occurs in approximately 1 out of 500 newborns. Most cases with congenital deafness are of genetic origin. We identified a homozygous founder mutation in the alternatively spliced exon 8B of *CACNA1D*, the gene encoding the pore-forming αλπηα1-subunit of voltage-gated $Ca_v1.3$ L-type calcium (Ca^{2+}) channels, in two consanguineous deafness families. The mutation results in an insertion of a glycine residue in a highly conserved region near the channel pore. $Ca_v1.3$ channels tightly control Ca^{2+}-dependent glutamate release at cochlear inner hair cell (IHC) ribbon synapses in response to sound and the diastolic depolarization in sinoatrial node (SAN) pacemaker cells. Targeted deletion of $Ca_v1.3$ channels in mice causes deafness and pronounced, non-fatal SAN arrhythmia and bradycardia. Strikingly, all patients also had pronounced SAN dysfunction with SAN arrhythmia, bradycardia and junctional escape rhythms. We termed the condition SANDD syndrome (**s**ino**a**trial **n**ode **d**ysfunction and **d**eafness). We analyzed the biophysical properties of wildtype and mutant $Ca_v1.3$ channel complexes using whole-cell patch-clamp recordings. Homozygous individuals lack significant L-type Ca^{2+} currents from exon 8B-containing $Ca_v1.3$ channels. The SANDD phenotype and mouse mRNA expression studies suggest that the exon 8B splice variant is predominant in human IHC and SAN pacemaker cells. The *CACNA1D* mutation underlying SANDD results in non-conducting calcium channels and altered voltage-dependent gating. Our results constitute the first evidence that $Ca_v1.3$ channels are involved in human cardiac pacemaking, implying them as a potential drug target for controlling heart rate in disease conditions. Regular cardiological follow-up of SANDD patients seems appropriate to avoid cardiovascular complications.

C12.3

Validating massive parallel sequencing as a diagnostic tool for seizure disorders

J. Lemke[1], *D. Boehm*[2], *E. Riesch*[2], *T. Scheurenbrand*[2], *C. Courage*[1], *S. Gallati*[1], *T. Dorn*[3], *M. Wolff*[4], *Y. Weber*[5], *H. Lerche*[5], *S. Biskup*[2];
[1]*Department of Paediatrics, University Hospital Inselspital, Bern, Switzerland,* [2]*CeGaT GmbH, Tuebingen, Germany,* [3]*Swiss Epilepsy Center, Zurich, Switzerland,* [4]*Department of Paediatrics, University of Tuebingen, Tuebingen, Germany,* [5]*Department of Neurology, University of Tuebingen, Tuebingen, Germany.*

Introduction: The epilepsies are common neurological disorders with a strong genetic impact. Consequently, understanding the genetic basis of seizure disorders will provide novel insights into the underlying pathophysiology and result in novel diagnostic and therapeutic avenues. With our approach we aim to reveal the genetic basis of epileptic disorders in so far unresolved cases.
Methods: Genomic DNA is enriched for a panel of 485 genes using a custom designed Agilent SureSelect in solution kit. 265 of the 485 genes are known causative genes for seizure disorders comprising all relevant epilepsy phenotypes. The remaining genes on the panel represent putative candidate genes for epileptic disorders. Sequencing is performed on the SOLiD 4 platform. We developed a diagnostic pipeline to (i) identify regions that are underrepresented with reads, (ii) identify potentially pathogenic SNVs, (iii) identify small insertions and deletions and (iv) identify larger indels including whole exon deletions and duplications. All variants and putative deletions are then validated using conventional methods.
Results: We sequenced 20 so far genetically undiagnosed cases with a broad spectrum of epilepsy phenotypes. We present an overview of the number of detected sequence alterations comprising mutations, possibly damaging variants as well as benign SNPs in both well-known epilepsy genes and putative candidates.
Conclusion: We have successfully established a fast and cost efficient genetic screening method for patients with seizure disorders. By applying this approach we hope to uncover both known and unknown sequence variants and give new insights in genetic factors involved in epileptogenesis.

C12.4

The XLID protein PQBP1 is a novel regulator of RNA metabolism

L. Musante, *U. Fischer, A. Grimme, V. M. Kalscheuer;*
Max-Planck Institute for Molecular Genetics, Berlin, Germany.

The polyglutamine binding protein 1 (PQBP1) gene plays an important role in X-linked intellectual disability (XLID). To date, about 25 families with a mutation in this gene have been identified. Common clinical features include intellectual disability, microcephaly, and short stature. Most of the mutations cause frameshifts, which result in premature stop codons. Interestingly the mutant mRNA is only partially degraded

via nonsense mediated mRNA decay and truncated protein exists (Musante et al., 2010).
To unravel the pathomechanism of the disease, we have searched for novel PQBP1 interactors. We have found several splicing factors, belonging to the SR protein family, which are important regulators of alternative splicing. One of the newly found PQBP1 interactors, SRp20, is highly expressed in brain. In RNA-protein immunoprecipitations, we could show that, in addition to SRp20 protein, the PQBP1 protein complex contains SRp20 mRNA. As other SR proteins, SRp20 is able to modulate its own protein level, by regulating alternative splicing of its RNA. To test whether PQBP1 is involved in this feedback mechanism, we have knocked-down PQBP1 and overexpressed a minigene containing the alternatively spliced exon of SRp20. RT-PCR experiments indicated that knock-down of PQBP1 significantly increased skipping of the alternatively spliced exon. Real time RT-PCR on endogenous SRp20 mRNA confirmed these results. Interestingly, rescue experiments performed with mutant PQBP1 constructs revealed deficient splicing activity. Confirmation of several PQBP1 regulated target RNAs are in progress. Taken together, we provide the first evidence that the XLID PQBP1 protein plays a key role in nuclear RNA metabolism.

C12.5*

Genetic cause for infantile mitochondrial cardiomyopathy identified by exome sequencing

H. Tyynismaa[1], *A. Götz*[1], *L. Euro*[1], *P. Ellonen*[1], *T. Hyötyläinen*[2], *R. H. Hämäläinen*[1], *J. Tommiska*[1], *T. Raivio*[1], *M. Oresic*[2], *R. Karikoski*[1], *K. O. J. Simola*[3], *A. Paetau*[1], *T. Tyni*[1], *A. Suomalainen*[1];
[1]*University of Helsinki, Helsinki, Finland,* [2]*VTT, Espoo, Finland,* [3]*Tampere University Hospital, Helsinki, Finland.*

Mitochondrial dysfunction is an important cause of infantile cardiomyopathies, but most patients with the devastating, fatal disorder still remain without a molecular diagnosis. Here we investigated the molecular background of the disease in a patient who died at the age of 10 months of hypertrophic mitochondrial cardiomyopathy. The mitochondrial respiratory chain complexes were severely disturbed in the patient's heart and to a lesser extent in the skeletal muscle and brain. Since pathogenic mitochondrial DNA mutations were excluded as the cause of disease, we sequenced the whole-exome of the patient to reveal the underlying nuclear disease gene. Over 65,000 SNPs were identified and filtered using our on-site-pipeline. The data analysis led to a single gene encoding a novel mitochondrial protein, which was found to contain a homozygous missense mutation. Compound heterozygous mutations in the same gene were identified in a second family, with two affected children, who died of antenatal/neonatal hypertrophic cardiomyopathy. Protein modeling predicted different functional consequences of the two mutations for the enzyme activity, offering an explanation for the neonatal vs infantile disease onset in the patients. Our example shows that disease mutations of single patients can be identified by whole-exome sequencing. Consequently, the genetic background of pediatric mitochondrial cardiomyopathies is now starting to unravel. In conclusion, we have identified a new genetic cause of infantile cardiomyopathy, which may also underlie unexplained antenatal death.

C12.6

A novel GPI-deficiency related disorder: multiple congenital anomalies-hypotonia-seizures syndrome is caused by a mutation in *PIGN*

G. Maydan[1], *I. Noyman*[2], *A. Har-Zahav*[3], *Z. Ben Neriah*[4], *M. Pasmanik-Chor*[3], *A. Yeheskel*[3], *A. Albin-Kaplanski*[1], *I. Maya*[1], *N. Magal*[1], *A. J. Simon*[5], *G. Rechavi*[5,3], *M. Shohat*[1,3], *R. Straussberg*[2,3], ***L. Basel-Vanagaite***[6,3];
[1]*Rabin Medical Center, Petah Tikva, Israel,* [2]*Schneider Children's Medical Center of Israel, Petah Tikva, Israel,* [3]*Tel Aviv University, Tel Aviv, Israel,* [4]*Hadassah Hebrew University Hospital, Jerusalem, Israel,* [5]*The Chaim Sheba Medical Center, Ramat Gan, Israel,* [6]*Schneider Children's Medical Center of Israel and Rabin Medical Center, Petah Tikva, Israel.*

Background. There are currently three human diseases known to be caused by mutations in proteins involved in GPI synthesis. We report on a hitherto undescribed GPI-deficiency related disorder. This autosomal recessive syndrome is characterised by dysmorphic features and multiple congenital anomalies together with severe neurological impairment, chorea and seizures leading to early death. Methods. Homozygosity mapping was performed using Affymetrix Human Mapping 250k NspI arrays. Sequencing of all coding exons of the candidate genes was performed with primer sets designed using the Primer3 program. Fluorescence Activated Cell Sorting was performed using conjugated antibody to CD59. Staining, acquisition and analysis was performed on a FACSCalibur flow cytometer.
Results. We mapped the disease locus to 18q21.32-18q22.1 and identified the disease-causing mutation, c.2126G>A (p.Arg709Gln), in *PIGN*, which encodes glycosylphosphatidylinositol (GPI) ethanolamine phosphate transferase 1, a protein involved in GPI-anchor biosynthesis. Arginine at the position 709 is a highly evolutionarily conserved residue located in the PigN domain. The expression of GPI-linked protein CD59 on fibroblasts from patients as compared to that in a control individual showed a ten-fold reduction in expression, confirming the pathogenic consequences of the mutation on GPI-dependent protein expression. Conclusions. The abundant expression of *PIGN* in various tissues is compatible with the diverse phenotypic features observed in the patients and with the involvement of multiple body systems. The presence of developmental delay, hypotonia and epilepsy combined with multiple congenital anomalies, especially ano-rectal anomalies, should lead a clinician to suspect a GPI deficiency-related disorder.

C13.1*

Copy Number Variants in a Large Pedigree of Inbred Mice

C. N. Henrichsen, *E. Chaignat, A. Valsesia, J. Chrast, N. Walters, A. Reymond;*
University of Lausanne, Lausanne, Switzerland.

Copy number variation (CNV) is an important source of genomic diversity that plays a role in disease, adaptation and evolution. Recent reports suggested the existence of hotspots favouring the appearance of CNVs in germline and somatic tissues, however the mutation rate of these variants remains largely unspecified. Rates of 3.6x10-3 to 1.1x10-2 have been estimated from 10 CNVs of 14 sub-populations of the C57BL/6J strain. Similarly, human parent-offspring trios allowed estimating a rate of 3x10-2 for a broader CNV size range. To assess how CNV alleles are transmitted from one generation to the next and estimate their mutation rate, we setup a large brother-sister mating of C57BL/6J mice over nine generations, for a total of 692 mice. We used high-resolution CGH arrays (2.1M features, mean probe spacing 1.2kb) to detect CNVs in 45 representative individuals from this cohort. We combined three independent detection methods, a Bayesian HMM, GADA and Nexus5.1, to identify 485 CNV regions (CNVRs) covering 24Mb (1%) of the mouse genome. We selected 185 high-confidence CNVRs and determined their absolute copy number with nanoString nCounter in the complete pedigree. To infer CNV alleles from absolute copy number for each individual, we devised a semi-automated strategy relying on trio information. We followed the inheritance of existing CNVs and identified de novo CNVs, some of which appeared multiple times independently in different branches of the pedigree. This allowed calculating a genome-wide mutation rate and ascertain general or gender-specific segregation bias of a large number of CNVs in a large pedigree.

C13.2

Balanced translocation and copy number detection in hematologic disorders by array CGH

L. G. Shaffer[1], *R. Schultz*[1], *V. Cawich*[1], *C. Valentin*[1], *S. Minier*[1], *L. McDaniel*[1,2], *N. Neill*[1], *S. Byerly*[1], *A. Morton*[1], *B. C. Ballif*[1];
[1]*Signature Genomics, Spokane, WA, United States,* [2]*Sacred Heart Medical Center, Spokane, WA, United States.*

Microarray-based comparative genomic hybridization (aCGH) can detect submicroscopic copy-number alterations (CNAs) throughout the genome, but the technique cannot detect balanced translocations, which are important markers for hematologic disease. We report the development of a microarray-based technology coupled with linear DNA amplification, termed translocation-CGH (tCGH), that can identify and characterize balanced translocations in addition to CNAs. With this technology, we have developed tCGH assays for eight different hematologic disorders that simultaneously test for the presence of multiple, clinically relevant balanced translocations associated with each disease. Our data demonstrate the utility of the assay with the detection of >20 different balanced translocations in a variety of disease specimens. The ability of this technology to detect

clinically relevant balanced translocations, to identify specific partner chromosomes precisely, to delineate the molecular breakpoints within the single genes involved and to reveal submicroscopic CNAs at these breakpoints provides distinct advantages over the current standard of chromosome and fluorescence *in situ* hybridization (FISH) analysis. In addition, this technology is of value when cytogenetics or FISH fails, is ambiguous, or is discordant. The novel findings revealed by tCGH will have a profound impact on future algorithms used in the diagnosis, prognosis and treatment of individuals with hematologic and other malignancies.

C13.3
A standardized statistical decision procedure for mosaic detection by array CGH.

***B. Sikkema-Raddatz**, L. F. Johansson, T. Dijkhuizen, C. M. A. van Ravenswaaij-Arts, R. J. Sinke, G. J. te Meerman;*
Department of Genetics, Groningen, Netherlands.

Somatic chromosomal mosaicism is a well established cause for mental retardation and multiple congenital abnormalities (MR/MCA). In 0.4 - 1% of patients with MR/MCA a mosaic pattern is detected (Hoang et al, 2010). It has been reported that array-CGH is able to detect up to 5% mosaicism (Conlin et al, 2010). However, until now, detection of mosaicism is predominantly based on visual inspection of the graphical representation of the array results.

We developed a statistical decision procedure to detect mosaic genotypes. Input parameters are the assumed a priori probability, e.g. the chance of 0.0001% that at a certain chromosomal region mosaicism is present, the variability of probe intensities, the desired area under the curve (AUC) of the receiver operating characteristic (ROC) curve and the mean deviation of a specific interval. The output is the minimal number of adjacent probes needed for a significant deviation of the interval from the mean array intensity. For practical use we constructed tables. If an observed number of probes in an interval with a known average ratio surpass the threshold number of probes needed for the specific interval ratio given in the table, mosaicism is a reasonable explanation and confirmation studies should be performed. We aim to evaluate this decision procedure in a retrospective approach using 2000 patients with MR/MCA including 14 confirmed mosaics detected by visual inspection of the graph. The results of this retrospective study will be presented as well as a practical guideline for the use of the table in daily practice.

C13.4
A significant proportion of private inherited CNVs has pathogenic relevance in intellectual disability: clinical-genetic survey in 40 families.

***M. Zollino**, D. Orteschi, G. Marangi, S. Lattante, M. Murdolo, S. Ricciardi, G. Neri;*
Institute of Medical Genetics, Università Cattolica del Sacro Cuore, Roma, Italy.

During routinary array-CGH analysis applied to the diagnosis of intellectual disability, private CNVs inherited from an apparently healthy parent represent an emerging category of chromosome imbalances with no clear-cut significance. It was recently suggested that rare inherited CNVs have to be considered benign variants.

We analyzed by a-CGH a total of 756 patients with intellectual disability usually associated with multiple phenotypical anomalies. Chromosomes imbalances were detected in 230 of them (30%). We classified the observed CNVs in the following categories: 1) clearly pathogenic, 132/756 (17.5 %); 2) likely benign: 58/756 (7.7 %); 3) with uncertain significance: 40/756 (5.3 %). This last category included private CNVs inherited from an apparently healthy parent, but not reported in Database of Genomic Variants. Each private inherited CNV was evaluated for gene content, size and nature of the rearrangement (deletion vs duplication), parental origin and the associated clinical phenotype. New and more detailed information about clinical history of the family were collected in each case. To speculate whether the observed CNV could act as pathogenic factor in intellectual disability, we looked at the following mechanisms: 1) mosaic status in unaffected parents (FISH on metaphase chromosomes or interphase nuclei) 2) reduced expressivity; 3) imprinting effects; 4) uncoverage of a recessive allele.

A total of 18 of 40 private inherited CNVs (44%), resulted to have pathogenic relevance. Specificity of both the genetic and clinical profile, and mechanisms, are discussed.

C13.5*
The power of high resolution non-targeted array-CGH in identifying intragenic rearrangements responsible for Cohen syndrome

***S. EL Chehadeh-Djebbar**[1], L. Faivre[1], A. Moncla[2], B. Aral[3], C. Missirian[2], C. Popovici[2], P. Rump[4], A. van Essen[4], A. Frances[5], N. Gigot[3], V. Cusin[1], A. Masurel-Paulet[1], M. Payet[6], C. Ragon[6], N. Marle[6], A. Mosca-Boidron[6], F. Huet[1], I. Balikova[7], J. Teyssier[3], F. Mugneret[6], C. Thauvin-Robinet[1], P. Callier[6];*
[1]Centre de Génétique, Hôpital d'Enfants, CHU de Dijon, Dijon, France, [2]Département de Génétique Médicale, Hôpital d'Enfants de la Timone, marseille, France, [3]Laboratoire de Génétique Moléculaire, Plateau Technique de Biologie, CHU Dijon, Dijon, France, [4]Department of Genetics, University Medical Center, Groningen, Netherlands, [5]Service de Génétique, Hôpital Font-Pré, Toulon, France, [6]Laboratoire de Cytogénétique, Plateau Technique de Biologie, CHU de Dijon,, Dijon, France, [7]Centre for Human Genetics, University Hospitals, Leuven, Belgium.

Cohen syndrome (CS) is a rare autosomal recessive inherited disorder that results from mutations of the *VPS13B* gene. It has been recently showed that copy number variation (CNVs) at *VPS13B* locus could result in CS when present in a compound heterozygous state associated to a point mutation or in a homozygous state. We screened for the *VPS13B* gene 54 patients from 46 families with CS and identified at least one mutation in 12 families, 6 of which had mutations in compound heterozygous state, 1 in a homozygous state and 5 had only one mutation. 244K array-CGH was performed in 2 groups, group 1 including the 5 families with one mutation and group 2 including families with no mutation but fulfilling the Chandler and Kolehmainen's criteria, to seek to identify a large intragenic event. We identified a CNV in 3/5 families from group 1 and in 1/9 families from group 2. A targeted 8x15K array-CGH was used in the 2 groups to look for a smaller intragenic rearrangement not detected by the 244K array-CGH but did not reveal any additional rearrangement. When pooling the different series, we found that a CNV could be detected in 33% of families with CS and showed that all of them could be detected by 244K array-CGH. These results confirm that CNVs are a major cause of CS and allowed us to suggest that non-targeted 244K array-CGH could be easily used as an initial screening method for the molecular diagnosis of CS.

C13.6*
Nasal speech and hypothyroidism are common hallmarks of 12q15 microdeletions.

***S. Vergult**[1], D. Krgovic[2], B. Loeys[1,3], S. Lyonet[4], A. Liedén[5], B. Anderlid[5], F. Sharkey[6], S. Joss[7], G. Mortier[3], B. Menten[1];*
[1]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [2]Laboratory of Medical Genetics, University Medical Centre Maribor, Maribor, Slovenia, [3]Departement for Medical Genetics, Antwerp, Belgium, [4]INSERM, Paris, France, [5]Department of Clinical Genetics and Institution of Molecular Medicine and Surgery, Centre of Molecular Medicine, Karolinska Universitetssjukhuset, Stockholm, Sweden, [6]South East Scotland Cytogenetics Laboratory,Western General Hospital, Scotland, United Kingdom, [7]West of Scotland Regional Genetics Service, Institute of Medical Genetics, Yorkhill Hospital, Glasgow, United Kingdom.

Array CGH has led to the identification of several microdeletion syndromes by screening individuals with shared phenotypical characteristics. By combining array CGH data from large cohorts of patients, the screening of overlapping microdeletions is made possible, which in turn can lead to the identification of shared phenotypic characteristics. Here we present the clinical and molecular data of three previously unreported patients with submicroscopic overlapping deletions distal to the 12q14 microdeletion syndrome at chromosome bands 12q15q21.1. The deletions presented in this study vary from 2.5 Mb to 2.59 Mb in size with a 1.34 Mb common deleted region containing six RefSeq genes. To our knowledge, only seven patients have been reported with deletions in this region (Meinecke et al., 1987; Watson et al., 1989; Perez Sanchez et al., 2004; James et al., 2005; Tocyap et al., 2006;.Yamanishi et al., 2008; Schluth et al., 2008). The deletion breakpoints in the literature vary from 12q13 to 12q23 and are associated with growth retardation, developmental delay and dysmorphic features. The previously reported cases were detected with standard cytogenetic techniques, except for the patient of Tocyap et al. (2006) where localization of microsatellite markers was investigated and the patient from Schluth et al. (2008) which

was fine mapped using a 1 Mb resolution array. Although a variable clinical phenotype is present in all patients, the three patients reported here all present with developmental delay or learning disability, nasal speech and hypothyroidism. In this study we further elaborate on the genotype-phenotype correlation associated with this deletion.

C14.1*

Cutting edge technology and old-fashioned relationships: ethical reflections on incidental findings arising from whole genome and exome sequencing

***G. M. Christenhusz**, K. Devriendt, K. Dierickx;*
Katholieke Universiteit Leuven, Leuven, Belgium.

Incidental findings, a common issue in neurology and oncology, are a pressing ethical issue in next generation sequencing because of that technology's potential to deliver an enormous amount of often unsought for information of widely varying significance. This paper is based on a systematic literature review of ethical reflections on the issue of incidental findings, specifically those arising from whole genome and whole exome sequencing in clinical and research genetics. A number of electronic databases were searched using the term "incidental findings" and variations of (bio)ethics, (bio-) medical and research, and 25 articles were ultimately included for systematic review as being detailed ethical reflections on incidental findings in general or incidental findings in clinical and research genetics in particular. The ethical issues raised can be divided into two main clusters. One cluster revolves around the incidental findings themselves. This cluster includes ongoing debate on how to classify incidental findings, a classification that determines whether and how disclosure to the patient or research participant will proceed. A second cluster revolves around the relationships between the various parties involved: professionals, patients or research participants, their families, the wider society, and overseeing bodies such as Institutional Review Boards. Where the emphasis is placed in each relationship has a bearing on the disclosure process, and there is a notable tension between research and clinical practice. We conclude that, cutting edge technologies notwithstanding, personal relationships between medical professionals and patients or research participants are key in realising the full promise of whole genome and exome sequencing.

C14.2

Public attitudes towards genetic testing revisited. Comparing opinions between 2002 and 2010

***E. Vermeulen**, L. Henneman, C. G. Van El, M. C. Cornel;*
VUmc, Amsterdam, Netherlands.

Background: Ten years after the Human Genome Project, medicine has yet to see any large part of the promised benefits, and experts have tempered their high expectations. Aim of this study is to compare public attitudes and expectations concerning genetic testing over the years (2002 vs. 2010).

Methods: Cross-sectional questionnaire survey of a consumer panel representative for the Dutch population. The questionnaire was sent to 1,385 members (>20 years). A similar panel was used in 2002.

Results: In 2010 and 2002, the response was 70% (978) and 63% (817), respectively. More respondents (64%) now believe that knowledge about the genetic background of disease will help people to live longer as compared to 2002 (43%). Respondents want genetic tests to be available (64% vs. 61% in 2010 and 2002, respectively). Respondents also think that genetic testing will become more normal in different situations (57% vs. 45%).

Expectations on negative aspects of testing changed over time. On the one hand, respondents think more often that a dichotomy will emerge between people with 'good' and 'bad' genes as a consequence of testing (38% vs. 22%). On the other hand, respondents seemed less concerned that genetic tests would become necessary for establishing the height of health insurance premiums (34% vs. 42%).

Conclusions: The results suggest that over the past ten years, expectations of benefits, potential use and impact on society of genetic testing have increased among the public, as have worries on inequity, while worries about genetic testing for health insurance have decreased.

C14.3

Survey of European clinical geneticists on awareness, experiences and attitudes towards direct-to-consumer genetic testing

***P. Borry**, H. C. Howard;*
Centre for Biomedical Ethics and Law, 3000, Belgium.

An increasing number of private companies are now offering direct-to-consumer (DTC) genetic testing services. The tests offered range from tests for single gene, highly penetrant disorders to susceptibility tests for genetic variants associated with common complex diseases or with particular non-health-related traits. The aim of this study was to collect information regarding the awareness, experiences and attitudes of European clinical geneticists about genetic tests and test interpretations sold directly to consumers. European clinical institutes where genetic counselling is offered to patients were contacted. One-hundred and thirty-one of the three-hundred eligible respondents (44%) answered a questionnaire. Eighty-six percent (110/128) of the clinical geneticists said they were aware that companies are advertising and selling genetic tests directly-to-consumers. Of the 44% (54/121) of the respondents who had been contacted by patients who underwent DTC testing, almost all respondents (98%, 47/48) did discuss test results with the patients. The following respondents somewhat or strongly agreed that DTC genetic tests should be legally banned for following tests: prenatal gender tests (69%, 77/112); genome scans (63%, 70/112), 54%, athletic performance (54%, 61/113), preconceptional carrier tests (53%, 59/112) and ancestry testing (27%, 30/113). The results indicate that most European clinical geneticists have only limited experience with patients who have accessed direct-to-consumer genetic testing, however, these physicians are entering into patient-physician interactions with patients when requested to do so.

C14.4

Familial Breast cancer: Is it time to move from a reactive to a proactive role?

***I. Nippert**[1], H. Harris[2], C. Julian-Reynier[3], J. Schmidtke[4], C. J. van Asperen[5], A. Tibben[6], D. G. Evans[7];*
[1]Women's Health Research, Westfälische Wilhelms-Universität, Münster Medical School, Münster, Germany, [2]GenEd Coordinating Centre, University of Manchester, Manchester, United Kingdom, [3]U912, INSERM, IRD, Aix-Marseille Université, Institut Paoli-Calmettes, Marseille, France, [4]Institute of Human Genetics, Hannover Medical School, Hannover, Germany, [5]Centre for Human and Clinical Genetics, Department of Clinical Genetics, Leiden University Medical Centre (LUMC), Leiden, Netherlands, [6]Centre for Human and Clinical Genetics, Department of Clinical Genetics, Section Genetic Counselling, Leiden University Medical Centre (LUMC), Leiden, Netherlands, [7]Genetic Medicine MAHSC, Central Manchester University Hospitals NHS Foundation Trust, St Mary's Hospital, Manchester, United Kingdom.

Introduction: Until recently there was little evidence base that interventions would affect life expectancy in familial breast cancer other than from theoretically based decision analysis in *BRCA1* or *BRCA2* mutation carriers. In 2004 the UK NICE guidelines for familial breast cancer on women unaffected with the disease determined that 'Health Care Professionals should not actively seek to identify women with a family history of breast cancer'. Since 2004 a wealth of evidence on the efficacy of MRI screening and risk reducing surgery has emerged including the first real impact on survival.

Methods: A total of 1197 GPs and 1223 surgeons completed a questionnaire on risk communication and management of familial breast cancer in four EU countries (UK, France, the Netherlands and Germany). One question addressed whether or not health care professionals should actively seek to identify women with a family history of breast cancer.

Outcome: Responses were overwhelmingly against current NICE guidance on identification of women at risk of familial breast cancer. Amongst GPs 74.8% in Germany up to 97% in France either disagreed or strongly disagreed with the non proactive approach. Amongst surgeons the disagreement ranged from 73.1 in Germany to 90.8% in France.

Conclusion: We have shown there are strong views against the current reactive approach to familial breast cancer amongst GPs and surgeons. We believe the time is right to become more proactive in identifying women at increased risk of breast cancer so that advice on

surveillance and possible genetics referral can be reviewed.

C14.5*

Risk predictions from direct-to-consumer personal genome testing: What do consumers really learn about common disease risk?

R. R. J. Kalf[1], *R. Mihaescu*[1], *P. de Knijff*[2], *R. C. Green*[3], *A. C. J. W. Janssens*[1]; *[1]Erasmus University Medical Centre, Rotterdam, Netherlands, [2]Leiden University Medical Centre, Leiden, Netherlands, [3]Harvard Medical School, Boston, MA, United States.*

Objective: Direct-to-consumer (DTC) companies predict risks of common complex diseases on the basis of genetic markers. Given the low number of markers involved and their small effect sizes, it is unclear whether high-risk groups can be identified. We investigated the risk distributions generated by two DTC companies for 8 diseases.
Methods: We simulated genotype data for 100,000 individuals based on published genotype frequencies. Predicted risks were obtained using the formulas and risk data provided by the companies.
Results: The table presents observed and trimmed ranges of predicted risks. The two companies used different formulas to calculate risks. One company predicted risks higher than 100% for 5 out of 8 diseases, which for AMD concerned 1 in 200 individuals. Observed ranges were smaller for the second company, except for Type 1 Diabetes. Predicted risks higher than 50% were frequently observed for company 1, but were exceptions for company 2. When predicted risks of company 1 were calculated using the formulas of company 2, observed ranges were substantially smaller.
Conclusion: Whether companies can currently predict high risks of disease predominantly depends on the method used for their calculation.

Condition	Company 1			Company 2		
	Average risk	Range	Trimmed range	Average risk	Range	Trimmed range
AMD	8	0.1-100	0.3-100	7	0.4-46.9	0.9-46.9
Atrial fibrillation	25	13.8-100	15.0-67.2	27.2	23.2-63.3	23.2-55.4
Celiac disease	1	0.0-56	0.1-21.7	0.1	0.0-5.1	0.0-2.9
Crohn"s disease	0.5	0.0-8.6	0.0-3.0	0.5	0.0-8.4	0.1-2.1
Heart attack	42	9.0-100	14.3-100	21.2	17.5-25.5	17.5-25.5
Prostate cancer	16	1.9-100	3.4-68.4	17.8	1.2-59.4	3.5-40.8
Type 1 Diabetes	0.4	0.0-10	0.0-2.7	1	0.1-41.4	0.1-13.7
Type 2 Diabetes	25	4.1-100	8.2-69.5	23.7	9.1-48.6	12.2-41.4

Values are percentages. AMD=Age-related Macular Degeneration; Trimmed range=0.5% outliers removed (two-sided)

C14.6*

Clinical, biochemical and molecular overview of the Ehlers-Danlos Syndrome, vascular type: the Ghent experience

S. Symoens, *F. Malfait, P. Vlummens, J. De Backer, A. De Paepe; Center for Medical Genetics, Ghent, Belgium.*

Mutations in *COL3A1*, encoding type III (pro)collagen, cause vascular Ehlers-Danlos syndrome (EDS), a life-threatening heritable connective tissue disorder characterized by thin translucent skin, arterial/intestinal/uterine rupture, easy bruising and characteristic facies.
We reviewed clinical/biochemical/molecular data of 211 probands fulfilling the Villefranche criteria for vascular EDS. All probands were subjected to biochemical and molecular collagen analysis. In 100/211 (47%) probands a causal *COL3A1* mutation was identified. Evaluation of this *COL3A1*-mutation-positive group revealed that 57% of the probands fulfilled the Geneclinics criteria. This result shows that while the Villefranche criteria lack sensitivity, the Geneclinics criteria are too strict. Importantly, biochemical analysis revealed an abnormal type III (pro)collagen pattern in all but 6 *COL3A1*-mutation-positive patients, three of whom harboured a *COL3A1*-null-allele. In the *COL3A1*-mutation-negative group, only five probands revealed an abnormal pattern for type III (pro)collagen and only four probands showed an abnormal pattern for type I (pro)collagen, with an underlying *COL1A1* mutation. In one *COL3A1*-mutation-negative proband a *TGFBR2* mutation was identified.
In addition, we performed collagen analysis in 60 probands with isolated carotid dissection, all with normal results, which suggests another underlying cause for this disorder Based on these observations, we designed new, age-specific clinical criteria for vascular EDS which are more specific than the Geneclinics criteria and more stringent than the Villefranche criteria. Re-evaluation of the 211 probands showed that 97% of the *COL3A1*-mutation-positive probands (versus 57% with Geneclinics criteria) fulfilled these adapted criteria. Additionally, these results confirm the biochemical collagen analysis as highly sensitive for the diagnosis of vascular EDS.

C15.1

Epigenetic regulation of learning & memory in a *Drosophila* model for Kleefstra syndrome

J. M. Kramer[1], *K. Kochinke*[1], *M. A. W. Oortveld*[1], *H. Marks*[1], *D. Kramer*[1], *E. K. de Jong*[1], *Z. Asztalos*[2], *J. T. Westwood*[3], *H. G. Stunnenberg*[1], *M. B. Sokolowski*[3], *K. Keleman*[4], *H. Zhou*[1], *H. van Bokhoven*[1], ***A. Schenck***[1]; *[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Biological Research Center of Hungarian Academy of Sciences, Szeged, Hungary, [3]University of Toronto, Toronto, ON, Canada, [4]Institute of Molecular Pathology, Vienna, Austria.*

The epigenetic modification of chromatin structure and its effect on complex neuronal processes like learning and memory is an emerging field in neuroscience. However, little is known about the "writers" of the neuronal epigenome and how they lay down the basis for proper cognition. Here, we have dissected the neuronal function of the *Drosophila* euchromatin histone methyltransferase (EHMT), a member of a conserved protein family that methylates histone 3 at lysine 9 (H3K9). We identify EHMT as a regulator of peripheral dendrite development, larval locomotor behavior, non-associative learning and courtship memory. The requirement for EHMT in memory was mapped to a subset of neurons in the adult brain and memory was restored by EHMT re-expression during adulthood, indicating that cognitive defects are reversible in EHMT mutants. To uncover the underlying molecular mechanisms, we generated genome-wide H3K9 dimethylation profiles using ChIP-seq technology. Loss of H3K9 dimethylation in EHMT mutants occurs at 5% of the euchromatic genome and is enriched at the 5' and 3' ends of distinct classes of genes that control neuronal and behavioural processes that are corrupted in EHMT mutants. This study identifies *Drosophila* EHMT as a key regulator of cognition that orchestrates an epigenetic program featuring classic learning and memory genes. Our findings are relevant to the pathophysiological mechanisms underlying Kleefstra Syndrome, a severe form of intellectual disability caused by mutations in human *EHMT1*, and have potential therapeutic implications. Our work thus provides novel insights into the epigenetic control of cognition in health and disease.

C15.2*

Mutations in the *NSUN2* and *ZNF526* genes cause autosomal recessive intellectual disability in Middle Eastern populations with elevated frequency

L. Abbasi Moheb[1], *S. Mertel*[2], *L. R. Jensen*[1], *L. Nouri Vahid*[3], *S. Ghadami*[3], *K. Wrogemann*[1,4], *H. Hu*[1], *R. Weissmann*[1], *M. Mohseni*[3], *K. Kahrizi*[3], *A. Tzschach*[1], *D. Wieczorek*[5], *M. Garshasbi*[1], *S. Cirak*[6], *S. Abedini*[3], *H. Najmabadi*[3], *H. Ropers*[1], *S. Sigrist*[2], *A. Kuss*[1,7]; *[1]Max Planck Institute for Molecular Genetics, Berlin, Germany, [2]Genetics, Institute for Biology, Freie Universität Berlin, Berlin, Germany, [3]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [4]University of Manitoba, Winnipeg, MB, Canada, [5]Institut für Humangenetik, Universitätsklinikum, Essen, Germany, [6]The Dubowitz Neuromuscular Centre, University College London Institute of Child Health, London, United Kingdom, [7]*Current address: Institute for Human Genetics, Interfaculty Institute for Genetics and Functional Genomics, Ernst Moritz Arndt University, Greifswald, Germany.*

So far no more than six hotspot loci for unspecific or non-syndromic autosomal recessive intellectual disability (NS-ARID) have been identified (Kuss et al. 2011, Human Genetics Vol.129, 141-148). In this study we now resolved the underlying gene defect of MRT 5 and report three deleterious mutations in *NSUN2*. This gene encodes a methyltransferase, which catalyzes the intron-dependent formation of 5-methylcytosine at C34 of tRNA-leu(CAA). Two of the observed changes were nonsense mutations (p.Q227X and p.Q372X), which

cause a complete loss of *NSUN2* transcripts in the patients. In the third family we found an intronic exchange of an adenosine for a guanine 11 nucleotides upstream of exon 6. This change causes exon 6 to be skipped during splicing and results in the loss of the main transcript. Hence all mutations lead to a loss of NSUN2 protein function in homozygous mutation carriers and thus in all likelihood cause the patient phenotype. In order to gain further evidence for an involvement of NSUN2 in cognitive functions, we studied fruit fly mutants that lack the NSUN2 ortholog. These experiments revealed a marked learning impairment in mutant flies, which clearly underscores the relevance of NSUN2 in higher brain functions.

Moreover we present mutation screening results for another hot spot locus (MRT11) in three Iranian families with several NS-ARID patients overlapping on Chr19q13.2-q13.31. Mutation screening by hybridization based enrichment of the exonic regions of all genes from the respective intervals and subsequent next-generation sequencing revealed two different single nucleotide changes in *ZNF526*. Mutations in other genes were not observed.ZNF526 encodes a brain expressed C2H2 zinc finger protein with DNA binding properties that is thought to be involved in gene regulation. Each mutation affects a functional domain of ZNF526 and both alter the protein conformation, causing a putative functional impairment as suggested by *in silico* protein modelling. A decrease in DNA affinity was confirmed by CHIP-seq and array-based gene expression studies showed specific changes in the expression patterns of patient lymphoblastoid cells, which could be recapitulated in ZNF526-deficient neuroblastoma cells. Functional annotation showed significant enrichment of the deregulated genes in pathways that play a role in protein synthesis, mitochondrial dysfunction, energy metabolism and gene regulation. Several zinc finger proteins were found to be involved in the pathogenesis of X-linked ID, but ZNF526 is the first to be implicated in NS-ARID. Our results show that both *NSUN2* and *ZNF526* belong to the still few genes known to carry NS-ID-causing mutations in independent families, which suggests that defects in either gene belong to the more common causes of NS-ARMR, at least in the Iranian population.

C15.3*

Mutations in genes encoding adaptor protein complex 4 (AP-4) subunits cause a clinically recognizable autosomal recessive syndrome.

O. Philippe[1], *R. Abou Jamra*[2], *A. RAAS-ROTHSCHILD*[3], *G. Borck*[1], *R. Buchert*[2], *T. Strom*[4], *S. Eck*[4], *A. Munnich*[1], *L. Colleaux*[1], *A. Reis*[2];
[1]*INSERM U781, Université Paris Descartes, Hôpital Necker-Enfants Malades, PARIS, France,* [2]*Institute of Human Genetics, University of Erlangen, Erlangen, Germany,* [3]*Department of Genetics and Metabolic Diseases, Hadassah University Hospital, Jerusalem, Israel,* [4]*Institute of Human Genetics, Helmholtz Center Munich, Neuhergerg, Germany.*

Autosomal recessive inheritance accounts for nearly 25% of intellectual disability (ID) but the extreme heterogeneity of these conditions markedly hampers gene identification. Using a combination of autozygosity mapping combined to Sanger sequencing of candidate gene or identity-by-descent filtering of exome sequence data, we identified three mutations in the genes encoding adaptor protein complex 4 subunits : a nonsense mutation within the AP4S1 gene (c.124C>T;p.R42X), a frameshift mutation within the AP4B1 gene (c.487-488insTAT;p.E163X) and a splice mutation within the AP4E1 gene (g.542+1_542+4delGTAA). All affected patients presented with severe ID, normal head circumference or mild microcephaly, hypotonia that progressed to spastic paraplegia with hyperreflexia and hypertonia, deformities of feet, and little muscle mass of the lower extremities. Finally, patients show an extreme shy and amicable character with stereotypic laughter.

Adaptor complexes (AP1-4) are evolutionarily conserved heterotetrameric complexes that mediate different types of vesicle formation and the selection of cargo molecules for inclusion into these vesicles. Interestingly, two mutations affecting the AP4M1 and AP4E1 genes (a splice donor site mutation in the AP4M1 gene and a 192kb-long deletion encompassing the 5' end of the AP4E1 gene) have been recently found to cause cerebral palsy associated with microcephaly and severe intellectual disability.

Combined to previous observations, these results support the hypothesis of a crucial role of AP4-mediated trafficking in brain development and functioning and demonstrate the existence of a clinically recognizable AP-4 deficiency syndrome.

C15.4*

A novel dynamic mutation in AFF3 associated with developmental delay

S. Metsu[1], *L. Rooms*[1], *J. Gecz*[2], *D. R. FitzPatrick*[3], *R. F. Kooy*[1];
[1]*Department of Medical Genetics, University of Antwerp, Antwerp, Belgium,* [2]*Women's and Children's Hospital, Neurogenetics, Genetics and Molecular Pathology, Adelaide, Australia,* [3]*Medical Genetics Section, MRC Human Genetics Unit, Edinburg, United Kingdom.*

Many types of dynamic mutations are cytogenetically expressed as fragile sites. Although it is known that fragile sites of the rare, folate sensitive type occur more frequently in cohorts of patients with cognitive disorders, few have been characterized at the molecular level. We studied three families with FRA2A expression. The probands were characterized by slow early motor and language development and learning disability. As the molecular basis of this fragile site we identified an elongated polymorphic CGG repeat in the 5' region of AFF3. This gene is a member of the family of nuclear transcription factors including AF4, AF5q31 and FMR2, involved in regulation of gene expression, cell expansion, embryonic development and fulfill a role in the central nervous system. Interestingly, AFF3 is a paralog of FMR2, causative of FRAXE non-syndromic mental retardation. Loss of expression of FMR2 occurs through dynamic repeat expansion of a CGG repeat in the 5' untranslated region of the gene and subsequent hypermethylation of the promoter. This mechanism was first described in the fragile X syndrome. Expansion of the AFF3 associated repeat was shown in the probands of the 3 families and in five family members using Southern blot analysis. By cSNP-analysis we could confirm that methylation of the promoter region silences transcription of the AFF3gene. All patients but not all parents were methylated. In conclusion we collected compelling evidence that transcriptional silencing of the AFF3 gene could play a role in the cognitive impairment present in all patients.

C15.5

Mutation in ARID1B as a frequent cause of intellectual disability

A. B. Ekici[1], *J. Hoyer*[1], *C. Petsch*[1], *I. Goehring*[1], *C. Zweier*[1], *A. Wiesener*[1], *M. Zweier*[1], *A. Rauch*[1,2], *A. Reis*[1];
[1]*Institute of Human Genetics, Erlangen, Germany,* [2]*Institute of Medical Genetics, Zurich, Switzerland.*

Interstitial deletions of chr.6q are rare findings ranging from 0.3 to several megabases. Some associated features are common, including intellectual disability (ID), hypotonia and facial dysmorphism.

We detected a 2.3Mb *de novo* deletion in chr.6q25 with molecular karyotyping in an infant with ID, facial dysmorphism, strabismus and hyperopy.

This deletion lies within previously reported regions and encompasses only 5 known genes. We hypothesized that haploinsufficiency for one of these may impair normal development. To identify the phenocritical gene we screened these five positional candidates for point mutations in 331 patients with moderate to severe ID.

In one of these genes, ARID1B, highly expressed in brain and encoding a subunit of the mammalian SWI/SNF complexes important for different neuronal developmental programs, we found four *de novo* sequence alterations. One 11bp deletion resulting in a premature stop codon, which shortens the protein by 58AA, a stop mutation in exon 16 and an in-frame 3bp deletion. We thus identified a sequence alteration in ARID1B in nearly 1% of patients with unexplained intellectual disability. Additionally, CNV screening in 1,986 patients with intellectual disability revealed a validated *de novo* duplication of three exons resulting in a frame shift. All five patients display a pronounced clinical overlap like ID, especially regarding expressive speech and similar facial phenotype.

Moreover, recently the disruption of ARID1B was also reported in a translocation patient with ID, supporting our hypothesis of ARID1B mutation as a frequent cause of ID.

This study is part of the German Mental Retardation Network (www.german-mrnet.de).

C15.6*

Haploinsufficiency of microRNA-137 is associated with intellectual disability in patients with overlapping deletions in 1p21.3.

M. H. Willemsen[1], *L. Kirkels*[2], *M. Mastebroek*[3], *A. Vallès*[4], *N. OldeLoohuis*[1], *A. Kos*[1], *W. Wissink-Lindhout*[1], *A. de Brouwer*[1], *M. Coppens-Hofman*[1], *H. Rensen*[1,3], *B. Hamel*[1], *H. van Bokhoven*[1], *A. Aschrafi*[1], *T. Kleefstra*[1];
[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Radboud University Nijmegen,The Netherlands, Nijmegen, Netherlands,* [3]*Pluryn, Service provider for people with intellectual disability, Oosterbeek, Netherlands,* [4]*Radboud University Nijmegen Medical Centre and Maastricht University, Nijmegen, Netherlands.*

Introduction: Genome-wide array technologies have led to the identification of several microdeletion and microduplication syndromes and genes involved in intellectual disability (ID). Microdeletions and/or duplications restricted to chromosomal region 1p21.3 have rarely been reported before. Several ID syndromes have been linked to the microRNA (miRNA) pathway, but there are no previous reports of genome wide array studies that have led to the identification of miRNAs associated with ID.

Methods: We characterized the clinical and molecular features of three sibs and 2 non-related patients with overlapping 1p21.3 deletions, detected by genome-wide array analysis. The deletions in the two unrelated patients were *de novo*. We determined the shortest region of overlap (SRO) to identify candidates for the phenotype.

Results: Clinical features comprised mild ID and autism spectrum disorder. The SRO was 1.22 Mb and included one annotated gene, *DPYD* (dihydropyrimidine dehydrogenase deficiency), which was unlikely to cause the phenotype, since no associated metabolic defect was detected. Interestingly, the SRO also comprised microRNA-137 (miR-137), which was shown to be under epigenetic regulation of *MeCP2* and involved in adult neurogenesis in previous studies in mice. Our patients had a significantly altered expression of miR-137 and downstream targets. Furthermore, in mouse synaptosomes we found significant enrichment of miR-137 at the synapse as assessed by qRT-PCR, suggesting a role for miR-137 as a modulator of local translation at the synapse.

Conclusion: We propose that these patients represent a novel microdeletion syndrome that is caused by haploinsufficiency of miR-137.

C16.1

High-resolution whole genome sequencing reveals specific chromatin domains from most human chromosomes associate with nucleoli

S. van Koningsbruggen[1], *M. Gierlinski*[2], *P. Schofield*[2], *D. M. Martin*[3], *G. J. Barton*[3], *Y. Ariyurek*[4], *J. T. den Dunnen*[5], *A. I. Lamond*[1];

TThe nuclear space is mostly occupied by chromosome territories and nuclear bodies. While the nuclear organisation of chromosomes affects gene function, relatively little is known about the role of nuclear bodies in the organization of chromosomal regions. The nucleolus is the best-studied subnuclear structure and forms around the ribosomal RNA repeat-gene clusters on the acrocentric chromosomes. In addition to rDNA, other chromatin sequences also surround the nucleolar surface and may even loop into the nucleolus. These additional nucleolar-associated regions have not been characterized.

We present here a whole-genome, high-resolution analysis of chromatin endogenously associated with a subnuclear body. We have used a combination of three complementary approaches, namely fluorescence-comparative-genome in situ hybridisation, high-throughput deep-DNA-sequencing and photoactivation combined with time-lapse fluorescence microscopy to study nucleolar-associated chromatin.

The data show that specific sequences from most human chromosomes associate with nucleoli in a reproducible and heritable fashion. The nucleolar-associated loci have in common a high density of AT-rich sequence elements, low gene density and a striking and significant enrichment in transcriptionally repressed genes. Unexpectedly, both the direct DNA sequencing and fluorescence photoactivation data show that certain chromatin loci can specifically associate with either the nucleolus or the nuclear envelope.

We are currently comparing nucleolar-associated loci in a model for cancer versus non-cancer cells. This will allow us to identify genomic regions that are mis-localized and of which gene expression maybe deregulated in cancer cells, and therefore can possibly be used as a probe to diagnose specific cancers or cancer stages.

C16.2*

Interrogation of high purity primary cell subsets demonstrates the majority of eQTLs operate in a cellular discrete manner

B. P. Fairfax, *S. Makino, K. Plant, J. Radhakrishnan, J. C. Knight;*
Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

A functional consequence of genetic variation is the regulation of transcript abundance - the formation of expression quantitative traits (eQTLs). In cultured umbilical-cord derived cells it is clear that many SNPs form eQTLs dependent upon the cell type. The degree to which these loci are reproducibly associated with gene expression in primary tissues and whether they act in a cell-specific manner is unclear. We have sought to identify polymorphisms acting in a cell specific manner from physiologically relevant tissue - freshly purified positively selected lymphoid derived CD19+ B-cells and myeloid derived CD14+ monocytes.

Cells were purified from a cohort of 288 healthy adult Caucasians. Subjects were genotyped at 731,442 markers (Illumina HumanOmniExpress) and expression analysed using whole genome microarrays (Illumina HumanHT-12, n=566). At a p-value <1x10-11 we identify 1960 SNPs with eQTLs unique to B-cells and 3700 SNPs with eQTLs unique to monocytes. Whilst the most significant eQTLs tend to be shared between cell type, over 90% of SNPs with eQTLs at a p-value <0.01 are cell specific. Furthermore, we identify a subset of ~20 genes with SNPs that lead to opposing directional effects on expression in a cell dependent manner. We confirm the microarray results for multiple genes using quantitative PCR and analyse several monocyte and B-cell specific eQTLs in a third cell type - Natural-Killer cells. Interrogation of this dataset suggests that several GWAS loci are associated with regulation of expression of genes in cis with the putative functional gene, indicating alternative candidate genes for several disease associations.

C16.3

Whole-exome sequencing of DNA from peripheral blood mononuclear cells (PBMC) and EBV-transformed lymphocytes from the same donor

E. R. Londin[1], *M. A. Keller*[1], *K. Delgrosso*[2], *A. Ertel*[2], *S. Surry*[2], *M. R. D'Andrea*[1], *K. Gwinn*[3], *P. Fortina*[2];
[1]*Coriell Institute for Medical Research, Camden, NJ, United States,* [2]*Thomas Jefferson University Hospital, Philadelphia, PA, United States,* [3]*National Institute for Neurological Disorders and Stroke, Bethesda, MD, United States.*

The creation of lymphoblastoid cell lines (LCLs) through Epstein-Barr virus transformation of B lymphocytes can result in a valuable and renewable biomaterial. Many biobanks, including the NINDS Human Genetics DNA and Cell Line Repository, establish and distribute LCLs and LCL-derived DNA samples. While LCLs have been extensively used in cellular and genetic studies, the process of cell immortalization and expansion during culturing may introduce genomic changes that could impact interpretation of genetic findings. We tested this hypothesis by performing whole exome-sequencing using both PBMC- and LCL-derived genomic DNA from a family of 4 individuals. Using the Agilent SureSelect Human All Exon Kit and SOLiD 4 Sequencer the DNA samples were sequenced to over 100X read depth with both DNA sources yielding similar sequencing efficiencies. An average of 17,730 SNPs were identified with 2% novel SNPs, as defined by no representation in dbSNP and/or the 1000 Genomes dataset. A comparison of sequence data from peripheral blood- and LCL-derived DNA from the same individual will be presented, including concordance rates, categorization of variant types and a breakdown

of novel variants by their potential impact. These findings will aid the research community in identifying the optimal starting material for deep sequencing studies.

C16.4
Unmasking of pathogenic rare variants by inherited deletions detected with multiplexed capture array-based re-sequencing.

R. Hochstenbach[1], *I. Nijman*[2], *M. Poot*[1], *W. Kloosterman*[1], *I. Renkens*[1], *K. Duran*[1], *E. van Binsbergen*[1], *B. van der Zwaag*[1], *V. Guryev*[1], *S. Koval*[2], *H. Ploos van Amstel*[1], *E. Cuppen*[1];

[1]*Department of Medical Genetics, University Medical Center Utrecht, P.O. Box 85090, 3508 AB Utrecht, Netherlands,* [2]*Hubrecht Institute and University Medical Center Utrecht, Uppsalalaan 8, 3584 CT Utrecht, Netherlands.*

We investigated the hypothesis that a familial deletion, transmitted by a healthy parent to a child with mental retardation and congenital anomalies unmasks a recessive mutation transmitted by the other healthy parent. To detect such mutations, we designed two capture arrays with 60-mer probes tiled with an off-set of 10 nt covering the entire coding sequence (1.53 Mb capture footprint) of all genes within 20 transmitted deletion regions (covering in total 57.9 Mb genomic DNA). Deletions varied in size from 0.15 to 11.0 Mb and contained up to 36 protein coding genes. The patient DNA samples were sheared, ligated with short adaptors and SOLiD library barcodes, hybridized simultaneously (as pools of 9 and 11 samples, respectively) onto capture arrays, recovered and sequenced on a SOLiDv3.5 sequencer. Sequencing reads were mapped against the human reference genome and all Single Nucleotide Variations (SNVs) were compiled using in-house developed SNP-calling algorithms. Except for SNVs coinciding with indels and segmental duplications, all SNVs were close to 0 or 100% non-reference calls, confirming the mono-allelic nature of the regions studied. In all three cases tested, SNVs showed high concordance with SNP calls by Illumina HumanHap 300v3 BeadChips. Most of the 668 SNVs detected occurred in multiple samples. Only 9 SNVs located exclusively to the cognate deletion regions of the patients and were confirmed by capillary sequencing. Two patients carried a second, smaller loss within their inherited deletion region. All SNVs were evaluated for potential pathogenicity using inheritance patterns, Grantham matrix scores and evolutionary conservation.

C16.5
De novo copy number variations causing mental retardation show a significant paternal origin bias and are associated with increased paternal age

J. Y. Hehir-Kwa[1], *B. Rodríguez-Santiago*[1,2], *L. E. Vissers*[1], *N. de Leeuw*[1], *R. Pfundt*[1], *L. A. Pérez-Jurado*[2], *J. A. Veltman*[1];

[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Unitat de Genètica, Universitat Pompeu Fabra, and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain.*

De novo mutations and structural rearrangements are a common cause of mental retardation (MR) and other disorders with reduced or null reproductive fitness. Insight into the genomic and environmental factors predisposing to the generation of these *de novo* events therefore is of significant clinical importance. In this study we used information from SNP microarrays to determine the parent-of-origin of rare *de novo* CNVs from a large mental retardation cohort (3,443 patients, 227 *de novo* CNVs). The large majority of these CNVS originated on the paternal allele (78%, $p=3.4x10^{-9}$). This paternal bias was independent of CNV length and CNV type. Interestingly, the paternal bias was less pronounced for CNVs flanked by low-copy repeat (LCRs), suggesting that molecular mechanisms involved in the formation of rare *de novo* CNVs may be dependent on the parent-of-origin. In addition, a significantly increased paternal age was only observed for those CNVs which were not flanked by LCRs (p=0.009). This indicates that *de novo* CNVs are increasingly being generated with advanced paternal age by replication-based mechanisms during spermatogenesis.

C16.6*
Functional validation of GWAS loci for platelet traits in *Danio rerio* reveals new regulators of haematopoiesis

J. Serbanovic-Canic[1], *A. Cvejic*[1], *N. Soranzo*[2], *D. L. Stemple*[2], *K. Freson*[3], *W. H. Ouwehand*[1];

[1]*Department of Haematology, University of Cambridge, Cambridge, United Kingdom,* [2]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [3]*Center for Molecular and Vascular Biology, University of Leuven, Leuven, Belgium.*

A recent meta-analysis of the genome-wide association study (GWAS) in 68,000 individuals of European ancestry has identified 68 genomic loci (53 new) associated with platelet count and volume. Our functional study in *Danio rerio* by the means of gene silencing, has demonstrated a role for five genes from the associated loci (*ak3, arhgef3*, *jmjd1c*, *rnf145* and *tpma*) in regulation of thrombopoiesis. Additionally, lineage relatedness of megakaryocytes and erythrocytes prompted us to explore the putative role of these genes in erythropoiesis. Morpholino (MO) knockdown of all five genes but *tpma* resulted in a variable decrease in the number of erythrocytes. *Arhgef3*-depletion had the most profound effect on erythropoiesis, leading to further detailed studies. Examination of peripheral blood from *arhgef3* MO-injected embryos revealed microcytic, hypochromic erythrocytes, a classic feature of iron deficiency. Anaemia was rescued by intracellular supplementation of iron to *arhgef3* MO-injected embryos, demonstrating that *arhgef3*-depleted erythroid cells, once provided with intracellular iron are fully capable of haemoglobinisation. Disruption of the *arhgef3* target, RhoA, also produced severe anaemia, which was again rescued by iron injection. Moreover, silencing of *ARHGEF3* expression in the erythromyeloblastoid cell line K562 revealed that the uptake of iron transporter, transferrin, was severely impaired. This is the first study to provide evidence for ARHGEF3 being a regulator of transferrin and iron uptake in erythroid cells, through activation of RhoA.

In conclusion, our findings demonstrate the value of pursuing GWAS signals as a new and exciting forward genetics approach in identifying novel regulatory molecules and signalling pathways in haematopoiesis.

C17.1
Hypofunctional CHD1L variants in patients with congenital anomalies of the kidneys and urinary tract (CAKUT)

A. Brockschmidt[1], *B. Chung*[1], *S. Weber*[2], *D. Fischer*[3], *M. Kolatsi-Joannou*[4], *L. Christ*[1], *G. Klaus*[5], *G. D. Simonetti*[6], *M. Konrad*[7], *P. Winyard*[4], *D. Haffner*[3], *F. Schaefer*[2], ***R. G. Weber***[1];

[1]*University of Bonn, Institute of Human Genetics, Bonn, Germany,* [2]*University Children's Hospital Heidelberg, Division of Pediatric Nephrology, Heidelberg, Germany,* [3]*University Children's Hospital Rostock, Department of Pediatrics, Rostock, Germany,* [4]*University College London, Institute of Child Health, London, United Kingdom,* [5]*KfH-Pediatric Kidney Center, Marburg, Germany,* [6]*University Children's Hospital Berne, Division of Pediatric Nephrology, Berne, Switzerland,* [7]*University Children's Hospital Münster, Department of General Pediatrics, Münster, Germany.*

Background. Recently, we identified a microduplication in chromosomal band 1q21.1 encompassing the *CHD1L/ALC1* gene encoding a chromatin remodeling enzyme in a CAKUT-patient.

Methods. To explore the role of *CHD1L* in CAKUT, we screened 85 CAKUT-patients for mutations in the *CHD1L* gene and performed functional analyses of the three heterozygous missense variants detected. In addition, we quantitatively determined *CHD1L* expression in multiple human fetal and adult tissues and analyzed expression of CHD1L protein in human embryonal, adult and hydronephrotic kidney sections.

Results. Two of three novel heterozygous missense variants identified in three patients were not found in more than 200 control chromosomes. All variants lead to amino acid substitutions in or near the CHD1L macro-domain, a poly-ADP-ribose(PAR) binding module interacting with PAR polymerase 1 (PARP1), and showed decreased interaction with PARP1 by pull-down assay of transfected cell lysates. Quantitative mRNA analysis demonstrated high *CHD1L* expression in human fetal kidneys, and levels were four-times higher than in adult kidney. In the human embryo at 7-11 weeks gestation, CHD1L immunolocalized in the early ureteric bud and the S- and comma-shaped bodies, critical stages of kidney development. In normal postnatal sections, CHD1L was expressed in the cytoplasm of tubular cells in all tubule segments. CHD1L expression appeared higher in the hydronephrotic kidney of one patient with a hypofunctional *CHD1L* variant than in normal kidneys, recapitulating high fetal levels.

Conclusions. Our data suggest that *CHD1L* plays a role in kidney development and that hypofunctional *CHD1L* variants may induce deficits in nephron differentiation leading to CAKUT.

C17.2*

First implication of STRA6 mutations in isolated anophthalmia, microphthalmia and coloboma

J. P. Casey[1], *R. Kawaguchi*[2], *M. Morrissey*[1], *H. San*[2], *P. McGettigan*[1], *J. Nielsen*[1], *J. Conroy*[1], *R. Regan*[1], *P. Tormey*[3], *M. Ní Chróinín*[4], *B. Kennedy*[1], *S. Lynch*[5,1], *A. Green*[5,1], *S. Ennis*[1,5];

[1]*University College Dublin, Dublin, Ireland,* [2]*David Geffen School of Medicine at UCLA, Los Angeles, CA, United States,* [3]*Waterford Regional Hospital, Waterford, Ireland,* [4]*Cork University Hospital, Cork, Ireland,* [5]*National Centre for Medical Genetics, Dublin, Ireland.*

Microphthalmia, anophthalmia and coloboma are structural congenital eye malformations that cause a significant percentage of childhood visual impairments. Several disease genes and risk loci have been identified but do not account for all MAC cases, suggesting that additional disease loci exist. Using SNP homozygosity mapping and targeted sequencing of the candidate homozygous segments, we identified a novel disease gene, *STRA6*, for isolated autosomal recessive colobomatous micro-anophthalmia (arCMIC). The *STRA6* missense mutation was subsequently detected in additional families that presented at the genetics clinic, including one patient with Matthew-Wood syndrome (MWS). We have shown that the mutant STRA6 protein is not expressed on the cell surface and has severely reduced vitamin A uptake activity. Furthermore, inhibition of retinoid synthesis in zebrafish embryos recapitulated the arCMIC phenotype, suggesting that diminished retinoid levels due to decreased vitamin A uptake by STRA6, account for the eye malformations in the arCMIC patients. We demonstrate that *STRA6* mutations can cause isolated arCMIC in addition to MWS, which opens the debate as to the genetic and environmental factors which determine whether patients with *STRA6* mutations develop isolated eye malformations or multisystem congenital anomalies. Currently, *STRA6* screening for diagnostic purposes is only offered to patients with MWS. Our findings suggest that patients with isolated eye defects of unknown etiology should also be considered for *STRA6* screening. The study also illustrates that the combination of homozygosity mapping together with targeted array-based sequencing is a powerful tool for identifying disease genes for recessive disorders.

C17.3*

Mutations in the 5' UTR of ANKRD26, the Ankirin Repeat Domain 26 Gene, cause an Autosomal-Dominant form of inherited Thrombocytopenia, THC2

Balduini*[6];

[1]*Medical Genetics Unit, Department of Gynaecological, Obstetric, and Paediatric Sciences, University of Bologna, Bologna, Italy,* [2]*Department of Reproductive and Developmental Sciences and Public Medicine Sciences, University of Trieste, Trieste, Italy,* [3]*Laboratory of Genetics, Institute for Maternal and Child Health, Istituto di Ricovero e Cura a Carattere Scientifico "Burlo Garofolo,", Trieste, Italy,* [4]*Department of Paediatrics, Second University of Naples, Naples, Italy,* [5]*Autonomous University of Barcelona & Platelet Pathology Unit, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [6]*Department of Internal Medicine, Istituto di Ricovero e Cura a Carattere Scientifico Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy,* [7]*Department of Clinical Genetics, Erasmus Medical Centre, Rotterdam, Netherlands,* [8]*Department of Biology, University of Bologna, Bologna, Italy,* [9]*Department of Oncology, Azienda "Santobono-Pausilipon," Pausilipon Hospital, Naples, Italy.*

Thrombocytopenia 2 (THC2 [MIM 188000]) is one of the rarest forms of autosomal-dominant thrombocytopenia. Until recently, it has been reported in only two families. THC-2 affected individuals have a degree of thrombocytopenia ranging and platelets showing no relevant morphological abnormality. It had been mapped to chromosome 10p11.1-p12 and ascribed to mutations in MASTL or ACBD5. We showed that ANKRD26, another gene within the THC2 locus, and neither MASTL nor ACBD5, was mutated in eight unrelated families. ANKRD26 was also found to be mutated in the family previously reported to have an ACBD5 mutation. We identified 6 different ANKRD26 mutations, which were clustered in a highly conserved 19 bp sequence located in the 5' untranslated region. Mutations were not detected in 500 controls and are absent from the 1000 Genomes database. Available data from an animal model and Dr. Watson's genome give evidence against haploinsufficiency as the pathogenetic mechanism for ANKRD26-mediated thrombocytopenia. The luciferase reporter assay suggests that these 5' UTR mutations might enhance ANKRD26 expression. ANKRD26 is the ancestor of a family of primate-specific genes termed POTE, which have been recently identified as a family of proapoptotic proteins. Dysregulation of apoptosis might therefore be the pathogenetic mechanism, as demonstrated for another thrombocytopenia, THC4. Further investigation is needed to provide evidence supporting this hypothesis. (Am J Hum Genet. 2011 Jan 7;88(1):115-20)

C17.4

Genomic instability represents the unifying molecular pathology of progressive muscular dystrophies and muscle-derived sarcomas

W. M. Schmidt[1], *M. H. Uddin*[1], *S. Dysek*[1], *K. Moser-Thier*[1], *S. Kummer*[1], *A. Lauermann*[1], *D. Maddaluno*[1], *C. Pirker*[2], *H. Höger*[3], *I. M. Ambros*[4], *P. F. Ambros*[4], *W. Berger*[2], *R. E. Bittner*[1];

[1]*Neuromuscular Research Department, Center of Anatomy & Cell Biology, Vienna, Austria,* [2]*Institute of Cancer Research, Department of Medicine I, Vienna, Austria,* [3]*Division for Laboratory Animal Science and Genetics, Vienna, Austria,* [4]*CCRI, Children's Cancer Research Institute, St. Anna Kinderkrebsforschung, Vienna, Austria.*

Muscular dystrophies (MDs) represent genetically heterogeneous disorders, characterized by progressive loss of functional muscle fibres and its replacement by adipose and fibrous tissue. Despite earlier promises based on the discovery of molecular defects underlying several MDs there is still no causative therapy, which underscores the need for a comprehensive understanding of the molecular mechanisms underlying the common MD pathology.

Investigating age-related phenotypes of MD mouse models, we observed the frequent occurrence of spontaneous skeletal muscle-derived tumors in mice lacking dystrophin, dysferlin, calpain-3, or Large, respectively. The primary gene defect and genetic background influenced tumor incidence, latency, localization, and gender prevalence. Combined loss of dystrophin and dysferlin or calpain-3 showed a strong synergistic effect. We found that these musculature-derived tumors are mixed sarcomas with rhabdomyo-, fibro-, and liposarcoma elements. Molecularly, these sarcomas shared non-random genomic alterations including frequent losses at the *Cdkn2a* and *Nf1* loci, amplification of oncogenes (*Met*, *Jun*), and recurrent duplications of whole chromosomes 8 and 15. Skeletal muscles of aged MD-mice without overt sarcomas regularly harbor sarcoma-specific genetic lesions. Consequently, we discovered that also dystrophic muscles and cultured cells from human MD patients are very similarly affected by DNA damage and chromosome copy number aberrations.

Thus, we present a novel, unifying concept for the molecular pathogenesis of MDs. Our identification of tumor-related DNA-pathologies in muscular dystrophies builds a bridge between a whole group of different rare diseases and the common entity of cancer diseases. This will foreseeably make the arsenal of anti-cancer therapies available for combating muscular dystrophies.

Due to the unique history of dog breeds, the proximity between dog and human lifestyle, physiology and genetic diseases, dog constitutes a unique model to unravel the phenotype/genotype relationships and to provide new insights into human genetic diseases. In the golden

retriever breed, a high incidence of an autosomal recessive form of ichthyosis, resembling human autosomal recessive congenital ichthyoses (ARCI), has been diagnosed. Ichthyoses consist of a heterogeneous group of genodermatoses characterized by abnormal desquamation over the whole body, for which the genetic causes of several human forms remain unknown. We carried out a genome-wide association study on 40 unrelated golden retriever dogs (20 cases and 20 controls), using the canine 49,000 SNPs array (Affymetrix v2). The statistical analysis demonstrated a significant associated locus of 7 Mb on canine chromosome 12. Sequencing metabolic candidate genes revealed a recessive exonic indel mutation leading to a premature stop codon in one annotated gene. We then searched for alterations in the orthologous human gene in ARCI families, for which no genetic cause has been identified so far. We identified two recessive mutations in the catalytic domain of the orthologous human gene in two families. In addition to identify a seventh gene for human ARCI, electronic microscopy investigations highlighted the implication of this new gene product in the lipid metabolism of the skin barrier. Other breeds are affected by different ichthyoses, therefore using the canine model might facilitate the identification of rare gene variants responsible of human ichthyoses.

C17.6*

siRNA silencing of proteasome maturation protein (POMP) expression activates the unfolded protein response and constitutes a model for KLICK syndrome

J. Dahlqvist, *H. Törmä, J. Badhai, N. Dahl;*
Uppsala University, Uppsala, Sweden.

KLICK genodermatosis is an autosomal recessive skin disorder associated with a single-nucleotide deletion in the 5'untranslated region (UTR) of the proteasome maturation protein (*POMP*) gene. The deletion causes a relative switch in transcription start sites for *POMP*, predicted to decrease levels of POMP protein and mature proteasomes in terminally differentiated keratinocytes. In order to understand the pathophysiology behind KLICK we created an *in vitro* model of the disease using siRNA silencing of *POMP* in epidermal air-liquid cultures. Immunohistochemical analysis of tissue constructs transfected with siRNA against *POMP* revealed aberrant staining of POMP, proteasome subunits and the skin differentiation marker filaggrin when compared to control tissue constructs. The staining patterns of *POMP* siRNA tissue constructs were strikingly similar to those observed in skin biopsies from KLICK patients. Furthermore, knock-down of *POMP* expression in regular cell cultures resulted in decreased amounts of proteasome subunits and an increase in subunit transcripts. Prolonged silencing of *POMP* in cultured cells induced an increase in C/EBP homologous protein expression consistent with an activation of the unfolded protein response and increased endoplasmic reticulum (ER) stress. The combined results indicate that KLICK is caused by reduced levels of POMP, leading to proteasome insufficiency in differentiating keratinocytes. This disturbs terminal epidermal differentiation, presumably by increased ER stress and incomplete filaggrin processing. Our findings underline a critical role for the proteasome in human epidermal differentiation and suggest that tissue constructs with siRNA induced POMP insufficiency can serve as a model for KLICK genodermatosis *in vitro*.

POSTERS

P01.01
The factors associated with the structure of the public attitude toward the genome research by the latent class analysis in Japan

Z. Yamagata[1], *T. Maeda*[2], *K. Muto*[3], *A. Nagai*[1], *A. Tamakoshi*[4], *I. Ishiyama*[5];
[1]*University of Yamanashi, Yamanashi, Japan,* [2]*The Institute of Statistical Mathematics, Tokyo, Japan,* [3]*The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [4]*Aichi Medical University, Aichi, Japan,* [5]*Teikyo-Gakuen Junior College, Yamanashi, Japan.*

The purpose of this study was to clarify the factors associated with the structure of the public attitude toward the genome research by the latent class analysis. The participants of the national wide surveys on the attitude toward the genome research were comprised of 4,000 people (age, 20-69) in 2005 and in 2009, selected from the Japanese general population by using the two-step stratified random sampling method. Five clusters ("Group of aggressive promotion", "Group of passive support", "Group not making judgment", "Group making prudent judgment", "Group not interested in genome".)were assumed as an explanation model of six variables related to the knowledge of genome and attitudes toward genomic research promotion about three themes; basic genome research, genome research related to agriculture and medicine at the survey in 2005. These clusters are associated with academic background, socioeconomic status, to donate to their blood for genome research, interest of science, to want to genome lectures. These factors become the basis of genome research outreach programs.

P01.02
Genetic causes of pervasive developmental disorders

G. C. Cozaru, *A. C. Papari;*
Andrei Şaguna University, Constanta, Romania.

The pervasive developmental disorders (PDDs), or autism spectrum disorders (ASD), range from a severe form, called autistic disorder, to a milder form, Asperger syndrome.
This paper will focus on classic autism and Asperger syndrome, intending to review the current understanding of the etiologies and the multiple pathogenetic pathways that are likely to lead to the autistic phenotype. Like mental retardation, autism is likely to be caused by many different genetic mechanisms and genes rather than a single, or few, major genes or environmental effects. Applying routine genetic testing in clinical (CLIA-certified) diagnostic laboratories it's possible to identify the specific etiology and recurrence risk in 10% to 15% of autism cases and is clinically indicated for any child with autism.
In this study we report 5 cases with different genetic syndromes in which ASD has been described as one of the possible manifestations: Down syndrome, 22q13 deletion, ,,cri du chat" syndrome - 5p15 deletion, Cornelia de Lange syndrome, Sotos syndrome.
Conclusions: The etiologies of ASD are complex and presence of a wide variety cytogenetic abnormalities are providing us with extremely valuable information about the role played by genetics in autism and collaboration with psychiatrists. Such recognition and understanding will help clinicians implement syndrome-specific treatments of patients identified with a genetic cause of autism spectrum disorder. Early identification of this genetic disorder is critical not only to the individual patient but for the entire family.

P01.03
Assessment of Assisted Reproductive Technology and its associated risk with Autism Spectral Disorder in Indian population

M. P. Mamidala, *C. Rahul, N. Rajesh, V. Rajesh;*
Birla Institute of Science and Technology, Pilani-Hyderabad Campus, Hyderabad, India.

Autism Spectral Disorders are hypothesized to be on a rise across the globe and developing countries like India are no exceptions. According to unconfirmed estimates there are about 1.7 million affected individuals in India. Increased globalisation and changing socio- economical development seen in last two decades have led to changing lifestyles and increased exposure to various risk factors of Autism Spectral Disorder.
In India, metropolitan cities like Chennai, Hyderabad etc. are showing an increased incidence of stress related disorders like Thyroid malfunction, Polycystic Ovarian Disease, infertility etc., and hence assisted reproduction is on the rise among the young urban population. Though similar indications are available in other countries, the suspected association between increased rate of Assisted Reproduction and Autism Spectral Disorder in India needs to be established.
To explore this link, a questionnaire based case-control cohort study was conducted in Indian Autistic population and preliminary results indicate that ART cases represented 8-10% of the autistic subjects analysed. This is the first report from Indian population indicating the link between Assisted Reproduction and Autism Spectral Disorder.

P01.04
Mutation analysis of familial NF1 pedigrees with multiple affected individuals

Y. Tunca[1], *S. Celik*[2], *F. Tangi*[2], *C. Oktenli*[3], *M. Upadhyaya*[4];
[1]*GATA, Gulhane Military Medical Faculty, Ankara, Turkey,* [2]*GATA, Gulhane Military Medical Faculty, Istanbul, Turkey,* [3]*Department of Internal Medicine, Anadolu Medical Center,, Kocaeli, Turkey,* [4]*Institute of Medical Genetics, Cardiff University, Heath Park Campus,, Cardiff, United Kingdom.*

Neurofibromatosis is the one of the most common autosomal dominant inherited disorders that occurs 1 in 3500 live births. The penetrance of NF1 is virtually 100 %. NF1 is characterized by multiple cafe-au-lait spots, cutaneous or subcutaneous neurofibromas, plexiform neuromas, axillary or inguinal freckling, optic gliomas, and iris Lisch nodules. Here we present two families with multiple affected individuals. One of the case was diagnosed as bicytopenia (leukopenia and thrombocytopenia) and splenomegaly. Cases had multiple café-au-lait spots and immobile tumors. Histopathological analysis of tumors diagnosed as neurofibroma. Also ophthalmological examination showed Lisch nodules. Cases are clinically diagnosed as NF1. We performed DNA analysis for family and c2041 C>G p.R681X mutation which is located at exon 13. Second family has six affected individuals, which are diagnosed as NF1 with clinical findings. Also at family history there was two suspicious deaths because of brain tumor without certain diagnosis. DNA analysis of six individuals revealed c.4084 C>T p.R1362X mutation which is located at exon 23.2. These two mutations are defined before at literature. Molecular diagnosis of NF1 is challenging and expensive, but DNA analysis are required for these kind of families which have multiple affected individuals for genetic counseling and further prenatal diagnosis.

P01.05
The participation of minors in biobank research: reflections and recommendations

K. Hens, K. Dierickx, ***G. Christenhusz****;*
Centre for Biomedical Ethics and Law, Leuven, Belgium.

The participation of minors in biobank research poses specific ethical questions that are not analogous to those raised by the participation of adults. Specifically, issues regarding parental consent, assent, the question of minimal risk and benefit and the return of individual research results to parents and minors need in depth reflection. For example, should parents be given the opportunity to consent to each possible genetic research on the samples of their children, or should they only be allowed to give specific consent? At which age is a child able to understand genetic research on his or her sample and/or assent to such research? What, if any, risks do children face when they participate in biobank research? Should such research specifically benefit children? Do parents have the right to access all genetic data that are generated by the research? Do researchers have a duty to return individual results that may be of potential health benefit to the child? We have finished a three year project investigating these issues. This project involved reviews, empirical research to query the opinion of lay people and professionals, theoretical reflections and recommendations. In this paper we shall present our findings and especially focus on the recommendations that were the conclusion of the investigation.

P01.06
BRIF: Bio-resource Research Impact Factor. Towards a working tool to promote and recognise sharing of biological samples and associated data.

*L. Mabile[1], **A. Cambon-Thomsen**[1], o. the BRIF Working Group[2];*
[1]INSERM, Toulouse, France, [2]Gen2Phen Knowledge Centre, University of Leicester, Leicester, United Kingdom.

A bio-resource can be a database, a biobank, a set of bioinformatics software tools etc. As part of the work on incentivisation to construct, to share and to use bio-resources, the concept of a Bio-resource Research Impact Factor (BRIF) has been introduced. The concept relies on a quantitative parameter for bio-resource use, similar to the Impact Factor for publications. Such a BRIF would make it possible to document: 1. the quantitative use of a bio-resource, 2. the quality and the importance of research results involving it, and 3. the scientific and management efforts of those who set up and made available a valid bio-resource. A working group has been set up towards the creation of this BRIF, starting with an online forum http://www.gen2phen.org/groups/brif-bio-resource-impact-factor in EU projects. The work addresses several steps: 1. Creating a bio-resource unique identifier, or digital ID; 2. Standardising bio-resource acknowledgement in papers; 3. Cataloguing bio-resource data access and sharing policies; 4. Identifying the other factors to take into account when calculating the Impact Factor; 5. Prototype testing, involving volunteer bio-resources and the help of journal editors. Such a system could be used to rationally evaluate bio-resource activities over time. Such a system could be used to rationally evaluate bio-resource activities over time. Specificities in data sharing versus biological samples have to be considered. Also, if taken into account in assessing researchers/contributors professional activity, the use of BRIF would probably promote both quality and sharing of Bio-resources and contribute to harmonising sharing policies.

P01.07
Cafe for Routine Genetic Data Exchange

O. Lancaster[1], *D. Atlan[2], R. Dalgleish[1], R. K. Hastings[1], G. A. Thorisson[1], A. J. Brookes[1];*
[1]University of Leicester, Leicester, United Kingdom, [2]Phenosystems SA, Lillois, Belgium.

Diagnostics laboratories assess DNA samples from many patients with various inherited disorders, producing a wealth of data on the genetic basis of disease. Unfortunately, those data are not usually shared with others. To address this deficiency, a novel system has been constructed that facilitates the discovery and controlled transfer of diagnostic laboratory data to the wider community, via an internet-based 'Café for Routine Genetic data Exchange' (Café RouGE http://www.caferouge.org/).

Actually, diagnostic laboratories are not reluctant to release their data, but merely face practical obstacles: First, their personnel do not have time nor funding to manually submit data to internet depositories such as Locus Specific databases (LSDBs). Second, they would receive no recognition or reward for releasing their data, giving them no incentive. Café RouGE takes account of these real-world obstacles and the needs of diverse LSDBs and aims to minimize the effort required to publish variant data by:

a) Endowing data analysis tools used by diagnostic laboratories with a 'data submission' function that automatically pushes processed data onto the internet

b) Producing a single internet depot (café) to receive and display the existence of these data, with options for controlled download by diverse third parties.

A modified version of the Gensearch sequence analysis package (PhenoSystems SA) now offers this submission functionality, and other tool providers are encouraged to do likewise. Several hundred mutations per month are now released by users of the Gensearch tool alone.

GEN2PHEN is funded by the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement 200754.

P01.08
BRCA1 mutation carriers self-reported levels of anxiety, depression, quality of life> 1 year after genetic testing.

I. Rønning[1], *H. Vetti[1], K. Nordin[2], C. Bjorvatn[1,2];*
[1]Western Norway Familial Center, Haukeland University Hospital, Bergen, Norway, [2]Department of Public Health and Primary Health care, University of Bergen, Bergen, Norway.

Background: Genetic testing for hereditary cancer is expected to involve an increasing number of individuals in the years to come due to the rapid development in molecular genetics. The main aim of this cross-sectional study was to investigate the long-term psychological effect of being a BRCA1 mutation carrier and compare this to a matched normal population. Secondly, we wanted to explore if losing a close relative in childhood due to cancer or being affected by cancer were associated with symptoms of anxiety and depression or the level of health related quality of life.

Method: Of the 100 eligible participants, 78 consented to participate and were included in the study. Questionnaires were sent to them at least one year after a positive BRCA1 test result had been revealed to them.

Result: Compared to the Norwegian general population, participants reported higher level of anxiety and low level of depression. Mutation carriers who experienced losing a close relative in childhood due to cancer reported higher levels of anxiety and depression and lower psychological health (WHOQOL-BREF) compared to those without this experience. There was no significant difference between mutation carriers affected by cancer and those not affected.

Conclusion: The results from the present study show that living with knowledge of being a mutation carrier may affect anxiety and physical health. Those who had lost a close relative due too cancer during childhood seemed to be a more vulnerable group, and may need extra intervention from genetic counsellors.

P01.09
Does time frame matter? Communicating age-related or lifetime risks in breast cancer risk communication

D. R. M. Timmermans[1], *C. J. Van Asperen[2], J. C. Oosterwijk[3], F. H. Menko[1], C. F. Ockhuysen-Vermey[1], L. Claassen[1], L. Henneman[1];*
[1]VU University Medical Center, Amsterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University Medical Center Groningen, Groningen, Netherlands.

Introduction: Many women overestimate their breast cancer risk. Evidence suggests that people fail to adjust their risk perception to account for longer time frames. It has been argued that using narrower time frames (e.g. 10 years) are more appropriate than life time frames. The aim of this study was to compare the effects of presenting risk information on breast cancer in age-related 10 years frames in addition to life time risks on the counselees' understanding and perception of risks, psychological well-being, and intentions regarding breast cancer surveillance.

Methods: In a randomized controlled multicenter intervention trial, unaffected women with a breast cancer family history were recruited. Women received one of two breast cancer risk presentation formats: lifetime risk in frequencies (i.e. X out of 100) (n=63) or life time risks and age-related 10 years risk in frequencies (n=69). Baseline, 2-week and 6-month follow-up measurements were assessed using questionnaires.

Results The added age-related risk led to a more accurate understanding of 10 years breast cancer risk but not of life time risks, and gave women more clarity. The added age-related risk also lowered women's perceived relative risk of getting breast cancer. However, participants evaluated their own risk as less imaginable when expressed as age-related risk compared to life time risk. The addition of age-related risk had no effect on well-being or preventive intentions.

Conclusion: Our results suggest that the addition of age-related risk to life time risk of breast cancer may have an additional value in breast cancer risk counseling.

P01.10***

Comparison of three different formats of breast cancer risk communication: percentages, frequencies and graphical displays

L. Henneman[1], *J. C. Oosterwijk*[2], *C. J. Van Asperen*[3], *F. H. Menko*[1], *C. F. Ockhuysen-Vermey*[1], *L. Claassen*[1], *D. R. M. Timmermans*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]*Leiden University Medical Center, Leiden, Netherlands.*

Introduction: Inaccurate risk perception is a common finding in genetic counseling of women with a breast cancer family history. It is however unclear how risks should best be communicated. It has been suggested that some risk communication formats (e.g. frequencies, graphs) are better than others (e.g. percentages). We compared the effects of three risk presentation formats on the counselees' understanding and perception of risks, psychological well-being, and intentions regarding breast cancer surveillance.

Methods: In a randomized controlled intervention trial, unaffected women with a breast cancer family history referred to three clinical genetic centers in the Netherlands were recruited. Women received one of three breast cancer risk communication formats: lifetime risk in percentages (i.e. breast cancer risk is X%) (n=38), in frequencies (i.e. X out of 100 women will get breast cancer) (n=63) or in frequencies plus graphical display (100x100 human figure icons) (n=91). Baseline, 2-week and 6-month follow-up measurements were assessed using questionnaires.

Results: No differences were found between women who received the percentages and those who received frequencies in terms of cognitive outcomes, psychological well-being and preventive intentions. Neither was there an effect of an added graphical display. In all three groups women were highly satisfied with the risk information provided.

Conclusion: No evidence was found for different effects of percentages or frequencies with or without a graphical display when communicating breast cancer risks in genetic counseling. Methodological and psychological explanations will be discussed.

P01.11

Gender differences in forming intent-to-obtain cancer susceptibility genetic testing - a group-based structural equation modeling approach.

A. Botoseneanu*, V. T. Motoc;*
School of Public Health, Ann Arbor, MI, United States.

Objective: Cancer-susceptibility genetic testing (GT) can advance cancer prevention only if it leads to improvements in current screening behaviors. The gender distribution of breast and prostate cancer genetic risk profiles argues for elucidating gender differences in forming intent-to-obtain GT. We use a theory of reasoned action derived model to test for such differences.

Methods: Cross-sectional analysis of 1,824 US adults. Structural equation modeling tested for gender differences in total/direct/indirect effects of *attitudes* towards GT, *knowledge* about genetic diseases and testing, prior *experience* with GT, and *religious involvement* on intent-to-obtain GT.

Results: 765 men and 1,059 women were surveyed. Despite similar willingness-to-test for curable disorders (77%), men showed higher willingness-to-test for incurable disorders (54% vs. 46% in women). Men were significantly more likely to have had prior experience with GT (7.5% vs. 5.1%). Prior experience with GT had a direct positive effect on intent-to-test among men ($b=0.68$; $p<0.01$), but no effect among women ($p>0.05$). For both genders, attitudes towards GT had a significant direct positive effect on intent-to-test ($b=0.536$ for men; $b=0.391$ for women; $p<0.001$) and individuals with high religious involvement held more negative attitudes towards GT and were less willing to obtain GT ($b=-0.020$ for men; $b=-0.017$ for women; $p<0.05$). The model explained 24% of the variance in intent-to-test among men, but only 12.1% among women.

Conclusion: Significant differences exist between men and women in the pathways to formation of intent-to-obtain GT and underscore the need to refine genetic counseling and outreach to account for gender influences on GT behaviors.

P01.12

Cancer Genetic Counselling in Cyprus: Review of the first six years

V. C. Anastasiadou[1], *E. S. Aristidou*[1], *M. Kotti*[2], *A. Hadjisavvas*[3], *M. Loizou*[3], *Y. Marcou*[4], *E. Kakouri*[4], *D. Papamichael*[4], *T. Delikurt-Tuncalp*[1], *K. Kyriacou*[3];
[1]*Clinical Genetics Clinic, Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [2]*Makarios Medical Center, Nicosia, Cyprus,* [3]*Department of Electron Microscopy and Molecular Pathology, Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [4]*Bank of Cyprus Oncology Centre, Nicosia, Cyprus.*

Cancer Genetic Counselling in Cyprus was established in 2004. Patients are referred based on type of cancer, family history and age of diagnosis. Referred patients are offered counselling appointments to be appropriately informed of the risks, benefits, and limitations prior to decision making for testing. Results are communicated in person and also in a written report while further appointments are scheduled according to the needs of the patients and their families.

During the six years of CCGC's running, more than 450 families with cancer history were seen. The patients were mainly referred by their oncologists. Among these 400 were breast/ovarian cancer families and 49 were colorectal cancer families.

Genetic counselling for cancer predisposition genes was in general well appreciated. Uptake of genetic testing by patients and their family members were diverse and the response to results varied. The aim of this study is to analyze demographic information, the variability within this patient group in terms of diagnosis, and also the reported reasons for uptake or denial of testing as well as other data.

P01.13

The StoryBank: A web-based resource of digital stories to meet the information and support needs of cancer genetics patients

J. Hilgart*, R. Iredale, L. Mundy;*
Cardiff University, Cardiff, United Kingdom.

The Cancer Genetics Service for Wales (CGSW) offers a range of services such as risk assessment, genetic counselling and genetic testing for people with a family history of hereditary cancer. As a result of the life-long nature of genetic conditions, a fundamental challenge is to meet the ongoing information and support needs of these patients. The internet is increasingly being used as a source of health information and is one mechanism through which this challenge can be met. Patients often want to hear from others that have been through a similar experience and digital stories are particularly useful for transmitting this information.

The CGSW Research Team have created an online collection of digital stories from 23 patients living with, or at risk of familial cancer, about their experience of cancer, genetics and their journey through CGSW. Staff from CGSW have also contributed to the *StoryBank* with stories answering questions about the service such as 'What is genetic counselling?' The stories can be freely accessed on the *StoryBank* website www.cancergeneticsstorybank.co.uk

The *StoryBank* is a web-based resource designed to meet the information and support needs of cancer genetics patients, new referrals, and anyone concerned about a family history of cancer. It provides reliable and engaging information and allows patients the opportunity to hear the experiences of other patients. It is hoped that hearing real stories about people's experiences can help those with, or at risk of, cancer and will raise awareness of cancer genetics amongst the public and health professionals.

P01.14

A french regional pilot experiment for multidisciplinary management of patients at risk of inherited cancers

C. Cordier[1,2,3], *D. Lejri*[1,2,3], *C. Kastner*[1,2], *M. Voltzenlogel*[1,2,3], *A. L. Wetzel*[1,3], *L. Haar*[1,2,3], *L. Gilleron*[1,2], *H. Nehme-Schuster*[2], *J. M. Limacher*[3], *J. P. Fricker*[2], ***C. M. Maugard***[1,3];
[1]*University Hospital Strasbourg, Strasbourg, France,* [2]*CRLCC Paul Strauss, Strasbourg, France,* [3]*Hopital Pasteur, General Hospital, Colmar, France.*

Recently, the French national cancer institute (INCA) launched an extramural program, the main goal of which was to integrate, facilitate and improve global risk management for patients at very high risk of cancer, based on their familial history and/or genetic testing result.

Six pilot experiments were supported in six different geographic area of France and received the following mandates : (1) to offer an individualized cancer screening and preventive recommendations

program to at risk patients, using the latest knowledge and individual patient medical history, (2) to coordinate the introduction of the new screening and preventive option procedures in each unit, (3) to insure access to multidisciplinary services, since patients shoud be offered adequate screening strategies and all necessary information and psychological support when prophylactic surgery is discussed and finally, (4) to offer necessary expertise when difficult cases have to be discussed.
Our pilot experiment takes place in the eastern part of France, in Alsace province. We began with the recruitment of a core team dedicated to these new missions comprising : a genetic counselor, an assistant-coordinator, two research assistants and two psychologists. We will present the first steps and will introduce the new tools we have developed to inform patients and specialists of the more recent national recommendation to be applied for follow-up of at risk patients. We will describe how we will assess the compliance to these recommendations of patients and the medical community. Finally, we will discuss issues encountered in the development and maintenance of this program.

P01.15
Do nurses have the requisite competences related to genetics? A systematic review of the evidence.

H. Skirton[1]*, A. O'Connor*[2]*, A. Humphreys*[2]*;*
[1]Faculty of Health, Taunton, United Kingdom, [2]Faculty of Health, Plymouth, United Kingdom.

The expansion of genetic testing in monogenic and complex disorders has increased the need for all healthcare practitioners to develop genetic competences. Nurses are the largest single group of healthcare professionals and core competences for nurses have been described by the European Society of Human Genetics. The aim of this systematic review was to determine the extent to which nurses are achieving the core competences in genetics. We conducted a systematic search of the published scientific literature held in four relevant databases, using a set of key words including nurs*, competen* and genet*. A total of 269 papers were retrieved, of these 11 (reporting 9 studies) fitted the inclusion criteria and were included in the review. The main themes extracted from the data were knowledge, skills, nurses' perception of the relevance of genetics to their roles, confidence and ethical issues. The evidence indicates that while nurses across a range of countries and practice areas perceive genetics to be important to their roles, generally their knowledge of genetics is low, as is their ability to perform basic clinical skills, such as taking a family history or referring to genetic services. This is reflected in nurses' low confidence in their ability to deal with genetics issues concerning their patients. In addition, some nurses have ethical concerns that genetic testing could cause discrimination against patients. It is clear that, despite calls for enhanced genetics education for nurses for over a decade, nurses are not equipped to deal with the genomics era.

P01.16
Consent for the feedback of individual research results in international consortia: Examples from the International Cancer Genome Consortium

S. E. Wallace*;*
Leicester University, Leicester, United Kingdom.

Returning individual research results to participants is an increasingly debated subject. It is suggested that, in order to be returned, findings should be scientifically valid and confirmed, have significant health implications and there should be therapeutic or preventative options available. However, the process by which these findings will be communicated will necessarily be different depending on the context of the research. Individual research projects are able to rely on available institutional guidance. Consortia whose members are all located in one country may need to deal with different institutional procedures, but will also have national law and regulations to guide their actions. International consortia face the additional problem of having projects that represent different legal, regulatory and cultural requirements for different aspects of the research process, including returning individual research results. Therefore, how should an international consortium deal with this pressing issue? The International Cancer Genome Consortium has created a policy where the consortium itself will not return results, but recognises that local member projects may choose or be required to return results. Model consent language has been created by the ICGC to assist projects as well as other researchers. Sample language from existing ICGC projects shows how the model consent has been adapted to suit local needs as well as those of the ICGC. As more international consortia are created, others may learn from the ICGC experience.

P01.17
Teaching counseling to students

A. Gugu[1]*, L. Bohiltea*[2]*, R. Dragotoiu*[2]*;*
[1]German Goethe College, Bucharest, Romania, [2]Medical and Pharmacy University "Carol Davila", Bucharest, Romania.

The intent of the present study is to continue researching whether ethical issues need to be learned for genetic counseling or whether they are already one of the human mind's perspectives for making moral decisions. Embedded in human behavioural patterns, ethical or moral principles look as if they were *inborn*, but it appears that that usually people only get alerted or react when their socially *acquired* ethical or moral rules and values are somehow out of balance compared to those of the surrounding world. If counseling is nothing more than exercising one's own moral concepts, are medical students gaining new ethical principles during their genetic training or are they just consolidating their previous opinions?
The target group in this study consisted of first year medical students who originate from other countries beside Romania. Their social, educational and moral backgrounds differ within the investigated group. To eliminate biases identified in a similar previous study, already during the first practical an article from the specialized literature was read by students and then they wrote down their opinions. The same questions were also answered at the end of their training in medical genetics, the changes of their views being discussed, if any. These new data are compared to those analyzed and presented last year, when only Romanian first year medical students read the same article and answered the same questionnaire.
Increased understanding of the students' views on moral issues can help organizing the teaching process of genetic counseling.

P01.18
Clinical experiences of genetic counselors ordering CYP 2D6 genetic testing for tamoxifen therapy in breast cancer

L. A. Johnson*;*
Charite Universitatmedizin, Berlin, Germany.

Personalized medicine is a field growing in both interest and practice. In terms of breast cancer therapy, genotyping of *CYP2D6* exists to determine a patient's tamoxifen metabolism. Despite the high incidence of breast cancer in the United States, the frequency with which tamoxifen is prescribed for treatment, and the shift towards personalized medicine, no data exists of the frequency of ordering CYP 2D6 genotyping in a genetic counseling setting, or the barriers that are faced when ordering the test. The purpose of this study was to identify both the frequency of genetic counselors ordering CYP 2D6 genotyping and the barriers that they faced - both experienced and perceived. An online survey was distributed over the NSGC Cancer SIG Listserv. Thirteen percent (n = 6) of respondents had ordered CYP 2D6 genotyping for a patient. Sixty-five percent (n = 30) of respondents provided information regarding barriers they faced when ordering the test, including uncertainty of clinical utility (77%), not my role/role of the oncologist (60%), unfamiliarity with the test (40%), recommendations of professional societies (40%), and lack of impact on patient's medical management (20%). Literature suggests that personalized medicine is the future of oncology; however this study found that genetic counselors have little experience with CYP 2D6 testing.

P01.19**
Cystic Fibrosis carrier screening: customer satisfaction study

L. Ditta*, S. Egiziano, C. Salbe, M. Mattiuzzo, L. Tognetto, A. Brugnoli, G. Romagnosi, M. Gion, L. Bartoloni;*
ULSS12 Veneziana, Dpt Clinical Pathology, Venezia, Italy.

We have been performing preconceptional identification of Cystic Fibrosis (CF) heterozygotes since 2001. 13168 subjects were analysed and 400 carriers found.
We refined the distribution of the different CFTR mutations in our population, defining a more sensitive and less expensive mutation

panel. To assess the impact of this test on the carriers, we performed 100 phone interviews. Even if the couples were followed by gynecologists and family doctors and received an informative leaflet and a written report, the majority of the carriers didn't know what CF was and what a carrier status meant. The majority of the women were prescribed the test during the pregnancy and not before, and there isn't an agreed protocol for testing (both members at the same time or one member first). Only 39% of the carriers decided to have a second level test for their partner, and the 12% of them got a positive response too. This five couples were not influenced in their reproductive choices by the positive test, and asked for a CF pre-natal test for all their pregnancies, with no double heterozygote babies to date. The 61% of carriers that did not screen the partner, did not report the birth of CF babies. Even if the interviewed carriers were happy with the test and suggest to their friends and family to be tested, the results of the questionnaire forced us to change the way we deliver the report and to improve the dissemination of informations among the physicians and the public.

P01.20

Genetic counseling in phenylketonuria (PKU) and cystic fibrosis (CF) patient's parents

V. L. Izhevskaya[1], *E. A. Borzov*[1], *L. Y. Ivanova*[2], *I. V. Zhuravleva*[2], *E. K. Ginter*[1]; [1]*Research centre for medical genetics, Moscow, Russian Federation,* [2]*Institute of Sociology of Russian Academy of Sciences, Moscow, Russian Federation.*

Mandatory newborn screening for PKU is spent in Russia since 90th years of XX century, and for CF since 2006. To estimate patient's parents opinion concerning different aspects of genetic services we have spent questioning of 187 PKU and 93 CF patient's parents. PKU patient's parents more often have learnt about the hereditary nature of their child disease from geneticist than CF patient's parents (75% and 51% respectively, $p<0.05$). CF patient's parents more often than PKU patient's parents have noted that they have not understood the information on repeated genetic risk (6.4% vs 1.2%, $p<0.05$) and incorrectly specified its value (32.0% vs 15.0%, $p<0.05$). However they more often regarded genetic risk as high whereas PKU patient's parents more often - as average ($p<0.05$). Prenatal diagnostics was more acceptable for CF patient's parents (64.9% vs 43.3%,$p<0.05$). Only 1.1 % of respondents have answered that they didn't want to terminate the CF foetus pregnancy, and 23.5% PKU patient's parents have selected the same answer ($p<0.05$).

P01.21

Cystic Fibrosis and Sickle Cell Diseases: Young adults' understanding of newborn screening

M. Noke*, F. Ulph;*

University of Manchester, Manchester, United Kingdom.

Recently implemented Newborn Screening (NBS) for Cystic Fibrosis (CF) and Sickle Cell Diseases (SCD) across the UK raises questions about the public's level of awareness of NBS. Pregnancy is believed to be a difficult time to communicate about NBS, as information is poorly absorbed and negative consequences may arise for parents during pregnancy and after birth. Although awareness of NBS is suggested to reduce the distress associated with screening, research fails to stipulate what information is required or when it should be provided. Furthermore, the extent of lay disease knowledge prior to screening is not established. This study explored i) young adults' existing knowledge of CF, SCD and NBS, ii) how awareness of NBS can be improved for future generations and iii) the feasibility of providing NBS information to a young adult population. Thirty four young adults took part in one of seven focus groups. Thematic analysis was conducted to generate codes and themes at a manifest level. Coupled with numerous misperceptions, students displayed limited knowledge of CF and SCD. Predominantly informed by Biological education, awareness of the severity of SCD was typically underestimated. Participants dismissed wanting further NBS information during young adulthood despite showing preoccupation with personal carrier risk. Lack of knowledge and perceived irrelevance of screening information causes concern about how to prepare the future generation of NBS programme users. The inclusion of carrier statistics, autosomal recessive inheritance and information about the severity of SCD are proposed to improve young adults' interest and understanding of NBS.

P01.22

Looking Forward: Involving young people with Cystic Fibrosis (CF) in developing an educational arts package exploring CF and gene therapy

L. Winters[1,2], *M. E. Palm*[1,2], *L. E. Holmes*[3], *K. W. Southern*[4], *B. Chapman*[5], *L. Morton*[6], *H. Kitchen*[5], *A. Smith*[7], *K. Dack*[1,2], *I. Starling*[1,2];

[1]*Nowgen (A Centre for Genetics in Healthcare), NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom,* [2]*Central Manchester University Hospitals NHS Foundation Trust, The University of Manchester, Manchester, United Kingdom,* [3]*Wellcome Trust, London, United Kingdom,* [4]*School of Reproductive and Developmental Medicine, The University of Liverpool, Liverpool, United Kingdom,* [5]*LimeArt, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [6]*Cystic Fibrosis Trust, Manchester, United Kingdom,* [7]*Science Learning Centre North West, Manchester, United Kingdom.*

Cystic Fibrosis (CF) is one of the most common genetic conditions in the UK, affecting approximately one in 2500 people. Patients with CF cannot meet up in person due to the risk of infection; therefore their opportunities to discuss the latest scientific research related to their condition can be limited. Gene therapy is often heralded as a potential future treatment for CF and first phase clinical trials are underway in the UK. Despite the frequent news headlines reporting continuing progress, the consistent and effective future use of gene therapy remains only a possibility.

The *Looking Forward* project brings young CF patients, clinicians, artists, scientists and educationalists together to develop an online educational arts package exploring CF and gene therapy. Young CF patients are brought together via web-based technologies such as social networking websites and videoconferencing, and will also work in one-to-one sessions with members of the project team. Creative and novel approaches will be used to explore the science behind gene therapy and the personal, social and ethical issues associated with this field of research. The resulting resource will be disseminated to a wide audience, including CF patients and their families, school pupils, teachers and health professionals. Importantly this project will explore methods of participatory engagement with individuals who cannot meet face-to-face (the CF patients).

This project is a unique collaboration that puts young people with CF at the centre of planning an educational arts package to ensure that the resource created is valuable and meaningful.

P01.23

The views of CF patient's parents on prenatal diagnostics

E. K. Ginter[1], *V. L. Izhevskaya*[1], *E. A. Borzov*[1], *L. Y. Ivanova*[2], *I. V. Zhuravleva*[2]; [1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Institute of Sociology of Russian Academy of Sciences, Moscow, Russian Federation.*

To estimated views on prenatal diagnostics (PD) we have spent questioning of and 93 CF patient's parents. Majority of respondents (83%) knew about the PD of CF, and 52 % have received this information from geneticist; 42 % from them answered, that the possibility of PD has changed their reproductive plans. The majority of parents (81 %) believed, that PD of CF is necessary procedure, 78 % believed, that it could solve family problems and for 65 % of them PD is acceptable. More than 50 % of respondents would terminate pregnancy with CF foetus. To reveal factors which can influence the relation to PD Spearmen rank correlations were calculated. Correlation of reproductive plans changing with burden of treatment of CF child, and storing the value of repeated genetic risk was shown. Acceptance of PD was correlated with the age and educational level of woman, whether or not she was referred for genetic counselling, and whether or not she has received an explanation about repeated risk. Correlation of reproductive plans changing and acceptance of PD was shown too.

P01.24**

Dravet syndrome caused by SCN1A mutations, and other genetic causes of epilepsy, with onset after vaccination in infancy

N. E. Verbeek[1], *M. J. A. van Kempen*[1], *F. E. Jansen*[1], *D. Lindhout*[1], *N. van der Maas*[2], *E. H. Brilstra*[1];

[1]*University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*RIVM, Bilthoven, Netherlands.*

Background: Vaccinations are one of the most cost-effective health interventions of the 20th century. Alleged adverse effects, like (a)febrile

seizures, may have great impact on public acceptance of vaccination programs. In this study we investigated the etiology of epilepsy following vaccination, in a national cohort.
Methods: Medical data of 1301 children, reported with convulsion(s) after vaccination in the first two years of life between 1997-2006 to the National Institute for Public Health and Environment in the Netherlands, were re-evaluated. Parents of children with onset of epilepsy within 24 hours after a DTP-IPV-+Hib vaccination, or 5-12 days after MMR-vaccination were re-contacted for follow-up.
Results: Twenty-seven children (2,1%) had epilepsy with onset after vaccination. Follow-up was available for 24. Ten children had a genetic cause: Dravet syndrome due to a SCN1A-mutation (8), epilepsy in females with mental retardation (EFMR) due to a PCDH19-mutation (1) and a submicroscopic 1q deletion (1). A genetic cause was presumed in four others: neuronal migration disorder (2) and autosomal dominantly inherited form of epilepsy (2). Of the remaining 10 children, three had a first or second degree relative with seizures. In one child the cause of the epilepsy was probably viral.
Conclusions: In the majority of cases with epilepsy onset following vaccination in the first two years of life, a genetic cause is detected or suspected (14/24). Early diagnosis of Dravet syndrome and other genetic causes is not only important for treatment and genetic counselling, but also for safety surveillance of vaccination programs.

P01.25
Views of relatives of children with Duchenne muscular dystrophy on their experience of diagnosis and population screening

S. A. Metcalfe[1], *S. H. Wong*[2], *A. D. Archibald*[3], *B. J. McClaren*[3], *A. J. Kornberg*[1,4];
[1]*Murdoch Childrens Research Institute and Dept Paediatrics, The University of Melbourne, Parkville, Vic, Australia,* [2]*Murdoch Childrens Research Institute and The University of Melbourne, Parkville, Vic, Australia,* [3]*Murdoch Childrens Research Institute, Parkville, Vic, Australia,* [4]*Dept of Neurology, Royal Children's Hospital (RCH), Parkville, Vic, Australia.*

Newborn screening (NBS) for Duchenne muscular dystrophy (DMD) is controversial as there is no treatment that can be implemented at birth, and the pros and cons are subject to debate.
We conducted a qualitative study exploring relatives' views on population screening for DMD in Australia. Participants were recruited through the Muscular Dystrophy Association and RCH Neuromuscular Clinic. A total of 13 families were interviewed: 15 parents, 1 grandmother and 2 adult sisters. Parents reported a 1-2 year gap between their first noticing signs of developmental delay and of receiving the DMD diagnosis; all found this delay in diagnosis to be very difficult. Most participants perceived population screening for DMD to be acceptable, preferring infant screening (6 months to 2 years) but generally opposing NBS. Two parents only felt resources would be better used for improving treatment. The main reason against NBS was potential for a negative impact on parental-child relationship. Participants supporting infant screening felt that a diagnosis in infancy would allow: implementation of early interventions; guidance with financial, practical and reproductive decision-making; and greater understanding of the child's struggle with developmental milestones. Some parents supported a more 'targeted' approach to population screening of infants at ≥ 1 year of age, the time at which most started to be concerned with their child's development. Based on these and our preliminary audit data (showing a median age of 5 years at testing for 70 boys [<18yr] in the 2005-2009 period), we are currently developing various models of offering population screening.

P01.26***
Genetic counsellor education and professional standing in 17 European countries

C. Cordier[1], *U. Hösterey Ugander*[2], *D. Lambert*[3], *M. Voelckel*[4], *H. Skirton*[5];
[1]*University Hospital of Strasbourg, Strasbourg, France,* [2]*Klinisk genetik, Göteborg, Sweden,* [3]*Children's University Hospital, Dublin, Ireland,* [4]*Timone's Hospital, Marseille, France,* [5]*Faculty of health, University of Plymouth, Tauton, United Kingdom.*

Quality genetic healthcare services should be available throughout Europe. However, due to enhanced diagnostic and genetic testing options, the pressure on genetic counselling services has increased. Appropriately trained genetic counsellors and genetic nurses can offer clinical care for patients seeking information or testing for a wide range of genetic conditions and the European Society of Human Genetics is making efforts to set up a system of accreditation for genetic counsellors, to ensure safe practice. We undertook a descriptive, cross-sectional survey to obtain baseline data on the role, education and practice of genetic counsellors and nurses in European countries. To collect the data, we approached a number of key informants (leaders in national genetics organisations or experienced practitioners) to complete an online
survey, reporting on the situation in their own country. Twenty-eight practitioners responded, providing data from 17 European countries. The findings indicate huge variation in genetic counsellor numbers, roles and education across Europe. In United Kingdom and the Netherlands there are more than 4 counsellors per million population, in five countries there is less than one counsellor per million, while in Turkey, Czech Republic and Germany there are no counsellors. There are specific educational programmes for genetic counsellors in seven countries but only France has a specific governing legal framework for genetic counsellors. We will present these and other data to demonstrate the disparity in approaches to the education and use of genetic counsellors across Europe. This study underpins the need for a coherent European approach to accreditation of counsellors.

P01.27
Deficiency of genetics standards for secondary education in the United States

M. Dougherty[1], *C. Pleasants*[1], *L. Solow*[2], *A. Wong*[1], *H. Zhang*[1];
[1]*American Society of Human Genetics, Bethesda, MD, United States,* [2]*Wesleyan University, Middletown, CT, United States.*

Recent changes in federal oversight of science education in the U.S. have imposed testing and accountability requirements at the national level through the No Child Left Behind Act (NCLB). Implementation of NCLB relies heavily on learning outcomes, or "standards." Those standards, in turn, drive curriculum and instruction. However, unlike many European countries where the science curricula are also national, in the U.S. curriculum is established at the state and local levels. Given the centrality of standards to teaching and learning, we investigated the quality of life science/biology standards with respect to genetics for all 50 states and the District of Columbia using core concepts developed by The American Society of Human Genetics as normative benchmarks. Our results indicate that the states' genetics standards, in general, are poor, with more than 85 percent of states receiving overall scores of 'inadequate'. In particular, the standards in virtually every state have failed to keep pace with changes in the discipline as it has become genomic in scope, omitting concepts related to genetic complexity, the importance of environment to phenotypic variation, differential gene expression, and the differences between inherited and somatic genetic disease. If the genetics standards (and, by inference, the curriculum) are not improved, the deficiencies we identified may adversely affect genetics instruction and learning, the preparation of future genetics researchers, and the genetic literacy of the U.S. citizenry as medicine becomes more informed by genomics.

P01.28
Enhancing knowledge about modern genetic medicine amongst secondary school students and their teachers in the UK

K. Dack[1], *P. Finegold*[2], *L. E. Holmes*[1], *I. Starling*[1], *L. Winters*[1], *M. E. Palm*[1], *A. Hall*[3], *J. Worthington*[1], *J. Harris*[1], *A. P. Read*[1], *D. Donnai*[1], *H. R. Middleton-Price*[1];
[1]*Nowgen (A Centre for Genetics in Healthcare), NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom,* [2]*Isinglass Consultancy Ltd, London, United Kingdom,* [3]*The Nuffield Foundation, London, United Kingdom.*

The *Nowgen Schools Genomics Programme* aims to change the way that genetics is taught in UK secondary schools. This three-year programme started in July 2009, funded by the Wellcome Trust, and has made significant progress to date. The multidisciplinary team use a range of approaches to help equip young people to assess the real potential of genomics, and to make informed decisions about future healthcare. This paper highlights three successful elements of the programme.
A series of broadcast educational films have been produced to enhance school science lessons and promote awareness of genetic medicine amongst teachers. They feature researchers explaining their

investigations on the role of genes in complex diseases. The films reflect many areas of uncertainty and the great challenges involved. Personal accounts are also given by some patients, who describe the real impact of the conditions. See films at: www.teachers.tv/series/genetics-and-medicine.
Two events were run with 25 researchers working with small groups of school students (aged 16 and 17) to give them a unique insight into the world of research. The students met researchers in their laboratories and found out about latest technologies and methods used in genetics and genomics research. Students also spent part of the day considering the wider implications of genetics research and bioethics.
One of the most important achievements of this work programme has been its influence on genetics taught in schools in England and Scotland. The project team has worked closely with curriculum developers and made a significance impact on the new school curricula.

P01.29
Nowgen's professional training courses in bioinformatics

T. E. Hancocks[1,2,3], *A. C. Davies*[1,4], *A. Devereau*[3], *A. Brass*[4], *D. Donnai*[1,2], *H. R. Middleton-Price*[1,4];
[1]*Nowgen A Centre for Genetics in Healthcare, Manchester, United Kingdom,* [2]*Central Manchester and Manchester University Hospitals NHS Trust, Manchester, United Kingdom,* [3]*The National Genetics Reference Laboratory, Manchester, United Kingdom,* [4]*The University of Manchester, Manchester, United Kingdom.*

Nowgen - A Centre for Genetics in Healthcare develops and delivers an exciting portfolio of training courses for academics, health and industry professionals. Nowgen's portfolio of training courses covers a wide range of topics including: ethical and social aspects of genetic research, pharmacogenetics, cancer, molecular biology next generation sequencing and bioinformatics.
Modernising Scientific Careers (MSC), led by the Chief Scientific Officer at the Department of Health, is a key programme designed to re-model career pathways for healthcare scientists. Nowgen with colleagues at NW e-health in The University of Manchester, the National Genetics Reference Laboratory (NGRL), Manchester, alongside the professional bodies' bioinformatics working group, are developing the MSC bioinformatics curriculum, in particular for genetics trainees and the wider life sciences MSC programme.
In addition, together with the NGRL and NW e-health, we are delivering a programme of bioinformatics training for healthcare practitioners and scientists in genetics, including: short bioinformatics courses for cytogeneticists, molecular geneticists and clinical geneticists, and the development of a distance learning module to complement the current short bioinformatics course for scientists.
We are also delivering next generation sequencing bioinformatics training for researchers, and clinical and industry based scientists: *Next generation sequencing bioinformatics* will be held on 14 June, 2011. This course is being delivered in collaboration with Genomatix, Life Technologies, Roche and Illumina.
For further information on Nowgen's bioinformatics courses contact: Tom.hancocks@cmft.nhs.uk

P01.30
Geographical origin and genetic isolation in southern Morocco

L. SBII*, M. LATIFI, H. HAMI, D. BENALI, A. MOKHTARI, A. SOULAYMANI;*
university Ibn Tofail fac Scienes Kenitra Maroc, Kenitra, Morocco.

The study of the endogamy provides information about the repartition, the structure and the heterogeneity of the genetic heritage of populations.
The main aim of this study is the evaluation of the level of geographical endogamy in the population of Souss-Massa-Draa in south of Morocco. This work consists in a prospective survey of 277 families sampled at random from October 2005 until April 2007. From survey's data, the choice of the spouse is studied according to the origin and the place of birth of the husband and the wife in the generation of the couples and in their parents' generation.
The results clearly showed tendency of couples to the geographical endogamy. In deed, in 83% of studied couples, the spouses chose each other from the same origin whereas in parents' generation, the choice of common origin represented 95%. Moreover, the intergenerational comparison of measured endogamy rates gave the same degree of genetic isolation for both studied generations ($p>0.05$).
In comparison to other results obtained in other regions of morocco, the region of Souss-Massa-Draa is considered to be closed.

P01.31
Break oder continuity? Human genetics in Germany after 1945.

H. I. Petermann*;*
Institute for Ethics, History and Theory of Medicine, Muenster, Germany.

In 1945 Human Genetics was not established at German universities and efforts were made to change this. After 1933 founded institutes for 'racial hygiene' or 'human heredity' did no longer exist. Therefore well-known people in the field of Human Genetics could carry on their research: 1946 Fritz Lenz in Goettingen, 1948 Wolfgang Lehmann in Kiel und 1951 Otmar von Verschuer in Muenster, in neurologic and psychiatric research supported by Gerhard Koch. The number of institutes increased up to the year 1980 to 24.
Those named Human Genetics can be called the **Pre-War-Generation**. They have in common their relationship to the *Kaiser-Wilhelm-Institute for Anthropology, Human Heredity and Eugenics*, as director (Verschuer), members (Lenz, Becker, Lehmann) or guest (Koch).
• Because of lack of scientists after 1945 the Pre-war-generation got a second chance. They continued with their research on 'old ideas'.
In 1960 the *Wissenschaftsrat* (German Science Council) stated that new professorial chairs at universities should only be for fields that were still in evolution. In medicine a chair for Genetics at every Medical faculty was regarded necessary, replenished by a chair for anthropology.
Right afterwards Helmut Baitsch was appointed professor in Freiburg (1961), Widukind Lenz in Hamburg (1961) und Friedrich Vogel in Heidelberg (1962). Those belong to the **Post-War-Generation** of German Human Genetists. They set the stimulus for the development and professionalization of Human Genetics in Germany. The institutionalisation was supported by public policy.
• The break came around 1960. The Post-war-Generation established Human Genetics at German universities.

P01.32
New Bioethics Law in France regarding human genetics: evolution, revolution or stagnation?

E. Rial-Sebbag[1,2], *S. Julia*[3,4,5], *A. M. Duguet*[3,4,6], *A. Cambon-Thomsen*[3,4,1];
[1]*Plateforme «Génétique et société» Genotoul, Toulouse, France,* [2]*Université de Toulouse, Toulouse, France,* [3]*Inserm, U1027, Toulouse, France,* [4]*Université de Toulouse, Paul Sabatier Toulouse 3, Toulouse, France,* [5]*Medical genetics department, University hospital, Toulouse, France,* [6]*University hospital, Toulouse, France.*

France is in the process of revising its bioethics law 5 years after its last revision (2004). This law addresses genetic testing among other aspects (e.g. embryo stem cell research, transplantation, medical aided procreation). In various French legal instruments genetic information is treated apart from other biologic information given its potential misuses and its familial dimension. The proposal for revising the law is focusing on two major points of genetics: communication of the genetic Information and optimisation of laboratory's quality. Based on professional secrecy medical doctors could not inform, on their own decision, family members about genetic characteristics, even if relevant for them. New procedures to allow medical doctors to disclose such information to family members are proposed; liability incurred in case of non transmission of the information and the role of patients associations to deliver relevant information are underlined. Although provisions on quality aspects in a bioethics law can be discussed, they aim to protect people through a high quality of laboratory tests and analyses performed, with regards to direct to consumer genetic tests on internet. A key role will be devoted to the "Agence de la Biomédecine" for assessing quality of laboratories and delivering information regarding such tests. Many other aspects have been discussed in the preparatory debates to the revision, such as consent issues (for deceased people) or biobanks and are absent from the proposal. However these issues are among the most problematic in research and practice. We will discuss the consequences of this lack of regulation.

P01.33
The Not So „Incidental“ Research Results

B. Knoppers;
McGill University, Montreal, QC, Canada.

Research itself has always been understood as the search for generalizable knowledge and not concerned with the individual per se. Today, the ability to perform whole-genome sequencing (WGS) at a fraction of what it used to cost is about to change the “no returns” policy of both longitudinal, population studies and some disease-specific cohorts. Moreover, as researchers begin to access such population biobanks for disease-specific studies using (WGS) or, when begin using WGS in their own clinical research, the concept of “incidental” findings (ie. unforeseen and unrelated to the disease under study) may also be challenged, (if not become obsolete), as the whole genome of a person is exposed. The classic duo of returning only those results with scientific validity and clinical utility is no longer a bulwark to refusal to communicate when ethics guidance requires that any results with “significant welfare implications for the participant, whether health-related, psychological or social” be returned. This raises the issue of which results exactly should be returned, when, by whom, and, to whom (if at all).

Unless the delineation of responsibilities is clarified, it will be health professionals and researchers who may be the most “at-risk” from incidental findings. Indeed, the no-returns policy for research results that includes the not so “incidental” result may no longer be acceptable. How to delimit this seemingly, open-ended avenue of potential professional responsibility and possibly, liability? What are the mechanisms available?

P01.34
Assessing the Assessment Tool: is the ELSI component of ACCE adequate?

C. Chen[1,2,3], *H. Howard*[1];
[1]*Centre for Biomedical Ethics and Law, Katholieke Universiteit Leuven, Leuven, Belgium,* [2]*Section Ethics, Philosophy and History of Medicine, IQ Healthcare, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Dipartimento di Filosofia, Università degli Studi di Filosofia, Università degli Studi di Padova, Padova, Italy.*

Genetic tests for susceptibility to common, complex disorders are proliferating, both in clinical and direct-to-consumer (DTC) settings. However, many of these tests, focusing on genes involved in multifactorial disorders, have limited clinical validity and utility. Due to the nature of the genetic information that these tests provide, coupled with the relative lack of end-user genetic information literacy, it is especially important that the quality of these tests (in both a clinical and DTC setting) be independently evaluated. A handful of tools and initiatives have been proposed to aid in the evaluation task. One such tool is the ACCE model; consisting of 44 questions, designed to assess the quality of a genetic test’s **A**nalytical validity, **C**linical validity, **C**linical utility and also, to address **E**thical, legal and social issues (ELSI) of the test. Of the 44 questions, three have been allocated to examine the ELSI. Although literature exists that discusses the adequacy of the ACC components in ACCE, little has been elaborated for the ELSI questions. As such, we used a literature review and a psychiatric genetic test case study to critically analyse the adequacy of the ELSI component of ACCE. Our analysis identified some potential gaps in the ELSI component of ACCE and we discuss how these may be reduced. The ELSI of genetic tests are particularly challenging and important, given among others, the possibility for the information to be simultaneously individual, familial and communal, and the short- and long-term impact it can have on all these three levels.

P01.35
Ethical dilemmas in predictive testing: challenges for genetic counselors

T. Cruz[1], *L. Velázquez*[1], *J. Sequeiros*[2], ***M. Paneque***[2];
[1]*Center for Research and Rehabilitation of Hereditary Ataxias CIRAH, Holguín, Cuba,* [2]*IBMC-University of Porto, Porto, Portugal.*

Predictive testing protocols are intended to help patients affected with hereditary diseases understand their condition and make informed reproductive choices. However, predictive diagnosis process may expose clinicians, consultands and families to ethical dilemmas that interfere with genetic counseling and the decision making process. We describe ethical dilemmas in a series of four cases involving predictive testing for hereditary ataxias in Cuba and Portugal. Ethical challenges demand a multidisciplinary approach, where genetic counselors, psychologists, social assistants, medical doctors and other health professionals integrate the psychological, socio-familial and medical issues of complex decisions surrounding predictive testing. The clinical scenarios presented and the general discussion could be useful for health professionals involved in predictive programs for hereditary ataxias and other neurodegenerative disorders.

P01.36
Ethics of personal genetic profiling

A. Lucassen[1,2];
[1]*University of Southampton Cancer Sciences Division, Southampton, United Kingdom,* [2]*Nuffield Council on Bioethics, London, United Kingdom.*

Following a two-year inquiry, the Nuffield Council on Bioethics, a UK independent advisory body, has published a report which explores the ethical issues raised by new developments in ‘personalised healthcare’, including commercial personal genetic profiling. The Council found that these services have a number of potential benefits, such as providing reassurance or enabling people to take preventative action. But potential harms were also identified. For example, the test results can be unreliable and difficult to interpret; ‘good’ results may lead to complacency in lifestyle; learning about risk of disease could be upsetting, particularly if no treatments are available; there is potential for misuse of personal genetic information; and people may seek unnecessary further tests or advice from their doctor. However, the number of people using genetic profiling services and whether this is currently leading to any actual harm is not known.

Several ethical values come into play, such as individuals’ ability to pursue their own interests and efforts by the state to reduce harm, and the report explores the extent to which genetic profiling tests really do lead to healthcare becoming more ‘personalised’. On the basis of this, the Council makes a number of recommendations for policy. For example, regulators are urged to request evidence for any claims being made by companies about the clinical value of their tests, and governments are encouraged to provide information on their websites about the risks and benefits of personal genetic profiling, including the relevance for insurance.

P01.37
Are published genomic data free for further uses? Legal and ethical issues in a context of data sharing

A. Pigeon[1,2,3], *G. Chassang*[1,2], *A. Cambon-Thomsen*[1,2];
[1]*Inserm, U1027, Toulouse, France,* [2]*Université de Toulouse, Paul Sabatier Toulouse 3, Toulouse, France,* [3]*Université de Toulouse, Faculté de droit, Centre de droit des affaires, Toulouse, France.*

The use of published information and data for generating electronic databases, such as LSDBs (locus specific databases), for meta-analyses and for new association studies is frequent. Current policies towards data sharing encourage access to and circulation of data. Nevertheless ethical issues are raised regarding informed consent of the person from whom the data were collected. Published, hence publicly available data are not necessarily data free to be used. Limitations given through the consent procedure may exist and the fact that data are published does not erase them. The problem is growing with the rapid technological advancement and more control by the citizens about the use of their data. Those issues are new challenges in the frame of the revision of the EU directive 95/47 on the protection of personal data. We analysed various possible solutions and studied the associated responsibilities of researchers, institutions, editors, ethics committees and data mining scientists. This reflexion led to propose to systematically indicate in the publication itself or as supplementary information possible other uses of data/samples included in the informed consent and other limitations and to ask the editors to consider introducing this in instructions to authors. It would provide useful information to potential users in order for them to decide whether to use the published data or not. It would be respectful of privacy rights and autonomy. Nevertheless it remains limited in cases where the consent is not indicating the possible further uses of data. Other solutions can be proposed in such cases.

P01.38
Secondary use of research data: ENGAGE and BioSHaRE as proof of concept

A. Tassé, *B. Knoppers;*
McGill University, Montreal, QC, Canada.

Biobanking activity is increasingly at the heart of research practice. Access to such resources is of major interest for research since it avoids the limitations of research conducted among smaller number of subjects. Alongside these benefits, however, remain the ethical issues of respect for the autonomy and privacy of research participants, most notably in the context of secondary use of data, i.e. where data is used for purposes falling outside the scope of the consent given by research participants.

The last decade has witnessed the attempt to establish the ethical acceptability of the secondary use of data. It has remained unclear however as when should research accessing biobanks be considered as "primary" vs. "secondary" use, and as to how to apply these criteria in the context of international research consortia such as ENGAGE and BioSHaRE.

The European Network for Genetic and Genomic Epidemiology (ENGAGE) is a research project performing meta-analyses in order to translate the wealth of data emerging from large-scale research in genetic and genomic epidemiology from 23 population cohorts into information relevant to future clinical applications.

The goal of BioSHaRE is to allow researchers to use data pooled from different cohorts and biobank studies, thereby creating sample sizes large enough to investigate questions relating to multifactorial diseases.

In order to determine whether the use of already collected samples and data in international research consortia should be considered as either "primary" or "secondary" use, both the ENGAGE and BioSHaRE consortia will serve as models for our study.

P01.39
Medical ethics and counseling genetic in SMA

A. C. Papari, *G. C. Cozaru;*
Andrei Şaguna University, Constanta, Romania.

Spinal muscular atrophy (SMA) is one of the most common autosomal recessive diseases, affecting approximately 1 in 10,000 live births, and with a carrier frequency of approximately 1 in 50. The SMA phenotype is widely variable, with the severity of symptoms influenced by several genetic factors. Genetic risk assessment is an essential and integral component of SMA genetic testing and impacts genetic counseling both before and after genetic testing is performed.

To better understand the ethical difficulties associated with a condition like SMA, we report a couple where the man was diagnosed with SMA type IV. He has a family history of SMA. Couple was provided information on SMA, including range of severity and test limitations. Parents was requested prenatal diagnosis because they did not accept residual risk.

More, it is almost certain that other father's family members are also carriers of genes mutation. Should the counselor be expected to break confidentiality to inform the at-risk family members of their genetic risk? Comprehensive SMA genetic testing, comprising PCR-RFLP assay, SMN gene dosage analysis and genetic counseling, offers the most complete evaluation of SMA patients and their families at this time. These cases illustrate that SMA testing, like other genetic testing, can lead to complicated scenarios and highlight the importance of genetic counseling for identified SMA carriers. A genetic counselor could help this couple to understand the risk for own children and to develop strategies to accurately inform their family members of their possible risk of SMA without being alarming.

P01.40
Personal genome testing: Characteristics of the test, the disease and the context to clarify the discourse on ethical, legal and societal issues

E. M. Bunnik, *M. H. N. Schermer, A. C. J. W. Janssens;*
Erasmus MC, Rotterdam, Netherlands.

Background: Personal genome tests are currently marketed directly-to-consumer to estimate genetic risks for a range of multifactorial diseases and other traits. These tests have spurred critical discussions of their ethical, legal and societal implications (ELSI), but not all personal genome tests raise the same ELSI. We offer a systematic approach towards questions regarding what ELSI to expect from specific applications, and why.

Methods: Review of the bioethical literature, expert interviews and conceptual analysis.

Results: ELSI may vary with the characteristics of the test, the disease and the context in which testing is offered. For example, tests of limited clinical validity are less likely to be utilized as a basis for discrimination than do those of higher levels of clinical validity. Further, testing for a multitude of diseases simultaneously brings along an unequalled quantity of information, thereby threatening the feasibility of informed consent. Also, testing for psychiatric diseases such as clinical depression, is surrounded by various psychological and ethical sensitivities, which are much less pressing in testing for (most) somatic diseases. A major context characteristic is direct-to-consumer access to personal genome testing, which is associated with ELSI of its own, such as lack of professional medical guidance. We have composed a comprehensive list of characteristics that are of relevance to the ELSI-debate.

Conclusion: In an informed and meaningful ELSI-debate on personal genome testing for multifactorial diseases, consideration of characteristics of the test, disease and the context is indispensable, for these characteristics determine the applicability of ELSI to specific personal genome tests.

P01.41
Patients' experiences and views of DNA testing and familial cascade screening for Familial Hypercholesterolemia (FH): a qualitative study

N. Hallowell[1], *N. Jenkins*[2], *M. Douglas*[3], *J. Lawton*[2];
[1]*Newcastle University, Newcastle upon Tyne, United Kingdom,* [2]*Edinburgh University, Edinburgh, United Kingdom,* [3]*NHS Lothian, Edinburgh, United Kingdom.*

Familial hypercholesterolemia (FH), an autosomal dominant disease, manifests as a disorder of cholesterol metabolism. Early detection and treatment with statins can be effective in reducing morbidity and mortality from CVD. Familial cascade DNA screening for FH mutations is a clinical reality throughout Europe. Questions have been raised about the most efficient and cost-effective way of implementing cascading. The argument for direct (clinician-mediated) versus indirect (patient-mediated) cascading is that the former overcomes patients' reticence about disclosure and thus, maximises the number of relatives approached and captured in the cascade. However, research suggests that family communication about genetic testing takes place without a need for this intervention. Moreover, direct cascading is reliant upon the index patient revealing family contact details, and this may raise issues about confidentiality for some. To date no research has been undertaken on the views of patients involved in indirect cascading. This paper looks at patients' experiences of DNA screening and mediating familial cascade screening. The data were gathered in in-depth interviews with 38 patients who had DNA testing in lipid clinics SE Scotland. 15(39%) were referred for cascade appointments in clinical genetics. Patients appreciate DNA testing being undertaken by known and trusted lipid clinic staff. DNA testing was seen as part of the normal lipid clinic routine. Having a genetics consultation to identify relatives for cascading was perceived as facilitating, and potentially increasing, family communication about FH. Patients expressed a preference for indirect cascading, commenting that it may be less threatening for relatives than unsolicited clinical contact.

P01.42
Conflicts regarding genetic counseling for Fragile X syndrome screening: A Survey of clinical geneticists and genetic counselors in Israel

S. Lieberman, *S. Zukerman, E. Levy-Lahad, G. Altarescu;*
Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel.

Although Fragile X screening has been offered in Israel since 1994, issues related to potential neurological and gynecological symptoms in carriers make counseling for Fragile X different from recessive disorders. We evaluated the attitudes of geneticists regarding genetic counseling given to the women undergoing screening. We performed a self-administered questionnaire including 13 study questions was mailed to all geneticists in Israel. The questions were

related to counseling for women pre and post screening regarding themselves and the affected fetuses (including the risk for Premature Ovarian Insufficiency; FXPOI and Fragile X-Associated Tremor Ataxia Syndrome; FXTAS). Out of a total of 80 geneticists 34 responded with no additional responses on e-mail re-call. There was no clear consensus for 11/13 (85%) presented questions. The most striking differences in opinion were observed for issues regarding FXTAS risk in prescreening counseling sessions ($p<0.05$).This study demonstrates that , there is no consensus on critical variables implying risk for fetus and mother and that counseling practices are dissimilar even in this small cohort of experts. We demonstrated a conflict between the detailed amount of information which should be given prior to the test in order to allow informed decisions and the overload of information which may cause confusion.

P01.43
The use of genealogy databases in genetic health care

V. Stefansdottir[1], *H. Skirton*[2], *O. T. Johansson*[3], *J. J. Jonsson*[1,4];
[1]*Dept. of Genetics and Molecular Medicine, The National University Hospital of Iceland, Reykjavik, Iceland,* [2]*University of Plymouth, Plymouth, United Kingdom,* [3]*Dept. of Medical Oncology, The National University Hospital of Iceland, Reykjavik, Iceland,* [4]*Dept. of Biochemistry and Molecular Biology, Univ. of Iceland, Reykjavik, Iceland.*

Background: The use of electronic genealogical databases could facilitate the construction of accurate and extensive pedigrees in genetic health care. Genealogical databases could be linked to specific disorder databases in order to increase the accuracy of pedigrees and inform the genetic risk assessment.
Aim: Systematic review of the published literature on the use of genealogy databases to construct pedigrees for risk assessments in genetic health care.
Design: A systematic literature search was undertaken using the following 12 combined search terms: “Genealogy database* AND genetic risk AND family history”, “Genealogy database* AND clinical genetics” , “Genealogy Database* AND medical AND family history”, “Cancer registry AND genetic service”, “Cancer registration AND clinical genetics AND genealogy”, “Database* AND family history AND genetic risk assessment”, “Genealogy database* AND cancer registry”, “Database* AND genealogy AND genetics”, “Genealogy OR heraldry AND database”, “Genetic counsel* and clinical genetics AND genealogy” and “Cancer genetic counsel* and genealogy”.
Data sources: EbscoHost, PubMed, Web of Science, Ovid, the Grey literature and reference lists of identified studies.
Results: Of 683 titles identified, one study described experience of using a genealogy database in a cancer registry in support of genetic health care. Two more papers discussed the potential use of genealogy databases. **Conclusions:** Limited published information exists on the use of genealogy databases in genetic health care although numerous such databases exist. This may reflect legal or regulative restrictions based on autonomy or information risk. Studies are needed to address the benefits and drawbacks of using genealogy databases in genetic health care.

P01.44
Genetic testing of children: report of a working party of the British Society for Human Genetics

T. Clancy[1], *A. Lucassen*[2], *J. Montgomery*[3], *A. Clarke*[4], *A. Hall*[5], *A. Fryer*[6], *A. Fenwick*[3], *M. Parker*[7];
[1]*St Mary’s Hospital and University of Manchester, Manchester, United Kingdom,* [2]*University of Southampton and Wessex Clinical Genetics Service, Southampton, United Kingdom,* [3]*University of Southampton, Southampton, United Kingdom,* [4]*University Hospital of Wales, Cardiff, United Kingdom,* [5]*PHG Foundation, Cambridge, United Kingdom,* [6]*Royal Liverpool Children’s Hospital, Liverpool, United Kingdom,* [7]*Oxford University, Oxford, United Kingdom.*

Genetic tests can offer immediate clinical benefits and should be utilised in the same way as any other investigation used to determine the best clinical management of a child. But, genetic tests can also generate information about children’s health in the medium to long term future, rather than about current health problems. Decisions about the optimum time to carry out a genetic test can therefore raise difficult issues for health professionals, for parents and for children and young people themselves. In 1994 a report from the UK’s Clinical Genetics Society recommended that predictive genetic testing was appropriate where a medical intervention was available and would usually be offered during childhood, but that such testing should not generally be undertaken for adult-onset disorders unless there were clear cut and unusual arguments in favour in a particular case. The report concluded that it was important to preserve or maximise children’s future choices where no clear benefits would accrue during childhood. The guidance has recently been reviewed by a working group on behalf of the British Society for Human Genetics, and a new report was published in 2010. This was informed by research, and took into account developments including other guidelines published over the last 15 years. The report includes recommendations about genetic testing of children, an explanation of the legal (in the UK) and clinical rationale for these and case studies to assist professionals in their use of the recommendations.

P01.45
Fourteen year’s experience of genetic counseling for hereditary hearing loss patients in Iran

S. Arzhangi[1], *N. Bazazzadegan*[1], *N. Nikzat*[1], *Z. Fattahi*[1], *M. Moheni*[1], *P. Jamali*[2], *K. Jalalvand*[1], *K. Kahrizi*[1], *H. Najmabadi*[1];
[1]*Genetics Research Center, USWR, Tehran, Islamic Republic of Iran,* [2]*Genetic counseling centre, Shahrood, Islamic Republic of Iran.*

Diagnosis and estimation of recurrence risk are components of a complete genetic evaluation of a child with hereditary hearing loss (HHL). The disease can be classified into syndromic or nonsyndromic forms. The most common pattern of inheritance in HHL is autosomal recessive (AR) with a 25% risk of transmission to the next generation. The aim of this study was to provide more accurate genetic information using in genetic counseling for Iranian HHL families.
Since 1996, genetic counseling has been provided for over 2650 deaf families. Majority of them had 2 and more affected child. Over sixty percent of the families who referred to us had consanguinities marriages. Out of 2650 families, 80% had AR pattern of HHL, 1% AD and X-linked, and the remaining cases were sporadic cases. Nonsyndromic and syndromic forms of HHL account for 79% (n=2094) and 9% (n=238) of families, respectively. Most of the deaf patients had congenital HL (n=2065). The mutation in *GJB2* accounted for overall 16% of the referred families; however, the prevalence of the mutation in this gene significantly varies among different ethnic groups in Iran. In Northwest of Iran the frequency was about 30% while in the East and South was as low as 4%.
We have been able to provide result for 30 to 50% of the referral families depending to ethnic population.
So far, we have provided genetic diagnosis, carrier detection, and recurrence risk estimation for 1500 families to help them in decision making for future pregnancies.

P01.46
The use of iPad in genetic counseling

V. Stefansdottir[1], *H. Skirton*[2], *O. T. Johansson*[3], ***J. J. Jonsson***[1,4];
[1]*Dept. of Genetics and Molecular Medicine, The National University Hospital of Iceland, Reykjavik, Iceland,* [2]*University of Plymouth, Plymouth, United Kingdom,* [3]*Dept. of Medical Oncology, The National University Hospital of Iceland, Reykjavik, Iceland,* [4]*Dept. of Biochemistry and Molecular Biology, Univ. of Iceland, Reykjavik, Iceland., Reykjavik, Iceland.*

Accurate information about genetic aspects of disorders is needed in genetic counseling. To address this need and enable clear and easily understood explanations, professionals in genetic health services have developed a number of educational aids. These aids can be used to inform the counselee of the inheritance pattern, risk to relatives, genetic testing options, symptoms and surveillance. They can also be used as decision aids regarding genetic testing and prevention. Most often these aids are visual; images, booklets, interactive computer-based programs, checklists and CD/DVD´s,
It has been shown that counselees using educational aids before or during genetic counseling session are more likely to remember their risk status, show significant knowledge improvement and are more satisfied with their decisions. However, the use of educational aids has not been shown to benefit the psychosocial aspects of genetic counseling and counselees prefer personal communication.
Recently, touch screen computers such as iPad, have made their way into the medical world. We have introduced the use of iPad in genetic counseling at The National University Hospital of Iceland. With an

iPad the genetic counselor can show the counselee defined packages of information, including small videos, and use the touch screen to draw further images for explanation. The flow of information can be controlled and it is possible to zoom in on images. The use of iPad combines the benefit of personal communication and an educational aid in genetic counseling to improve the overall experience.

P01.47
The medium and the message: Genetic counselling in the direct-to-consumer genetic testing industry

S. E. Kelly[1], *A. Harris*[2], *S. Wyatt*[2,3];
[1]*ESRC Centre for Genomics in Society (Egenis), University of Exeter, Exeter, United Kingdom,* [2]*Maastricht Virtual Knowledge Studio, University of Maastricht, Maastricht, Netherlands,* [3]*e-Humanities Group, Royal Netherlands Academy of Arts & Sciences (KNAW), Amsterdam, Netherlands.*

As part of a larger study of direct-to-consumer genetic testing (DTCGT) for psychiatric disorders, we investigated the role genetic counselling is coming to play in the DTCGT industry, and its implications for how genetic counselling is understood and provided, addressing a common critique of the DTCGT industry (Hudson et al. 2007; Nuffield Council on Bioethics 2010). We performed qualitative analyses of two web-based resources (a sample of DTCGT websites and genetic counselling blogs and forums), to answer the following research questions: with what types of genetic testing products is genetic counselling offered; what forms of genetic counselling are offered; how is genetic counselling represented in terms of function, trust, and expertise; how do genetic counselors discuss genetic counselling in the DTCGT industry? Findings: We identified 21 companies selling genetic tests for psychiatric disorders online. Of these, 15 do not provide genetic counselling (although several provide links to genetic counselling services or recommend genetic counselling). We identified the following types of genetic counselling provision: integrated genetic testing and counselling product; discretionary genetic counselling; genetic counselling for product advice; result interpretation counselling; future health and information strategy counselling. We further consider forms of interaction and information provision (e.g., email, phone); representations of genetic counselling as a profession; and ethical aspects of genetic counselling practice (e.g., privacy, confidentiality). We conclude that both the 'medium' of DTCGT and the 'message' of common genetic polymorphism-based risk assessment have implications for the field of genetic counselling.

P01.48
Informational needs and expectation prior to genetic counselling for hereditary cancer and fulfilment of these needs and expectations

C. Herland[1], *H. Vetti*[1], *K. Nordin*[2], *C. Bjorvatn1*[1,2];
[1]*Western Norway Familial Centre, Haukeland University Hospital, Bergen, Norway, Bergen, Norway,* [2]*Department of Public Health and Primary Health Care, University og Bergen, Norway, Bergen, Norway.*

Background: The fulfilment of counselees' expectations in cancer genetic counselling and how this affects the outcome of counselling have received little attention so far. The aims of the present study was to investigate the informational needs and expectations among counselees prior to their first genetic counselling for hereditary cancer. We investigated also whether these needs and expectations were fulfilled. Furthermore, we explored cancer specific worry, levels of anxiety and levels of depression among the counselees. Lastly, we investigated if there were any relations between fulfilled expectations and levels of anxiety or depression after the counselling.

Methods: One hundred and twenty-eight counselees (response rate 65%) participated in this study. Data were collected both before and after the counselling session. Levels of anxiety and depression were assessed by the Hospital Anxiety and Depression Scale, the level of worry by the Cancer Worry Scale and informational needs and expectations by the Quote-gene ca. .

Result: The majority of counselees were highly satisfied with the extent to which their informational needs and expectations were fulfilled, although some counselees were not satisfied regarding «emotional matters». The mean level of anxiety among the participants decreased after the counselling session. The result also indicates that if needs and expectations were not fulfilled, the counselees reported higher levels of anxiety and depression.

Conclusion: The result reveals that the counselees have high expectation prior to the counselling and these expectations are usually met. In this study,subjects whose expectations were not meet seem to be morevulnerable after the counselling.

P01.49
Recontacting patients: needed, expected or desired? A literature review

S. Jansen, *H. Meijers-Heijboer, L. Henneman, P. J. G. Zwijnenburg;*
VU university medical center, dept. Clinical Genetics, Amsterdam, Netherlands.

Aim: As our insights and knowledge in medical genetics is continuously expanding, recontacting patients as new information becomes available could be desirable. The purpose of this literature review was to establish the extent to which recontacting patients after previous genetic counseling is needed for, expected or desired by patients and recognised by counselors.

Methods: The starting point for the literature review was a Pubmed search using "Duty to Recontact"[MeSH] and using "recontacting"[All Fields] AND ("patients"[MeSH Terms] OR "patients"[All Fields]) and a search in Web of Science® on topic "RECONTACT OR RECONTACTING". The results were sifted by reading the title and (if available) abstract. The referencelists of relevant papers were also included.

Results: A total number of 22 publications, addressing this issue to some extent, were retrieved. There were few attempts to define the legal, ethical and social context of this issue, mostly based on expert opinion. We found two studies describing surveys among clinical geneticists and genetic counselors and three studies investigating patient's or relative's attitudes. The number of participants was 13-61 patients or relatives/study and 58-252 health care professionals/study. The results of most studies show significant variation in outcomes. A comparison between outcomes of the different studies is hampered by the differences in study population and methods.

Conclusion: We provide an overview on the literature on recontacting patients in medical genetics, indicating that this is a relatively under-researched area. Considering our rapidly growing insights and possibilities in medical genetics, future studies are needed.

P01.50
Congenital and genetic disorders in the Eastern Mediterranean Region: Challenges to public health and priorities to address

H. Hamamy[1], *I. Fadhil*[2], *H. Madi*[2];
[1]*Department of Genetic Medicine and Development, Geneva, Switzerland,* [2]*World Health Organization Eastern Mediterranean Regional Office, Cairo, Egypt.*

The Eastern Mediterranean Region (EMR) of the World Health Organization (WHO) includes 22 countries in the Middle East and North Africa that are currently facing major challenges in providing comprehensive and up-to-date community genetic services.

This study directed by WHO Eastern Mediterranean Regional Office (EMRO) reviews available data from EMR countries on the current situation of congenital and genetic disorders. Data on the epidemiologic profile and available services was collected from published literature, from questionnaire sheets sent to Ministries of Health, and from personal experience.

Consanguineous marriage is customary in most EMR communities and intra-familial unions currently account for 20-50% of all marriages, with first cousin unions amounting to 20-30% of all marriages.

Haemoglobinopathies in EMR countries show high population carrier rates of 2-7% for ß-thalassaemia , 2-50% for α-thalassaemia, and 0.3-30% for sickle cell, while G6PD deficiency ranges from 2.5 to 27%. In countries including Oman and UAE, birth rate of Down syndrome amounted to 2/1000 births.

Currently, community genetic services such as newborn screening, premarital carrier screening for thalassemias, prenatal screening, genetic counselling, education and birth defects registries are available in some EMR countries. Such genetic services, however, remain patchy and selective.

The basic strategies needed for implementing community genetic services that depend on a combination of basic public health measures, and the education and involvement of the primary health care network will be discussed.

WHO has a crucial role in helping EMR countries planning and

implementing community genetic services and in encouraging regional and international genetic collaborations.

P01.51
A critical appraisal of the private genetic and pharmacogenomic testing environment in Greece

*A. Sagia[1], D. N. Cooper[2], K. Mitropoulos[3], K. Poulas[1], V. Stathakopoulos[4], **G. P. Patrinos**[1];*
[1]University of Patras,, Patras, Greece, [2]Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom, [3]Golden Helix Institute of Biomedical Research, Athens, Greece, [4]Department of Marketing and Communication, Athens University of Economics and Business, Athens, Greece.

In the post-genomic era, we are witnessing rapid progress in the identification of the molecular basis of human inherited disorders and the elucidation of genotype-phenotype relationships. The rate of progress has been driven not only by the determination and ongoing decipherment of the human genome sequence but also by the advent of new technological developments that have dramatically reduced the costs of genetic analysis. Consequently, a considerable number of genetic testing centers have emerged, both in Europe and the United States, which offer a plethora of different genetic tests. We have performed a nationwide survey of 18 private genetic testing laboratories in Greece to acquire a better understanding of the genetic testing services that these centers provide, specifically the types of genetic test offered, the target groups, marketing channels, costs of analysis and accreditation. Molecular genetic and cytogenetic testing were found to be the predominant types of genetic testing services offered although there is an increasing demand for pharmacogenomic testing. The main target group for private genetic testing laboratories are physicians who are approached via the Internet, through personal contacts from sales representatives, and at scientific conferences. Genetic testing costs are fairly low in Greece. Although the majority of private genetic laboratories either employ or collaborate with a genetic counselor, few of them are accredited for the provision of genetic testing services. This study provides the basis for a critical appraisal of the private genetic testing environment in Greece and provides a model for replication in other European countries.

P01.52
The impact of genetic testing in reproductive medicine: anxiety and distress three and twelve months after disclosure - an index-control study

***F. Vansenne**, M. Goddijn, S. Snijder, B. Redeker, N. J. Leschot, F. van der Veen, P. M. M. Bossuyt, C. A. J. M. de Borgie;*
Academic Medical Center, Amsterdam, Netherlands.

As more and more genetic risk factors for disease are discovered, more genetic tests are offered to patients. None of these tests are properly evaluated for clinical utility, efficacy and psychosocial consequences. In reproductive medicine, couples with recurrent miscarriage (RM) and couples with a man with poor semen quality are karyotyped as part of the diagnostic work-up. We evaluated the psychological impact of receiving a genetic test result in both partners of couples with a genetic abnormality compared to controls.

Methods: Longitudinal prospective index-control study. Participants received 3 questionnaires; just before disclosure of genetic test result, 3 and 12 months after disclosure. Outcome measures were scores on the Becks Depression Inventory (BDI), State-Trait Anxiety Index (STAI) and Impact of Event Scale (IES).

Results: Between 2006-2009, 439 subjects were included. 172 patients from couples with RM (36 indexes, 35 partners, 101 controls), 267 patients from couples with poor semen quality (48 indexes, 42 partners, 177 controls). No differences were found between scores on BDI and STAI between the groups before disclosure or during follow-up. On the IES both indexes and partners had significant higher scores than controls ($p<0.001$). These effects were still present after 1 year follow-up.

Conclusion: Receiving an abnormal genetic test result seems to have negative psychological consequences for both partners of couples with RM or poor semen quality in short and in long term. In the light of ongoing discussions on the efficacy of karyotyping these couples, we need to realise that genetic tests can do harm.

P01.53
Test translation: from a research test to diagnostic test

***P. Pohjola**[1], M. Peippo[2], M. Penttinen[3], K. Elenius[1], H. Kääriäinen[4];*
[1]University of Turku, Institute of Biomedicine, Department of Medical biochemistry and Genetics, Turku, Finland, [2]The Department of Medical Genetics, The Family Federation of Finland, Helsinki, Finland, [3]The Clinical Genetics Unit, Department of Pediatrics, Turku University Central Hospital, Turku, Finland, [4]National Institute of Health and Welfare, Public Health Genomics Unit, Helsinki, Finland.

New molecular genetic methods provide a vast spectrum of tools for detecting various mutations. Every routine diagnostic laboratory has to evaluate which methods can be adopted from the research setting for routine diagnostics and which are the factors that dictate the applicability of a given method in a diagnostic laboratory. In most laboratories, instrumentation is not a limiting factor, but the challenge is to determine the most cost-effective test, taking into consideration the utility of the test for patients.

We have used Sotos syndrome as a model for test translation. The key issue in successful translation was a close collaboration between academic research and diagnostic laboratory, adding to that a close collaboration with a clinical genetics unit, ensuring the up-to-date knowledge in each phase of translation. We have tested altogether 150 Sotos syndrome samples, and detected a mutation in 30% of the samples. Many clinicians meet Sotos patients rarely and, consequently, the test has been mostly used in cases of suspected Sotos syndrome rather than in confirming the clinical diagnosis. Finding the mutation is valuable for the patient/family, while the value of negative result is less clear and other differential diagnostic diagnoses should be considered. The Sotos syndrome test has been a suitable model for test translation, because the genetic background and genotype-phenotype correlation are well characterised. However, in syndromes where mutational background or genotype-phenotype correlation are less clear, the test for the patients and diagnostic laboratory may remain of low utility, and test translation should be carefully considered.

P01.54
Direct-to-consumer genetic testing for non-health purposes in East Asia

***K. Muto**, Y. Inoue, H. Hong;*
The University of Tokyo, Tokyo, Japan.

Background: In 2010, DTC (direct-to-consumer) genetic testing for health purposes have been featured in Europe for its regulation or alert to the public by the ESHG and the HGC in the UK. In contrast, several Shanghai-based companies stated to advertise in Japan to sell DTC genetic tests for non-health purposes, such as tests advertised to identify genes related to an individual's talent, character traits and aptitude. Regulation of DTC genetic tests for non-health purposes have rarely discussed before.

Purpose and methods: To address broad ethical, legal and social implications arising from such tests, we've conducted 1) systematic literature review and policy analysis towards genetic testing in Asian countries including Japan, South Korea, Taiwan and China, 2) questionnaire survey to the Japanese general public to know their recognition and interests towards DTC tests.

Results: Advertisement is commonly observed in East Asia though some of the tests have been banned in South Korea. Our survey shows that 1.3% (47) of respondents has purchased DTC genetic tests, and 72.9% (2,627) of them hasn't recognized such tests. They show higher interests towards tests for health purposes (25.3-53.4%) than non-health purposes (8.2%-21.9%). Younger generation shows higher interests toward DTC genetic tests for their children.

Discussions: The trend of our survey shows the same trend from the survey conducted in 2007. Many parents are deeply concerned about providing education for their children and it's difficult to intervention parental decision to purchase such tests. We should more actively consider issues particularly arisen from such tests.

P01.55
EuroGentest Clinical Utility Gene Cards - guidelines for the clinically validated use of genetic testing

A. Dierking, *J. Schmidtke;*
Institute of Human Genetics, Hannover Medical School, Hannover, Germany.

The Additional Protocol to the Convention of Human Rights and Biomedicine, Concerning Genetic Testing for Health Purpose (Article 6) declares that clinical utility is an essential criterion for deciding to offer a genetic test to a person. Clinical utility refers to the ability of a genetic test to significantly affect the clinical setting and patient outcome. In order to assess this information and make it available to clinicians, geneticists, referrers, service providers and payers, EuroGentest, an EU-funded Network of Excellence, designed the Clinical Utility Gene Cards (CUGCs).

CUGCs are disease-specific guidelines written by international authorships. Based on the ACCE framework (Analytical validity, Clinical validity, Clinical utility, Ethical, legal and social issues) the CUGC backbone consists of three parts: disease characteristics, test characteristics and clinical utility. CUGCs represent concise and comprehensive documents for the clinically validated use of genetic testing. All guidelines are freely available on the websites of EuroGentest, the European Journal of Human Genetics (EJHG) and Orphanet.

As of January 2011, the clinical utility gene cards project receives support by EuroGentest 2 and the European Society of Human Genetics. Initial steps taken for each gene card include the selection of principal authors, the provision of document templates, as well as support during document publication. Subsequently, each CUGC is peer-reviewed and published by the EJHG. From 2011 to 2013, 300 new CUGCs are planned to be established. The regular revisions and inclusion of new developments and findings ensure that all published documents reflect the state-of-the-art.

P01.56
Genetic testing and common disorders in a public health framework - Recommendations of the European Society of Human Genetics

C. G. van El, ***M. C. Cornel****;*
Department of Clinical Genetics/EMGO+ Institute, VU University Medical Center, Amsterdam, Netherlands.

Currently, the genetics research community is sceptical about the possibilities of genetic susceptibility testing and screening. The Public and Professional Policy Committee of the European Society of Human Genetics, EuroGentest and the Institute for Prospective Technological Studies convened to discuss relevance and possibilities of genetic testing for common disorders in a public health perspective. It is suggested to take the spectrum ranging from monogenic disorders to common complex disorders into account. Associations between genetic variants and disease risk have been established, for instance for hereditary breast and ovarian cancer, colon cancer, diabetes mellitus (MODY subtypes), thrombosis, cardiovascular disorders, celiac disease and Alzheimer disease. Although these examples relate to monogenic sub-forms of common disease, they can nevertheless be used to reflect on possibilities and relevant obstacles in using the new genetics in public health. Recommendations have been formulated stressing: avoiding too high expectations of genomics applications; the need to establish clinical utility of genetic testing before introducing large-scale applications; in case clinical utility is not proven, but likely, research should accompany pilot projects; monogenic conditions can serve as examples for common complex diseases, when identifying etiological pathways and developing healthcare in a responsible way; sufficiently qualified health-care professionals should be involved in case of direct-to-consumer genetic testing; regulation is necessary to guarantee truth-in labelling and truthful promotion of genetic tests; stratified medicine will only be successful if health-care insurance is based on solidarity; especially in developing countries governments should avoid an access gap to genetic testing of proven clinical utility.

P01.57
Genomics education for primary care providers in Estonia

L. Leitsalu[1]*, L. Hercher*[2]*, A. Metspalu*[1,3,4]*;*
[1]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [2]*Sarah Lawrence College Joan H. Marks Human Genetics Program, Bronxville, NY, United States,* [3]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [4]*Estonian Biocentre, Tartu, Estonia.*

Since 2000, Estonian Genome Center of University of Tartu (EGCUT), in partnership with primary care providers (PCPs) nationwide, has recruited over 50,000 gene donors for the Estonian Biobank. This collaboration has ensured a collection of high quality health data, as pre-existing medical information has been included. Additionally, it represents a starting point in the working relationship between EGCUT and PCPs, who are expected to facilitate the use of genomic information in the clinical setting once genomic information has sufficient clinical validity and utility. This study investigated the knowledge base and expectations of PCPs. Of 130 PCPs surveyed, 64 responded, representing 8% of the 804 PCPs in Estonia. Overall, PCPs demonstrated eagerness to apply genomic information in practice, as well as a willingness to improve their knowledge base in genetics and genomics. Results also indicated that substantial improvements in genetics education are needed to achieve EGCUT's plans for personalized medicine in Estonia. It is a goal of EGCUT to implement a database that can be accessed by all physicians in Estonia that would contain genomic data, along with all other medically relevant information on the patient, and could be used in medical counseling for and effective application of genomic information in clinical care. Several additional factors in Estonia may help to realize that goal: the national health care system, availability of electronic health care records, and the fact that University of Tartu is responsible for the education of health care workers as the only medical school in the country.

P01.58
One more proof that practice makes perfect

R. Dragotoiu*;*
Medical and Pharmacy University Carol Davila, Bucuresti, Romania.

The aim of this study is finding a way to determine better achievements in learning genetics. Motivation for a more thorough learning at the end of the first semester is a final examination, although many students bear in mind the wish to practice in another field beside medical genetics. Because "practice makes perfect" in every field under the proper guidance, I have tried to discover if repeating the information could change the marks students obtained.

The study group consisted of 128 first year medical students, who were tested twice. During the middle of the term they received marks for answering two questions: one from the practicals' and one from the lectures' content. Then all the questions from the lectures were discussed, so students could learn what was expected as an answer. Despite lack of time, these answers were briefly repeated at the beginning of the next practical. To view the impact of repetition, I compared these marks in each of the two questions with those obtained at the end of the term. At this final test 88 students had to answer exactly the same two questions as the first time, while 30 control students received different ones, randomly distributed, but from the same question pool.

In both groups about 70% of students had better results at the second testing, supporting consequently the idea that when teaching medical genetics one can mould his activity, repetition providing a better and therefore more satisfying outcome for both trainer and trainee.

The importance of genetic and congenital factors which causes many diseases and disabilities is obvious over the world.In Iran,Prevention of Genetic Disabilities program has been planned with the aim of implementation of a genetic counseling network.For implementing this program The network has gradually expanded since the year 1997,now we have 169 genetic counseling centers throughout the country. One of the chief complaints of clients of these centers has been the history of hearing impairment.In this study we have gathered the data from 1999 until 2009 about hearing impairment in our provincial referral centers in genetic counseling network.The total number of files having deafness history in pedigrees among 118786 files are 6521(5.5%).The total number of files having deafness history in each of spouses is 960(14.7%),in both spouses is 625(9.6%), in offsprings is 1460(22.4%),in one Offspring is 957(14.7%)&in two or more offsprings is 503(7.7%).The total number of files which are positive for Connexin 26 is 168(2.58%),Connexin 26 & 30 is 8(0.12%),other nonsyndromic AR genes is 7(0.11%),other syndromic AR genes is 26(0.4%),nonsyndromic AD genes is 1(0.015%) and syndromic AD genes is 5(0.08).The total number of deaf people is 9817: 5313(54%) males and 4512(46%) females.The numbers of different types of consanguinity among the clients (the total number of files with deafness history) are double cousins: 87(1.33%), first cousins:2803(42.98%),first cousins once removed:310(4.75%),second cousins:720(11.04)&nonc onsanguineous: 2839(43.54%).The total number of files with deafness history due to different modes of inheritance in pedigrees are: environmental factors:87(1.33%), nonsyndromic AR:2961(45.41%), syndromic AR:269(4.13%), nonsyndromicAD:400(6.13%), syndromic AD:70(1.07%), nonsyndromic X-Linked:32(0.49%), syndromic X-Linked:9(0.14%), mitochondrial:3(0.05%) & unknown causes:1171 (17.96%).

P01.60

Are genetic testing technologies driving clinical practice?

S. Julia[1,2,3], *A. Soulier*[1,3], *A. Cambon-Thomsen*[1,3];

[1]*Inserm, U1027, Toulouse, France,* [2]*Clinical genetics department, University hospital, Toulouse, France,* [3]*Université de Toulouse, Paul Sabatier Toulouse 3, Toulouse, France.*

As the demand for genetic analysis is increasing in the health care system, the extension of diagnostic tests for genetic disorders is needed. The majority of genetic diseases are molecularly and clinically highly heterogeneous and until recently, the available techniques lacked the required capacity to test many genes in parallel. Next generation sequencing technologies already available in research provide a unique opportunity to develop new diagnostic tools for heterogeneous genetic diseases. But their clinical use raises major and previously unaddressed issues. In a context of innovation, implementing new technologies is aiming to optimize clinical care. How to preserve the essence of traditional clinical values and how to maximize the translational relevance of genetic research for patients and for society? A main concern is that the rapid penetration of systematic technologies into genetic medical departments blurs established frontiers between research and clinics. A huge amount of personal medical data will indeed be produced, including results irrelevant to any particular clinical problem but which may be of importance to the patient in other ways or in the future. Our present inability to interpret most of the data requires ethical consideration. Questions of personal data storage, possible updating and conditions to re-contact patients and families require the development of appropriate rules or guidelines prior to clinical implementation. Clinicians, public health practitioners and relevant decision-makers should also determine their strategies and approaches in an era of such rapid advances. Main general challenges raised by High Throughput Technologies will be discussed and some positions proposed.

P01.61

Genetic testing for Lynch syndrome: Psychological impact and opinion about reproductive decision-making among mutation carriers

A. Combes*, L. Roca, M. Ychou, C. Fiess, F. CASTAN, J. Duffour;*

CRLC Val d'Aurelle, Montpellier, France.

Background: New assisted-reproduction techniques as prenatal diagnosis (PND) and preimplantation genetic diagnosis (PGD) are sometimes proposed in inherited cancer predispositions. These techniques are debated in some European countries regarding Hereditary NonPolyposis Colorectal Cancer (HNPCC). This interview study aimed to assess the psychological impact and the opinion about reproductive decision-making in HNPCC mutated individuals, after genetic test results disclosure.

Methods: A self-report questionnaire including socio-demographic data, psychological status and reproductive options was retrospectively sent to 101 HNPCC mutation carriers (patients and their relatives) from a complete oncogenetic colorectal data-base between 1997 and 2010. The prevalence of posttraumatic stress disorder (PTSD) was assessed at the time of result disclosure and at least one year later, using IES-R(Impact of Event Scale-Revised)

Results: Complete data were available for 34 individuals (25 relatives, 9 patients): 17 males, 17 females, median age of 33.5(22-59), with mutations in hMLH1 (15) hMSH2 (15) and hMSH6 (4) genes.

Only 13.8% of participants reported significant immediate PTSD. They mainly explained their distress by fear of premature death (43.3%) and passing on mutated genes (41.9%). For 90.3% of respondents, reproductive decision-making remained unchanged after results. Among reproductive options, PND/PGD or spontaneous natural conception were equally reported (50%). None of socio-demographic or psycho-medical variables were significantly associated with both choices.

Conclusion: A minority of mutation carriers reported significant levels of distress after result genetic disclosure. Half of respondents were in favour of PND/PGD (as much as those interested by natural conception) but we are taking about an opinion and not their intention.

P01.62

Oncogenetics as a tool of cancer personalized medicine: a two-year experience in a public hospital in Brazil

A. A. P. Santa Rosa[1,2], *B. P. Costa*[3], *B. A. L. França*[3], *B. A. Fernandes*[4], *F. A. S. Ribeiro*[4], *R. J. Muharre*[4], *M. Valadão*[4], *R. A. C. Leal*[4], *D. César*[4], *P. R. Cotrim*[5], *T. Jeunon*[5], *A. Caldas*[5], *L. Zamagna*[6], *H. V. Moysés*[7], *J. C. C. Rocha*[2], *R. Facadio*[1], *S. S. Azevedo*[8];

[1]*Ministério da Saúde / Hospital Federal de Bonsucesso / Departamento de Pesquisa, Rio de Janeiro, Brazil,* [2]*COI - Clínicas Oncológicas Integradas, Rio de Janeiro, Brazil,* [3]*Ministério da Saúde / Hospital Federal de Bonsucesso / Serviço de Oncologia, Rio de Janeiro, Brazil,* [4]*Ministério da Saúde / Hospital Federal de Bonsucesso / Serviço de Cirurgia, Rio de Janeiro, Brazil,* [5]*Ministério da Saúde / Hospital Federal de Bonsucesso / Serviço de Dermatologia, Rio de Janeiro, Brazil,* [6]*Ministério da Saúde / Hospital Federal de Bonsucesso / Serviço de Ginecologia, Rio de Janeiro, Brazil,* [7]*Ministério da Saúde / Hospital Federal de Bonsucesso / Serviço de Urologia, Rio de Janeiro, Brazil,* [8]*Ministério da Saúde / Hospital Federal de Bonsucesso / Direção Geral, Rio de*

Janeiro, Brazil.

The purpose of Oncogenetics is twofold: to identify a portion of population with increased risk for cancer by identifying those with significant family history and to successfully intervene in these individuals reducing their incidence of and mortality from cancer by enhanced and directed genetic screening, early detection, prophylactic surgery, and so forth.

This individualized approach has been carried out for the last two years in Hospital Federal de Bonsucesso, the biggest and most important general hospital in Rio de Janeiro, performing almost 500 oncology consultations monthly and about 600 cancer surgeries yearly . As about 10% of these cases are familial and non-related, there are 60 new cancer-prone families undergoing our attention yearly. With regards to colorectal cancer, 20 HNPCC families and 3 FAP patients have been identified based on family history and pathology data, being referred to genetic counseling and specific cancer control strategies. As to less frequent conditions, patients with VHL Disease, Muir-Torre Syndrome and Nevoid Basal Cell Carcinoma Syndrome have been identified being under close follow-up and individualized genetic counseling.

In conclusion, the experience of our hospital shows that clinical geneticists working in close contact with oncologists and surgeons are of utmost importance for directing clinical investigation, especially in places where more specific examinations may be unavailable. Oncogenetics represents a true bridge closing the gap between basic sciences and clinical medicine, and can surely play a pivotal role in any interdisciplinary team devoted to cancer care and willing to provide a comprehensive approach to their families.

P01.63

Action research of genetic education on human diversity targeting mothers of pre-school children in Japan

H. Moriya[1], *K. Wada*[1], *H. Isibasi*[2], *i. Takahasi*[2], *i. Inoue*[1], *M. Mozoguchi*[1];
[1]*Tokai University, Isehara,Kanagawa, Japan,* [2]*Honda Memorial Kindergarten Attached to Tokai University, Isehara,Kanagawa, Japan.*

<Background> Japan is basically a homogeneous society in culture and population, therefore people are less aware of human diversity. We are intending to perform the action research of the genetic education to mothers of pre-school children. At first, it was necessary to know the participants' basic knowledge of genetics where understanding of human diversity is most preferable subject to discuss.

<Methods> We recruited 8 mothers participating in the University affiliated kindergarten who accepted the study and were willing to discuss a theme: "*everybody is different therefore everybody is valuable*". Throughout the Class and Discussion at eight times, the discussion was qualitatively analyzed. The study protocol was approved by the ethical committee of the Tokai University.

<Result> Three concerns were raised from discussion on the theme: "troublesome with surroundings", "inherent lack of individual ability", and "discrimination to disease/disablity". After the discussions, the participants felt the self-contradiction and genetic knowledge is needed for better understanding of human diversity.

<Discussion>The participants had conflicted thought to the human diversity, and were willing to know more about human diversity on the course of the discussion. In conclusion, importance of genetic education to general population for the society is confirmed.

P01.64

Psychological impact of presymptomatic DNA testing on Huntington's Disease gene carriers

S. Serpentini[1,2], *L. Dal Sasso*[1], *E. Pasquin*[1], *M. Balestrieri*[3], *G. Damante*[1,2], *I. R. Lonigro*[4,2];
[1]*Istituto di Genetica, A.O.U., Udine, Italy,* [2]*Dipartimento di Scienze e Tecnologie Biomediche, Università, Udine, Italy,* [3]*Clinica Psichiatrica, A.O.U., Udine, Italy,* [4]*Dipartimento di Medicina di Laboratorio, Università, Udine, Italy.*

Aim: The present study is finalized to explore the psychological and "quality of life" impact of genetic testing on presymptomatic Huntington's disease (HD) gene carriers. This is a part of a larger research and has only a descriptive and preliminary purpose.

Methods: From May 2009 to October 2010 we evaluated 18 presymthomatic subjects resulted carriers of HD gene, 6-12 months after the genetic testing. The instruments used are the following: 1) a semi-structured interview; 2) the Psychological General Well-being Index (PWBGI); 3) the Short Form 36 Health Survey Questionnaire (SF-36).

Results: Eighteen patients (M:5, F: 13; mean age: 48,52, range age:28-75) were assessed.

The means and standard deviations of the PWBGI scales are: Anxiety 16,38 (4,90), Depression 11,55 (2,57), Well-being 10,66 (3,56), Self control 10,56 (3,53), Global health 10,44 (4,55), Vitality 11,78 (4,18).

The means and standard deviations of the SF-36 scales are: Physical functioning 78,61 (30,83), Role-Physical 62,5 (50,62), Bodily pain 82,28 (30,13), General health 51,83 (31,66), Vitality 54,72 (25,34), Social functioning 72,92 (28,75), Role-emotional 70,39 (51,64), Mental health 60,67 (18,98). Sample mean scores were found lower than the normative scores.

Conclusions: The current preliminary findings show a critical impact of DNA testing on psychological well being and the quality of life of the presympotamic HD gene carriers: they were characterized by lower physical functioning, less vitality and social support, higher level of anxiety and depression. The data also suggest the importance of a specific psychological intervention. Further research with a larger sample is needed.

P01.65

Hypermobility Syndrome (Ehlers-Danlos Syndrome Hypermobility Type) in Japan

A. Watanabe[1], *M. Hatakeyama*[1,2], *T. Kosho*[3], *Y. Kawame*[2], *T. Shimada*[1];
[1]*Nippon Medical School, Tokyo, Japan,* [2]*Ochanomizu University, Tokyo, Japan,* [3]*Sinshu University, Matsumoto, Japan.*

Background: Hypermobility Syndrome (HMS, ICD-10 M357) is a connective tissue disorder characterized by generalized joint hypermobility and chronic pain (major criteria in Brighton criteria (2000)). Both the pathogenesis and the causative gene are not known. Even healthcare professionals are not normally familiar with HMS patients. We have developed a draft diagnostic criteria for HMS in Japan based on our past survey for clinical manifestations in our twenty patients and worldwide previous studies.

Method: With our draft diagnostic criteria and a summary of the condition from GeneReviews, we have sent 455 departments in university hospitals and orthopedic hospitals a survey form investigating whether they have any experience with patients with possible diagnosis of HMS. The departments included orthopedics, anesthesias, rheumatics and genetics. Our draft diagnostic criteria is as follows: Essential items 1. Generalized joint laxity (a Beighton Score of 4 or more), 2. Recurrent dislocations/subluxations in multiple joints without known/obvious trauma, 3. Chronic pain which persist more than 3 months. Notices 1. Skin hyperextensibility/loose skin is not necessarily seen in HMS patients, 2. Those who are already diagnosed with EDS will be included, 3. Joint laxities may recur after operation to stabilize the joint had done, 4. Other symptomatic diseases such as chromosomal abnormality should be excluded.

Result: 207 forms were collected (45%), 27 departments answered they have experienced HMS patients in the past, the total number of patients reported was 77 (47 if limited within past one year). Secondary survey is currently in progress.

P01.66

Attitudes toward termination of pregnancy based on prenatally detected genetic disease or malformations in selected groups of doctors-in-training

M. D. Ingerslev[1], *B. R. Diness*[2], *M. S. Norup*[3];
[1]*Department of Obstetrics and Gynaecology, Roskilde Hospital, Roskilde, Denmark,* [2]*Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark,* [3]*Department of Public Health, University of Copenhagen, Copenhagen, Denmark.*

Background: This study explores attitudes towards termination of pregnancy (TOP) in different scenarios between different groups of doctors-in-training working with TOP.

Danish law permits TOP on request of the woman until gestational age (GA) 11+6 and TOP by permission after application to a local abortion council until approximately GA 22+0.

Methods: Doctors-in-training aiming for specialisation in obstetrics and gynaecology (OG-i-T) or clinical genetics (CG-i-T) completed a questionnaire regarding their views on TOP in different scenarios.

A pro-abortion-index was derived from their responses.

Results: 96 doctors-in-training completed the questionnaire. Of these 77% aimed for specialisation in obstetrics and gynaecology, 20% aimed for clinical genetics and 3% were undecided. Mean number of years since graduation was 7.0; mean number of months in the specialty of choice was 25. The pro-abortion-index was normally distributed (mean 10.1, SD 3.2). CG-i-T were more pro-abortion as a group than OG-i-T (p = 0,02).
Results are summarised in table 1.
Discussion: Doctors-in-training were more acceptant of TOP based on genetic disease and foetal abnormalities than TOP for psychosocial reasons. A similar tendency has been reported for nurses and medical students. The responses for upper GA-limit varied with the specific diagnosis. Both groups favoured abortion on request longer than Danish law currently permits. Both groups agreed with current practice for late terminations.
Table 1

Scenario		GA in weeks (95% CI) until which participants thought that TOP should be possible		
		OBGYN-in-training	Clinical geneticists-in-training	P-value OG-i-T vs CG-i-T
Psychosocial problems	On request	13.1 (12.5-13.7)	15.3 (13.6-16.9)	0.003
	With permission from abortion council	19.9 (19.2-20.5)	19.8 (18.2-21.5)	0.84
Foetus with Down syndrome	On request	16.5 (15.2-17.8)	17.9 (16.2-19.5)	0.28
	With permission from abortion council	22.0 (21.2-22.8)	22.4 (21.7-23.1)	0.62
Foetus with cystic fibrosis	On request	15.8 (14.8-16.9)	16.9 (15.1-18.8)	0.31
	With permission from abortion council	21.3 (20.7-21.9)	21.2 (19.8-22.0)	0.88
Foetus with polycystic kidney disease	On request	14.1 (13.2-15.1)	15.7 (14.0-17.3)	0.12
	With permission from abortion council	20.0 (19.2-21.0)	19.2 (17.2-21.1)	0.35
Minor malformation (limb defect) detected with routine ultrasound	On request	13.8 (12.9-14.7)	15.4 (13.7-17.1)	0.09
	With permission from abortion council	17.5 (16.3-18.7)	18.9 (16.7-21.1)	0.27
Pro-abortion-index		9.7 (8.9-10.5)	11.7 (10.4-12.9)	0.02

P01.67
Neonatal screening for hemoglobinopathies in the City of São Carlos, São Paulo, Brazil: an analysis

*R. M. M. Moreira[1], I. F. Estevão[2], **D. G. Melo**[1];*
[1]Department of Medicine, Federal University of São Carlos, São Carlos, Brazil, [2]Hematologyst of the Municipal Health Secretary of São Carlos, São Carlos, Brazil.

The neonatal screening is the major Brazilian Unified National Health System (BUNHS)'s initiative in medical genetic's area and it embraces four diseases: inborn hypothyroidism, phenylketonuria, hemoglobinopathies and cystic fibrosis. This project intends to verify the National Neonatal Screening Program (NNSP)'s effectivity and to estimate the hemoglobinopathies' incidence in the City of São Carlos, São Paulo, Brazil. It concerns a descriptive study, undertaken between 2007 and 2010, when 11,818 children were born, of which 10,589 (93.55%) were subjected to the BUNHS's screening. The screening's results showed 360 abnormalities (3.39%), with an incidence of 1.85% falciform trace, 0.009% sickle-cell disease, 0.45% C trace, 0.37% alpha-thalassemia, 0.03% suspected beta-thalassemia, 0.07% low fetal hemoglobin and 0.14% undetermined hemoglobin, mean, a hemoglobin variant not identified by test. There was 1 (0.009%) falciform trace associated with Bart's hemoglobin and 2 (0.018%) C trace associated with Bart's hemoglobin. In 48 cases (0.45%) the results were inconclusive. Although the PNTN's reasonable cover, the numbers of inconclusive results and undetermined hemoglobins are considered high yet, as well as the newborn's percentage with low fetal hemoglobin, giving an indirect idea of the percentage of children who took the screening after 21 days of life, when the fetal hemoglobin is replaced by the adult hemoglobin. The results points to the need for a consolidation of a line of comprehensive health care for patients with hemoglobinopathies and their family in the City of São Carlos.

P01.68
Providing genetic risk information to parents of newborns with sickle cell trait: role of the general practitioner in neonatal screening

*F. Vansenne[1], C. A. J. M. de Borgie[1], M. Legdeur[1], M. Oey-Spauwen[2], **M. Peters**[1];*
[1]Academic Medical Centre, Amsterdam, Netherlands, [2]National Institute for Public Health and the Environment, Maarssen, Netherlands.

Purpose: In 2007 the neonatal screening program in the Netherlands was expanded, now including sickle cell disease (SCD). SCD carriers are also identified. The benefit of reporting SCD carrier ship includes detection of high risk couples (both parents are carriers) who can be informed about future reproductive choices, a responsibility of their general practitioner (GP). We evaluated knowledge, ideas and reported actions of GP's about SCD carrier ship and explored reported potential barriers.
Methods: A questionnaire study.
Results: 139 GP's responded to our questionnaire (49%). 90 GP's (90%) stated they informed parents of the test result. In only 23 cases (23%) both parents had themselves tested for hemoglobinopathies. 81 GP's (64%) stated they did not have enough clinical experience with SCD. Almost half of the GP's indicated they did not experience any barriers in counseling patients (n=60, 48%).
Conclusion: At the moment the goal of the neonatal screening for SCD carrier ship has not been achieved as the majority of parents were not tested for hemoglobinopathies after disclosure of carrier ship in their newborn. With GP's reporting few barriers in counseling parents and only indicating a lack of knowledge and clinical experience, more effort is required to provide better information to GP's to help facilitate their work.

P01.69
Parents' opinions on storage of heel-prick cards for research purposes

***S. R. F. van Teeffelen**[1,2], C. M. W. Douglas[1,2], C. G. van El[1,2], M. Radstake[2], R. J. G. van den Born[3], M. C. Cornel[1,2];*
[1]Section Community Genetics, Department of Clinical Genetics and EMGO Institute for Health and Care Research, Amsterdam, Netherlands, [2]Centre for Society and Genomics, Nijmegen, Netherlands, [3]Department of Philosophy and Science Studies, Institute for Science, Innovation and Society, Radboud University, Nijmegen, Netherlands.

This paper reports on a recent quantitative survey of over 1600 Dutch parents' views about the storage, management, and secondary use of heel-prick cards. Given the scale of neonatal screening, these blood samples present a wealth of biological data for medical research. While not a conventional biobank, the card collection could be treated as such if there would be societal support and a (new) management body and use policies could be developed. There is currently a discussion in the Netherlands about prolonged storage, independent management and extended secondary uses. Our survey was aimed at parents of children aged 0-5 whose heel-prick cards are presently in storage, as well as parents-to-be. The survey quantifies for the first time the views of this group about current and future options related to neonatal screening, permission for use in medical research, and issues related

to (length of) storage, management and secondary uses of the cards, including medical research, diagnostics, and identification. The survey contains questions on knowledge of current storage, management and use policies (6 items), personal experience with heel-prick testing (4 items), demographic information (9 items), and opinions on specific storage, management, and use issues (41 items). Respondents were able to indicate their level of support for 10 categories of secondary use, including "to determine how often certain medical conditions occur in the Netherlands" (prevalence studies) and "to find out how certain diseases develop" (etiology studies). Respondents were also asked how long the collection of heel-prick cards should be kept for medical research.

Patient and public involvement in genetic and developmental medicine research

M. E. Palm[1,2], *G. Hall*[3], *G. Black*[2,4], *J. Clayton-Smith*[3,4], *H. C. Kitchener*[2,3,4], *R. Albrow*[2], *S. Laura*[2], *K. Dack*[1,2], *D. Donnai*[1,3], *H. R. Middleton-Price*[1,2];
[1]*Nowgen (A Centre for Genetics in Healthcare), NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom,* [2]*The University of Manchester, Manchester, United Kingdom,* [3]*Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [4]*NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom.*

The Manchester Biomedical Research Centre (MBRC) specialises in genetics and developmental medicine, aiming to transform healthcare through translational research. Patients and the public are at the centre of the MBRC effort to move developments from the laboratory into clinics.
Patient and public involvement (PPI) in healthcare research has been shown to increase its relevance and effectiveness. A recent mapping exercise carried out at the MBRC showed a range of PPI activity taking place. This paper highlights three examples of good practice.
(1) A patient advisory group (PAG) was formed to help design, translate and disseminate the outcomes from a programme of research looking at improving services for patients with inherited retinal disease. The PAG is made up of patients, representatives from a range of charities for visual impairment and Genetic Alliance and is attended by the wider study team, including the primary investigator, health care researchers, genetic counsellor and health economist.
(2) A parent of an affected child is a partner on the Dyscerne guidelines group, whose aim is to develop and disseminate clinical management guidelines for rare dysmorphic conditions. This has resulted in the inclusion of important information aimed at professionals dealing with children who have rare syndromes.
(3) A public consultation was carried out with women at the surgery of their general practitioner. Women were asked to feedback their views of both cervical screening and proposed interventions to increase uptake via a questionnaire. The consultation increased confidence in the proposal and provided support for the study trial design.

P01.71
Newborn screening for Pompe disease? Exploring professional views

C. G. van El[1,2], *T. Rigter*[1,2], *S. Weinreich*[1,2], *A. Reuser*[3], *A. van der Ploeg*[2,4], *M. C. Cornel*[1];
[1]*Department of Clinical Genetics/EMGO+ Institute, VU University Medical Center, Amsterdam, Netherlands,* [2]*Center for Lysosomal and Metabolic Diseases, Erasmus Medical Center, Rotterdam, Netherlands,* [3]*Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands,* [4]*Department of Paediatrics, Erasmus Medical Center, Rotterdam, Netherlands.*

New developments in enzyme replacement therapy have kindled discussions on adding Pompe disease to neonatal screening programmes. Traditionally, expanding screening is being discussed among a restricted number of medical experts. In this research we aim to explore the views of a wide range of relevant professionals to gain more insight into the process of weighing pros and cons of neonatal screening for Pompe disease.
We conducted semi-structured interviews with over 25 professionals in the Netherlands. Some had experience with Pompe disease patients, such as paediatricians, neurologists, physiatrists, family doctors and patient organisation representatives. Others were involved in the organisation of screening or health care, such as representatives from the Centre for Population Screening, the Health Care Insurance Board, and well-baby clinic doctors. They were asked about their first reaction to neonatal screening for Pompe disease, after which benefits and harms and requirements for screening were explored in more detail.
This study shows that many professionals expect benefits from neonatal screening for Pompe disease, especially for early-onset cases, since it has been shown that prompt treatment improves survival and health status in many affected infants. A distinctive feature of this type of screening is the detection of late-onset cases that would otherwise present anytime between infancy and later in adulthood. Whereas some interviewees considered early detection a benefit in these cases as well, allowing for monitoring and timely treatment, others considered this a drawback or a reason not to screen, given the psychological burden.

P01.72**
Governance and future of genetic preconception carrier screening

P. Lakeman[1], *L. Henneman*[1,2], *E. Sistermans*[1], *P. Borry*[2,3], *L. P. ten Kate*[1], *H. Meijers-Heijboer*[1], *M. C. Cornel*[1,2];
[1]*VU University Medical Center, Department of Clinical Genetics, Amsterdam, Netherlands,* [2]*EMGO Institute for Health and Care Research, University Medical Center, Amsterdam, Netherlands,* [3]*Centre for Biomedical Ethics and Law, Katholieke Universiteit Leuven, Leuven, Belgium.*

Recessive disorders cause serious morbidity and mortality in 25/10,000 children. Most of them are born unexpectedly without family history of the condition. In about 1/100 couples, both partners are carriers of the same disorder, facing 25% risk of affected offspring in each pregnancy. Carriers are usually unaware of their carrier status.
Preconceptional carrier screening enables carrier couples to make informed reproductive decisions before pregnancy. Our offers of preconceptional carrier screening for cystic fibrosis (CF) and/or hemoglobinopathies (2002 and 2005) were favoured by the target population and stakeholders. Despite positive results in pilot studies, meeting genetic screening criteria and constructive debates about ethical, technical and financial aspects, in most European countries a systematic healthcare offer of preconceptional carrier screening for the general population is lacking. Meanwhile, uncontrolled commercial private testing is available online. Is this development desirable in terms of informed consent, counselling, and medical supervision? In the absence of a healthcare offer, the Clinical Genetics Department of VU University Medical Center in Amsterdam recently started to offer preconceptional CF screening tests on the hospital website, accompanied by sufficient medical information, without commercial goals and with availability of counselling. The experiences of (potential) users will be monitored and integrated when further developing the service. Is this the ideal answer in diversifying contexts of screening? Will screening for more recessive disorders become available in regular healthcare in the future? And how to enable beneficial application of whole genome sequencing, which allows parallel screening for all known recessive disorders, in this preconception setting?

P01.73
Effects of predictive genetic testing for cardiovascular risk in healthy overweight subjects.

V. V. Markova[1], *O. A. Makeeva*[1,2], *V. P. Puzyrev*[1];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Research Institute of Complex Problems of Cardiovascular Diseases, Kemerovo, Russian Federation.*

Aims: To compare effectiveness of common medical recommendations to reduce the weight as it is a confirmed risk factor for future cardiovascular pathology in a group of overweight healthy young subjects with the counseling supplemented by genetic test for cardiovascular disease predisposition. Materials & methods: two groups were collected in a similar way: group 1 (control) (n=95, average age 31 years, body mass 84.9 kg) got recommendations that they are overweight and have to reduce their body mass in order to lower the risk of future CV pathology; group 2 (experimental) (n=103, average age 30.8 years, body mass 89.0 kg) got similar recommendations and additionally got results of a genetic test assessing individual risk of CVD. Both groups were examined after a year and body mass was measured repeatedly. Results: Both groups reduced their weight significantly. Control group lost 1.51 kg ($p<0.0001$), while experimental - 2.29 kg ($p<0.0001$). The weight lost did not differ statistically between

two groups. Analyzing separately subgroups of men and women showed that men lost their weigh independently from the fact of getting personal genetic cardiovascular risk estimates (1.5 kg and 1.8 kg in groups 1 and 2 accordingly), while women reduced their weight mainly in the group with genetic testing - 4.2 kg compared to control group who lost 0.8 kg. Conclusions: Our data reports that there can be gender-specific reaction to genetic testing. It was shown in previous studies that women in our population have more positive attitudes and beliefs to predictive genetic testing.

P01.74
Ethical Issues in pre-implantation genetic diagnosis in Portugal: a comparative analysis of professional's opinions in years 2000 and 2010 using questionnaires

N. M. P. O. Teles[1,2];
[1]*INSA, I.P., Centro de Genética Médica Jacinto, Porto, Portugal,* [2]*Faculty Medicine, University of Porto, Porto, Portugal.*

Medical genetics has made significant progress in the last decades, especially in the field of prenatal testing. After the dramatic expansion of prenatal diagnosis that started in the seventies, pre-implantation genetic diagnosis (PGD) became a reality in 1990, following advances in the techniques of medically assisted reproduction (MAR). Ethical problems related to this technique start well before the analysis: it is necessary to offer appropriate genetic counselling, to obtain informed consent for the necessary procedures and to maintain strict confidentiality of the whole process. The main ethical problems concern the status of the embryo, the investigation and the manipulation of embryos, eugenic or sex selection and the provision of resources. In 2000 a questionnaire addressing several of the principal ethical concerns, namely the attitude towards PGD, embryos and genetic testing, was distributed to the Directors of the five largest MAR centres in Portugal; in 2010 the same questionnaire was sent to 27 MAR centres and answered by 11. In all cases it was required that the answers should be based on the general policy of each centre. This work presents the comparative analysis of all the obtained data, particularly focusing on the main ethical problems related to this diagnosis, i.e., the status of the human embryo and the attitude of the genetic professionals working in this still relatively new, and very specific, field of genetic diagnosis.

P01.75
Prenatal diagnosis based on informed choice

S. Izumi*, K. Takahashi, h. Moriya, S. Sato, Y. Goto, Y. Onuki, H. Yokoyama, A. Kondo;*
Tokai University, Isehara, Japan.

In general, prenatal test is recognized as population screening in many countries. For example, more than 80% women have maternal serum test as screening in the UK. In Japan, we do not offer maternal serum test as screening in most obstetrics services. We might provide the information of screening test and further chromosomal test such as CVS and amniocentesis with the information of genetic counselling. There is no regulation for prenatal diagnosis in ultrasound diagnosis, so some clinic would offer screening at some point and some do not. We do not scan the fetus as screening without patient's request at our hospital.

Historically, we have been concerned with prenatal diagnosis over 30 years at our hospital. At first, we had been doing only the test and given the result for referred patients; however we now offer genetic counselling for referred patients to avoid automatic screening and to have informed choice for prenatal diagnosis.

Prenatal diagnosis contains ethical issues all the time, but most pregnant women do not notice this problem until they consider termination at some point. Genetic counselling in prenatal diagnosis could be good support for the patient who has to face difficult ethical issues during pregnancy. It sometimes reduces unnecessary risk for worries and/or invasive test.

P01.76
Information related to prenatal genetic counseling: Interpretation by teenage students and ethical implications

P. A. Melas[1]*, S. Georgsson Öhman*[2,3]*, N. Juth*[4]*, T. H. Bui*[5]*;*
[1]*Department of Molecular Medicine and Surgery, Neurogenetics Unit, Karolinska Institute, Stockholm, Sweden,* [2]*Department of Women's and Children's Health, Karolinska Institute, Stockholm, Sweden,* [3]*Sophiahemmet University College, Stockholm, Sweden,* [4]*Department of Learning, Informatics, Management and Ethics, Stockholm Centre for Healthcare Ethics, Karolinska Institute, Stockholm, Sweden,* [5]*Department of Molecular Medicine and Surgery, Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden.*

Among current teenagers we find a large proportion of future parents, some of whom will be seeking prenatal genetic counseling. Getting raised in the genomic era may not only increase the knowledge of available genetic testing but may also have an impact on how genetic information is perceived. However, little is known about how this teenage group reacts to the language commonly used by health care professionals providing prenatal counseling. In addition, as risk communication is related to numbers and figures, having different educational backgrounds may be associated with separate risk perceptions. In order to investigate these issues, a previously developed questionnaire (Abramsky & Fletcher, 2002) was administered to high-school students in Sweden. A total of 344 questionnaires were completed by students belonging to a natural science or a social science program. Our data show that teenage participants were particularly worried by the use of technical jargon and words like *rare* and *abnormal*. Negative framing effects and perception differences related to numeric risk formats were also present. There were some cases of gender and educational program effects on risk assessment but this outcome was not generalizable. Besides the questionnaire results, we discuss the ethical implications of the data based on the norm of non-directiveness and try to provide some basic guidelines. In general, genetic counselors should be aware that the language used within clinical services can be influential on this group of upcoming counselees.

P01.77
From rationing to rationality: an n-of-one trial service for off-label medicines for rare (neuromuscular) diseases

C. Vrinten[1]*, S. S. Weinreich*[1,2]*, J. J. G. M. Verschuuren*[3,4]*, C. A. Uyl-de Groot*[5]*, M. R. Kuijpers*[6]*, E. Sterrenburg*[4,7]*, J. P. M. Scholten*[8]*, C. F. R. M. van Bezooijen*[9]*, M. F. T. Timmen*[2]*, M. C. Cornel*[1]*;*
[1]*Institute for Research in Extramural Medicine (EMGO), Amsterdam, Netherlands,* [2]*Dutch Association for Neuromuscular Disorders, Baarn, Netherlands,* [3]*Leiden University Medical Center, Leiden, Netherlands,* [4]*Dutch Neuromuscular Research Centre, The Hague, Netherlands,* [5]*Erasmus Medical Center, Institute for Medical Technology Assessment, Rotterdam, Netherlands,* [6]*Health Care Insurance Board, Diemen, Netherlands,* [7]*Princes Beatrix Fonds, The Hague, Netherlands,* [8]*Dutch Cochrane Centre, Amsterdam, Netherlands,* [9]*Stichting Eerlijke Geneesmiddelenvoorziening (Foundation for Equitable Provision of Medicines), Rotterdam, Netherlands.*

Background: In the Netherlands, expensive medicines are not reimbursed for off-label use without sufficient evidence of efficacy. Patients with rare diseases are disadvantaged because the burden of proof is difficult to meet. There are obstacles both for industry and academia to performing large-scale randomized, controlled trials. Moreover, reimbursement rules discourage doctors from prescribing expensive medicines off-label, even to small groups of patients. Examples of reimbursement problems with off-label medicines are known from many rare disease areas, including genetic disease. Controlled n-of-one (single-patient) trials with internal randomisation (e.g. AB-BA-BA) could generate new evidence for rare, chronic conditions where the aim of treatment is symptom control.

Objective: This project aims to initiate development of an n-of-one trial service, embedded in the Dutch health care system. Pilot implementation will be designed, focusing on neuromuscular diseases as a model.

Methods: Reimbursement problems with off-label medicines for rare neuromuscular diseases are being inventoried among neuromuscular specialists and patients with neuromuscular disease in the Netherlands. A consensus meeting will be organized to define legal, ethical and scientific preconditions for formalizing and sustaining an n-of-one trial service. An electronic data registry system for n-of-one trials will be designed, and several protocols will be written for specific trials to be performed in a pilot implementation of the n-of-one trial service.

Implications: If an n-of-one trial service is successfully designed, a subsequent project can pilot trials for off-label neuromuscular indications and eventually others. Societal acceptance of n-of-one evidence may also stimulate development of genomic therapies tailored to rare genotypes.

P01.78
Volunteers involved in working with NGOs for rare diseases

M. Gafencu[1], *G. Doros*[1], *D. Dan*[2], *I. Jurca Simina*[1], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy, Timisoara, Romania,* [2]*Romanian National Alliance for rare diseases, Zalau, Romania.*

In the absence of a national strategy for rare diseases (RD), in the last 20 years - the most neglected group of diseases in Romania - the information and social inclusion of these children remains to the initiative of NGO's. The start was in 2006 and working with volunteers was for the first moment, the solution. Aim of our work was to focus on the changes in life quality of children with these diseases, after teamwork and a multidisciplinary approach. Material and methods. The volunteering activity intend to contribute, both by involving as many volunteers as possible and by providing information, coming directly into contact with patients and their families, change their perception and in future the civil society perception towards the rare diseases' issue. Main activity was based on specialized volunteer-patient- family direct relationship, making use of playing games, art and group therapy in weekly meetings. Results. Every year since 2008, volunteers *Save the children* and ANBRARo have organized "Rare Diseases Day" by handing out leaflets to the people, for a week, in a crowded square from Timisoara and other Romanian cities. These informing campaigns were very well received by the passer- byes, media and people with (RD). Being medical students and in the company of children with RD, volunteers were able to participate at conferences and other meetings with scientific papers. They also provide active help to the children so that, the parents could stay and learn more about their children's disease in meetings dedicated to support groups.

P01.79
Orphanet UK 2011: More information, more specific and easier to retrieve

I. Gomez Paramio[1,2], *G. Sainz*[1,2], *D. Ward*[1,2], *S. Ayme*[3], *H. Middleton-Price*[1,2], *D. Donnai*[1,2,4];
[1]*Nowgen (A Centre for Genetics in Healthcare), NIHR Manchester, Manchester, United Kingdom,* [2]*The University of Manchester, Manchester, United Kingdom,* [3]*ORPHANET- INSERM SC11, Paris, France,* [4]*Central Manchester and Manchester University Hospitals NHS Trust, Manchester, United Kingdom.*

Orphanet is the largest international online portal for rare diseases and orphan drugs. Orphanet lists services for around 6,000 rare diseases in 36 countries. Among these services there are over 21,000 medical laboratory tests, 1,200 clinical trials, 1,000 registries and 4,900 expert centres.

Information regarding the UK has grown strongly over the last two years. Today there are over 70% more clinical trials, 45% more registries and biobanks, over 50% more medical diagnostic tests and 30 % more clinics.

Relevant information is highlighted and retrievable; from over 170 clinical trials available, 80% are ongoing and over 50% are recruiting participants. There are also over 80 registries and biobanks from which 25% are recruiting. Laboratories with accreditations are highlighted. Designated centres of expertise display the Reference Centre label.

All these services can be searched by disease or by gene. Moreover, research activities can also be retrieved by type, by institution/laboratory, by professionals, by sponsor/funding body and by substance/tradename (clinical trials). Diagnostic test can be filtered by city or type of accreditation and clinics by type of service (medical management/genetic counselling and paediatric/adult clinic).

The webpage has also improved its user friendliness with the addition of two new features: the "google translational tool" that allows the user to translate any page in different languages and the "autocompletion tool" that facilitates research by providing suggestions as terms are entered. Moreover, a new website for the UK has been created to offer national relevant information for patient and professionals.

P01.80
The "DICE-APER Registry": a new online tool to attend the patients with Rare Diseases in Primary Care.

M. Garcia Ribes[1], *I. Ejarque Domenech*[1], *M. Blanco Marenco*[1], *J. V. Sorli Guerola*[1], *R. De Celada*[1], *I. Garrell Lluís*[1], *I. Abaiuta Borda*[2], *G. Esteban Bueno*[1], *M. Posada de la Paz*[2];
[1]*Workgroup SEMFYC "Clinical Genetics and Rare Diseases"., Barcelona, Spain,* [2]*Institute of Research in Rare Diseases. Institute of Health Carlos III., Madrid, Spain.*

Our purpose was to design an online Registry in order to manage patients who suffer a Rare Disease (RD) in Primary Care (PC). This Registry might be a quick and useful tool for General Practitioners. It could help to follow-up the RD patients and their families in PC. Also to improve its National Spanish Registry.

The Workgroup of "Clinical Genetics and Rare Diseases" of SEMFYC in collaboration with the Institute of Research of Rare Diseases of the Institute of Health Carlos III, the Spanish Federation of Patients with RD (FEDER), and its families (CREER), has designed the online Registry "DICE-APER": http://dice-aper.semfyc.es

The PC is the "gateway" to access to the National Health System and most of the PC units have connection to Internet. Both resources have been used to design an online tool to manage "forgotten" or unknown aspects in the daily practice. As result we have an online tool that: 1) allows to identify every RD, 2) invites each patient to participate in the Biobank at the Spanish National Registry of RD, 3) coordinates genetic counselling, 4) offers health care and social resources 5) and encourages working with other Medical Specialities.

This online tool will help on growing the Spanish National Record of RD and, therefore, we might hope an increasement of the resources that are focused to these diseases in order to obtain the satisfaction of patients. It's important to create and to use new online tools to improve several aspects of the RD.

P01.81
Pre-marriage Screening Program for Beta-Thalassemia in Isfahan (center of Iran) (2005-2010)

M. Zeinalian Dastjerdi[1], *R. Fadaei*[1], *A. Moafi*[2];
[1]*Health Deputy of Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran,* [2]*Medicine School of Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran.*

Thalassemia is the most widespread single gene disease in Iran. This report presents the results of pre-marriage screening program applied in Isfahan province (center of Iran) within 5 last years (2005 -2010).

The information related to 22 screening and genetic counseling centers was collected throughout the province within this period. Data analysis was performed by excel soft ware.

Overall 233400 couples were screened from March 2005 till March 2010. Totally 86352 of couples (3.7%) were anemic. In 4.6% of anemic couples Hb A2 was more than 3.5% and they were confirmed for beta-thalassemia trait in the first stage. Overall 61% of anemic couples were undergone iron-therapy that it was in range of 30% in early years to more than 70% in the last one which genetic counseling centers had been developed. Also CBC indices were modified in 69.1% of these couples after treatment for 3 months. Finally genetic testing was performed in 94% of the couples who had not been treated and beta-thalassemia trait was ruled out in 76% of them. We concluded that genetic counseling and iron-therapy has a significant role to reduce under-care suspected couples (false suspected), so that if it is invigorated the surveillance system will be concentrated to care of real carriers.

P01.82
Pharmacogenetic Distribution of Warfarin and its Clinical Significance in Korean Patients during Initial Anticoagulation Therapy

Y. Lee[1], *A. Kwon*[1], *S. Jo*[2], *H. Im*[3], *Y. Jo*[1], *J. Park*[1], *H. Cho*[1];
[1]*Department of Laboratory Medicine, Hallym University College of Medicine, Anyang, Korea, Republic of,* [2]*Department of Internal Medicine, Hallym University College of Medicine, Anyang, Korea, Republic of,* [3]*Department of Occupational Medicine, Hallym University College of Medicine, Anyang, Korea, Republic of.*

During warfarin treatment, determining the optimal dose and maintaining the target PT-INR are challenging. Increasing evidence supports the theory that genotypic polymorphisms influence an individual's warfarin dose requirement. In this study, we evaluated allele frequencies and effects of *CYP2C9* and *VKORC1* on warfarin response during initial anticoagulation therapy in Korean patients. We enrolled patients who had initiated warfarin therapy and undergone PT-INR testing at least three times within the first month of anticoagulation therapy. All the participating patients were tested for the detection of *CYP2C9**3 (c.1075A>C) and *VKORC1*-1639G>A. A melting-curve analysis after

real-time PCR was performed using CYP2C9˚3 and VK1639 genotyping kits (Idaho Technology, USA). A total of 37 patients were enrolled in this study. *CYP2C9**1/*1 (86.5%) and *VKORC1*-1639AA genotypes (89.2%) were predominant in Korea. The *CYP2C9**3 and *VKORC1*-1639G alleles were found in five (13.5%) and four patients (10.8%), respectively. Patients with the *VKORC1*-1639G allele received a higher warfarin dose (*P*=0.002), with a significant dose change between days 1 and 30 (*P*=0.003). Patients with the *CYP2C9**3 allele tended to show a more rapid PT-INR increase and receive a lower warfarin dose, with a greater dose change between days 1 and 30. The *CYP2C9**3 and *VKORC1*-1639G alleles influenced warfarin response during the first month of anticoagulation therapy. Considering *CYP2C9* and *VKORC1* genotypes when estimating warfarin dose and frequency of PT-INR monitoring can improve therapeutic outcomes with fewer complications.

P01.83
DNA degradation analysis in post-mortem soft muscle tissues in relation to accumulated degree-days (ADD)

M. S. Nazir;
School of Forensic and Investigative Sciences, University of Central Lancashire, Preston, United Kingdom.

After the death of an organism DNA starts to degrade: as the organism's cell structure breaks down, nucleases are released and directly cause DNA degradation. Subsequent colonisation, action of insects and microorganisms also contributes to the DNA degradation. As the post-mortem interval (PMI) increases, DNA continues to degrade until no high molecular weight DNA (HMW-DNA) remains.

In order to assess DNA degradation in the model organisms chosen (pig and rabbit), two nuclear genes, Connexin 43 and RAG-1, were aligned to identify conserved regions. Primers were designed to amplify 70 bp, 194 bp, 305 bp and 384 bp amplicons. The primers were also designed to amplify human DNA, which allowed the use of commercially purchased DNA standards to be used as controls. Following DNA extraction PCR analysis was performed using the four primers sets in a multiplex (4-plex): the PCR was optimised so that it worked over a wide range of template amounts (0.1 ng to 75.83 ng). The multiplex (4-plex) PCR was found to work efficiently in triplicate samples of all three species down to 0.3 ng of DNA template.

This multiplex has been used to assess whether DNA degradation can be predicted by accumulated degree-days (ADD), which provides a measure of both time and temperature.

Full 4-plex profiles were generated until day 7 (ADD 111.93) from whole carcasses and body fragments and up to day 11 (ADD 172.48) from insect-activity-free muscle samples.

Future work will include; development of real-time PCR quantification assays, DNA Fragment analysis and DNA preservation.

P01.84
Attitudes of midwives and family physicians towards ethnicity based haemoglobinopathy carrier screening: exploring current behaviour and future intentions.

S. M. P. J. Jans[1], *A. de Jonge*[1], *M. C. Cornel*[1], *A. M. Lagro-Janssen*[2];
[1]*EMGO Institute for Health and Care research, Amsterdam, Netherlands,* [2]*Institute for gender studies, Radboud University Nijmegen, Nijmegen, Netherlands.*

Purpose: Globally approximately 5% of the world population is a carrier of a serious haemoglobin disorder. No formal recommendations concerning preconception or antenatal testing of carrier status exist in The Netherlands at present. Earlier research identified registration of ethnicity as an issue in deciding not to introduce a screening program in the past and found that health practitioners did not perceive ethnicity as an increased risk factor.

This study investigates attitudes, behaviour and intentions of midwives and FPs towards haemoglobinopathy carrier screening on the basis of ethnicity.

Methodology: A structured questionnaire based on the Theory of Planned Behaviour sent to 1800 midwives and 2100 FPs

Results: 1346 questionnaires were collected (35% response). Midwives and FPs were positive about offering ethnicity based screening but do not currently carry this out. Factors explaining intention were social norm, control over the ability to carry out the test and social norm (R^2 0.522). The main factor explaining intention was social norm: their perception of negative peer opinion. If screening would become national policy most midwives and FPs would carry out ethnicity based haemoglobinopathy carrier screening. Both practitioners favoured ethnicity registration for health purposes.

Conclusion: Whether ethnicity based haemoglobinopathy screening is offered, is partially influenced by FPs and midwives perception of their colleagues' opinion about carrier testing based on ethnicity. However most are willing to offer screening should this become national policy. In developing new policy, debate amongst midwives and FPs should be encouraged articulating the voices of colleagues who already actively offer haemoglobinopathy screening.

P02 Clinical genetics and Dysmorphology

P02.001
Genomic and clinical characteristics of six patients with partially overlapping interstitial deletions at 10p12p11

C. Wentzel[1], *E. Rajcan-Separovic*[2], *C. A. L. Ruivenkamp*[3], *S. Sandra Chantot-Bastaraud*[4], *C. Metay*[5], *J. Andrieux*[6], *G. Annerén*[1], *A. C. J. Gijsbers*[3], *L. Druart*[4], *C. Hyon*[7], *M. Portnoi*[4], *E. Stattin*[8], *C. Vincent-Delorme*[6], *S. G. Kant*[3], *M. Steinraths*[9], *S. Marlin*[4], *I. Giurgea*[5], *A. Thuresson*[1];
[1]*Department of Immumology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [2]*The Child and Family Research Institute and University of British Columbia, Vancouver, BC, Canada,* [3]*Department of Clinical Genetics, Center for Human and Clinical Genetics, Leiden University Medical Center (LUMC), Leiden, Netherlands,* [4]*Service de Génétique, Hôpital Armand Trousseau, Paris, France,* [5]*Service de Biochimie-Génétique, Plateforme de Génomique Constitutionnelle, Hôpital Henri Mondor, Créteil, France,* [6]*Laboratoire de Génétique Médicale, Hopital Jeanne de Flandre, CHRU de Lille, France,* [7]*Universite Paris decarte, Service de génétique hôpital necker Paris, Paris, France,* [8]*Department of Medical Biosciences, Medical and Clinical Genetics, Umeå, Sweden,* [9]*Department of Laboratory Medicine, Pathology and Medical Genetics, Victoria General Hospital, Victoria, BC, Canada.*

With the clinical implementation of genomic microarrays, the detection of cryptic unbalanced rearrangements in patients with syndromic developmental delay has considerably improved. Here we report the molecular karyotyping and phenotypic description of six new unrelated patients with partially overlapping microdeletions at 10p12.31p11.21 ranging from 1.0 Mb to 10.6 Mb. The smallest region of overlap is 306 kb, which includes *WAC* gene, known to be associated with microtubule function and to play a role in cell division. Another patient has previously been described with a 10 Mb deletion, partially overlapping with our six patients[1]. All seven patients have developmental delay and a majority of the patients have abnormal behaviour and dysmorphic features including bulbous nasal tip, deep set eyes, synophrys/thick eyebrows, and full cheeks, while other features varied. All patients also displayed various visual impairments and 6 out of 7 patients had cardiac malformations. Together with the previously reported patient, our study suggests that the detected deletions may represent a new contiguous gene syndrome caused by dosage sensitive genes that predispose to developmental delay.

1)Shahdadpuri R, de Vries B, Pfundt R, de Leeuw N, Reardon W: Pseudoarthrosis of the clavicle and copper beaten skull associated with chromosome 10p11.21p12.1 microdeletion. *Am J Med Genet A* 2008; 146A: 233-237.

P02.002
Vermis hypoplasia as part of a contiguous gene syndrome in a girl with microdeletion 10q26

K. M. Roetzer[1], *A. Schwerin-Nagel*[2], *P. Kroisel*[1], *M. Mach*[1], *E. Vallant*[1], *K. Wagner*[1], *M. Speicher*[1], *B. Plecko-Startinig*[2];
[1]*Institute of Human Genetics, Medical University of Graz, Graz, Austria,* [2]*Department of Pediatrics and Adolescence Medicine, Medical University of Graz, Graz, Austria.*

Microdeletions of 10q26 cause a contiguous gene syndrome described in about 60 patients until now. There is significant variation in deletion size and phenotype. Clinical symptoms include mental retardation, motor and speech delay, strabismus, characteristic facies, microcephaly, short stature, as well as in some cases feeding difficulties, behavioural problems, muscular hypotonia, ataxia, hearing loss, genitourinary anomalies and heart defects. We report on a 10-year-old girl who presented with moderate global developmental delay, severe speech delay, strabismus, intention tremor, ataxia, hydronephrosis

and mild dysmorphic features. Pregnancy was complicated by vaginal bleeding in gestational week 32. Furthermore, the mother recognized reduced fetal movements. Sectio was performed in gestational week 41 (APGAR score 3/8/9 at minutes 1/5/10, birth measurements within normal range). Developmental milestones were delayed with sitting at 8 months, walking at 22 months, first words at about 28 months. At the age of 30 months a brain MRI showed marked hypoplasia of the inferior part of the vermis cerebelli. Investigations regarding inborn errors of metabolism, congenital disorders of glycosylation as well as classical karyotyping were unremarkable. However, array CGH analysis revealed an interstitial 6.92 Mb microdeletion in 10q26. Further investigations showed that the deletion had occurred de novo. This is the first case of a 10q26 microdeletion with an abnormal MRI of the cerebellum. We hypothesize that the vermis hypoplasia might be causative for the ataxia and intention tremor in our patient.

Both underweight and obesity have been associated with increased morbidity and mortality. Weight faltering in childhood (or failure to thrive) have long-lasting deleterious effects on development, including adverse intellectual outcomes. In contrast to obesity, molecular abnormalities underlying low-weight remain elusive. While hemizygosity of a 600 kb region on the short arm of chromosome 16 (chr16:29.5-30.1Mb) causes a highly-penetrant form of obesity often associated with hyperphagia and intellectual disabilities, the corresponding reciprocal duplication is associated with underweight. We identified 108 carriers of this 16p11.2 duplication among 95,000 individuals. These carriers show significantly reduced weight (mean Z-score -0.6; $p<10^{-3}$) and adults have an 8.7-fold ($p<10^{-10}$) increased risk of being clinically underweight (defined by a BMI<18.5kg/m^2). An early onset gender-specific effect was found in cases ascertained through developmental and intellectual disabilities, with half of the boys younger than 5 years exhibiting failure to thrive. These features are only detectable postnatally and are associated with an unusually high frequency of selective and restrictive feeding behaviours. Duplication carriers also have a significant reduced head circumference ($p<10^{-5}$) which positively correlates with BMI. Weight, BMI and head circumference phenotypes as well as food intake behaviours are the converse of those reported in carriers of deletions at this locus, correlating with changes in transcript levels for genes mapping within the CNV, but not within flanking regions. The reciprocal impact of these 16p11.2 copy number variants evidences that severe obesity and being underweight can have mirror etiologies, possibly through contrasting effects on eating behaviour.

Auxological evaluation in patients with a 22q11.2 microdeletion syndrome: normal prevalence of obesity but neonatal length and gender influence on body mass index evolution

R. Reynaud[1], *D. Braunstein*[2], *J. Gaudart*[3], *F. Giuliano*[4,5], *A. Moncla*[1], ***N. Philip***[1,6];

[1]*Hopital d'Enfants de la Timone, Marseille, France,* [2]*University of the Mediterranean, Marseille, France,* [3]*University of the Medriterranean, Marseille, France,* [4]*Hopital Archet 2, Nice, France,* [5]*Reference center for developmental anomalies, Nice, France,* [6]*Reference center for developmental anomalies, Marseille, France.*

Aims: to evaluate auxological parameters in children and adults with a 22q11.2 microdeletion syndrome (22q11.2DS); to compare prevalence of obesity to that in the general French population.

Methods: 102 patients with 22q11.2DS (49 males, 53 females) were recruited from birth to adulthood through a reference center from Southern France.

Results: Mean Z score BMI and mean height were normal (0.07 ± 1.49 SD, -0.87±1.36 SDS, respectively). 16.1 % of patients were overweight (including obese), 57% of them were born SGA for length versus 25% of non overweight patients. During infancy, boy's BMI dramatically increased (+ 1.07 SD Z score) until normalization whereas girl's BMI increased from 2 to 4 years. Childhood: 14.7% were overweight, a prevalence similar to that in French children population. Adulhood: from 26 available measures, 19.2% were overweight. Male gender was significantly associated with a lower post pubertal BMI than female (β=-1,987). After 15 years of age, BMI and Z score of BMI were inversely correlated with neonatal length (β=-1.140) but positively associated with neonatal weight (β=+2.294) and female sex ($p<0.01$). From analysis of neonatal data, 22q11DS newborns were significantly shorter (-1.46± 1.2 SDS) with regard to their weight (-0.83 ±0.98 SDS) ($p<0.01$), even though mean neonatal measures were above -2SDS.

Conclusions: Our study did not find a higher prevalence of overweight in 22q11.2DS to that in French population. Post pubertal BMI was inversely correlated with neonatal length but positively associated with neonatal weight and female gender.

P02.005

3.7 Mb tandem microduplication in chromosome 5p13.1-p13.2 associated with developmental delay, macrocephaly, obesity, and lymphedema. Further characterization of the dup(5p13) syndrome.

K. Oexle[1], *M. Hempel*[1], *A. Jauch*[2], *T. Meitinger*[1], *S. Stengel-Rutkowski*[3], *T. Strom*[4];

[1]*MRI, München, Germany,* [2]*University Hospital, Heidelberg, Germany,* [3]*LMU, München, Germany,* [4]*Helmholtz Center, München, Germany.*

In a male patient with developmental delay, autistic behaviour, obesity, lymphedema, hypertension, macrocephaly, and facial features (dolichocephaly, short neck, low set posterior hairline, dysplastic ears, broad nasal root, short nose, microretrognathia) of chromosome 5p duplication (trisomy 5p) a 3.7 Mb de novo tandem microduplication of 5p13.1-13.2 (rs4703415-rs261752, i.e., chr5:35.62-39.36Mb) was identified. This observation contributes to the characterization and dissection of the 5p13 duplication syndrome. A comparison with previous case reports is provided. Similar to the patients with duplication of the entire NIPBL gene reported by Yan et al (2009) but different from several case reports on 5p13 duplication, there was, for instance, no heart defect in our patient. The possible role of genes within the duplicated region, especially of NIPBL, is discussed.

INTRODUCTION:

Partial deletions of the long arm of chromosome 18 lead to different clinical presentations. Patients whose deletions localized within the same region may exhibit distinct phenotypes. Conversely they can exhibit common clinical features. New molecular techniques such as array CGH allow for a more precise determination of deletion points leading to better-defined genotype-phenotype correlations. This method proved to be effective in determining molecular profiles with a resolution 5-10 times higher than conventional karyotyping methods.

MATERIAL- METHOD:

We had two patients admitted to our clinic; one of them, 13 years old boy with dysmorphic features and autism; the other 15 years old girl with inability to speak. We used array CGH method for diagnosis of these two patient. DNA samples which labelled according to the protocol, were hybridized with CytoSure Syndrome Plus(v2)4x44K microchips and scanned with Agilent Microarray Scanner. Obtained data were analyzed using Cytosure Analysis Software,v.2.0.8.

RESULTS:

According to array CGH analysis, 8.21 Mb deletion was detected in 18q21.31-q23 region. Important genes for this region are MALT1, RAX, LMAN1, MC4R, TNFRSF11A, BCL2, CTDP1 and FVT1. The conventional karyotype analysis was performed to these patients and 46XYdel(18)(q21.3-q23) was found. These results supported array CGH results.

CONCLUSION:
Although these patients possesed same deletions at the same region, their clinical manifestations was different and they had few common phenotypic features. Effects of the genes to the phenotype at this region is unknown but can be possible to investigate. These genes will provide new clues for pathogenesis and treatment of the disease.

P02.007
45,X/46,XY mosaicism: a cause of short stature in males

***A. Efthymiadou**;*
Department of Pediatrics, University of Patras, Patras, Greece.

45,X/46,XY mosaicism is associated with a broad spectrum of phenotypes ranging from apparently normal male development, individuals with incomplete sexual differentiation and males and females with clinical signs of Turner syndrome. The most common presentation for individuals with a 45,X/46,XY karyotype is sexual ambiguity, accounting for ~60%, and the least common category of 45,X/46,XY patients consists of those with bilaterally descended testes, found in 11-12%.
We report on two patients with an apparently normal male phenotype and 45,X/46,XY mosaicism who were diagnosed postnatally because of short stature.
Both of these boys presented at the age of 15 years with short stature, minor Turner-like stigmata, normal male external genitalia and spontaneous pubertal development. One of them had coarctaction of aorta with bicuspid aortic valve, an uncommon clinical feature in boys with 45,X/46,XY karyotype. The same patient had a trial of GH replacement therapy with poor response and his sperm analysis revealed azoospermia.
Like our patients, most mosaic 45,X/46,XY children with bilateral scrotal testes go unrecognised at birth and throughout childhood unless they have somatic features of Turner syndrome or significant growth retardation. We recommend that boys with otherwise unexplained short stature being short for their families should be karyotyped routinely as is recommended in short-stature girls. In addition, boys with 45,X/46,XY karyotype must be routinely followed-up for their potential to respond favourably to GH treatment and for late onset abnormalities, such as infertility and gonadal tumors.

P02.008
Cephalometric evaluation in a patient with 48,XXXX syndrome

***D. Belengeanu**[1], A. Podariu[2], R. Rotaru[3], N. Andreescu[4];*
[1]University of Medicine and Pharmacy, College of Dental Technique, Timisoara, Romania, [2]University of Medicine and Pharmacy, Department of Medical Dental Prevention and Oral Health, Timisoara, Romania, [3]Individual Dental Office, Timisoara, Romania, [4]University of Medicine and Pharmacy, Department of Medical Genetics, Timisoara, Romania.

The aim of this study is to investigate the cephalo-facio-dental relationships in the craniofacial complex and the use them for diagnostic and orthodontics treatment. We studied the changes of the cephalo-facio-dental relationships, using serial lateral cephalometric roentgenograms in a 29 years old female with 48,XXXX karyotype. By using cephalometric methods we evaluated 32 linear and 12 angular measurements of the craniofacial complex. We found smaller linear and larger angular measurements. Even if all face heights were diminished, we recorded a significantly shortening of the length of the anterior and posterior cranial bases, posterior face height, the length of the calvarium and mandibular ramus length, while the mandibular corpus demonstrated only a slight reduction. This can explain the significantly increased SNB angle as a compensatory mechanism between the accentuated shortening of the anterior and the slight reduction of mandibular corpus, ramus height reduction of was compensated by a smaller gonial angle. The angles between the palatal and occlusal planes and between the palatal and mandibular planes were increased due to the fact that the palatal plane that was canted upwards. The patient was included in skeletal Class III growth pattern and associated a modified dentoalveolar complex with upper incisors having a reduction of the proclination and lower incisors in retrocline position. We concluded that even if the underlying mechanisms are not known, the presence of supernumerary X chromosome influence the development of craniofacial complex conducting to smaller linear parameters and enlarged angular measurements.

P02.009
Phenotypic variations in Wolf-Hirshorn syndrome

***E. Sukarova-Angelovska**, M. Kocova, N. Angelkova, V. Sabolich-Avramovska;*
Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.

Wolf-Hirshorn syndrome is rare chromosomal disorder caused by terminal deletion of the short arm of chromosome 4. The haploinsuficiency of the deleted region is expressed as severe phenotype which includes growth retardation, severe mental retardation, characteristic face, seizures and midline defects in the brain, heart, palate, hypospadias, etc. The severity of clinical presentation is due to the size of the deleted region, as well as genes involved in the deleted region.
We present five children with Wolf-Hirshorn syndrome with variable clinical presentation. Present dysmorphic stigmata as Greek helmet-like forehead, hyperthelorism, broad nose, short philtrum, low-set dysplastic ears, and sacral dimple were classified as minor, mild and severe. Aditional congenital anomalies of the heart, kidneys, genitalia and intestine were taken into the consideration. Seizures were present in 4 children, and were of variable type. Two of the children have visible cytogenetic deletion, two had microdeletion detected with FISH probe, and one child with less characteristic clinical picture had mosaic type of the deletion.
The phenotype of the deletion of the short arm of cheomosome 4 is variable -from minor to full blown clinical presentation with characteristic facial dysmorphism and adjacent malformations. Characteristic appearance resembling “Greek helmet” facies is the basis for establishing the diagnosis of Wolf-Hirschhorn (WH) syndrome. Since it is a contiguous gene syndrome, different regions of chromosome 4p could be deleted. Recently used molecular techniques increase the number of diagnosed cases due to the detection of smaller deletions.

P02.010
4p15 deletion in a patient with apparently isolated metopic craniosynostosis.

*V. Alesi[1], G. Barrano[1], S. Morara[1], D. Darelli[1], K. Petrilli[1], A. Capalbo[2], M. Pacella[3], C. Haass[3], M. Finocchi[3], A. Novelli[2], **M. Bertoli**[1];*
[1]S. Pietro Fatebenefratelli Hospital Rome, Italy, UOSD Genetica Medica, rome, Italy, [2]IRCCS «Casa Sollievo della Sofferenza» and Mendel Institute,, rome, Italy, [3]S. Pietro Fatebenefratelli Hospital Rome, Italy, Neonatal Intensive Care Unit, rome, Italy.

Craniosynostosis, premature fusion of one ore more cranial sutures, affects approximately one in 3000 live births. Syndromic trigonocephaly has been associated with chromosomal imbalances or point mutations in single genes. Recently, it has been suggested that rare copy number variants (CNVs) in patients with isolated single-suture synostosis could contain genes important for cranial development. In fact, some of the involved genes play a role in osteoblasts proliferation, apoptosis and differentiation, whose deregulation can evolve in precocious suture closure. We report the case of a 12 months old boy with an apparently isolated craniosynostosis and harboring a de novo microdeletion in the cytoband 4p15. The imbalance, about 4 Mb in size is, up to date, the smallest deletion described in this region, encompassing 12 genes. SLIT2, originally characterized in the nervous system as a guidance factor for axons, looks interesting because it was recently described to have a role in in vitro osteoblast growth regulation. Further cases of CNVs including SLIT2 would be extremely useful in determining whether its deregulation could be implicated in premature suture closure. Among others, DCAF16 and NCAPG should also be considered for genetype phenotype correlation. In fact, these genes are involved in fundamental cell biological processes, and could be eventually associated with poor brain development. Up to now, developmental steps of our patient looked adequate for his age, but further follow up is needed in order to assess his psychomotor development. Genotype-phenotype comparison with other previously described cases with 4p15 deletion will be discussed in detail.

P02.011
Early-onset polycystic kidney disease (PKD) - a crucial additional finding of 4q deletion syndrome

***y. oto**, t. nagai, n. murakami, k. obata, y. tanaka, s. sakazume, y. kido;*
dokkyo university school of medicine, saitama, Japan.

Several reports describing chromosome 4q deletion have been published since 1980’s . In 2010, 9 cases with 4q deletion were

reported by Bonnet et al and the name of 4q deletion syndrome was established. This is a contiguous gene deletion syndrome showing several characteristic features including severe growth retardation, teeth defect and neurosensorial deafness. *PKD2* gene which was mapped at 4q21-q23 by Mochizuki in 1996 is related to autosomal dominant type PKD. *PKD2* gene is deleted in 4q deletion syndrome. However, few reports have described renal cysts in this syndrome. We assumed that deleted *PKD2* should result in autosomal dominant PKD.

Here we report on 2 cases of 4q deletion syndrome; one is a 15-year-old female patient who was previously reported by Harada in 2002 and the other is a 9-year-old female patient showing deletion 4q21-21.3 and 4q21.1-22.2, respectively. Both of them showed several typical characteristic findings of 4q deletion syndrome including severe growth and mental retardation, and teeth defect. In addition to these features, both of them showed severe PKD by echogram and MRI without renal dysfunction. Usually *PKD2* mutation develops PKD frequently in adulthood and rarely in childhood. Our cases with this deletion developed PKD in childhood, suggesting that early onset may be related to the deletion, not a mutation, of *PKD2*.

PKD should be added to the essential features of 4q deletion syndrome. Clinicians should perform renal imaging study in patients with this syndrome even without abnormal findings in routine blood tests and urinalysis.

P02.012

Dysmorphic features, short stature and deafness explained by a homozygous deletion of 15p15.33 involving the SLC12A7 (Kcc4) gene and the NKD2 gene.

M. Elting, *A. van Hagen, A. Nieuwint, H. Meijers-Heijboer, E. Sistermans, M. Weiss;*

VU University medical center, Amsterdam, Netherlands.

A fourth child of consanguineous parents was born with a Pierre Robin sequence and dysmorphic features concerning round eyes, low set- and cup shaped ears, flat midface, bowed tip of the nose, underdeveloped nostrils and flat philtrum. Growth on - 2 SD, no heart or kidney anomalies. Normal karyotype, no 22q11 deletion.

The girl developed short stature and perceptive deafness. DFNB1, SHOX and CHARGE were excluded. A skeletal survey was normal.

Array CGH (Agilent 180k) showed a homozygous deletion of 50 kb of 5p15.33 involving the 3' end of both the NKD2 and SCL12A7 (Kcc4) gene. The healthy parents and three sibs are heterozygous carriers of the deletion.

Kcc4 is a K^+- Cl^- cotransporter playing a role in the K^+ transport in the inner ear and in the Cl^- transport in the proximal tubules of the kidney. Mice lacking Kcc4 are deaf, have a low bodyweight and develop renal tubular acidosis.

Nkd 1 and *nkd2* inhibit wnt-signaling and are involved in morphogenic signaling. In mice *ndk2* is expressed in the snout and ears. In the *ndk1-ndk2* knockout mouse the nose is short.

In conclusion, this patient has a homozygous deletion syndrome in which the loss of *Kcc4*, likely explains her deafness and short stature, and the loss of *nkd2* causes specific dysmorphic facial features.

P02.013

De novo 9p duplication in a syndromic child

*A. Bakken[1], K. O. Clausen[1], A. K. Eek[1], **H. Høyer**[1], S. Skei[2], G. J. Braathen[1,3];*

[1]Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway, [2]Department of Pediatrics, Section of Habilitation, Telemark Hospital, Skien, Norway, [3]Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway.

Background. 9p duplication syndrome is a rare chromosomal disorder often with well characterized clinical features. Array Comparative Genomic Hybridization (aCGH) have revealed that duplicated areas on 9p may have different clinical impact, i.e. 9p24.3 to 9p23 as a potential autism spectrum disorder locus, 9p22.3 to 9p22.2 as the critical region for the 9p duplication syndrome, 9p22.1 to 9p13.1 as a probable normal variant and 9p11.2 to 13.1 definitely as a normal variant

Methods. We describe a child with *de novo* 9p duplication and the genetic analyses performed in the family.

Results. Both chromosomal analysis and array Comparative Genomic Hybridization (aCGH) identified the duplication.

Conclusions. ACGH makes it easier to assess different clinical aspects such as developmental delay, autism and deformities with regard to the chromosomal findings.

P02.014***

Evidence for AXIN2/IRF6 interaction in oral facial clefting

Oral-facial clefts (OFC) have a multigenic etiology that involves many different signaling pathways. We recently reported that families segregating OFCs present an increased history of cancer when compared to control families, and that AXIN2 is associated with OFCs in a US population. Since Axin2 is an important negative regulator of the Wnt pathway, and the Wnt pathway is integral to craniofacial development, we expanded our initial study to explore the association of AXIN2 markers with OFCs in 724 cleft families from North America, Europe, Asia, and Latin America. Thirteen AXIN2 SNPs were genotyped using TaqMan chemistry and tested for association with OFC using the Family-Based Association Test (FBAT). An association between SNP rs7224837 and OFC was identified in the pooled populations (P=0.001), while SNP rs3923086 showed association with Chinese families from Beijing and Shanghai presenting cleft lip and palate individuals only (P=0.004). We found statistical evidence of interaction between these AXIN2 SNPs and IRF6 SNPs rs2235371 and rs642961 (P<0.05). We assessed mouse Axin2 expression during mouse palatogenesis, and also detected co-localization of Axin2 and IRF6 proteins in the palate, oral and molar tooth epithelia. Taken together, our results support an important role for AXIN2 during craniofacial and palatal development. Further, these results provide insights into potentially etiologic AXIN2-IRF6 interactions that may contribute to the etiology of OFCs in humans.

P02.015**

COL4A2 mutation associated with familial porencephaly, aneurysm and secondary developmental anomalies

*H. A. Verbeek[1], F. W. Verheijen[1], **M. E. C. Meuwissen**[1], P. Govaert[2], D. Licht[3], D. S. Kuo[4], C. Poulton[1], R. Schot[1], M. H. Lequin[5], J. Dudink[2], D. J. Halley[1], I. R. F. de Coo[6], J. den Hollander[7], R. Oegema[1], D. B. Gould[8], G. M. S. Mancini[1];*

[1]Dept. of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Netherlands, [2]Dept. of Neonatology, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Children's Hospital and University of Pennsylvania Medical School, Philadelphia, PA, United States, [4]Department of Ophthalmology, University of California, San Francisco, CA, United States, [5]Dept. of Radiology, Erasmus University Medical Center, Rotterdam, Netherlands, [6]Dept. of Child Neurology, Erasmus University Medical Center, Rotterdam, Netherlands, [7]Dept. of Pathology, Erasmus University Medical

Center, Rotterdam, Netherlands, [6]Dept. of Ophthalmology and Anatomy, Institute for Human Genetics University of California, San Francisco, CA, United States.

Background. Familial porencephaly results from cerebral stroke during pregnancy or around birth and has been described with dominant mutations in the gene encoding for type IV collagen alpha 1 (*COL4A1)*. We observed three porencephaly families that lack *COL4A1* mutations. Mice harbouring mutations in either *Col4a1* or *Col4a2* suffer from cerebral and ocular bleeding and developmental defects. We hypothesized that *COL4A2* mutations could cause porencephaly in families without *COL4A1* mutations.

Methods. We sequenced *COL4A2* in three families with porencephaly, and characterized clinical, neuroradiological and cellular phenotypes by biochemistry and EM of skin.

Results. Sequencing of *COL4A2* identified the heterozygous pathogenic mutation Gly1389Arg and two probable pathogenic c.3206delC and Met813Leu in three families with cerebrovascular disease. In patients with mutations, phenotypes varied including porencephaly, microcephaly, white matter tract abnormalities, secondary cerebellar and optic nerve hypoplasia, stroke at adult age and carotid aneurysm. However, in two families, patients without the mutation were described. In support of pathogenicity, fragmentation and duplication of epidermal basement membranes was observed by electron microscopy in c.3206delC and Met813Leu patient skin biopsies, consistent with abnormal collagen IV network. Cultured fibroblasts of one c.3206delC patient showed significantly increased rates of apoptosis under stress conditions, but, interestingly, no associated signs of ER stress.

Conclusions. Dominant *COL4A2* mutations are a novel risk factor for porencephaly, stroke and brain developmental defects. Basement membrane defects appear to underly pathology, but abnormal regulation of apoptosis may be a contributing factor.

P02.016
G1138A mutation in FGFR3 gene in patients with achondroplasia

***S. BUCERZAN**[1], C. Al-Khzouz[1], R. Popp[2], A. Trifa[2], C. Denes[1], M. Crisan[1], P. Grigorescu-Sido[1];*

[1]FIRST PEDIATRIC CLINIC, CLUJ-NAPOCA, Romania, [2]Department of Medical Genetics, CLUJ-NAPOCA, Romania.

Introduction. Achondroplasia is a common form of chondrodyplasia with a frequency of 1/15.000 - 40.000 new borns. It is transmitted by autosomal dominant trait with full penetrance but approximately 75-80% of the cases are caused by de novo mutations. The disease is determined by mutations in receptor-3 gene of the fibroblast growth factor (FGFR3), mapped to band 4p16.3, resulting in decreased endochondral ossficication, inhibited proliferation of chondrocytes in growth plate cartilage and decreased cartilage matrix. The most frequent mutations (up to 99%) are G1138A and G1183C. The aim of this study is to establish the prevalence of G1138A mutation in FGFR3 gene in patients with achondroplasia in our care.

Patients and method. The study group consisted of 27 patients (17 girls and 10 boys), aged between 1 year 8 months - 22 years, who were registered in the Centre of Genetic Diseases of First Pediatric Clinic Cluj in the period 2007-2010. The method consisted in: clinical assessment and radiological examinations (radiograms of the skull, upper and lower limbs, spinal column and pelvis). The DNA analasys was performed by PCR-RFLP technique.

Results. Between 2007 - 2010, 80 patients were diagnosed with bone dysplasia; 27 of them (33,75%) were diagnosed (on clinical and radiological basis) with achondroplasia. Out of this group, 13 patients (48,14%) were identified as heterozygotes for G1138A mutation in FGFR3 gene; this prevalence is very low comparatively with other studies (Hung CC, Alderborn A).

Conclusions. It is the first study that reports the prevelance of this mutation in Romania.

P02.017
Acro-Cardio-Facial syndrome: description of a new case.

***B. Toschi**[1], C. Congregati[1], A. Michelucci[1], V. Bertini[1], A. Valetto[1], P. Simi[1], B. Murzi[2], M. Cantinotti[2], N. Assanta[2];*

[1]U.O. Citogenetica e Genetica Molecolare, PISA, Italy, [2]Fondazione Monasterio, Pasquinucci Hospital, National Research Council, Massa, Italy.

Acro-Cardio-Facial syndrome (ACFS) is a very rare genetic condition with nine patients been published until now. ACFS is clinically heterogeneous, but split-hand and split-foot malformation and congenital heart defect (CHD) are the most important diagnostic features. Other malformations and clinical signs reported are: cleft lip/palate, genital anomalies, facial dysmorphisms and mental retardation. Genetic cause is unknown and autosomal recessive inheritance is supposed.

We describe a male born to non-consanguineous parents, with hand malformations, CHD and peculiar morphologic facial features. Fetal ultrasound at 20 week gestation showed a complex CHD. At birth, he presented with cleft left hand and lack of flexion at the interphalangeal joints of the fifth right hand finger. On echocardiography the CHD detected consisted of truncus arteriosus type 1, ventricular septal defect and pulmonary atresia. Morphologic features of the face were: high forehead, broad nasal bridge, long philtrum, microretrognatia and large and dysmorphic low-set ears. TC scan showed the presence of schisis of the posterior arch of the lumbar vertebrae. Karyotype was 46,XY, and array-CGH is ongoing.

We underline the clinical variability of this condition and the wide range of malformations reported requiring a multidisciplinary approach. Clinical genetic assessment is important in order to define the diagnosis and genetic counselling is recommended for parents for high recurrence risk.

P02.018
Apert Syndrome With Fused Thalami

***K. Ludwig**[1], R. Salmaso[1], M. Cassina[2], R. Manara[3], V. Citton[3], M. Baldi[4], M. Rugge[1];*

[1]Department of Medical Diagnostic Sciences & Special Therapies, Pathology Unit, Padova, Italy, [2]Department of Pediatrics, Clinical Genetics Unit, Padova, Italy, [3]Department of Medical Diagnostic Sciences & Special Therapies, Neuroradiology Unit, Padova, Italy, [4]Human Genetics Laboratory, E. O. Ospedali Galliera, Genova, Italy.

An increased nuchal translucency had been detected at 12 weeks of gestation and second level ultrasounds (2-D, 3-D and 4-D) at 20+1 weeks of gestation revealed multiple cranio-facial dysmorphisms including turricephaly, frontal bossing, midface hypoplasia and ocular hyperthelorism. The pregnancy was terminated at 20+3 weeks of gestation.

External examination of the female fetus revealed a clinical phenotype indicative of Acrocephalosyndactyly type I (Apert Syndrome), confirmed by molecular analysis of the FGFR2 gene.

In addition, due to a transvaginal ultrasound detection of probable holoprosencephaly, a post mortem MRI scan was preformed revealing a minimal form of holoprosencephaly with fusion of the thalami.

Apert syndrome and holoprosencephaly occur with prevalences of approximately 1:55000 and 1:8000, respectively. Various central nervous system anomalies, such as ventriculomegaly, corpus callosum anomalies, hydrocephaly, defective septum pellucidum and mesial temporal abnormalities have been reported in patients with Apert syndrome.

While there are numerous patients affected simultaneously by HPE and craniosynostosis (one of the cardinal signs of Apert syndrome), cases of holoprosencephaly in Apert syndrome have never been reported so far.

P02.019
Subtle risk of dissection in thoracic aneurysms associated with mutations of smooth muscle alpha-actin 2 (ACTA2)

***E. Disabella**, M. Grasso, F. Gambarin, N. Narula, R. Dore, V. Favalli, A. Serio, L. Gesa, E. Antoniazzi, M. Mosconi, A. Odero, M. Pasotti, E. Arbustini;*

IRCCS Policlinico San Matteo, Pavia, Italy.

To evaluate the prevalence and phenotype of smooth muscle alpha-actin (ACTA2) mutations in nonsyndromic thoracic aortic aneurysms and dissections (TAAD).Observational study of ACTA2 mutations in TAAD.Setting : Centre for Inherited Cardiovascular Diseases.

Patients A consecutive series of 100 patients with TAAD. Exclusion criteria included genetically confirmed Marfan syndrome, LoeyseDietz type 2, familial bicuspid aortic valve and EhlerseDanlos type IV syndromes.

Multidisciplinary clinical and imaging evaluation, genetic counselling and testing of ACTA2, and family screening.

Main outcome measures Prevalence of ACTA2 mutations and corresponding phenotypes.

Results TAAD was familial in 43 cases and sporadic in 57 cases. Five mutations in the familial TAAD group (12%) were identified that were absent in controls. The known p.Arg149Cys and the novel p.Asp82Glu, p.Glu243Lys and p.Val45Leu mutations affected evolutionarily conserved residues. The IVS4+1G>A mutation was novel. Of 14 affected relatives, 13 were carriers of the mutation identified in the corresponding proband while one deceased relative had no genetic test. Type A dissection was the first manifestation of aortic aneurysm in four probands and occurred unexpectedly in five relatives. The aortic aneurysm was age dependent and absent in mutated children. Of nine patients who had acute dissection, five died following surgery. At dissection, the size of the aortic aneurysm ranged from 40 mm to 95 mm. Extravascular, ocular, skeletal, nervous and pulmonary traits were variably associated with TAAD, with iris flocculi being most common.
Conclusions Timely diagnosis of TAAD in the probands, genetic counselling and family screening identify predisposed relatives and prevent catastrophic aortic dissections.

P02.020
Four new cases of Acute Necrotizing Encephalopathy caused by mutation in RANBP2 gene

M. Rio[1], *A. Lebre*[1], *R. Armando*[1], *D. Grévent*[2], *M. Willems*[1], *N. Brahimi*[1], *A. Kuster*[3], *M. Holder*[4], *a. Munnich*[1], *A. Rotig*[1], *P. de Lonlay*[5], *I. Desguerre*[5], *N. Boddaert*[2];
[1]*Department of genetics, Necker Hospital, paris, France,* [2]*Department of pediatric radiology, Necker Hospital, paris, France,* [3]*Department of Pediatrics, nantes, France,* [4]*Department of genetics, lille, France,* [5]*Department of Pediatrics, Necker Hospital, paris, France.*

Acute necrotizing encephalopathy (ANE), first described in East Asia, affects mainly young and healthy children who develop acute encephalopathy, seizures and rapid progression to coma 2 or 3 days after the onset of a viral illness. An autosomal dominant form, ANE1, has been recognized and linked to mutations in the gene encoding the nuclear pore protein Ran Binding Protein 2 (RANBP2). We report the clinical, MRI, and molecular genetic findings of ANE1 in 4 non-related French patients. In all patients, the disease was manifested as a rapidly progressing acute febrile encephalopathy. The patients were previously neurologically normal, with the exception of one child who had residual neurologic problems following a previous febrile encephalopathy. Interestingly two of them were initially referred with the diagnosis of mitochondrial disease because of oxidative phosphorylation deficiency demonstrated in muscle biopsy. The disorder was fatal in two patients. The two other patients recovered from the coma but experienced significant neurologic disability. Cerebrospinal fluid protein was consistently elevated among patients during the acute illness. Imaging findings showed multiple symmetrical lesions affecting primarily the brainstem, the thalami and the external capsule. The four patients were heterozygous for the same missense mutation (c.1880C/T, p.Thr585Met) in the gene (RANBP2). The mutation occurred de novo in two patients and was inherited from healthy parents in two. These observations emphasize the distinctive brain MRI, the possible role in energy maintenance and the not fully penetrant phenotype associated with RANBP2 mutations.

P02.021
Consolidated clinical genetic testing for Aicardi-Goutières syndrome and related conditions: a service package covering *TREX1*, *RNASEH2B*, *RNASEH2C*, *RNASEH2A*, and *SAMHD1*.

L. A. Mavrogiannis[1], *N. Kumar*[1], *Y. J. Crow*[2], *T. Lamb*[1], *R. S. Charlton*[1];
[1]*Regional Genetics Service, St James's University Hospital, Leeds, United Kingdom,* [2]*Genetic Medicine, University of Manchester, Manchester, United Kingdom.*

Clinical and molecular research in Aicardi-Goutières syndrome (AGS), a severe genetic encephalopathy resembling congenital infection, uncovered a range of immune-mediated brain and lupus-like conditions associated with dysregulation of nucleic acid metabolism and/or innate immunity mechanisms. Apart from classical AGS, the AGS spectrum comprises atypical AGS, retinal vasculopathy with cerebral leukodystrophy, chilblain lupus, and certain types of systemic lupus erythematosous, linked by a common genetic etiology. All can be caused by mutations in one, typically, of five known genes involved in nucleic acid clearance and/or innate immunity: TREX1, specifying the major 3'→5' DNA exonuclease in mammals; RNASEH2A, RNASEH2B, and RNASEH2C, encoding the components of the RNASEH2 RNA:DNA endoribonuclease complex; and SAMHD1. At least another, but minor, AGS-related gene is likely to await identification. The AGS system is of both biological and medical interest. For clinical use, we have developed and launched a comprehensive testing package consisting of high-throughput conventional sequencing of the coding regions of the above five genes. Our GeneTests-listed AGS service is estimated to have a clinical sensitivity around 80% and is available with a target turnaround time of 8 weeks for routine diagnostic requests; responding to urgent diagnostic queries is also possible. Overall, this cost-effective strategy reduces testing bias and enables more conclusive reporting while fully complementing, or even superseding, radiological, immunological, and biochemical investigations. Additionally, carrier and prenatal testing, in families with previously characterised mutations, is streamlined.

P02.022
A case of right-sided cardiac developmental abnormality due to a novel mutation in JAG1

B. Brasseur[1,2], *N. Revencu*[1];
[1]*Centre de Génétique Humaine, Bruxelles, Belgium,* [2]*Clinique Saint-Pierre, Ottignies, Belgium.*

Introduction
The JAG1 gene encodes jagged-1 protein, a highly conserved ligand for the Notch1 receptor. Jagged/Notch interactions are critical for determination of cell fates in early development. JAG1 mutations cause the well-known Alagille syndrome (ALGS, MIM: #118450), but growing evidence implicates this gene in various non-syndromic right-sided cardiac defects (1).
Clinical case
We report on a case of a 4-year-old boy referred for evaluation of peripheral pulmonary stenosis. His weight and height were 20kg (0 SD) and 111cm (-1SD) respectively. Developmental milestones were normal. He showed some dysmorphic features: broad and prominent nasal bridge with bulbous nasal tip, long upslanting palpebral fissures and broad chin. There were no other clinical or radiological features of ALGS. Bidirectionnal sequencing of JAG1 (NM_000214.2) revealed a c.820G>T transversion in the exon 6, responsible for a p.Gly274Cys change in the second EGF-like repeat.
Discussion
The interest of this case is the link with a previously described large kindred with a JAG1 mutation in the same codon p.Gly274Asp (2). Interestingly, the affected family members presented striking similar facial features and right-sided cardiac defects, mainly Tetralogy of Fallot and peripheral pulmonary stenosis, but no other signs of ALGS. These findings suggest a genotype-phenotype correlation. Patients with right-sided cardiac defects should be carefully screened for dysmorphic features and family history of cardiac defects and even in the absence of other signs of ALGS, JAG1 should be screened.

P02.023
A case of misdiagnosis of Angelman syndrome, the role of MLPA genetic analysis in diagnosis

N. Khazamipour[1], *S. Rezaee*[1], *N. Mirfatahi*[1], *M. Noruzinia*[2];
[1]*Sarem Cell Research Center and Sarem Women Hospital, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetic and Hematology, faculty of medical sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

Angelman syndrome (AS) is a neurodevelopmental disorder characterized by severe developmental delay or mental retardation, ataxia and dysmorphic facial features. The unique clinical features of AS manifest after 1 year of age, and it can take several years before the correct clinical diagnosis becomes obvious.
Microdeletions on chromosome 15q11.2q13 of maternal origin are the commonest genetic mechanism, occurring in approximately 70-75% of AS. Other mechanisms include paternal uniparental disomy, imprinting defects and point mutations or small deletions within the *UBE3A* gene. We report an interesting case of an 8-year-old male with MR, partial seizure, nystagmus and albinism. The EEG and MRI were abnormal. He showed a normal karyotype. The phenotypic presentation is not of

classical AS syndrome, however FISH analysis of PWS/AS had been performed in another laboratory, which showed no deletion.
Analysis of a DNA sample using the MLPA kit P297-B1 for detection of any interstitial microdeletion found no deletion. Subtelomeric microdeletion analysis using P70 and P36 kits showed loss of heterozygosity in the '15q11 probe' which corresponds to the AS/PWS region.
As these regions are in the critical region for PWS/AS, we further analyzed the region for imprinting defects and found an LOH of maternal origin. Further genetic and epigenetic analysis of the AS/PWS region was performed and confirmed an imprinting defect and LOH of the maternal allele in this patient. This genetic analysis confirmed the diagnosis of Angelman syndrome.
This is an interesting example of rigorous scientific work which could reveal a laboratory misdiagnosis and confirm the clinical diagnosis.

P02.024
Associated malformations among infants with anophthalmia and microphthalmia

***C. Stoll**, B. Dott, Y. Alembik, M. Roth;*
Genetique Medicale, Strasbourg, France.

Infants with anophthalmia and microphthalmia very often have other associated congenital anomalies. The reported frequency and types of associated malformations vary between different studies.The purpose of this investigation was to assess the frequency and types of associated malformations among infants with an/microphthalmia in a geographically well defined population from 1979 to 2004 of 346,831 consecutive births. Of the 87 infants with an/microphthalmia born during this period (prevalence at birth of 2.5 per 10,000), 89.6 % had associated malformations. Infants with associated malformation were divided into recognizable conditions (22 (25.3%) infants with chromosomal and 15 (17.2%) with non chromosomal conditions), and non recognizable conditions (41 (47.1%) infants with multiple malformations). Trisomies 13 and 18 were the most frequent chromosomal abnormalities. Amniotic bands sequence, CHARGE association, Meckel-Gruber syndrome and VACTERL association were most often present in recognizable non chromosomal conditions. Malformations in the musculoskeletal, cardiovascular and central nervous systems were the most common other anomalies in infants with multiple malformations and non recognizable conditions. A de novo heterozygous loss-of-function point mutation in SOX2 was reported in 10 to 20 % of severe bilateral an/microphthalmia. The frequency of associated malformations in infants with anophthalmia and microphthalmia emphasizes the need for a thorough investigation of these infants. Routine screening for other malformations especially musculoskeletal, cardiac and central nervous systems anomalies may need to be considered in infants with anophthalmia and microphthalmia, and referral of these infants for genetics evaluation and counseling seems warranted.

P02.025
Analysis of SOX2, OTX2, and PAX6 genes in 89 Brazilian patients with severe eye malformation

*L. A. Ribeiro-Bicudo[1], **R. G. Quiezi**[1,2], A. Richieri-Costa[1], D. FitzPatrick[2];*
[1]Hospital de Reabilitacao de Anomalias Craniofaciais, Bauru, Brazil, [2]Medical Research Council, Edinburgh, United Kingdom.

Anophthalmia/ microphthalmia (A/M) are major structural eye malformations. The best estimates of the birth prevalence of microphthalmia and anophthalmia from well maintained population based registers are 14 and 3 per 100 000 births, respectively. A/M is a heterogenous condition with various etiologies. One-third of individuals with A/M have associated malformations. Heritable causes of A/M include chromosome abnormalities and syndromic or nonsyndromic single gene disorders fashion. A/M is clinically and etiologically heterogeneous, and it has been estimated that only 20-40% of patients receive accurate molecular information regarding the pathogenesis of their malformation.
Homozygous mutations in the *PAX6* gene in the RAX and VSX2 (CHX10) genes have been described as causing A/M. Mutations in *SOX2* that segregate in an autosomal dominant pattern have been described in individuals with A/M. Mutations in OTX2 have been reported in up to 5% of individuals with A/M. Here, we analyzed *SOX2*, *OTX2*, and *PAX6* genes in 89 Brazilian patients with severe eye malformations who were ascertained from the Hospital for Rehabilitation of Craniofacial Anomalies, Bauru-SP, Brazil . They were divided in 9 groups: A/M + cleft lip and/or atypical cleft; Oculo-Ariculo-Vetebral Spectrum (OAVS); A/M isolated; Cerebro-Oculo-Nasal; Frontonasal dysplasia and/or Oculo-Ariculo-Frontonasal; Holoprosencephaly; Anoftalmia-Waardenburg syndrome; CHARGE.
No disease-causing mutations were identified in any groups. This study suggests that mutations in *SOX2*, *OTX2*, and *PAX6* do not appear to be a common cause of ocular defects other than anophthalmia/ microphthalmia. Further studies with larger numbers of different phenotypes may reveal mutations in these genes.

P02.026
Isolated congenital anosmia

***H. G. Karstensen**, N. Tommerup;*
Wilhelm Johansen Centre for functional Genome Research, Copenhagen N, Denmark.

Which sense would you rather lose? A majority would answer smell. Despite this, smell has a major impact on our lives, i.e. related to food consumption, daily hygiene, detection of dangerous gasses and partner selection. Approximately 5% of the general population are anosmic, but although many are unaware of their condition, anosmia has repeatedly been related to loss or gain of weight, depression and generally a poor quality of life. The majority of individuals suffering from anosmia have an acquired condition, which develops throughout life due to head trauma, allergies, sinonasal disease etc. A much smaller minority (~1% of the anosmic population) have no recollection of ever being able to smell and are thus classified as having isolated congenital anosmia (ICA). A genetic origin is likely to explain the anosmia in this group, however human mutations have yet to be found. The scope of this review is to focus on the genetic basis of ICA through i) published families and cases with ICA, ii) anosmia in combination with other anomalies and iii) olfactory signal transduction pathway genes and animal models which may shed light on potential candidate genes and pathways involved. The lack of knowledge about specific genetic causes of ICA is a challenge but also an opportunity, which should now be within reach by application of the newest technological developments in genetic and genome research.

P02.027
One mutation fits all: Phospholamban R14del underlies both arrhythmogenic right ventricular cardiomyopathy and dilated cardiomyopathy

***P. A. van der Zwaag**[1], A. Asimaki[2], J. D. Jongbloed[1], M. P. van den Berg[1], A. C. Wiesfeld[1], M. G. Cox[3], L. T. van Lochem[4], R. A. de Boer[1], K. Y. van Spaendonck-Zwarts[1], I. C. van Gelder[1], D. P. Judge[5], H. Calkins[5], A. J. Suurmeijer[1], R. N. Hauer[3], J. E. Saffitz[2], A. A. Wilde[4], J. P. van Tintelen[1];*
[1]University Medical Center Groningen, Groningen, Netherlands, [2]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA, United States, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]Academic Medical Center, Amsterdam, Netherlands, [5]Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Background Although considered separate entities, arrhythmogenic right ventricular cardiomyopathy (ARVC) and dilated cardiomyopathy (DCM) show considerable clinical overlap. We hypothesized that phospholamban gene (*PLN*) mutations could underlie both DCM and ARVC.
Methods We screened 240 DCM and 97 ARVC index-patients for *PLN* mutations and evaluated clinical characteristics. Immunohistochemistry (IHC) was performed in 16 myocardial samples from *PLN* mutation carriers.
Results Mutation R14del in *PLN* was identified in 31 of 240 (13%) DCM and 12 of 97 (12%) ARVC index-patients. This mutation was also present in an ARVC cohort from a different continent. Haplotype analysis revealed a common founder mutation, estimated to be 575-825 years old. A low voltage ECG was present in 42% of R14del+ patients. R14del+ DCM patients more often demonstrated: appropriate ICD discharge (42% vs. 9%, P<0.001), cardiac transplantation (19% vs. 3%, P<0.01), and a family history for sudden death (35% vs. 14%, P<0.01), when compared to R14del- DCM patients. In ARVC patients, these differences were not significant. IHC revealed absent/depressed levels for the desmosomal protein plakoglobin at intercalated disks in 5 of 7 (71%) R14del+ ARVC samples and in 1 of 9 (11%) R14del+ DCM

samples (P=0.03).
Conclusions The *PLN* R14del founder mutation underlies both ARVC and DCM in a substantial number of patients. R14del+ DCM patients demonstrate a severe phenotype. Reduced plakoglobin at the intercalated disk appears to track with the ARVC phenotype instead of the genotype. These findings challenge the distinction of DCM and ARVC as separate entities and support the concept of 'arrhythmogenic cardiomyopathy'.

P02.028
Molecular Genetic Investigation of the ATM gene in Iranian population

E. Mohamadi Pargoo[1,2], *O. Aryani*[1], *M. Houshmand*[1,3];
[1]*Special Medical Center, Tehran, Islamic Republic of Iran,* [2]*Science & research branch of Islamic Azad University, Tehran, Islamic Republic of Iran,* [3]*National Institute for Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.*

Ataxia-telangiectasia (A-T) is characterized by progressive cerebellar ataxia beginning between ages one and four years, oculomotor apraxia, choreoathetosis, telangiectasias of the conjunctivae, immunodeficiency, frequent infections, and an increased risk for malignancy, particularly leukemia and lymphoma.
ATM is the only gene known to be associated with ataxia-telangiectasia. The normal gene has 66 (62 coding) exons and a 13-kb cDNA. More than 500 unique mutations are known. No common mutations ('hot spots') have been identified. Most affected individuals in Europe and USA inherit different mutations from each parent, i.e., they are compound heterozygotes. Most mutations result in absence of ATM protein.
In this study, peripheral blood samples from 5 patients were extracted by salt out method to isolate total genomic DNA. Methods were used for the detection of mutations were PCR amplification and direct sequencing.
We found in 5 Iranian AT patients a homozygous nucleotide deletion was identified in ATM gene. We are going to discuss about clinical and molecular aspects of our patients. We need further investigation to prove this mutation as founder effect in Iranian population.

P02.029
Antithrombin III defeciency; a case report

A. Kondo, *A. Narita, H. Ishii, S. Sato, T. Matsumoto, H. Ishimoto, S. Izumi; Tokai University, Isehara, Japan.*

Antithrombin III deficiency is first reported by Egeber et al. in 1965. The incidence for Japanese is 0.18% and is almost same as Caucasian. This lady is 30 y/o, G1P0 and has been followed up by vascular surgeon since she had deep vein thrombosis at 19 y/o. She is on low-dose aspirin since then and came to us because of her pregnancy.
When she came to us first time, she had doubted a bit of familial condition but not been sure about that. She mentioned her mother side uncle had cerebral infarction and her second cousin had lost her first child because of thrombosis. However, her mother does not have any history of thrombosis. We talked about the possibility of inheritance because of family history and gave her information about genetic test as well.
Her pregnancy went good and had a baby safely. The baby has been tested ATIII and ATIII activity which came back as normal. We talked about some worries of her mother with the patient and she wanted her mother to take a blood test for ATIII, but her mother declined. We finally did not have any chance to talk to her mother in this case.
It is still difficult to talk about familial condition sometimes in Japan. This could be big issue for us how to provide more information if there are some prevention of life threatening situation.

P02.030
Severe micrognathia, question mark ears - auriculo-condylar syndrome: case report

M. Volosciuc[1], *E. Braha*[2], *A. Rugina*[1];
[1]*Paediatric Hospital "Sfanta Maria", Iasi, Romania,* [2]*University of Medicine and Pharmacy, Iasi, Romania.*

Auriculo-condylar syndrome (ACS) is an autosomal dominant disorder of first and second branchial arches, with complete penetrance and great intra- and inter-familial phenotypic variation; ACS is characterized by dysplastic ears ('question mark ears'), micro-retrognathia, microstomia, mandibular condyle hypoplasia, prominent cheeks. The psyhological development is normal. The genetic defect for ACS is still unknown; the gene could be probably map in 1p21.1-q23.3 region.
We describe a pacient CPN, a 6 months old girl, with a highly suggestive dysmorphic face (severe micro-retrognathia, round facial appearance, prominent cheeks, dysplastic ears with abnormal lobule). The patient is the one child of a young and non-consanguineous couple. The mother revealed the same facial malformations as the child. We discussed a possible differential diagnosis.
We underline the importance for a good knowledge of the clinical features and syndromes of first and second pharyngeal arches for a correct diagnosis, clinical assessment and genetic counseling.

P02.031
New case of Primrose syndrome with mild intellectual disability.

R. Posmyk[1], *R. Leśniewicz*[1,2], *M. Chorąży*[3], *A. Jakubiuk-Tomaszuk*[1], *S. Wołczyński*[4];
[1]*Department of Clinical Genetics, Podlaskie Center of Clinical Genetics, Bialystok, Poland,* [2]*Department of Reproduction and Gynecological Endocrinology, Medical University of Białystok, Białystok, Poland,* [3]*Department of Neurology, Medical University, Bialystok, Poland,* [4]*Department of Reproduction and Gynecological Endocrinology, Medical University, Bialystok, Poland.*

We report on a 27 years old man, who represents the sixth and the youngest published case of Primrose syndrome. Primrose syndrome (PS) (OMIM#295090) belongs to an extremely rare entities of unknown etiology characterized by the progressive wasting of distal muscles of the legs, the small muscles of the hands resulting in contractures, the presence of mental retardation, hearing problems, cataracts, brain calcification and the leading feature- ossification of ear cartilage. All the main manifestations, were present in our patient. Despite of strict phenotypic similarity to five other PS cases our patient represented with a mild mental retardation. Additionally we have found hypergonadotropic hypogonadism and a low bone density due to progressive osteoporosis. We discuss our observations in relation to previously published cases and we stress a need of the detail phenotypic descriptions of further cases as a syndrome remains a very rare finding and a genetic basis of PS is still undiscovered.

P02.032
ZEB2 missense mutations leading to an unusual presentation of Mowat-Wilson syndrome with moderate intellectual disability

J. Ghoumid[1], *A. Briand-Suleau*[1], *L. Drévillon*[1], *L. Goodwin*[2], *P. Raymond*[1], *N. Bondurand*[1], *J. Amiel*[3], *M. Goossens*[1], *S. Lyonnet*[3], *D. Mowat*[4], *I. Giurgea*[1];
[1]*Service de biochimie et génétique and INSERM U955 IMRB équipe 11, Hôpital Henri Mondor, Creteil, France,* [2]*Department of Clinical Genetics, Nepean Hospital, Sydney, Australia,* [3]*Département de Génétique and INSERM U-781, Hôpital Necker Enfants-Malades, Paris, France,* [4]*Department of Clinical Genetics, Sydney Children's Hospital, Sydney, Australia.*

Mowat-Wilson syndrome (MWS, MIM#235730) is an intellectual disability-multiple congenital anomaly syndrome characterized by severe intellectual disability, epilepsy, agenesis of the corpus callosum, distinctive facial dysmorphism, heart defects, urogenital malformations and Hirschsprung disease. ZEB2 truncating mutations or deletions are disease causing. SIP1 (Smad Interacting Protein 1), the encoded protein, is a two-handed zinc finger/homeodomain transcriptional factor. Two separate clusters of zinc fingers have been characterized (in N-terminus and in C-terminus), and both must bind for transcriptional regulation. SIP1 target genes are numerous, and the best characterized is E-cadherin. SIP1 is early expressed by several tissues during embryonic development, including the neural crest, neuroepithelium and limb buds.
We report two patients with heterozygote missense mutations (c.3164A>G, p.Tyr1055Cys; c.3211T>C; p.Ser1071Pro) localized in the C-terminus zinc finger, and possibly resulting in ADN/protein interactions. We performed in vitro functional tests, using the luciferase reporter system and confirmed that both mutations abolished transcriptional repression of SIP1 on E-Cadherin. Both patients have a facial gestalt of MWS and milder intellectual disability and no congenital malformations.
In conclusion, we report an unusual clinical presentation of MWS with moderate intellectual disability and a distinctive facial appearance ascribed to ZEB2 missense mutations.

P02.033
Recurrent duplication Xp11.22-p11.23 can be associated with propensity to autoimmune disease: a case report and review of the literature

O. M. Vanakker[1], *H. Verhelst*[2], *L. De Groote*[3], *R. Mercelis*[4], *B. Menten*[1], *R. Van Coster*[2], *A. De Paepe*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Paediatric Neurology, Ghent University Hospital, Ghent, Belgium,* [3]*Department of Neurology, Maria-Middelares Hospital Ghent, Ghent, Belgium,* [4]*Department of Neurology, Antwerp University Hospital, Ghent, Belgium.*

Introduction. A recurrent 4.5 Mb duplication of Xp11.2 has been reported in females with variable degree of intellectual disability and language impairment associated with endocrine abnormalities, epilepsy and skeletal abnormalities.
Case report. The proband is the first daughter of healthy non-consanguineous parents. She was born at term with normal antropometric measurements. At age 10, she was diagnosed with a de novo 4,5 Mb Xp11.2p11.23 duplication syndrome because of mild intellectual disability and speech delay, hirsutism, obesity and epilepsy. At age 12, she presented with rapidly progressive proximal muscle weakness of arms and legs. A positive Tensilon test was suggestive for Myasthenia Gravis. EMG evaluation revealed low evoked compound motor action potentials, consistent with Lambert-Eaton myasthenic syndrome (LEMS). LEMS is a paraneoplastic disorder of neuromuscular transmission, based on auto-immunity to the voltage-gated calcium channel. Only rare cases have been reported in childhood. Reviewing the histories of other female patients reported with a similar Xp11.2 duplication revealed that 3 out of 11 patients suffered from (potential) auto-immune disease such as rectocolitis, Wegener's granulomatosis and hypothyroidism with hyperinsulinism.
Conclusion. The observation of a rare autoimmune myasthenic syndrome in a young patient with a Xp11.2 duplication in conjunction with previously reported autoimmune disorders suggest that carrier females of this recurrent duplication might have a propensity towards autoimmune disease. Some genes within the duplication are involved in either immune response (e.g. FOXP3) or calcium homeostasis (e.g. RGN) and could have a potential role in the occurence of auto-immunity in general or LEMS specifically.

P02.034
A 273-kb duplication at 22q13.33 encompassing the SHANK3 gene in 2 sibs with microcephaly, behavioral disorder and learning disabilities

A. Destrée*, P. Hilbert, S. Boulanger, C. Verellen - Dumoulin, I. Maystadt; Centre de Génétique Humaine - IPG, Charleroi (Gosselies), Belgium.*

The 22q13 deletion syndrome is a not uncommon condition associated with global developmental delay, absent or delayed speech and hypotonia. Pure distal trisomy of the long arm of chromosome 22 are rare. Twenty patients, including our two cases, with variable clinical phenotype extending from mild psychomotor delay to severe delay with congenital malformations, have been shown to have a pure distal 22q trisomy. The size of the duplicated segment is extremely variable. Here we report on a brother and a sister presenting the smallest cryptic 22q13.33 duplication ever reported, detected by a salsa MLPA P188 kit 22q13. The duplicated region spans about 273-kb which encompasses 11 genes, including SHANK3. Both patients live in an institution because of the desertion of the parents and show developmental delay, especially in the language sphere, mild intellectual disabilities, behavioral disturbance, microcephaly, growth retardation and mild dysmorphic features. This phenotype was previously described in patients with larger duplication 22q13.3 and a recognizable phenotype was suggested. We confirm here this phenotype and delineate a critical chromosomal region of 273-kb, including the SHANK3 gene, which appears to be a strong candidate gene for the 22q13.33 duplication phenotype.

P02.035
De novo 7q deletion in a family with 16p duplication, autism and dyslexia

G. J. Braathen[1,2], *A. K. Eek*[1], *R. Stornes*[3], *K. O. Clausen*[1];
[1]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway,* [3]*Department of Pediatrics, Telemark Hospital, Skien, Norway.*

Background. Copy number variations (CNV) in several chromosomal regions have been associated with increased risk of autism spectrum disorders (ASD). Chromosomal regions implicated in studies of ASD and associated phenotypes such as schizophrenia, mental retardation and developmental delay include 1p, 1q, 3p, 5q, 7q, 10q, 15q, 16p, 17p, 20p, 22q and Xq.
Methods. We describe a child with *de novo* 7q deletion and maternal 16p duplication and the genetic analyses performed in the family.
Results. The chromosomal analyses were normal while array Comparative Genomic Hybridization (aCGH) identified the 7q deletion and the 16p duplication.
Conclusions. ACGH makes it easier to assess different clinical aspects of neurodevelopmental disorders such as autism with regard to the chromosomal findings.

P02.036
Autism Spectrum Disorders and Seizure Syndrome

D. Bauze[1,2], *L. Kevere*[1], *Z. Kronberga*[1], *A. Rizevs*[1], *S. Jelisejevs*[1], *R. Andrezina*[3], *B. Lace*[4];
[1]*Children's University Hospital, Child Psychiatry Clinic, Riga, Latvia,* [2]*Children's University Hospital, Medical Genetics Clinic, Riga, Latvia,* [3]*Riga Stradins University, Riga, Latvia,* [4]*Children's University Hospital, Medical Genetics Clinic, Riga, Latvia.*

INTRODUCTION: Autism and autism spectrum disorders (ASD) are serious early childhood neurodevelopment disorders with a genetic aetiology and increasing prevalence. Patients often have co-morbid disorders. 11-39% may have seizure syndrome. According to the literature, 42% of patients with autism, ASD and mental retardation have seizure syndrome. The aim of the study was to obtain information about patients with autism, ASD and seizure syndrome.
METHODS: 158 patients with autism and ASD were ascertained who had been treated in the Children's University Hospital, Child Psychiatry Clinic and Medical Genetics Clinic from 2006 - 2010. We recorded the patients' clinical symptoms (ICD-10), ADOS, electroencephalography (EEG) and IQ. SPSS 13 was used for statistical analysis. The frequency of seizure syndrome in both patient groups was calculated.
RESULTS: Seizure syndrome was identified in four patients with autism and 11 patients with ASD. Two patients in the autism group had their IQ within normal limits, four patients were moderately mentally retarded. In the ASD group, one patient had IQ within normal limits, four patients were mildly mentally retarded, four patients had severe mental retardation.
CONCLUSION: The incidence of seizure syndrome was 9.5% in both patient groups. Seizure syndrome is more frequent in patients with some degree of mental retardation than in patients with normal IQ.

P02.037
Sub-microscopic chromosomal imbalances in two children with idiopathic autism spectrum disorder

D. Avdjieva-Tzavella[1], *S. Hadjidekova*[2], *B. Rukova*[2], *D. Nesheva*[2], *E. Simeonov*[3], *T. Todorov*[4], *A. Todorova*[5], *I. Dimova*[2], *R. Tincheva*[1], *D. Toncheva*[2];
[1]*Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria, Sofia, Bulgaria,* [2]*Department of Medical Genetics, Medical Faculty, Medical University, Sofia, Bulgaria,* [3]*Clinic of Pediatrics, University Hospital "Alexandrovska", Sofia, Bulgaria,* [4]*Department of Medical Chemistry and Biochemistry, Sofia Medical University, Sofia, Bulgaria,* [5]*Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria.*

Autism is a childhood neurodevelopmental disorder apparent by 3 years of age and characterized by qualitative impairments in reciprocal social interaction, deficits in verbal communication, restricted interests and repetitive behaviors. The exact aetiology of autism remains unknown, although it is likely to result from a complex combination of genetic, neurological, and environmental factors. Recent high resolution microarray-based studies in autism have identified a number of novel submicroscopic copy number variants (CNVs) including both deletions and duplications.
We report two children with autistic behavior and mental retardation. We have used genomic array CytoChip Oligo (BlueGnome, Cambridge, UK), format 2x105K, version 1.1. and BlueFuse Multi software, version 2.2. The 2x105K array detects 35 Kb imbalances on the backbone and has tiling of 20 probes over 137 OMIM disease loci. Array CGH-

analysis revealed cryptic deletion of 16p11.2 region spanning 513 kb in first patient and an amplification spanning 1,624 Mb of Xp22.31 region in second patient. Deletions and duplications at chromosome 16p11.2 appear to be associated with ~1% of unexplained, idiopathic and nonsyndromic autism. Several of the genes that reside within the 16p11.2 microdeletion represent promising candidates for autism based on known expression and functional data. Submicroscopic duplication of Xp22.31 has been reported as either a possible cause of intellectual disability and/or autistic behavior or a benign variant. . The Xp22.31 duplication included the steroid sulfatase (STS) gene.
Our results indicate that array-CGH is a powerful tool to detect sub-microscopic pathogenic imbalances in patients with idiopathic autism and/or mental retardation.

P02.038
Children autism and mitochondrial DNA mutations

B. I. Radeva;
Medical Center "Childen's Health", Sofia, Bulgaria.

In the data of the WHO (World Health Organization) the prevalence of autism in children
is reported as 1-6 per 1000. The number in Bulgaria is currently unknown. But the hospitalization
of patients with speech, hearing and communication problems has increased in the past 10 years. Our experience in clinical genetics proved that childhood autism is a heterogeneous syndrome. The aim of our work was to analyze children with autism for mitochondrial DNA mutations and discuss the possibility of their treatment. We made clinical and laboratory investigations and sequenced mt DNA regions in peripheral blood by the PCR-SBT method in 4 of our patients with autism.
We found different mt DNA mutations and polymorphisms. In a girl suspected for Rett syndrome we found G6852A in mt-CO1,which changed Gly>Ser. In the 3 boys with autism we found the polymorphism T4216C (connected with predisposition to LHON or insulin resistance) in the first,
the polymorphism G9055A (protective of Parkinson disease) in the second, and a polymorphism connected with predisposition to LHON in the third. The children with mt DNA changes improved on treatment with a casein- and gluten-free diet and high dose vitamin Q10. We propose that children with autism should be investigated for mtDNA mutations and treated as mitochondrial disorders.

P02.039
Axenfeld-Rieger syndrome in a neonate with non-immune hydrops fetalis.

***S. Jougheh Doust**, A. Guerin, J. So;*
Division of Clinical and Metabolic Genetics, Hospital for Sick Children, University of Toronto,, Toronto, ON, Canada.

Axenfeld-Rieger syndrome (ARS) comprises a spectrum of rare, heterogeneous autosomal dominant disorders mainly affecting the anterior segment of the eye. ARS leads to blindness from glaucoma in about 50% of patients. Extra-ocular clinical manifestations of ARS are highly variable and can include mid-face hypoplasia, dental anomalies and redundant umbilical skin. To date, several genes and loci on chromosomes 4, 6, 13 and 16 have been found to be associated with ARS, among them mutations in *PITX2* and *FOXC1*, which are responsible for the majority of ARS cases.
We are reporting a neonate who was born at 32 weeks due to non-immune hydrops and maternal mirror syndrome. Ocular findings in this patient consisted of bilateral anterior segment dysgenesis, glaucoma and posterior embryotoxon. Facial dysmorphic features included edema of head and face, depressed nasal bridge, hypertelorism, upturned nose and posteriorly rotated, low-set ears. MRI of the brain showed slightly small vermis, and echocardiogram revealed PFO and PDA.
No mutations were found on sequencing of *PITX2* and *FOXC1*, with MLPA studies pending. Microarray analysis revealed a duplication at chromosome 3p26 of unknown significance, and parental chromosomal studies are pending.
This case is the first report of an ARS patient with non-immune hydrops fetalis, further expanding the phenotypic spectrum in this group of disorders. To date, about 60% of ARS patients have no identifiable genetic defect. The highly variable phenotype of ARS necessitates further studies to identify the pathogenetic mechanisms that play a critical role in the development of the eye and other organs.

P02.040
Baraitser-Winter syndrome: A new Tunisian case

*M. Trabelsi[1], F. Maazoul[1], Y. Laaribi[1], M. Kossentini[1], I. Ouertani[1], M. Chaabouni[1], R. kammoun[2], L. Ben Jemaa[1], **R. Mrad**[1], H. Chaabouni[1];*
[1]Service des Maladies Congenitales et Hereditaires, EPS Charles Nicolle, tunis, Tunisia, [2]Service d'ophtalmologie, EPS Charles Nicolle, tunis, Tunisia.

Introduction: Baraitser-Winter syndrome is a rare multiple congenital anomalies characterized by iris coloboma, ptosis, hypertelorism, and mental retardation. It was first described by Baraitser and winter in 1988. The genetic mechanism underlying this syndrome has not been elucidated
Case report: We report the case of a 9-year-old male who was the third child of unrelated parents. He was referred to our genetic counseling service, since the age of 9 months, for evaluation of dysmorphic features and psychomotor delay
His face was characterized by brachycepahaly, hypertelorism, bilateral ptosis, short nose, long philtrum, micrognathia, malformed ears and short neck. Limbs examination showed valgus flat feets and genu varum. Evaluation of his mental development revealed a mild intellectual deficiency (IQ=62)
Ophtalmologic examination identified a right retino-choroidal coloboma and a bilateral optic nerve coloboma. Brain TDM demonstrated a bilateral atrophy of the frontal cortex. The remaining investigations including caryotype, cardiac and abdominal ultrasonographies were normal
Discussion: In this report we have presented a child with coloboma; ptosis; hypertelorism and mental retardation. This phenotype resembles the previous descriptions of patients with the Baraitser-Winter syndrome. Some of the peculiar craniofacial features (hypertelorism, bilateral ptosis,and short nose) which are highly characteristic and crucial to the diagnosis of the Baraitser-Winter syndrome are present in our patient. None of the multiple cerebral hemispheric malformations that have been described in the Baraitser-Winter syndrome like lissencephaly, pachygyria, cortical heterotopias or agenesis of the corpus callosum was described in our patient. This observation underlines the phenotypic heterogeneity of this syndrome.

P02.041
Mutation spectrum in Iranian patients with Bardet-Biedl syndrome

***P. Rostami**[1], A. Najmabadi[1], Z. Fatahi[2], A. Kariminejad[1];*
[1]Kariminejad–Najmabadi Pathology & Genetics Center, tehran, Islamic Republic of Iran, [2]Genetic Research Center, University of Social Welfare and Rehabilitation Sciences, tehran, Islamic Republic of Iran.

Bardet-Biedl syndrome (BBS) is a rare genetic disorder that affects the brain and can cause multiple physical problems including a deterioration of the intellect and neurological functions. BBS is typically inherited in as autosomal recessive manner. Fourteen genes are known to be associated with BBS: *BBS1*, *BBS2*, *ARL6/BBS3*, *BBS4*, *BBS5*, *MKKS/BBS6*, *BBS7*, *TTC8/BBS8*, *B1/BBS9*, *BBS10*, *TRIM32/BBS11*, *BBS12*, *MKS1/BBS13*, and *CEP290/BBS14*. In some families, mutations in more than one BBS gene may result in a clinical phenotype of BBS. However, such families are difficult to identify and may account for less than 10% of all BBS patients.
The object of this study was to detect the mutation spectrum of BBS genes in our patients. probands of 10 Iranian families with clinical symptoms of BBS were tested for BBS1 and BBS2 gene mutations, which account for 23% and 20% of the mutations in BBS patients. Sequencing of *BBS1* and *BBS2* genes revealed a heterozygous mutation in one of the families, and 4 novel polymorphisms (c420, GCC>CCC, Ala>Pro, c424, AAA>AAT, Ala>Asn, c. 428 GCC>TCC, Ala>Ser & c.227 GAG>CAG, Glu>Gln) in *BBS1* gene. We could not detect any mutation except one polymorphism in *BBS2* gene.
Since we could not detect any mutations in the two most prevalent genes which account for over 40% of the mutations in BBS patients, our results suggest that other known or population specific genes may be involved in pathogenesis of BBS in Iranian population. Sequencing of the remaining genes is under way.

P02.042
Natural history, diagnosis and genetic aspects of Barth syndrome. New findings from a nationally commissioned service for Barth syndrome patients

R. A. Newbury-Ecob[1], *B. Tsai-Goodman*[1], *M. Williams*[2], *A. Bowron*[1], *M. Pennock*[2], *C. Steward*[1];
[1]*Bristol Royal Hospital for Children, Bristol, United Kingdom,* [2]*Molecular Genetics, Southmead Hospital, Bristol, United Kingdom.*

Barth syndrome (BTHS) is an x-linked disorder presenting as a triad of cardiomyopathy, neutropenia and 3 methylglutaconic aciduria.
A National clinic for patients and families with BTHS has been established in Bristol UK. This has allowed a comprehensive prospective clinical and genetic study of a cohort of boys with BTHS.
We have shown that BTHS is a multisystem disorder or syndrome. Facial dysmorphism gives BTHS boys a recognisable appearance. Other features include early short stature followed by later tall stature, a nonspecific skeletal myopathy and food fads. Dilated cardiomyopathy and left ventricular compaction both occur and conduction defects are common and a cause of sudden death. Transplantation in earlier life is successful. Neutropenia may be cyclical and responds to treatment with GCSF.
Pedigree analysis showed that families had a history of miscarriages, stillbirths and male neonatal deaths. One family had three pregnancies presenting as fetal hydrops in the mid trimester
Caused by mutations in TAZ , BTHS can be reliably diagnosed by measuring cardiolipin. This is a cheaper and quicker diagnostic test which can be followed by TAZ analysis in order to detect female carriers. Retrospective diagnosis in affected males has been made on samples from newborn screening tests.
Based on our figures for the prevalence of BTHS in the south west of England we suspect that BTHS remains and underdiagnosed condition and should be screened for in all boys presenting with cardiomyopathy and neutropenia and suspected in families with multiple unexplained male fetal loss or sudden death.

P02.043
Nevoid basal cell carcinoma syndrome: a report of a case

A. G. Zamani[1], *K. Ozturk*[2], *M. S. Yildirim*[1], *A. Acar*[1];
[1]*Selcuk UniversityMeram Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*Selcuk University Selcuklu Medical Faculty, Department of Otolaryngology, Konya, Turkey.*

Nevoid basal cell carcinoma syndrome (NBCCS), also known as Gorlin syndrome, is a rare autosomal dominant disease.It shows a high level of penetrance and variable expressiveness. This multisystem disorder characterized by multiple basal cell naevi, cysts of the jaw, pits of the palms and soles, skeletal anomalies, and various other defects. Patients with Gorlin syndrome have a predisposition to basal cell carcinomas and other neoplasms.
We present a patient with NBCCS who was diagnosed when he was 20 years old. He had a course face ,hoarse voice, hypertelorism, broad nasal bridge,pouting lips, parietal bossing with prominent supraorbital ridges and heavy and fused eyebrows . He was tall and marfanoid. On his physical examination, nevoid basal cell carcinomas were seen over his neck,shoulders,arms thrunk and face . He has developed basal cell carcinomas (BCCs) ,in particular on his lower eye lids and he was operated. He has palmar pits on his both hands. He was threated for dentical problems several times. He had malocclusion(i.e. displaced, impacted or missing teeth)and jaw cysts. He had pectus excavatum and synostic, bifid and partially missing ribs detected in his X-ray examination. Thoracolumbar spine films revealed scoliosis,too. Because of the autosomal dominant inheritance of this syndrome, the patient's family was then investigated. A multidisciplinary approach to management, together with periodic follow-up, are advocated for the general well-being of all NBCCS patients and their families.

P02.044
MS-MLPA technique in diagnosis of Beckwith-Wiedemann syndrome

D. Jurkiewicz, *A. Tanska, E. Ciara, D. Piekutowska-Abramczuk, M. Borucka-Mankiewicz, S. Luczak, P. Kowalski, M. Pelc, J. Trubicka, M. Kugaudo, A. Jezela-Stanek, K. Chrzanowska, M. Krajewska-Walasek;*
Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland.

Beckwith-Wiedemann syndrome (BWS) is an overgrowth syndrome characterized by macroglossia, macrosomia, abdominal wall defects and predisposition to embryonal tumor development. BWS is caused by defective expression of imprinted genes (*IGF2*, *H19*, *CDKN1C*, *KCNQ1*, *KCNQ1OT1*) located on chromosome 11p15.5. The genes are functionally divided into two domains that are controlled by two Imprinting Centers: IC1 (H19DMR) and IC2 (KvDMR1). The most common defects in BWS patients are uniparental paternal disomy at 11p15.5 region, gain of methylation at IC1 and loss of methylation at IC2. Here we present six Polish patients with clinical diagnosis of BWS. Molecular analysis was performed by methylation sensitive multiplex ligation-dependent probe amplification using MS-MLPA BWS/RSS ME030-B2 kit (MRC-Holland). The kit enables determination of methylation status of the 11p15.5 region, as well as duplications or deletions in that region. The analysis demonstrated hypomethylation in KvDMR1 region in four patients, hypermethylation of H19DMR region in one patient and both KvDMR1 hypomethylation and H19DMR hypermethylation in one patient. Molecular analysis confirmed the diagnosis of BWS in all investigated patients. To our knowledge the presented study is a first attempt to introduce MS-MLPA in the molecular diagnosis of Polish BWS patients. We plan to conduct further studies to characterize the genetic background of BWS in Polish population.
The study was supported by project no. N407 114940.

P02.045
A girl with the features of Binder syndrome and partial trisomy of the pericentromeric region of chromosome 5

K. Hadzsiev[1], *G. Szabó*[2], *D. Dávid*[3], *M. Czakó*[1], *B. Melegh*[1], *G. Kosztolányi*[1];
[1]*Department of Medical Genetics, Pécs, Hungary,* [2]*Department of Dentistry, Oral and Maxillofacial Surgery, Pécs, Hungary,* [3]*Department of Genetics, Lisboa, Portugal.*

In 1962 Binder assigned maxillonasal dysplasia as a distinct entity characterized by midfacial hypoplasia, flat vertical nose, and malocclusion. The etiology of Binder syndrome (BS) is unknown. Here we describe a 10-year-old girl with facial dysmorphism characterized by features of BS, in whom a small ring from chromosome 5 was found. The proposita was born at term after uneventful pregnancy to non-consanguineous parents. She visited our genetic clinic at 10 years of age because of facial dysmorphism and moderate mental retardation. She had pointed chin, flat nasal bridge, left-deviated nasal septum, hypertelorism, mid-facial hypoplasia, blepharophimosis, prognatism, pectus excavatum and inverted nipples. Radiographic survey detected hypoplasic maxilla and ossis nasi, hypoplastic cervical vertebrae I-II. Psychological survey showed slight developmental delay. Chromosome analysis showed a small supernumerary marker chromosome, which showed clear ring form. FISH analysis confirmed that the marker chromosome derived from chromosome 5.
Array analysis revealed that the ring 5 chromosome contains a 19,168kb genomic region comprising cytogenetic bands 5p13.3 to p11.1., detailed analysis of the region lead to identification of 62 genes. Of these, three were disease associated dosage-sensitive genes, the nipped-B homolog gene (*NIPBL*), the oncostatin M receptor gene (*OSMR*) and the fibroblast growth factor 10 gene (*FGF10*). A causal relationship is suggested between these genes and BS.

P02.046
Microduplications 22q11.21 frequently associated with classic bladder exstrophy

M. Ludwig[1], *M. Draaken*[2,3], *F. Baudisch*[2], *E. Bartels*[2], *A. Ebert*[4], *W. H. Rösch*[5], *T. Boemers*[6], *A. Schröder*[7], *R. Stein*[7], *S. A. Boyadjiev*[8,9], *P. Hoffmann*[2,3], *M. M. Nöthen*[2,3], ***H. Reutter***[2,10];
[1]*Dept. of Clinical Biochemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany,* [2]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [3]*Department of Genomics, Life & Brain Center, Bonn, Germany,* [4]*Department of Pediatric Urology, University of Regensburg, Regensburg, Germany,* [5]*Dept. of Pediatric Urology, University Regensburg, Regensburg, Germany,* [6]*Department of Pediatric Surgery and Pediatric Urology, Children's Hospital, Köln, Germany,* [7]*Department of Urology, University of Mainz, Mainz, Germany,* [8]*Section of Genetics-Dept. of Pediatrics, University of California Davis, Baltimore, MD, United States,* [9]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [10]*Dept. of Neonatalogy, University of*

Bonn, Bonn, Germany.
Classic exstrophy of the bladder (CBE) is part of the rare exstrophy-epispadias complex (BEEC), a spectrum of urogenital anomalies in which part or all of the distal urinary tract fails to close. Previously, four CBE cases with underlying microduplication 22q11.2 in a cohort of 102 BEEC patients have been reported (Lundin et al., 2010; Draaken et al., 2010).
Screening of additional 250 patients with CBE (223) as well as epispadias (9) and exstrophy of the cloaca (18) using multiplex ligation-dependent probe amplification (MLPA) analysis identified additional five CBE patients with a microduplication 22q11.2. Paternity was confirmed in all families. Among the nine cases the duplication had been inherited three times from an unaffected parent (two mothers, one father). All duplications differ in size ranging from about 0.07 Mb to 2.71 Mb. MLPA results were confirmed using Illumina's Beadchips thereby specifying the maximum region from SNPs rs2543958 to rs12484186. According to hg18 this region on chromosome 22 (nt:17,257,787-19,965,324) comprises 2.71 Mb, harbouring 47 genes as well as the sequence information of at least four microRNAs.
Given these observations, we were able to confirm the association of causally underlying microduplications 22q11.2 in cases of isolated CBE and hypothesize that a single phenocritical gene might reside in the smallest region of overlap.

P02.047
What management for the asymptomatic men carriers of *BRCA1* and *BRCA2* mutation? Inquest to the French oncogenetics centres.

*I. Brachot-Simeonova[1], **G. Morin**[2], C. Gillaux[1], F. Amram[2], B. Demeer[2], J. Gondry[1], M. Mathieu[2], R. Fauvet[1];*
[1]Gyneco-obstetric Centre, Amiens, France, [2]Clinical Genetics and Oncogenetics, Amiens, France.
Objective: To define in the absence of guidelines, the management in France of asymptomatic men bearing a mutation of *BRCA1-2* gene.
Material and method: This multicentre study is a descriptive survey of practice. A questionnaire was addressed to the professionals working in the 90 French oncogenetics centres.
Results: We obtained the answers of 46 practitioners working in 58 centres. 100% of the responders offered this screening to determine the risk of transmission to the descent and 86% to offer a personal follow-up. This follow-up concerned for 94% the prostate cancer, for 68% the breast cancer, for 49% the pancreatic cancer, and for 12% the melanoma.
The screening of the prostate cancer was proposed mainly to the men bearing a *BRCA2* mutation and from the age of 40 years. It was based on the clinical examination and the prostate-specific antigen.
The screening of breast cancer was offered to the patient bearing a *BRCA2* mutation. It was proposed by self-palpation and/or medical clinical examination and started between the age of 30 and 50 years. Imagery was only realized in case of symptoms.
The screening of the pancreatic cancer was offered after the age of 40 years and by computed tomography and/or pancreatic MRI. It was mainly proposed in case of familial history of pancreatic cancer.
The general practitioner was considered to be the best to perform all these screenings.
Conclusion: These experts' opinions can help to establish recommendations for the management of the asymptomatic men carriers of *BRCA1-2* mutation.

P02.048
Rapid genetic counseling and testing in newly diagnosed breast cancer patients: Preliminary results of the TIME-trial

***M. R. Wevers**[1,2], M. G. E. M. Ausems[2], E. M. A. Bleiker[1], D. E. E. Hahn[1], T. Brouwer[2], M. Kuenen[1], J. Melis[1,2], E. J. T. Rutgers[1], A. J. Witkamp[2], R. B. van der Luijt[2], F. B. L. Hogervorst[1], N. K. Aaronson[1], S. Verhoef[1];*
[1]Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]University Medical Centre Utrecht, Utrecht, Netherlands.
Introduction: Female breast cancer patients carrying a BRCA1/2 mutation have an increased risk of second primary breast and ovarian tumors. Rapid genetic counseling and testing (RGCT) may aid in making informed decisions about therapeutic and preventive surgery and adjuvant treatment. Little is known about the effect of RGCT on treatment decisions and psychosocial health. We are currently carrying out a randomized controlled trial to investigate these issues.
Methods: Newly diagnosed breast cancer patients with minimally 10% risk of a BRCA1/2 mutation have been recruited from 12 Dutch hospitals. They were randomized to an intervention group (RGCT) or a usual care control group. Study outcomes include uptake of RGCT, surgery choice, cancer risk perception, cancer-specific distress, quality of life and decisional satisfaction. Assessments take place at study entry, and at 6 and 12 months follow-up.
Results: Between November 2008 and December 2010, 271 women were recruited and randomized to the intervention (n=184) or control (n=87) group. Currently, 106 women have completed all assessments (intervention group n=70). Of the 70 women in the intervention group, 63 chose DNA-testing (90%) and 40 (57%) opted for accelerated DNA test procedures: 22 (31%) for rapid testing (<4 weeks) and 18 (26%) for semi-rapid testing (4 weeks-4 months). Normally, test results are only available after 4 months. Eight (13%) patients were BRCA1/2 mutation carriers.
Conclusion: Preliminary results indicate high uptake of RGCT among high-risk breast cancer patients. Thus far, the majority of patients who are offered RGCT take advantage of this accelerated DNA-testing procedure.

P02.049
A case of breast cancer after radiation therapy for a skin haemangioma in childhood in a woman carrying a BRCA1 mutation

***K. Baudry**[1], D. Azria[2], P. Pujol[1,3];*
[1]CHU Arnaud de Villeneuve, Montpellier, France, [2]CRLC Val d'Aurelle, Montpellier, France, [3]INSERM U896 CRLC Val d'Aurelle, Montpellier, France.
It has been shown that radiation therapy, most of all during infancy, increases the risk of developing cancers later on. Here we present the case of a patient who received phosphorus ionizing therapy before the age of 1 for a skin haemangioma on the left breast. At the age of 25, the patient noticed a lump at the exact place where she received radiation therapy. At the age of 30, she was diagnosed with breast cancer. It was an infiltrating stage III ductal carcinoma, estrogen receptor negative, progesterone receptor negative and cerb2 negative, located exactly beneath the spot where she was treated while a child. Because of her young age when she was diagnosed, she was offered a genetic analysis of the *BRCA1* and *BRCA2* genes. A large deletion of 5 exons (8 to 13) of the *BRCA1* gene was found.
We are making the hypothesis that the radiation therapy she received during her infancy caused late toxicity that increased the risk she already had to develop breast cancer because of the mutation she carries on the *BRCA1* gene. We thus made a radio-induced and lymphocyte apoptosis test.
The patient herself is worried that her breast cancer was caused by the treatment she received for her haemangioma and therefore refused to receive radiation therapy and refuses to undergo breast x-rays for her follow-up.

P02.050
Brittle Cornea Syndrome in an Omani family with a novel mutation in *ZNF469* gene

***A. AlKindy**;*
Sultan Qaboos University Hospital, Muscat, Oman.
Brittle cornea syndrome (BCS-OMIM # 229200) is a rare autosomal recessive disorder that affects a variety of connective tissues with variable expressivity. The most dramatic feature of the disorder is the ocular phenotype presenting in 50% of cases with recurrent rupture of the thin and fragile cornea either spontaneously or secondary to minor trauma causing progressive visual loss and blindness. All affected individuals have blue sclera with many patients myopic. Secondary glaucoma and retinal detachments has rarely been reported. Systemic manifestations of other organs with connective tissues are common but less severe including skin elasticity, hyper mobility of joints with dislocation of large and small joints; kyphoscoliosis; dental anomalies; reduced bone mass density, congenital hearing loss and minor cardiac defects. BCS affects diverse ethnic groups with most patients reported from Middle East. We describe the clinical and morphologic features of affected individuals in a highly inbred Omani family affected with BCS and molecular confirmation of a homozygous c.1444delC mutation in the first exon of the *ZNF469* gene. This is the first case

report of an Omani family with BCS with a novel mutation in *ZNF469* gene. The ZNF469 protein has 30% homology to the helical parts of highly expressed corneal collagens, COL1A2, COL4A1 and COL1A1 and its proposed function is in the synthesis and/or organization of these collagen fibers. The differential diagnosis of BCS is the EDS type VI. Though the life expectancy of BCS patients is usually normal, affected patients usual have progressive visual loss despite protective measures.

[1]Centre de Génétique Humaine, CHU Besançon, France, [2]Service de Génétique, CHU Lille, France, [3]Service de Biologie Moléculaire, CHU Dijon, France, [4]Service de Cytogénétique, CHU Dijon, France, [5]Service de Pédiatrie, Hôpital Kremlin-Bicêtre, Paris, France, [6]Service de Dermatologie, CHU Besançon, France, [7]Service de Génétique, CHU Rouen, France, [8]Service de Génétique, CHU Tours, France, [9]Centre de Référence pour la prise en charge des maladies neuromusculaires et SLA, APHM Marseille, France, [10]North West Thames Regional Genetics Service, NHS, London, United Kingdom, [11]Service de Dermatologie, CHU Montpellier, France, [12]Service de Génétique, Hôpital Necker, APHP Paris, France, [13]Service de Dermatologie, CHU Dijon, France, [14]Centre de Référence Maladies Rares « Anomalies du Développement et Syndromes Malformatifs » de la région Grand Est, Centre de Génétique, Hôpital d'Enfants, CHU Dijon, France.

Poikiloderma occurs in a number of hereditary syndromes, the best known of which is Rothmund-Thomson syndrome (RTS). Differential diagnoses include Dyskeratosis congenita and Clericuzio-type poikiloderma with neutropenia (CPN). CPN is a rare autosomal-recessive genodermatosis characterized by poikiloderma, pachyonychia and chronic neutropenia, exhibiting phenotypic overlap with RTS. The clearest distinction seems to lie in the neutropenia with an increased susceptibility to infections. Mutations in the *RECQL4* gene observed in two third of RTS patients appear to be absent in CPN patients. Recently, mutations in the *C16orf57* gene has been identified in CPN patients. To date, the 33 reported patients with *C16orf57* mutations presented with neutropenia. In this study, we report on the clinical data and the *C16orf57* molecular analysis in 10 *RECQL4*-negative patients referred for syndromic poikiloderma. Other symptoms included photosensitivity (6/10), growth retardation (2/9), dysmorphism (6/10), dysplastic hair (7/10), nail dystrophy (2/10), bone abnormalities (1/10) and cataract (1/10). None had absent knee caps, gastrointestinal problems nor osteosarcoma. Two *C16orf57* heterozygous nonsense mutations (p.W81X and p.Y89X) were identified in one 5-year-old patient presenting with dental dysplasia, gingivitis, nail dystrophy, palmoplantar keratoderma, pachyonychia of the great toenails and generalized poikiloderma. No history of recurrent infections was reported. Previously undetected neutropenia was discovered after *C16orf57* molecular analysis. Neutropenia was absent in *C16orf57*-negative patients. Our report confirms that neutrophil count should be performed in all patients with poikiloderma to target the *C16orf57* gene sequencing analysis, prior to *RECQL4* study.

Impaired vasoreactivity in CADASIL patients without significant disability

M. Frontali[1], *J. Campolo*[2], *R. De Maria*[2], *S. Romano*[1], *E. Puca*[3], *F. Taroni*[4], *C. Tomasello*[5], *C. Mariotti*[5], *D. Inzitari*[6], *F. Pescini*[6], *L. Pantoni*[6], *A. Federico*[7], *M. Dotti*[7], *M. Stromillo*[7], *A. Tavani*[8], *O. Parodi*[2];

[1]INMM-CNR, ROME, Italy, [2]CNR Clinical Physiology Institute, MILAN, Italy, [3]Neuroscience Dept. La Sapienza University, ROME, Italy, [4]Istituto neurologico 'Carlo Besta', MILAN, Italy, [5]Istituto Neurologico 'Carlo Besta', MILAN, Italy, [6]Depts. Neurologic & Psychiatric Sciences Univ. Florence, Florence, Italy, [7]Institute Neurological Sciences, Univ. Siena, Siena, Italy, [8]Istituto di Ricerche Farmacologiche 'Mario Negri', MILAN, Italy.

Background and Purpose. CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) is a rare genetic disease caused by mutations in the NOTCH3 gene. A dysfunction in vasoreactivity has been proposed as early event in the pathogenesis of the disease. Aims of our study was to verify whether endothelium-dependent and -independent function is impaired in CADASIL patients compared to age-, gender-matched controls stratified by the presence of cardiovascular risk factors (CVRF).

Methods. We studied vasoreactivity in 49 CADASIL patients (30-65 years), 32 male (58%) without significant disability (Rankin scale score equal or less than 2) and 25 controls by a non invasive pletismographic method. Endothelium-dependent vasodilation was assessed by reactive hyperemia (FMD-PAT) while endothelium-independent vasoreactivity was studied by glyceryl trinitrate (GTN-PAT) administration.

Results. FMD-PAT scores were similar (1.88 [1.57-2.43] vs 2.08 [1.81-2.58], *P*=ns), while GTN-PAT values were significantly lower in CADASIL (1.54 [1.01-2.25] than controls 1.89 [1.61-2.59], *P*=0.041*)*. Among CADASIL patients, values below the 10 percentile of FMD-PAT scores in the control population were found in 17 (35%) , *P*=0.013. FMD-PAT and GTN-PAT values correlated significantly both in controls (rho=0.648 P<0.001) and CADASIL patients (rho=0.563 P<0.001)

Conclusions. The impaired vasoreactivity observed in our CADASIL patients highlights that both endothelial and smooth muscle functional alterations may occur already in pre symptomatic subjects. The improvement of vascular function could be a new target for pharmacological trials in the CADASIL population.

P02.053
Cantrell's Pentalogy with Complete Thoracoabdominal Ectopia Cordis and Asplenia - Expanding the Clinical Phenotype?

L. Ilaria[1], *E. Cosmi*[2], *K. Ludwig*[1], *R. Manara*[3], *R. Salmaso*[1], *M. Rugge*[1];

[1]Department of Medical Diagnostic Sciences & Special Therapies, Pathology Unit, Padova, Italy, [2]Department of Gynecological Science and Human Reproduction, Padova, Italy, [3]Department of Medical Diagnostic Sciences & Special Therapies, Neuroradiology Unit, Padova, Italy.

Cantrell's Pentalogy (CP) is a rare, mainly sporadic, spectrum of congenital midline thoracoabdominal defects, including sternal defects, ventral diaphragmatic hernia, partial absence of the pericardium, supraumbilical abdominal wall defects, and congenital heart defects. The approximate incidence is 1 in 100000, with a 2:1 male predominance.

We report the case of a fetus affected by complete ectopia cordis, absence of the sternum and pericardium, defect of the ventral diaphragm, common aorticopulmonary trunk, cranio-facial dysmorfisms (microtia and bilateral cleft lip and palate) and asplenia without detected chromosomal anomalies on fetal karyotyping; thus leading to the diagnosis of CP with associated anomalies.

The severity of CP may range from incomplete to severe clinical phenotypes with the involvement of further organs/systems. Most of CP cases are sporadic and have been associated viral infections, maternal abuse of beta-aminopropionitrile, chlorine inhalation and numerical chromosomal aberrations.

Since the original Toyama's classification, a number of non-typical CP presentations have been reported (with a wide spectrum of multi-organ malformations). To our best knowledge, however, the association of CP with asplenia has never been previously reported.

P02.054
Cat-eye syndrome phenotype and extragonadal mature teratoma: an unusual case of dup 22q11.1q11.21

S. Kitsiou-Tzeli[1], *K. Stefanaki*[2], *A. Syrmou*[3], *K. Kosma*[3], *K. Giannikou*[3], *V. Oikonomakis*[3], *M. Choulakis*[4], *A. Kolialexi*[3], *P. Makrythanasis*[1], *M. Tzetis*[1];

[1]Medical Genetics Laboratory, Choremio Research Laboratory, University of Athens, Present Address: Service of Genetic Medicine, University Hospitals of, Athens, Greece, [2]Department of Pathology and Anatomy, "Aghia Sophia Children's Hospital",, Athens, Greece, [3]Medical Genetics Laboratory, Choremio Research Laboratory, University of Athens, Athens, Greece, [4]Otorynolaryngology Department, "Aghia Sophia Children's Hospital", Medical, Athens, Greece.

We report the clinical and molecular findings of a 9 month old girl presented with a palpable midline neck mass, proved to be a extragonadal mature teratoma and also features of Cat-Eye Syndrome (CES). Cytogenetic analysis revealed a supernumerary marker chromosome which was identified by molecular cytogenetic analysis with fluorescence in situ hybridization (FISH) to derive from

chromosome 22. High resolution micro-array based comparative genomic hybridization (array-CGH) confirmed the marker and additionally clarified the size, breakpoints and gene content of the duplication [dup 22q11.1q11.21, 1.6 Mb; breakpoints: 15,438,946-17,041,773]. Cat-Eye syndrome is a disorder with a large variability, ranging from almost normal phenotype to severe malformations, but to our knowledge teratoma has not been previously reported. Also this is the first case of CES with well delineated breakpoints identified with high resolution array-CGH. Our findings extend the phenotypic spectrum of the 22q11.1-q11.2 duplication syndrome, pointing out specific dosage sensitive genes that might contribute to specific phenotypic features.

P02.055
CCR5 chemokine receptor polymorphism in HIV-1 patients from Western India

U. Shankarkumar, *A. Shankarkumar, K. Ghosh;*
National Instiute of Immunohaematology, Mumbai, India.

Background: Entry of HIV-1 into target cells requires both CD4 and chemokine receptors. A 32-nucleotide deletion (?32) within the â-chemokine CCR5 gene has been described in HIV-1 subjects who remain uninfected. Our objective was to determine the frequency of ?32 deletion in CCR5 among HIV-1 infected patients and compare them with normal uninfected healthy individuals belonging to the same ethnic background. **Materials & Methods**: A total of 153 HIV-1 infected patients confirmed for their HIV-1 status were and a total of 68 normal Healthy individuals from the same ethnic background confirmed HIV-1 negative were studied. Genomic DNA from patients and controls were extracted and amplified for CCR5 gene segment using PCR. Amplified products were analyzed on 12% acrylamide gel, which yielded an 189bp fragment for wild type allele and 157bp fragment for the deleted (mutant) allele. **Results:** The results revealed that 7.19% were homozygous ,0.65% were heterozygous and the remaining 92.16% had no deletion for ?32 allele among the infected subjects.10.29% were homozygous ,0.00% were heterozygous and the remaining 89.71% had no deletion for ?32 allele among the control subjects. **Conclusion:** This study shows that the CCR5 allele frequency varies in different ethnic groups. Around 7.84% of the Patients have not been protected though they have the presence of the 32bp deletion.

P02.056
Congenital malformations and perinatal complications in CDG syndrome

S. Funke[1], *E. Korsch*[2], *M. Adamowicz*[3], *J. Voduiputz*[4], *L. Al-Gazali*[5], *D. Lefeber*[6], *R. Wevers*[6], *É. Morava*[7];
[1]*Department of Obstetrics and Gynecology, University of Pécs, Faculty of Medicine, Pécs, Hungary,* [2]*Pediatric Hospital, Amsterdamerstrasse, Köln, Germany,* [3]*Department of Metabolic and Endocrine Disorders, Children's Memorial Health Inst., Warsaw, Poland,* [4]*University Children's Hospital, Vienna, Austria,* [5]*Department of Paediatrics and Pathology, United Arab Emirates University, Al Ain, United Arab Emirates,* [6]*Laboratory of Pediatrics and Neurology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [7]*Department of Pediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Congenital Disorders of Glycosylation is a growing group of more than 30 different types of inborn errors with multisystem involvement and central nervous system presentation. Supportive therapy and adequate counselling rely on early diagnosis of the underlying defect. Recently several patients were reported with CDG syndrome and perinatal complications.

We assessed 48 CDG patients from our patient cohort for the presence of prenatal and perinatal findings in various CDG forms. We included 29 children with a type I transferrine isoelectric focusing pattern: 6 patients with PMM2-CDG, 2 with ALG6-CDG, 1 female with DMP3-CDG, 7 children with ALG1-CDG, 12 patients with SRD5A3-CDG and 1 child with PMI-CDG. We evaluated 19 children demonstrating a type II TIEF pattern: 3 patients with COG7-CDG, 1 with B4GALT1-CDG, 12 patients with ATP6V0A2-CDG, and 3 with CDG-IIx.

We found maternal complications in 4 cases, including maternal eclampsia and reduced fetal movements. Prematurity/dysmaturity were observed in 9 cases. Microcephaly and neonatal seizures were common, especially in ALG1-CDG, COG7-CDG, ATP6V0A2-CDG. Dysmorphic features were present in almost all cases, however, mostly nonspecific, except for cutis laxa in ATP6V0A2-CDG. Ophthalmologic malformations and ichthyosis were characteristic in SRD5A3-CDG. Neonatal complications included feeding problems, microcephaly, hypotonia and neonatal bleeding. Three children diagnosed with either PMM2-CDG or ALG6-CDG had abnormal neonatal screening results for hypothyreoidism. Liver function tests were elevated in all neonatally evaluated cases.

Dysmaturity, microcephaly, congenital eye malformations and skin anomalies can be early signs of CDG syndrome. Screening for glycosylation disorders in these neonates is essential to obtain timely diagnosis.

P02.057***
Cerebellar malformations: clinical and genetic heterogeneity

U. Kini[1,2], *E. S. Akha*[3,2], *P. Anslow*[4], *A. Deng*[5], *V. Harrison*[1], *V. Murphy*[6], *G. Quaghebeur*[4], *H. Stewart*[1,2], *J. Taylor*[3,2], *D. Keays*[7,2], *S. Knight*[3,2], *J. Flint*[3,2];
[1]*Department of Clinical Genetics, Churchill Hospital, Oxford, United Kingdom,* [2]*Oxford Biomedical Research Centre, Oxford, United Kingdom,* [3]*Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom,* [4]*Department of Neuroradiology, John Radcliffe Hospital, Oxford, United Kingdom,* [5]*University of Oxford, Oxford, United Kingdom,* [6]*Department of Psychiatry and Learning Disabilities, Ridgeway Partnership, Oxford, United Kingdom,* [7]*Research Institute of Molecular Pathology, Vienna, Austria.*

Cerebellar malformations (CM) are common structural brain abnormalities, which are neuroradiologically, clinically and genetically heterogeneous. Several autosomal recessive genes such as *RELN, VLDLR, SLOS, PMM2, TSEN54, etc* have been implicated in its causation, as well as some X-linked genes such as *OPHN1* and *CASK*. Chromosomal abnormalities have been described rarely. Access to genetic testing is limited. **Aim**: To investigate the role and prevalence of copy number variants in patients with CM. **Methods**: We performed CGH (comparative genomic hybridisation) on 120 patients with varied brain abnormalities, recruited through the Oxford Brain Abnormalities Research Group, using customized 4x180K Agilent technologies arrays. Twenty five of these patients presented with a CM. **Results**: 4/25 patients (16 %) were found to have a microarray abnormality. Three of the abnormalities were on the X chromosome (involving CASK and OPHN1) and the remaining was a homozygous deletion (involving NPHP1). The cerebellar phenotypes associated with these findings ranged from mild vermis hypoplasia to cerebellar hypoplasia with brainstem involvement. Clinically, ataxia and developmental delay were the most consistent findings, although developmental delay ranged from mild to severe. Other putative aberrations were identified, but have not been proven to be pathogenic as yet. **Conclusion**: CGH is a useful genetic test for determining the cause of CM. X-linked CM should be kept in mind due to its implication on reproductive risks. Furthermore, genotypic and phenotypic variability highlights the need for a targeted high throughput sequencing approach that can be used as a single diagnostic platform.

P02.058
Cardiofaciocutaneous syndrome (CFC) - a novel mutation and six new patients

D. Gieruszczak-Białek[1,2], *E. Ciara*[3], *M. Pelc*[2], *A. Skórka*[1,2], *K. Chrzanowska*[2], *M. Krajewska-Walasek*[2];
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*Departmet of Medical Genetics, The Children Memorial Health's Institute, Warsaw, Poland,* [3]*Department of Clinical Genetics, Children Memorial Health's Institute, Warsaw, Poland.*

Cardiofaciocutaneous syndrome (CFC) is a rare genetic condition with sporadic occurrence. About 100 cases have been published, but this number seems to be underestimated. CFC is characterized by distinctive facial features, heart defects, ectodermal abnormalities and mental impairment. The syndrome is caused by gain-of-function mutations in four different genes BRAF, KRAS, mitogen-activated protein/extracellular signal-regulated kinases: MEK1 and MEK2.

We present six new patients with CFC syndrome, confirmed by molecular studies. We identified five different mutations. One of these mutations has not been reported in the literature (c.785A>C in BRAF gene). A patient with a novel mutation manifested typical dysmorphic features, ectodermal anomalies and a heart defect. He presented with only mild learning difficulties, contrary to the most patients with CFC syndrome, who are moderately or severely mentally retarded.

Clinical and molecular findings will be discussed hereby in relation to the patients previously reported in the literature.
The study was supported by the Polish Ministry of Science and Higher Education (grant Nr 0056/B/P01/2008/35) and CMHI (grant No 190/08).

P02.059
A CGH-Array study in non-syndromic (primary) autism disorder
E. Gumuslu[1], *N. Cine*[1], *B. Kara*[2], *H. Savli*[1];
[1]*Kocaeli University Medical Genetics Department, Kocaeli, Turkey,* [2]*Kocaeli University Department Of Pediatrics, Kocaeli, Turkey.*
INTRODUCTION:
Autism is a neurodevelopmental disorder with a strong genetic basis in its etiology. Cytogenetic abnormalities have been detected in 5-10% of the patients with autism. Conventional karyotype analysis has revealed that chromosomal structural aberrations such as translocation, inversion, deletion, and duplication play a role in causing autism spectrum disorders (ASD). Unfortunately, there is not a single specific biological marker clearly responsible from autism. Array CGH is a molecular karyotyping method remarkable with fast analysis and highly sensitive diagnostic value.We aimed to use this technology to screen autistic patient's whole genome in order to investigate new dchromosomal abberations.
MATERIAL AND METHOD:
We isolated DNA samples of 35 primary autism patients between 0-18 years(median age:8.5).DNA samples which labelled according to the protocol, were hybridized with CytoSure Syndrome Plus(v2) 4x44K (Oxford Gene Technology, Oxford, UK) microchips and scanned with Agilent Microarray Scanner(Agilent Technologies, Palo Alto, CA). Obtained data were analyzed using Cytosure Analysis Software v.2.0.8 software(Oxford Gene Technology, Oxford, UK).
RESULTS:
We found 16p13.11 deletion in thirteen patients, 16p11.2 deletion in twelve patients, 1q21 deletion in ten patients, 2q21.1 deletion in eight patients, 2p21 deletion in seven patients, 8p23.1 deletions in seven patients.
CONCLUSION:
Accordig to these data, we can postulate that 16p13.11 region and related genes also represent a predisposition to autism in our patients. Verification of the data belonging to these regions, may provide important clues for gene expression and proteomics studies responsible from the pathogenesis of the disease and treatment strategies.

P02.060
Char Syndrome: A rare dysmorphic patient with new clinical findings
A. Yesilyurt[1], *A. Cifci*[2];
[1]*Zekai Tahir Burak Women Health Training and Research Hospital, Genetic Center, Ankara, Turkey,* [2]*Ankara Children's Health and Diseases Hematology Oncology Hospital, Ankara, Turkey.*
Char syndrome is an extremely rare disorder, and exact prevalence of this syndrome has not been determined. Char syndrome is characterized by the triad of typical facial features, patent ductus arteriosus (PDA), and aplasia or hypoplasia of the middle phalanges of the fifth fingers. The patients with Char Syndrome have peculiar facial features incluiding flat midface, flat nasal bridge and broad
flat nasal tip, wide-set eyes, downslanting palpebral fissures, mild ptosis, short philtrum resulting in a triangular mouth, and thickened (patulous) everted lips. Our patients was born to a non-consangineous family after 37 week-old gestation under medical supervision because of oligohydramnios. According to our knowledge tracheomalacia, astigmatism and oligohydramnios is being published in Char Syndrome for the first time. New findings will be discussed and compared as well as other clinical findings with previously reported patients with Char Syndrome.

P02.061
Ectopic calcification in the Azores - Genetic aspects of DISH and chondrocalcinosis families
A. R. Couto[1,2], *A. Timms*[3], *M. R. Santos*[1], *J. P. Pinheiro*[4], *M. J. Peixoto*[1], *J. Sequeiros*[2], *J. Bruges-Armas*[1], *M. A. Brown*[5];
[1]*SEEBMO, Angra do Heroísmo, Portugal,* [2]*IBMC - Universidade do Porto, Porto, Portugal,* [3]*Botnar Research Centre, Oxford, United Kingdom,* [4]*SEEBMO - HSEAH, Angra do Heroísmo, Portugal,* [5]*University of Queensland, Brisbane, Australia.*
Twelve families with early onset of calcium pyrophosphate dehydrate (CPPD) chondrocalcinosis (CC) and diffuse idiopathic skeletal hypersostosis (DISH) were identified in Terceira Island, the Azores, Portugal. The interest in this disorder results from its unusual and exuberant radiological characteristics, its disabling potential at a young age and the fact that it appears to be monogenic.
After clinical and radiological characterization, 92 individuals, from 12 unrelated families, were selected for a whole genome linkage study. DNA was extracted and HLA typing was carried out in probands and several family members; hereditary haemochromatosis mutations were screened and microsatellite amplification was performed using LMS V.2. Mendelian inheritance errors were checked using PEDCHEK. Parametric and non-parametric linkage analysis was performed using GENEHUNTER and MERLIN.
No association with HLA alleles was seen; haemochromatosis mutations were identified in 31 individuals from 9 families. Suggestive linkage to an area of chromosome 16 (16q12.1-16q22.1) was obtained in the whole genome analysis performed.
Although the molecular basis of this disorder has not been totally clarified, this study showed that these families were not associated to chromosomal areas previously linked to either DISH or CC. Through the analysis of pedigrees this disorder seems to be monogenic. Thus, the results of this study suggest the involvement of a possible new major gene in the aethiopathogenesis of this disorder.

P02.062
Case report: additional malformations in isochromosome 18p syndrome
J. R. M. Protta, *I. C. Sgardioli, T. P. Vieira, V. L. Gil-da-Silva-Lopes; Department of Medical Genetics, University of Campinas(UNICAMP), Campinas, Brazil.*
INTRODUCTION: Tetrasomy 18p resulting from an isochromosome 18p is a rare karyotype and is not well established phenotypically. To date, there are more than 40 patients described, mostly presenting mental retardation and minor features. CASE REPORT: A six month old baby girl was referred for genetic evaluation because of psychomotor retardation and dysmorphic features. She is the first child of young and healthy non-consanguineous parents. Familial history was negative. The pregnancy was complicated by preterm labor and threatened abortion. She was born by cesarean due to pelvic presentation. The clinical evaluation of the proposita showed hypotonia, a broad forehead, high hairline in front and back, oval facial shape, sparse hair and eyebrows, low-set and malformed ears, telecanthus, down-slanting palpebral fissures, convergent strabismus, infantile hemangioma in front, glabela and philtrum, small nose, microstomia, retrognathism, and proximally set thumbs. A cranial computed tomography scan showed abnormal enlargement of sulci and cistern around the brain, with predominance of frontal areas. Echocardiogram revealed interventricular communication with hemodynamic effect. The cytogenetic analysis with GTG-banding karyotype showed 47,XX,+mar. Based on dysmorphic features and cytogenetics characteristics, it was performed FISH with the centromeric probe chromosome 18, confirming the origin of the chromosome marker. Subtelomeric probe (RP11-324G2) detected isochromosome 18p; karyotype was defined as 47,XX,i(18)(p10). DISCUSSION: Despite of common dysmorphic signs described in tetrasomy 18p, this girl presents two major features which have not been described. Thus, this report contributes to the delineation of this chromosomal aberration.

P02.063
Clinical and cytogenetic findings in a girl with dup16 (q12.1q21)
L. Odak[1], ***I. Barisic***[1], *I. Petkovic*[1], *M. Riegel*[2], *A. Schinzel*[3];
[1]*Children's Hospital Zagreb, Clinical Hospital Center Sisters of Mercy Zagreb, Zagreb, Croatia,* [2]*Institut für Medizinische Genetik, Medizinische Fakultät Universität Zürich, Zurich, Switzerland,* [3]2*Institut für Medizinische Genetik, Medizinische Fakultät Universität Zürich, Zurich, Switzerland.*
We describe a three year old girl admitted for evaluation because of speech delay, aggressive behaviour and dysmorphic facial features. Family history and pregnancy were unremarkable. Newborn period and early childhood were complicated with respiratory, gastrointestinal

and urinary tract infections. Associated structural anomalies of respiratory or urogenital tract as well as immune deficiency have been ruled out. Clinical examination revealed mild dysmorphic features: dysplastic ears, lower forehead, palpebral fissures slant down, hypoplastic supra-orbital ridges, blepharophimosis, epicanthic folds, flat nasal bridge, bulbous nose, long philtrum, thin upper lip, small mouth, and short neck. Marked lumbar lordosis and broad thorax were observed. Hands and feet were small with thick fingers. Audiometric findings were normal. Ophthalmologic examination revealed left side strabismus and hypetmetropy. Ultrasound examination of abdomen and pelvis was normal as well as EEG and CT of the brain. Routine cytogenetic chromosome analysis showed additional material on chromosome 16. FISH analysis with WCP-16 probe revealed that this material originates from chromosome 16. Microarray analysis with a ≈75 kb resolution showed a gain on the long arm of chromosome 16 at bands q12.1 through q21, which is approximately 9.92 Mb in size. To the best of our knowledge, this is a first description of a patient with dup16 (q12.1q21). The possible influence of the triple dosage of genes located in this region on clinical presentation of our patient is discussed.

P02.064
Chromosome instability syndrome with congenital heart disease.

S. I. Olga;
Petrovsky Russian Research Center of Surgery RAMS, Moscow, Russian Federation.

Clinical case: Female patient, 4 y.o., came under our observation with congenital heart disease (CHF, atrial septum defect) required surgical correction. During clinical examination additional phenotypic features (mental retardation, hidden facial cleft, epicanthi, clinodactyly) were found. She had verbal development delay, and normal hematological parameters.

Cytogenetic analysis was performed to identify chromosome aberrations. Two consecutive karyotyping was carried out to confirm primary finding. Lymphocytes from peripheral blood samples were obtained from 72-h mitogen stimulated cultures, prepared according to standard cytogenetic procedures. The GTG-banding analysis revealed normal female karyotype, 46, XX, with common chromosome instability in 30-40% percent of cells.

Discussion: Patient was discharged after successful surgical correction of CHD with chromosome instability syndrome diagnosis. There were no additional features usually associated with chromosomal breakage syndrome. The chromosome instability syndromes are group of conditions associated with chromosomal instability and breakage, and high risk of malignancy. In this case chromosome instability can modulate the risk of lympho-proliferative disease. The mean age of leukemia manifestation is 5-6 years old. We did unmask high risk of hematological complications in patient with primary cardio surgical problem.

Conclusion: Routine karyotyping performed for CHD patients can reveal chromosomal aberration in about 20%. We suppose this analysis has to be done routinely for such a group of patients even after neonatal period.

P02.065
Genetic polymorphism of human Y chromosome and risk factors for cardiovascular diseases: a study in WOBASZ cohort

G. Kostrzewa[1], *M. Konarzewska*[1], *R. Ploski*[1], *G. Broda*[2];
[1]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland,* [2]*Department of Cardiovascular Epidemiology and Prevention, Institute of Cardiology, Warsaw, Poland.*

Genetic variants of Y chromosome predispose to hypertension in rodents whereas in humans the evidence is conflicting. Our purpose was to study the distribution of a panel of Y chromosome markers in a cohort from a cross-sectional population based study on prevalence of cardiovascular risk factors in Poland (WOABSZ study). The HindIII and YAP Y chromosome variants previously shown to influence blood pressure, lipid traits or height were typed in 3026 and 2783 samples. In addition 4 subgroups (N~100 each) representing extremes of LDL concentration or blood pressure (BP) were typed for a panel of SNPs defining main Y-chromosome haplogroups and 19 STRs. The HindIII or YAP polymorphism were not associated with any of the studied traits. Extended analyses suggested a link between haplogroup N3* and lower mean diastolic BP (P=0.009) but this finding was not replicated when a larger group of subjects (N=1077) was analyzed (P=0.69, a trend in opposite direction). Analysis of STRs did not show statistically significant differences apart from the DYS385II marker whose distribution suggested effects on both BP (P=0.015) and LDL (P=0.034) concentration. In conclusion, our study shows that the widely studied Y chromosome HindIII variant and the YAP variant do not influence blood pressure, lipid traits or anthropological characteristic. Although we cannot exclude an association between DYS385II and BP/LDL concentration our results do not support a major role of Y chromosome genetic variation as defined by major Y chromosome haplogroups in determining cardiovascular risk in Poles.

P02.066
Orofacial phenotype of van der Woude and Poplyteal Pterygium Syndrome patients mutated for IRF6

M. Quentric[1,2], *A. Petraud*[3], *M. Legendre*[4], *M. Ghassibé*[1], *L. Desmyter*[1], *I. Jeru*[4], *S. Marlin*[4], *M. Gonzales*[5], *S. Amselem*[4], *M. P. Vazquez*[2,3], *A. Berdal*[2], *M. Vikkula*[1], *A. Picard*[2,3];
[1]*Laboratory of Human Genetics, de Duve Institute, Université catholique de Louvain, Brussels, Belgium,* [2]*Laboratoire de Physiopathologie Orale Moléculaire, Centre de Recherche des Cordeliers, Université Pierre et Marie Curie-Paris 6, INSERM, UMRS 872, Paris, France,* [3]*AP-HP, Hôpital d'enfants Armand-Trousseau, Service de Chirurgie Maxillo-Faciale et Chirurgie Plastique, UFR de Médecine Pierre et Marie Curie, Paris, France,* [4]*Institut National de Santé et de Recherche Médicale (INSERM) U.933, Université Pierre et Marie Curie-Paris 6 and Assistance Publique-Hôpitaux de Paris, Hôpital Armand-Trousseau, Paris, France,* [5]*AP-HP, Hôpital d'enfants Armand-Trousseau, Unité de Génétique du Développement Embryo-Foetal, Paris, France.*

Van der Woude syndrome (VWS, OMIM #119300) is a dominantly inherited developmental disorder characterized by pits and/or conical elevations of the lower lip, cleft lip and/or palate, and hypodontia. Popliteal pterygium syndrome (PPS, OMIM #119500) shares the clinical features of VWS, with the addition of other signs such as popliteal webs (pterygia), synechiae connecting the upper and lower jaws, ankyloblepharon, syndactyly and genital anomalies.

Since many signs occur in the orofacial region and the penetrance is incomplete, it is of great interest to better characterize VWS/PPS patients to see if an oral phenotype-genotype correlation exists. For this, nineteen families (17 VWS + 2 PPS) from Trousseau hospital (Paris) were seen by a multidisciplinary staff, focusing on the orofacial phenotype. Panoramic imaging were used to check for dental agenesis. The coding exons of the IRF6 gene, including intron-exon boundaries, were sequenced, and Multiplex Ligation-dependent Probe Amplification was performed to test for intragenic deletions or amplifications. We identified a mutation in IRF6 in 82% (14/17) of VWS and 100% (2/2) of PPS families. Affected individuals had clefts (79%), lower lip pits (78%), dental agenesis (72%), and abnormal dental morphology (60%). The upper lateral incisors and the second upper premolars were the most affected.

This prospective study demonstrates the high frequency of dental anomalies in VWS/PPS patients, affecting mostly the upper lateral incisors and the second upper permanent premolars. This may be a useful clinical clue for correct diagnosis, as lips pits are not always present.

P02.067
Duplication of chromosome 15q22 in patient with severe dysmorphic features

A. Matulevičienė[1,2], *V. Dirsė*[1,2], *V. Kučinskas*[1,2];
[1]*Centre for Medical Genetics at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania,* [2]*Department of Human and Medical Genetics Faculty of Medicine, Vilnius, Lithuania.*

We report on one-year-old girl with chromosome 15 duplication and severe dysmorphic features. Our patient is the second child of uncomplicated pregnancy with high risk of biochemical testing on second trimester from non-consanguineous parents. The girl's phenotype is characterised by microcephaly, ocular hypertelorism, downslanting palpebral fissures, intensive blue sclera, prominent nasal bridge with periorbital fullness, short triangular philtrum, microstomia, partial cleft hard and soft palate, preauricular sinuses, short neck, expressed hypertrichosis on the whole body, pilonidal

sinus, psychomotor retardation and grow delay.
Patient was karyotyped and a normal female karyotype was detected. We used subtelomeric FISH (ToTelVysionTM) for search of subtelomeric microdeletions/microduplications for the possible cause of intellectual disability and congenital malformations of the patient. Analysis of FISH signals of chromosome 15 indicated additional control signal (15q22 LSI PML) on terminal arm of other chromosome of undetermined origin. We suggest that duplicated region of 15q22 may be an appreciable cause of various severe dysmorphic features of the patient. Array CGH analysis for verification and specification of this duplicated region is under the investigation.

P02.068
Cholestasis in patients with Cockayne syndrome and suggested modified criteria for clinical diagnosis

*T. Abdel Ghaffar[1,2], E. Elsobky[1,3], **S. Elsayed**[3,1,2];*
[1]Children's hospital, Ain Shams University, Cairo, Egypt, [2]1Yassin Abdelghaffar Charity Center for Liver Disease and Research, Cairo, Egypt, [3]Medical Genetics Center, Cairo, Egypt.

Cockayne syndrome (CS) is a rare autosomal recessive neurodegenerative disease characterized by growth failure; brain dysmyelination, cutaneous photosensitivity; pigmentary retinopathy, cataract, sensorineural hearing loss and hepatomegaly. To the best of our knowledge, cholestatic liver disease was not previously reported in these patients.
Aim: To highlight the presence of cholestasis and liver dysfunction in this group of patients and to suggest modified criteria for clinical diagnosis.
Methods: The study included nine patients with CS from four different families (five males and four females) in which CS was suspected clinically. For all patients cytogenetic analysis revealed spontaneous chromosomal breakage that was increased after mitomycin C treatment. Diagnosis was confirmed by DNA repair assay.
Results: Seven of these patients had evident liver affection ranging from mild elevation in liver enzymes to cholestatic liver disease and liver cell failure. The attacks were recurrent in two patients and were sometimes preceded by infection. These attacks may lead to deterioration of liver condition or neurological symptoms or it may end in liver cell failure that may recover completely or it may end in death.
Conclusion: liver disease could be considered common in Egyptian patients with CS with the cholestatic form being the most evident. Chromosomal breakage study and positive family history should be included as major criteria for clinical diagnosis of CS especially in a population like ours whereas consanguineous marriage is very high and molecular testing and UV sensitivity tests are considered unaffordable.

P02.069
Cleft palate and bilateral congenital cataract: a familial observation

***C. FRANCOIS-FIQUET**[1,2,3], A. Lorot[1], O. Wavreille[4], H. Ludot[5], D. Gaillard[2], E. Landais[2], P. Jonveaux[6], M. Beri[7], M. Poli-Merol[1], M. Doco-Fenzy[2,3];*
[1]Pediatric surgery, American memorial Hospital, Reims, France, [2]department of genetics, Hôpital Maison Blanche, Reims, France, [3]EA 3801, University of Champagne Ardenne, Reims, France, [4]Department of Ophtalmology, CHU, Lille, France, [5]Department of anesthesiology, American memorial Hospital, Reims, France, [6]Genetics laboratory, Brabois Hospital, Nancy, France, [7]genetics laboratory, Brabois Hospital, Reims, France.

We report the observation of a family with a rare association of congenital bilateral cataract (**CBC**) and cleft palate. The family pedigree has unveiled abnormalities over 4 generations, affecting 21 persons with CBC +/- cleft palate. The transmission seems autosomal dominant.
Clinical history
We report 4 brothers and sisters (2G-2B), followed in pediatrics surgery, presenting a CBC associated to a cleft palate:
-Case 1: Propositus, girl, CBC, Pierre Robin (Sub-mucous cleft (**SMC**), palate fistula), ptosis and growth delay (-2DS)
-Case 2: girl, CBC, Pierre Robin (cleft of the soft-palate), strabism, facial dysmorphism with mongoloid palpebral fissures and large nose
-Case 3: boy, CBC, SMC and bifid uvula, facial dysmorphism with mongoloid palpebral fissures, large nose and language delay.
-Case 4: boy, CBC, bifid uvula
-There is a fifth healthy female sibling.
The mother has facial dysmorphism, CBC, SMC, clinodactyly and scoliosis.
The propositus' karyotype was normal. Array-CGH analysis showed an interstitial amplification in Xp21.1, found in: the mother, propositus (case 1), but also in the healthy girl and not found in Case 2.
Discussion
The clinical association of cleft palate and ophthalmic abnormalities is not rare and has been reported in over 50 syndromes, but there are few familial observations with 4 affected generations.
In conclusion
Based on the genetic-clinical discordance we can wonder about the deleterious impact of the Xp21.1 amplification that might be a copy number polymorphism. It seems relevant to further study the underlying genetic mechanisms of this clinical association.

P02.070
Coffin-Lowry syndrome: report of 3 novel mutations in RPS6KA3 gene

***M. Kugaudo**[1], D. Jurkiewicz[1], D. Gieruszczak-Białek[1,2], D. Piekutowska - Abramczuk[1], E. Ciara[1], A. Skórka[1,2], M. Krajewska-Walasek[1];*
[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland.

Coffin-Lowry syndrome (CLS) is an X-linked semidominant disorder characterized in male patients by mental retardation, facial dysmorphism and skeletal malformations. Affected females usually show variable features. The only known gene associated with CLS is RPS6KA3 that encodes the serine/threonine kinase. Loss-of-function mutations are distributed throughout the gene. To date over 140 different mutations have been identified.
Here, we present 3 patients (two males and female) with CLS caused by novel RPS6KA3 gene mutations. The molecular analysis was performed by single-strand conformation polymorphism (SSCP) followed by sequencing of the gene.
The first male patient (1y3m) presented with hypotonia, developmental delay, and typical dysmorphic features: hypertelorism, frontal bossing, down-lanting palpebral fissures, anteverted nares, thick lips, broad and tapering fingers. Molecular analysis revealed a substitution mutation c.1443+3A>C. His two sisters and mother had dysmorphic features suggesting CLS carrier status.
The second male patient (1y1m) presented with hypotonia, developmental delay and facial anomalies (hypertelorism, down-slanting palpebral fissures, broad nose, everted lower lip). His hands were fleshy with simian creases and tapering fingers. Molecular testing showed a deletion c.889_890 del AG. Mother revealed tapering fingers as her only feature.
The third proband, female (2y4m), was referred for genetic evaluation because of developmental delay. She had dysmorphic features: hypertelorism, down-slanting palpebral fissures, frontal bossing, soft hands with tapering fingers and persistent anterior fontanelle. Molecular analysis revealed a substitution c.823G>T.
All mutations change the function of the serine/threonine kinase which with typical symptoms of CLS in patients confirm the pathogenic character of changes.

P02.071
Frequency of 22q11.2 microdeletion in children with congenital heart defects in Western Poland

***A. Wozniak**[1], D. Wolnik-Brzozowska[2], M. Wisniewska[2], R. Glazar[2], A. Materna-Kiryluk[2], T. Moszura[3], M. Badura-Stronka[2], J. Skolozdrzy[4], M. R. Krawczynski[2], J. Zeyland[5], W. Bobkowski[3], A. Latos-Bielenska[2], M. Szalata[1,5], R. Slomski[1,5], A. Siwinska[3];*
[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [2]Department of Medical Genetics, Poznan University of Medical Sciences, Poland, Poznan, Poland, [3]Department of Paediatric Cardiology and Nephrology, Poznan University of Medical Sciences, Poland, Poznan, Poland, [4]Center for Medical Genetics Genesis, Poznan,, Poznan, Poland, [5]Department of Biochemistry and Biotechnology, Poznan University of Life Sciences, Poland,, Poznan, Poland.

The 22q11.2 microdeletion syndrome refers to congenital abnormalities, including heart defects and facial dysmorphy, thymic hypoplasia, cleft palate and hypocalcaemia. Microdeletion within chromosomal region 22q11.2 constitutes the molecular basis of this syndrome. The aim of

this study was to determine the frequency of 22q11.2 microdeletion in 87 children suffering from a congenital heart defect (conotruncal or non-conotruncal) coexisting with at least one additional 22q11.2DS feature and to carry out 22q11.2 microdeletion testing of the deleted children's parents. We also attempted to identify the most frequent heart defects in both groups and phenotypic traits of patients with microdeletion to determine selection criteria for at risk patients.
The analysis of microdeletions was conducted using fluorescence *in situ* hybridization (FISH) with molecular probe specific to the *HIRA* region at 22q11.
Microdeletions of 22q11.2 region were detected in 13 children (14.94% of the examined group). Microdeletion of 22q11.2 occurred in 20% and 11.54% of the conotruncal and non-conotruncal groups respectively. Tetralogy of Fallot was the most frequent heart defect in the first group of children with 22q11.2 microdeletion, while ventricular septal defect and atrial septal defect/ventricular septal defect were most frequent in the second group. The microdeletion was also detected in one of the parents of the deleted child (6.25%) without congenital heart defect, but with slight dysmorphism.
Our study suggests that screening for 22q11.2 microdeletion should be performed in children with conotruncal and non-conotruncal heart defects and with at least one typical feature of 22q11.2DS as well as in the deleted children's parents.

P02.072
Molecular and clinical characterization of Estonian congenital heart disease patients with septal defects: screening of NKX2.5, GATA4 and TBX5 genes.

I. Kalev[1], *K. Muru*[2,3], *E. Vaidla*[1], *T. Reimand*[4,5,6], *R. Teek*[7], *S. Virro*[8], *M. Sõnajalg*[5], *K. Köbas*[9], *L. Ginter*[5], *K. Õunap*[2,5];
[1]*Institute of general and molecular pathology, Tartu, Estonia,* [2]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [3]*Children's Clinic, Tartu university hospital, Tartu, Estonia,* [4]*Department of Genetics, United Laboratories, Tartu university hospital, Tartu, Estonia,* [5]*Children's Clinic, Tartu University Hospital, Tartu, Estonia,* [6]*Department of Obstetrics and Gynaecology, Tartu University hospital, Tartu, Estonia,* [7]*Department of Genetics, United Laboratories, Tartu University hospital, Tartu, Estonia,* [8]*Cardiology Clinic, Tartu, Estonia,* [9]*Children's Clinic, Tartu University hospital, Tartu, Estonia.*

Congenital heart disease (CHD) is one of the most common birth defects (0.5-1% live births), but the genetic causes remain largely unknown. The most frequent forms of the CHD are the septal defects (SD). In earlier studies have been referred that mutations in genes *NKX2.5, GATA4, TBX5* may be associated with SD. The aim of our study was the clinical and molecular characterization of patients with CHD.
Study group consisted of patients who were referred to genetic counseling during 1990-2010 due to CHD, which included SD. SD was isolated or one part of combined malformation. *NKX2.5*, *GATA4* and *TBX5* coding exons and intron-exon boundaries were analysed by PCR amplification and sequencing. In the study group there were 22 patients (nine familiar cases): 15 index cases (8 females, 7 males) and 7 family members. In most of the cases there were combined CHD, which included SD (atrio- and/or ventriculo-SD). During analyses of *NKX2.5* found a new mutation (C.178 G>C, p.Glu60Gln) in a patient with Fallot' tetrad and 60% of probands had a known synonymous mutation E21E (rs2277923) in exon 1. In *GATA4* gene we found a known mutation c.1647 A>G, p.S377G in the exon 6 in one affected family member and in *TBX5* gene we found a frequent intronic SNP rs2236017 in 53% of index cases. Analyzed transcription factor genes *NKX2.5, GATA4* and *TBX5* probably have modest effect on the formation of SD in CHD. The research of the regulatory variants may add some more information. Supported by GARMP6573 and GARLA6808

P02.073
Congenital heart defects in association with dextrocardia

M. C. Panzaru[1], *M. Volosciuc*[2], *E. Braha*[1], *L. Butnariu*[1], *L. Caba*[1], *R. Popescu*[1], *F. Rusen*[1], *A. Sireteanu*[1], *C. Rusu*[1];
[1]*"Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania,* [2]*Medical Genetics Centre, Iasi, Romania.*

Dextrocardia is a congenital anomaly in wich the heart is positioned abnormally within the right side of the chest with the apex pointing to the right. Sometimes it is associated with situs inversus totalis or heterotaxy. The prevalence and the type of associated heart defects are variable.
We have analysed the prevalence and types of congenital heart defects in 16 children with dextrocardia recorded in the files of Iasi Medical Genetics Center. There were 5 girls and 11 boys; 10 had associated situs inversus totalis, 5 had situs solitus and 1 heterotaxy. Heart defects were present in 10 children (62.5%) - septal defect (27.7%), Fallot tetralogy (12.5%), transposition of great arteries (12.5%), aortic stenosis (6.25%), single ventricle(6.25%), left ventricle hypoplasia (6.25%), anomalous venous return (6.25%) and mitral valve prolapse (6.25%). The prevalence of heart defects was similar in boys (63.63%) and girls (60%). Complex heart defects were present only in males and more frequent in situs solitus and heterotaxy group (50%) than in situs inversus group (40%). In the literature common atrium, septal defects, pulmonic stenosis, transposition of great arteries and right aortic arch are the most frequent congenital heart defects associated with dextrocardia. In conclusion we present a study of 16 cases with dextrocardia, 62.5% of them having heart defects. Cardiac defects are commonly associated with dextrocardia and males are more severely affected than females. When dextrocardia occurs in the context of situs solitus or heterotaxy, the risk of associated congenital heart defects is higher.

P02.074
Low level mosaicism detected by array CGH in congenital malformations syndrome

D. V. Nesheva[1], *I. Dimova*[1], *R. Tincheva*[2], *Y. Uzunova*[3], *D. I. Toncheva*[1];
[1]*Department of medical genetics, Medical University – Sofia, Sofia, Bulgaria,* [2]*Department of Clinical Genetics, University Pediatrics Hospital, Sofia, Bulgaria,* [3]*Department of Urology, Medical University – Sofia, Sofia, Bulgaria.*

Congenital malformations present at delivery of an infant are due to genetic or non genetic factors and occur in 15-20% of stillborn children. Most can be diagnosed prenatally by ultrasound examination, but some can only be diagnosed after birth. Seven to 10% of infants with abnormal phenotype have numerical or structural chromosomal abnormalities that require identification for accurate diagnosis and genetic counseling. Molecular-cytogenetic and array-based techniques have enabled screening at higher resolution for congenital anomalies that result from genomic imbalances. We have examined four children with congenital anomalies, with or without mental retardation, of unclear etiology. In one child, we detected a deletion (about 28 Mb) of the region 18q21.1-18q23, in mosaic form. This abnormality was missed in a routine cyto genetic examination. We detected different polymorphic copy number variations (CNVs) in the other children. After repeating the cytogenetic analysis in high number of metaphases, we observed the deletion cytogenetically in 17% of the cells. We conclude that array-based comparative genomic hybridization (CGH) is a powerful diagnostic tool for the detection of low level mosaicism.

P02.075
Congenital anomalies and legal abortion in Iran

M. Amirian[1], ***S. Seyedhassani***[2,3], *A. Seghatol-eslami*[1], *M. Saffar*[4], *Z. Nafaei*[4];
[1]*Yazd legal medicine organization, Yazd, Islamic Republic of Iran,* [2]*Research and clinical center for infertility, Yazd, Islamic Republic of Iran,* [3]*Seyedhassani genetic center, Yazd, Islamic Republic of Iran,* [4]*Yazd medical science university, Yazd, Islamic Republic of Iran.*

Multiple congenital anomalies are common disorders that maybe occur in fetus due to acquired, genetical or multifactorial causes. Every time pregnant women or fetuses are seriously suffering from critical disorders can lead to infirmity, and the legal abortion is recommended. This is done based on forensic permission in Iran.
This case was referred to genetic counseling center for evaluation of fetal health. Some anomalies were found by sonography including intra uterine growth retardation, microcephaly, and club foot and finger anomalies. The pregnancy was terminated after three genetical and embryological consultations based on forensic ordinance. The proband was gravid 3 and the result of consanguineous marriage. Two previous pregnancies led to neonatal death following to congenital heart disease. Two other unknown cases of multiple congenital anomalies, one case of congenital heart disease, one case of mental retardation, one case of visual loss and two cases of hearing loss were seen in familial pedigree. In proband, the other fetal clinical manifestations

consisted of cleft palate, short and webbed neck, micrognathia, simian crease, clinodactyly, ectrodactyly, lung hypoplasia and joint stiffness. The search of signs revealed several autosomal recessive differential diagnosis such as Smith-Lemli- Opits syndrome type II, and Fryns syndrome. Bioethics which is the most important concept in medical evaluation and intervention is affected by the law and religion. There are important conflicts in principle branches of Islam. Any disorder which can lead to infirmity or critical condition for pregnant woman is considerable in legal medicine.

P02.076
Pediatric intestinal cancer and polyposis due to bi-allelic *PMS2* mutations: case series, review and follow-up guidelines

J. C. Herkert[1], *R. C. Niessen*[1], *M. J. W. Olderode-Berends*[1], *H. E. Veenstra-Knol*[1], *Y. J. Vos*[1], *H. M. van der Klift*[2], *R. Scheenstra*[1], *C. M. J. Tops*[2], *A. Karrenbeld*[1], *F. T. M. Peters*[1], *R. M. W. Hofstra*[1], *J. H. Kleibeuker*[1], *R. H. Sijmons*[1];

[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands.*

Bi-allelic germline mutations of one of the DNA mismatch repair genes, so far predominantly found in *PMS2*, cause constitutional MMR-deficiency syndrome. This rare disorder is characterized by pediatric intestinal cancer and other malignancies. We report the clinical, immunohistochemical, and genetic characterization of four families with bi-allelic germline *PMS2* mutations. We present an overview of published gastrointestinal manifestations of CMMR-D syndrome and propose recommendations for gastro-intestinal screening.

The first proband developed a cerebral angiosarcoma at age 2 and two colorectal adenomas at age 7. Genetic testing identified a complete *PMS2* gene deletion and a frameshift c.736_741delinsTGTGTGTGAAG (p.Pro246CysfsX3) mutation. In the second family, both the proband and her brother had multiple intestinal adenomas, initially wrongly diagnosed as familial adenomatous polyposis. A splice site c.2174+1G>A, and a missense c.137G>T (p.Ser46Ile) mutation in *PMS2* were identified. The third patient was diagnosed with multiple colorectal adenomas at age 11; he developed a high-grade dysplastic colorectal adenocarcinoma at age 21. Two intragenic *PMS2* deletions were found. The fourth proband developed a cerebral anaplastic ganglioma at age 9 and a high-grade dysplastic colorectal adenoma at age 10 and carries a homozygous c.2174+1G>A mutation.

Tumors of all patients showed microsatellite instability and/or loss of PMS2 expression.

Our findings show the association between bi-allelic germline *PMS2* mutations and severe childhood-onset gastrointestinal manifestations, and support the notion that patients with early-onset gastrointestinal adenomas and cancer should be investigated for CMMR-D syndrome. We recommend yearly follow-up with colonoscopy from age 6 and simultaneous video-capsule small bowel enteroscopy from age 8.

P02.077
Multi-Exon Deletion of *SMC1A* in a Severely Affected Female with Cornelia de Lange Syndrome

D. Babovic-Vuksanovic, *N. Hoppman-Chaney, J. Jang, J. Jen, J. C. Hodge;*
Mayo Clinic, Rochester, MN, United States.

Cornelia de Lange Syndrome (CdLS) is a genetically heterogeneous disorder characterized by dysmorphic facial features, cleft palate, limb defects, growth retardation and developmental delay. Approximately 60% of patients with CdLS have an identifiable mutation in the *NIPBL* gene at 5p13.2. Recently, an X-linked form of CdLS with milder phenotype was attributed to mutation of the structural maintenance of chromosomes 1A gene (*SMC1A*) at Xp11.22. Only a handful of male CdLS patients with mutations in *SMC1A* are known. The phenotype in female carriers is limited to minor developmental and cognitive deficiency. To date, all mutations identified in *SMC1A* are missense or small in-frame deletions that likely have a dominant negative effect. We report a Turner mosaic female with a severe form of CdLS who presented with growth and mental retardation, multiple congenital anomalies and facial dysmorphism. Array CGH identified a novel deletion of *SMC1A* spanning multiple exons which suggested a possible loss-of-function effect. Additional molecular studies were initiated to more precisely define the deletion boundaries and the effect of this genetic alteration. Expression of a truncated RNA message was detected in lymphocytes. Sequencing of both genomic and cDNA demonstrated an 8,152 base pair deletion of genomic DNA from exon 13 to intron 16. Although the loss-of-function effects of this deletion cannot be excluded, the resulting mRNA remains in-frame suggesting a dominant negative effect. We hypothesize that the size of this deletion compared to previously reported mutations and the presence of mosaic monosomy X likely contributes to the severity of her phenotype.

P02.078
HRAS mutation analysis in Polish patients with Costello syndrome

M. Pelc, *E. Ciara, M. Kugaudo, D. Piekutowska-Abramczuk, J. Trubicka, S. Luczak, D. Jurkiewicz, A. Tanska, P. Kowalski, M. Borucka-Mankiewicz, K. Chrzanowska, M. Krajewska-Walasek;*
The Children's Memorial Health Institute, Warsaw, Poland.

Costello syndrome (CS) is a rare congenital disorder with multiple anomalies including characteristic dysmorphic craniofacial features, short stature, failure to thrive, developmental delay, skin anomalies, cardiac and musculoskeletal defects and an increased risk of malignancy (about 10-15%). It has been demonstrated that *de novo* missense mutations in the proto-oncogene *HRAS* resulting in increased activation of Ras-MAPK pathway cause Costello syndrome. We present a group of five unrelated Polish patients with clinical diagnosis of CS. Mutation analysis of *HRAS* gene revealed heterozygous missense substitutions affecting aminoacid 12 of the protein product: c.34G>A (p.G12S) in two and c.35G>C (p.G12A) in three patients. Analysis of the available parental DNA confirmed four of the mutations as *de novo* cases. The evaluated group represented relatively homogenous Costello phenotype with coarse facial features, feeding difficulties and redundant skin with hyperpigmentation and deep plantar creases on hands and feet. Neonatal macrocephaly was present in all of the patients, as well as developmental delay, hypotonia and cardiac defects (cardiomyopathy, arrhythmia or pulmonary stenosis). Interestingly, in one study case the coexistence of Turner and Costello syndrome was observed. Our results deliver the first important information on the molecular basis of Costello syndrome in Polish population. They indicate certain heterozygous missense mutations in *HRAS* to be responsible for CS cases worldwide and confirm that the molecular analysis of *HRAS* provide a reliable diagnostic test for Polish patients diagnosed with Costello syndrome. The research was financed by MNiSW Project no. PB 0056/B/P01/2008/35 and CMHI Project no. 190/08.

P02.079
Craniofacial indices as a tool in evaluation dysmorphological features in parents with cleft children

E. Nagle[1], *U. Teibe*[1], *I. Grinfelde*[2];
[1]*Riga Stradiņš University, Riga, Latvia,* [2]*Clinic of Medical genetics, Children`s Clinical University Hospital, Riga, Latvia.*

Introduction. There are many genetic diseases associated with abnormal craniofacial morphology. Comparison of craniofacial indices in family members of patients with clefts and healthy individuals can be used to evaluate dysmorphological features of the head and face. **Objective.** To ascertain whether craniofacial indices could be used in evaluation dysmorphological features**. Materials and methods.** The subjects of our study were parents of children with a clefts, and clinically healthy individuals. Eight measurements were used in calculation of the indices. **Results.** Five craniofacial indices were calculated separately for males and females. Results are presented in the table1 (for males) and table 2 (for females).

Table 1

	Clefts (N = 57)	Control (N = 39)				
Index	**Mean**	**SD**	**Mean**	**SD**	**MD**	**p**
Cephalic index	0,82	0,04	0,80	0,06	0,02	0,090
Facial index	0,85	0,06	0,94	0,10	-0,09	0,001*
Intercanthal index	0,33	0,03	0,27	0,03	0,06	0,001*
Upper face index (R)	0,94	0,12	0,95	0,03	-0,01	0,577
Upper face index (L)	0,96	0,03	0,96	0,03	0,00	0,954

Table 2						
	Clefts (N = 67)	Control (N = 38)				
Index	**Mean**	**SD**	**Mean**	**SD**	**MD**	**p**
Cephalic index	0,82	0,04	0,80	0,04	0,02	0,010*
Facial index	0,82	0,05	0,97	0,08	-0,14	0,001*
Intercanthal index	0,34	0,03	0,26	0,02	0,08	0,001*
Upper face index (R)	0,97	0,03	0,97	0,03	0,00	0,890
Upper face index (L)	0,97	0,03	0,98	0,03	0,00	0,405

* Statistically significant(p<0,05)

Conclusions. Basic craniofacial indices show differences between 2 study groups and therefore could be useful in evaluation craniofacial dysmorphology.

A novel de novo mutation within *EFNB1* gene in a young girl with Craniofrontonasal syndrome

D. Apostolopoulou[1,2,3], *A. Stratoudakis*[3], *A. Hatzaki*[2,3], *K. Panagopoulos*[3], *O. Kaxira*[3], *P. Kollia*[1], *V. Aleporou*[1];

[1]*Department of Genetics and Biotechnology, Faculty of Biology, School of Physical Sciences, National and Kapodistrian University of Athens, Athens, Greece,* [2]*Department of Genetics and Molecular Biology, "MITERA" General, Maternity and Children Hospital, Athens, Greece,* [3]*Hellenic Craniofacial Center, "MITERA" General, Maternity and Children Hospital, Athens, Greece.*

Craniofrontonasal syndrome (CFNS) is mainly characterized by frontonasal dysplasia, telorbitism, broad nasal root and frequently a bifid nose and coronal craniosynostosis. CFNS is an X-linked disorder with an unusual pattern of inheritance, as heterozygous females are more severely affected than hemizygous males. The CFNS-causing gene is EFNB1, localized in the border region of chromosome Xq12 and Xq13.1, encoding for protein ephrin-B1. Ephrin-B1 belongs to the B-subclass of ligands of Eph receptors (receptor tyrosine kinases). Eph/ephrin signaling is important for the developmental processes of the embryo, including skeletal and craniofacial development. Here we aim to investigate the underlying genetic defect of a young girl with CFNS. The patient underwent surgical correction of her craniofacial deformities. Genetic analysis was carried out by Polymerase Chain Reaction (PCR). Products of exon 2 of EFNB1 gene were sequenced as well as digested with BpmI enzyme. A novel de novo missense mutation 373G>A was identified within EFNB1 gene, leading to the replacement of Glutamic acid at amino acid position 125 with Lysine. The replacement of Glu125 with Lys, which lies within the G-H loop, part of the dimerization ligand-receptor interface, is expected to disrupt the interaction between Eph receptor and ephrin B1 ligand, thus leading to CFNS. Missense mutations in exon 2 of *EFNB1* gene in patients with CFNS leading to aminoacid changes within the dimerization ligand-receptor interface have been described elsewhere.

P02.081
An atypical 5p deletion, involving part of the critical region for Cri-du-chat syndrome, in a girl with mild mental retardation

A. Blomhoff*, T. Barøy, E. Frengen, O. Rødningen, E. Ormerod, M. Fannemel; Department of Medical Genetics, Oslo University Hospital, Oslo, Norway, Oslo, Norway.*

Cri-du-chat syndrome results from a deletion of variable size on the short arm of chromosome 5. The chromosomal region implicated in the syndrome has been mapped to 5p15.1p15.3. Main clinical features are a high-pitched cat-like cry, distinct facial features, microcephaly and severe psychomotor and mental retardation. The phenotype varies depending on the size and location of the deletion. The critical regions for the typical cry and the mental retardation have been mapped to 5p15.3 and 5p15.2, respectively. *SEMA5A* and *CTNND2* located within the 5p15.2 critical interval have been suggested as candidate genes for the mental retardation. *CTNND2* is highly expressed in the brain, and is implicated in neuronal function. Furthermore, *CTNND2* knock out mice show severe cognitive dysfunction, and a correlation between deletion of *CTNND2* and severe mental retardation in humans has been reported. We report on a patient with a 3.2 Mb deletion of 5p15.2p15.1 (chr5:11902869-15234290, hg19) that displays mild mental retardation and developmental delay, but no dysmorphic features. Her deletion involves the genes *CTNND2*, *TAG*, *DNAH5*, *TRIO*, *FAM105A*, *FAM105B* and *ANKH*. We suggest that haploinsufficiency of *CTNND2* causes the mild mental retardation in our patient, and that other genes in the region contribute the significantly more severe cognitive impairments frequently seen in patients with Cri-du-chat syndrome.

P02.082
A novel mutation in HLXB9 gene in Currarino syndrome in an adult man: a case report

E. Domínguez-Garrido[1], *J. Aguirre Lambán*[1], *C. Sainz Gómez*[2], *C. Pérez Vega-Leal*[2];

[1]*Center for Biomedical Research (CIBIR), Logroño, Spain,* [2]*Hospital San Pedro, Logroño, Spain.*

The Currarino syndrome (CS; OMIM 176450) has been described as a triad of partial sacral agenesis with intact first sacral vertebra (sickle-shaped sacrum), presacral mass, and anorectal malformations. The sacral agenesis in CS is typically incomplete and only involves vertebrae S2-S5, a sacral anomaly distinct to this syndrome CS exhibits variable expressivity, reduced penetrance and remarkable variability of objective findings and subjective complaints, with a clinical spectrum ranging from anomalies localised only to the caudal region to those involving complex malformations of other organ systems including the kidneys, brain and spinal cord.

Currarino syndrome is autosomal dominant inheritance and has been associated with mutations of HLXB9, a homeobox gene that maps to chromosome 7q36. The prevalence is unknown and presentation in adulthood is extremely uncommon.

Here, we present a case of a 36-year old man with Currarino triad. He was diagnosed of CS after he suffered a motorbike accident. Until that moment, he presented chronic constipation. Mega-rectosigmoides and partial sacral agenesis was confirmed on X-ray and IRM. We performed direct sequencing for HLXB9 gen. We identified one novel mutation, c.264C>A, p. C88X.

The presence of variable phenotypes suggests DNA alterations in HLXB9 noncoding regions and/or in other genes encoding HLXB9 regulatory molecules or protein partners.

P02.083
Duplication of 11p with clinical features of Costello Syndrome and cutis laxa

T. Gardeitchik[1,2], *N. de Leeuw*[1], *L. Nijtmans*[1,2], *P. Jira*[3], *T. Kozicz*[4], *I. van de Burgt*[1], *E. Morava*[1,2];

[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Institute for Genetic and Metabolic Disease, Nijmegen, Netherlands,* [3]*Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands,* [4]*Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands.*

Cutis laxa (CL) is a disorder of wrinkled, abundant skin with abnormal elasticity. Several genetic defects have been elucidated to cause cutis laxa, still, the etiology in the majority of cases remains unknown. We describe a CL patient with duplication of the short arm of chromosome 11. Our patient had birth parameters at 90 percentiles, cutis laxa, cleft lip, several dysmorphic features, macroglossia, deep palmar/plantar creases, abnormal hair growth and hypotonia. She was diagnosed with hyperinsulinism, Meckel diverticulum, umbilical and inguinal hernias, ventricular septum defect, aqueductal stenosis feeding difficulties and developmental delay. Histology of skin showed severe abnormalities of elastin fibers. Genetic analysis revealed a duplication of 11p of paternal origin, which is associated with Beckwith Wiedemann syndrome (BWS). Many features in our patient are explained by the diagnosis of BWS, except for cutis laxa. Several clinical findings in our patient, including extensive skin wrinkling, could, however, also fit into the diagnostic criteria of CS. Intriguingly, the *HRAS* gene, in which gain-of-function mutations cause CS, is also located on 11p15.5. QPCR analysis in our patient showed an increase in *HRAS* expression in fibroblasts. Based on this genetic dosage effect and the observation of similar phenotypes in other 11p duplication cases we suggest that cutis laxa and the clinical features comparable to those of Costello Syndrome in our patient, occurred due to duplication of *HRAS*.

P02.084
Cytochrome P450 2C19 genetic polymorphisms and symptoms of gastroesophageal reflux disease.

N. Zendehdel[1], *H. Gholami*[2], *E. Ravanasa*[2], *S. K. Hosseiny*[2], *H. Sarie*[3], *M. Doughaiemoghaddam*[3], *N. Zendehdel*[4], *A. Poorshams*[1];
[1]*Digestive Disease Research Center, Tehran University of Medical Science, Tehran, Islamic Republic of Iran,* [2]*Iranian Tissue Bank, Tehran University of Medical Science, Tehran, Islamic Republic of Iran,* [3]*Fayyazbakhsh Hospital, Tehran, Islamic Republic of Iran,* [4]*Shahid Beheshti University of Medical Science, Tehran, Islamic Republic of Iran.*

Background: Gastroesophageal reflux disease is a common disease worldwide and has typical and atypical symptoms such as heartburn and hoarseness.Cytochrome p450 (CYPs) enzymes, located mostly in the liver, are responsible for the metabolism of omeprazole. Cytochrome P450 2C19 (CYP2C19) gene has several polymorphisms, the most common of which are the CYP2C19* 2 and CYP2C19* 3 alleles.These two polymorphisms both decrease enzyme activity. This study was performed to evaluate the influences of two common CYP2C19 polymorphisms on the frequencies of typical and atypical symptoms in the Iranian patients with gastroesophageal reflux disease.
Methods: One hundred and sixteen patients with gastroesophageal reflux disease were enrolled in the study. A gastroesophageal reflux questionnaire was completed for each patient by direct interview. It was comprised of information such as age, sex, BMI and symptoms of disease. A volume of 2 ml of venous blood was sampled from each subject. CYP2C19 genetic polymorphisms were detected using the PCR-RFLP method.
Results: There was an association between the frequencies of some atypical gastroesophageal reflux disease symptoms such as belching, anorexia, chest pain and hoarseness and CYP2C19 polymorphism, as the frequencies of these symptoms were higher in the variant CYP2C19 genotype (P<0.040).
Conclusion: CYP2C19 genotype might influence the appearances of some atypical symptoms in the patients with gastroesophageal reflux disease.

P02.085
Developmental delay and facial dysmorphism in a girl with a 9.5Mb de novo interstitial deletion of 12q: further delineation of chromosome 12q15-q21 deletion syndrome

N. Zarrouk[1], *B. Parmentier*[1], *B. Grisart*[1], *P. Lehette*[2], *M. Deprez*[3], *C. Verellen-Dumoulin*[1], *I. Maystadt*[1];
[1]*Institut de Pathologie et de Génétique, Gosselies Charleroi, Belgium,* [2]*Centre Hospitalier du Grand Hornu, Hornu, Belgium,* [3]*Grand Hôpital de Charleroi, Charleroi, Belgium.*

Mental retardation, as isolated symptom or as part of syndrome, is a common condition affecting 2-3% of individuals worldwide. Chromosomal rearrangements identified by karyotype or array-based comparative genomic hybridization (CGH-arrays), account for about 15-20% of mental retardation etiologies. Interstitial deletions of the long arm of chromosome 12 are rarely described in the literature.
Here, we report on a 4-year-old girl presenting with a deletion involving the 12q15-q21.31 region. Her clinical features include microcephaly at birth, developmental and speech delay, growth retardation with progressive macrocephaly, facial dysmorphism, strabismus and small joints hyperlaxity.
A 9.5 Mb deletion was detected by standard karyotype and confirmed by CGH-array. This rearrangement was not found in the parents, consistent with a de novo occurrence. The deleted region involves 27 genes, 3 of them being hyperexpressed in the brain.
To our knowledge, only 4 other cases of deletion encompassing the 12q15-q21 region are reported in the literature. All patients had developmental delay and mental retardation. Most of them presented with microcephaly at birth, intra-uterine and postnatal growth delay, cardiac malformations and common facial dysmorphism (high forehead, broad nasal bridge, low-set ears, arched or cleft palate, and micrognathia).
Description of additional patients in the future will help to refine genotype-phenotype correlations in this chromosomal region, improving genetic counseling for pre- and postnatal 12q deletion cases.

P02.086
An emerging phenotype of microdeletion Xq24 involving UBE2A gene - case report and literature review

L. Wallin[1], ***C. Chrapkowska***[1], *L. Samuelsson*[2], *E. Kärrstedt*[2], *M. Stefanova*[2];
[1]*Queen Silvia's Children Hospital, Sahlgrenska University Hospital, Gothenburg, Sweden,* [2]*Department of Clinical Genetics, Sahlgrenska University Hospital, Gothenburg, Sweden.*

Microdeletion Xq24 encompassing SLC25A43, SLC25A5, CXorf56, UBE2A, NKRF, and two non-coding RNA genes, 0.24-0.37 Mb in size, was described in five males from four unrelated families (Honda et al, 2010; Leeuw et al, 2010). Patients presented with intellectual disability, absent speech, seizures, craniofacial dysmorphism, multiple brain and inner organs anomalies.
Here we describe a 4-months-old boy with a 0.4 Mb maternally inherited Xq24deletion. He showed neonatal hypoglycaemia, low voice, swallowing difficulties, oesophageal atresia with tracheo-oesophageal fistula, aortic isthmus hypoplasia, postnatally developed microcephaly, multiple arachnoidal cysts and white matter changes, divergent strabismus, short neck, arachno- camptodactyly, vertebral anomalies, hypospadias as well as developmental delay, vision and hearing impairment. Marked dysmorphic features include: wide fontanels, hypertelorism, palpebral fissures slant up, depressed nasal bridge, small nose, long philtrum, large mouth with thin vermilion of the lip, crumpled ears. Initial diagnose severe form of Beals syndrome was ruled out by a negative FBN2 gene analysis. SNP-array analysis (Affymetrix 250k NspI) detected a 0.4 Mb Xq24 deletion which spans between base pair 118303222-118699727 (hg 18). The healthy mother was a carrier of the same deletion which originated de novo with her. She showed a complete skewed X-inactivation. A copy number variation, 1.3Mb deletion of 1p12, was detected in the boy, his mother and the maternal grandfather.
Clinical and molecular data evaluation of all six patients with deletion Xq24 suggests a new deletion syndrome different than the UBE2A deficiency syndrome. The role of the other genes involved in the deleted region remains to be further investigated.

P02.087
X-Inactivation studies in two different subtypes of Dent disease

I. Vlasak, *O. Rittinger, A. Mang;*
Children's Hospital, Paracelsus Medical University, Salzburg, Austria.

Background. A subset of X-linked genes escape X-inactivation (XI) and are expressed - randomly or skewed - from both X-chromosomes. We report on 2 patients affected with 2 genetically different forms of X-linked hypercalciuric nephrolithiasis (Dent disease 1 and 2) mapped to Xp11.22 and Xq26, respectively. We hypothesized that X-inactivation patterns might suggest the more likely genetic subtype. Here we discuss the clinical impact of XI results.
Case reports and results. 2 male unrelated normally developed patients, 4 and 5 y old, both with proteinuria, hypercalciuria, hypouricaemia and microhematuria with normal renal function. Dent disease, an X-linked proximal tubular dysfunction disorder, was confirmed by molecular analysis showing a mutation in the CCl5-gene in patient 1 and OCRL1 mutation patient 2. X-inactivation studies revealed a significant skewing in the mother of proband 1 and random XI in the other.
Discussion. Non-random X-inactivation is more common in heterozygous carriers of X-linked disorders and can be an important diagnostic clue in MRX-syndromes. Moreover, there may be a distinct correlation between the clustered fashion of genes which escape inactivation and the likelihood of skewing. Our observation of clearly different XI-patterns in two clinically similar but genetically different subtypes of an X-linked tubulopathy supports this relationship. Given the multitude of X gene loci of interest this may be useful for the proper timing of molecular investigations. Additional XI analyses in other females heterozygous for Dent disease are needed to prove this hypothesis.

P02.088
Desbuquois dysplasia type I and fetal hydrops due to novel mutations in the CANT1 gene

F. Laccone[1], *K. Schoner*[2], *B. Krabichler*[3], *B. Kluge*[1], *R. Schwerdtfeger*[4], *B. Schulze*[5], *J. Zschocke*[3], *H. Rehder*[1];
[1]*Institute of Medical Genetics, Vienna, Austria,* [2]*Institute of Pathology, Philipps-University Marburg, Marburg, Germany,* [3]*Division of Human Genetics, Medical*

University Innsbruck, Innsbruck, Austria, [4]of Prenatal Diagnosis and Human Genetics, Hannover, Germany, [5]Center of Prenatal Diagnosis and Human Genetics, Hannover, Germany.

We report on three hydropic fetuses of 17, 22 and 25 gestational weeks from three distinct families presenting with Desbuquois dysplasia type 1. All fetuses showed brachymelia and characteristic dysmorphic features. X-ray studies revealed delta-shaped extraphalangeal bones and disease-specific prominence of the lesser trochanter, varying in severity with fetal age. Early lethal manifestation of the disorder was reflected in lung hypoplasia and in early death of similarly affected siblings in cases 1 and 2. All families were German by descent. Sequence analysis of the CANT1 gene revealed two frameshift mutations, c.228_229insC and c.277_278delCT, in homozygous and compound heterozygous configuration respectively and a homozygously novel missense mutation, c.336C>A (p.D112E) located within a higly conserved region of exon 2. Haplotype analyses by high-resolution single nucleotide polymorphism array showed that the haplotype associated with c.228_229insC may be traced to a single founder in the German population.

P02.089

Yield of genetic testing in patients with familial vs. non-familial idiopathic dilated cardiomyopathy.

M. Rodríguez-García[1], *D. García-Giustiniani*[2], *X. Fernández*[2], *M. Ortiz-Genga*[2], *R. Barriales-Villa*[2], *L. Núñez*[3], *E. Maneiro*[2], *L. Cazón*[2], *M. Pérez*[2], *E. Álvarez*[2], *E. Veira*[2], *M. Crespo-Leiro*[1], *A. Castro-Beiras*[1], *L. Monserrat*[1];

[1]CHUAC.Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), A Coruña, Spain, [2]Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), A Coruña, Spain, [3]Universidad de A Coruña.Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), A Coruña, Spain.

Purpose: It has been estimated that 20% to 50% of idiopathic DCM cases are of familial/genetic origin, generally with autosomal dominant inheritance, but information about the efficiency of mutation screening is scarce.

Methods : We report the results of ongoing genetic and familial study of 125 index cases with idiopathic DCM (mean age at diagnosis 44±20 years, 74% males) followed-up in a single reference unit. DCM was considered “familial” when there was at least one relative with DCM. Genetic study has included the screening by a Sequenom platform of 600 previously described mutations and the sequencing of LMNA in all the patients.

Results: Familial DCM was present in 29 cases (23%). Till now we identified a potentially pathogenic mutation in 21 cases (13%): 9 of 29 in cases with familial DCM (31%), and 12 in 96 (13%) in non-familial cases (p=0.024). The majority of them were identified in MYH7 (45%) MyBPC3 (25%) and LMNA (20%). Thirteen mutations had been previously described in association with either DCM (LMNA: R190W, S573L; MYH7: I201T; TNNT2: R131W), HCM (MYH7: G716R ; MyBPC3: IVS23+1G>A, A833T, V771M and A627V) or both (MYH7: I736T, R787H, T1019N and MYH6: A1004S). Five mutations had not been previously described (LMNA:S22X, R349L; MyBPC3: P873L, E838Q and MYH7: A1128T). We found two double and one compound heterozygote. Conclusion: The probability to identify a causal mutation was significantly higher in patients with familial vs. non-familial idiopathic DCM thus, familial evaluation would be the first step to improve the mutation screening efficiency in DCM.

P02.090

Possibilities and limits in facial dismorphic syndrome in small child -disscutions on a Hallermann-Streiff syndrome case

O. D. Marginean[1], *I. D. Simedrea*[1], *C. I. Gug*[2], *T. E. Marcovici*[1], *A. K. Miliatru*[1], *C. I. Daescu*[1], *D. M. Chiru*[1], *L. T. Olaru*[1];

[1]1 Ist Pediatric Clinic, Timisoara, Romania, [2]University of Medecine and Pharmacy, Timisoara, Romania.

Introduction: Hallermann-Streiff syndrome (HSS) is a disorder of unknown origin. The early diagnosis of HSS is important for management because many complications may occur early in this syndrome.

Case report: We report N.D, a 1 year 4 month old boy, born at term, with 3010g , 49 cm , Apgar 9, the second child of a non consanquineous family. The child was admitted to our hospital for seizures, fever secondary to pharyngitis and dysmorphic facial features. Anthropometric criteria revealed short stature (height 73 cm, below 3rd percentile) and dystrophy (weight 9200 g, below 3rd percentile). The child presented with an unusually small mouth, small teeth with dentinal spots and improper alignment, small chin, small eyes, incipient cataract; small head and a prominent forehead, a small underdeveloped jaw, sparse hair, particularly that of the scalp, brows, and lashes. On the right cheek there was a scar secondary to surgical intervention for a mucous cyst done in the neonatal period. The karyotype of the child was 46, XY, 16qh+. The X-ray of the skull showed hypoplastic facial bones, large skull and frontal bossing. Clinical and radiological findings from our child meet six of seven criteria of HSS reported by Lee, Choi and Jung (dental anomalies, dischephalya, dwarfism, hypotrichosis, congenital cataract, microphthalmia).

Conclusions:

1. Hallermann-Streiff is a rare syndrome but underdiagnosed.
2. The disease is transmitted in a dominant manner but there are no specific anomalies of the karyotype.
3. Sophisticated genetic analysis is required for diagnosis of this syndrome.

P02.091

DNA-diagnostics of various forms of X-linked primary immunodeficiencies at the Russian patients

I. Sermyagina, *V. Zabnenkova, A. Poliakov;*

Research Center for Medical Genetics, Moscow, Russian Federation.

Primary immunodeficiencies (PID) are the hereditary diseases caused by rough infringement of functions of various links of immunity. They grow out of the genetic defects leading to infringement proliferative, a differentiation and functions immune cells. By this time are known about 80 PIDs. Despite their relative rarity, they occupy an important place in structure of disease and death rate in the developed countries. PIDs are characterised by difficultly recurrent infections, a high incidence of autoimmunity, and an increased risk of malignancies.

The greatest quantity are X-linked forms of congenital immunodeficiency though there are also other types of inheritance. In laboratory of DNA-diagnostics of the Research centre for Medical Genetics of the Russian Academy of the Medical science the molecular genetic analysis of the reasons of such diseases as is carried out: X-linked hyper-IgM syndrome (CD40L gene), X-linked ag-globulinemia (BTK gene), Interleukin-2 receptor gene deficiency (IL2R gene), X-linked lymphoproliferative disease (SH2D1A gene), Wiskott-Aldrich syndrome (WASP gene) and chronic granulomatous disease (CYBB1 gene).

Presence of a certain mutation at patients with PIDs allows to show a molecular aetiology, to establish heterozygous carriers in relatives in a probands family and does possible performance of the prenatal diagnosis.

We made DNA-diagnostics for 189 probands with various forms of primary immunodeficiencies, 110 various mutations are registered and 22 prenatal diagnostics are executed.On the basis of the accumulated data (a spectrum of mutations, presence of “hotspots”) in laboratory are developed effective algorithms of the mutational analysis of various forms of PIDs.

Whole genome sequencing enables optimized patient management

W. Wiszniewski[1], *M. N. Bainbridge*[1], *D. R. Murdock*[1], *J. Friedman*[2], *C. Gonzaga-Jauregui*[1], *I. Newsham*[1], *J. G. Reid*[1], *J. K. Fink*[3], *M. B. Morgan*[1], *M. Gingras*[1], *D. M. Muzny*[1], *L. D. Hoang*[4], *S. Yousaf*[4], *R. A. Gibbs*[1], *J. R. Lupski*[1];

[1]Baylor College of Medicine, HOUSTON, TX, United States, [2]University of California, San Diego, CA, United States, [3]University of Michigan, Ann Arbor, MI, United States, [4]Life Technologies, Carlsbad, CA, United States.

Whole Genome Sequencing (WGS) has revolutionized genetic diagnoses, but its impact has not yet been realized in guiding immediate patient treatment. Dopa Responsive Dystonia (DRD) is a genetically heterogenous, clinically complex, movement disorder that can be misdiagnosed as cerebral palsy. Although L-DOPA is the primary treatment mode for DRD, alternate treatments are available, however, diagnosis and optimal management of the disorder requires extensive clinical investigation. A 14 year old fraternal male and female twin pair with a 9 year diagnosis of DRD was identified. Prior treatment

was exclusively L-DOPA with carbidopa. Inheritance was apparently recessive but point mutation negative for TH and GCH1. We interrogated the genomes of both affected siblings by whole genome sequencing (WGS) and array comparative genomic hybridization (aCGH) to identify causative variants. Three genes with compound heterozygous, protein altering, mutant alleles were identified. Two of these genes (ZNF515, C2orf16) have no known function whereas homozygous mutations in the third gene, sepiapterin reductase (SPR) have been previously associated with DRD. The alleles in SPR were inherited from heterozygous carrier parents. Interestingly the carrier mother has been diagnosed with fibromyalgia; a condition that can be responsive to serotonin reuptake inhibitors. Our findings conclude a specific molecular diagnosis, suggest optimizing medical management with L-DOPA and Carbidopa using 5-hydroxy tryptophan (5-HTP) supplementation in the DRD affected twins.

P02.093
Hypothyroidism and oxidative stress in Down syndrome

***S. Briuglia**, D. Comito, C. Giovanna Elisa, M. Caterina, M. Emanuela, S. Marzia, F. Valeria, S. Damiano Carmelo, A. Teresa;*
Dipartiment of Paediatric Science Messina, Messina, Italy.

Background and aims: Thyroid disorders in Down syndrome (DS) subjects have been reported to have a prevalence of 15-54%. The spectrum of thyroid abnormalities ranges from congenital hypothyroidism, primary hypothyroidism, autoimmune thyroiditis, compensated hypothyroidism. The existence of a DS-specific thyroid disorder was hypotized. Thyroid hormones are the most important factors involved in the regulation of the basal metabolic condition and are associated to the oxidative and antioxidative status. Literature's data on the oxidative status of hypothyroidism are limited and controversial. The aim of this study was to assess the measurement of serum MDA/HNE in DS patients with or without hypothyroidism, to evaluate biomarkers of oxidative stress. Methods: we enrolled a selected group of 30 children affected by DS (18 male and 12 female, mean age 6 years), 15 with hypothyroidism (8 in LT4 therapy) and 15 without. All subjects had not inflammatory/infective diseases. Serum MDA/HNE levels were measured by means of a colorimetric assay. Results: serum MDH/HNE levels were significantly higher ($p<0.05$) in hypothyroid subjects without LT4 treatment than in those euthyroid and on LT4 therapy. Conclusions: the present study evidences an increased circulating MDA/HNE levels in DS. We confirm the presence of chronic oxidative stress in children with DS. This condition can contribute to development of consequent oxidative cell damage and long-term complications. In DS with hypothyroidism, therapy with LT4 reduces oxidative stress.

P02.094
Dynamic frequency of Down syndrome in the Republic of Moldova during the years 2005-2009

***M. Sprincean**[1], M. Stratila[2], N. Barbova[1], E. Halabudenco[1], A. Misina[2];*
[11]National Center of Reproductive Health and Medical Genetics, [2]State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of, [21]National Center of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of.

Prevention of birth of children with chromosomal abnormalities, especially with Down syndrome (DS), represents the main task of medical genetic services. Average frequency of trisomy 21 or DS is 9.5 / 10,000 births in the countries EUROCAT. Was established correlation between frequency of DS and maternal age. The risk of having children with DS is 1/1000 births for 20 years old mothers, rising to 1/35 in pre-menopausal age births.

Totally 232 cases with DS have been identified during the period 2005-2009, according to the cytogenetic laboratory data of the NCRHMG. From this number, 209 cases have been detected after the birth of children. Other 23 DS cases have been identified during the interruption of pregnancy after prenatal medical indications. The frequency of DS in the population of Republic of Moldova was 12.02 / 10 000 (1:924), registered during the years 2005-2009, which exceeds the average frequency of this pathology in countries EUROCAT and corresponds to the frequency of Down disease in Ukraine (12.4 / 10,000) and Norway (13.1 / 10,000). Maximal frequency of DS has been recorded in 2005 - 1:967 children, minimal in 2008 - 1:685 births with this chromosomal abnormality. Frequency of DS in Moldavian population could be 1:832, without applying of prenatal cytogenetic diagnostic methods. Using the cytogenetic method of prenatal diagnosis allows us to prevent the birth of children with DS and to decrease the frequency of this disease by 10%.

P02.095
Genetic polymorphisms of MTHFR (677T AND 1298C) and homocysteine metabolism as maternal risk factor for Down 's syndrome patients in North Indian population.

***S. K. Pandey**, P. Singh, S. K. Polipalli, S. Kapoor;*
Department of Pediatrics, Maulana Azad Medical College, University of Delhi, New Delhi, India.

Background &Aim: Down syndrome (DS) is caused by the presence of three copies of chromosome 21, in most cases due to the failure of chromosomal segregation during maternal meiosis, as there was scanty data available from India the study was designed to investigate the MTHFR C677T and A1298C polymorphisms, with homocysteine as a maternal risk factor for DS. **Materials and Methods:** Eighty mothers of individuals with confirmed full trisomy 21, and 100 control mothers of north Indian population were evaluated. Molecular analysis of MTHFR C677T and A1298C polymorphisms was performed by PCR-RFLP. **Results:** The frequency of genotypes of *MTHFR were* 677CC (82.5%), 677CT (15%) and 677TT (2.5%) in the patients with Down's syndrome, and among the 100 individuals of the control group, genotypes 677CC (91.0%), 677 CT (6.0%) and 677TT (3.0%) were found. As for polymorphism 1298C, the patients with Down's syndrome presented genotypes with frequencies 1298AA (15.0%), 1298AC (52.5%) and 1298CC (32.5%) respectively and in the control group the frequencies of genotypes were 1298AA (61.0%), 1298AC (22.0%) and 1298CC (17.0%) respectively. Homocysteine concentrations were significantly different in women with an *MTHFR* 1298CC genotype according to the groups, being higher in DS mothers than in control mothers. **Conclusion**: No correlation was observed in *MTHFR* gene polymorphism 677T in DS. However, the *MTHFR* gene polymorphism at position 1298, mainly genotype 1298CC that reduces the enzyme efficiency, was more frequent in the group of Down's Syndrome patients, suggesting its involvement in mechanisms related to chromosomal imbalances.

P02.096
Characterization of dysmorphic features in 1q21.1 microduplication syndrome: description of two patients and review of the literature

***S. Moortgat**[1], A. Destrée[2], B. Grisart[2], C. Verellen - Dumoulin[2], I. Maystadt[2];*
[1]Fonds de la Recherche Scientifique (FRS-FNRS), 6041, Belgium, [2]Centre de Génétique Humaine (IPG), 6041 Charleroi (Gosselies), Belgium.

Array-CGH screening in large patient cohorts with unexplained mental retardation, congenital anomalies or autism has recently lead to the characterisation of novel microdeletion/microduplication syndromes. The low-copy-repeats spanning the region 1q21.1 mediate nonallelic homologous recombinations that result in rearrangements of 1q21.1.

Recent data suggest that a recurrent 1,35 Mb microduplication on chromosome 1q21.1 predisposes to autism spectrum disorder, developmental delay and mental retardation. Other clinical features include macrocephaly, hypertelorism and a wide range of congenital anomalies. Variable expressivity, incomplete penetrance and non-specific phenotypic features associated with 1q21.1 microduplication complicate genetic diagnosis and counselling.

We report on two unrelated girls of two and three years old, presenting with developmental delay and similar facial dysmorphism such as hypertelorism, flat nasal bridge, short nose with anteverted nostrils, prominent philtrum and thin upper lip. Head circonferences were in normal ranges. At the age of three, one of them developed behavioral disorder with hallucinations and aggressivity.

Array-CGH detected an identical 2.5Mb microduplication on 1q21.1, encompassing the minimal critical region of 1.35Mb. Parental origin is undetermined (paternal DNA was not available for analysis).

These two additional patients confirm that identification of 1q21.1 microduplication by array-CGH should be considered as a predisposition factor for developmental delay and behavioral disorders. We refine the 1q21.1 microduplication syndrome by suggesting a distinctive common phenotype, comparing facial dysmorphic features of our patients with previously reported cases.

P02.097
Spondylocostal dysostosis associated with duodenal diaphragm: a case report.

M. Cutrupi, *R. Gallizzi, A. Talenti, A. Deak, I. Loddo, B. Piraino, C. Salpietro Damiano, S. Briuglia;*
UOC of Pediatric Genetic and Immunology,University of Messina, Messina, Italy.

We report a case of a 2-year-old boys, the only son of healthy non consanguineous parents. He presented skeletal abnormalities, short stature with short trunk in proportion to height, and dimorphisms (facial asymmetry, strabismus, micrognathia, low-set ears, two preauricular tags right, short neck). The radiological picture shows multiple abnormalities of the spine (hemivertebrae, absence of vertebrae, vertebral hypoplasia), fusion of ribs (5-6-7 right) and malformation (6th left). These skeletal abnormalities are diagnostic of the spondylocostal dysostosis, a rare condition of variable severity. The disease is inherited as an autosomal recessive or autosomal dominant and four genes known are associated with autosomal recessive spondylocostal dysostosis: DLL3, MESP2, LFNG and HES7. The condition is characterized by multiple segmentation defects of the vertebrae (fusion of vertebrae, hemivertebrae), presence of malalignment of the ribs with variable points of intercostal fusion, and a reduction in rib number. Deformity of the chest with reduction of size of the thorax, short neck, scoliosis, inguinal hernia are frequent complications of this condition. Spina bifida, meningocele, renal abnormalities, hypospadias, congenital heart disease, anomalous pulmonary venous return have been reported, but are not common. The our proband was affected by duodenal diaphragm, characterized by the presence of a mucosal diaphragmatic membrane with an intact muscle wall. He presented bilious vomiting ,feeding intolerance and failure to thrive in neonatal period. At one years old, he underwent surgical correction. We report the first case, in absence of other data from the international literature, of spondylocostal dysostosis associated with duodenal diaphragm.

P02.098
The arthrochalasis type of Ehlers-Danlos syndrome: phenotype at different ages

M. Klaassens[1], *E. Reinstein*[2], *Y. Hilhorst-Hofstee*[3], *F. Malfait*[4], *H. Staal*[1], *L. Speth*[5], *J. Schrander*[1], *D. Krakow*[2], *A. De Paepe*[4], *M. van Steensel*[1], *G. Pals*[6], *J. Graham*[2], *C. Schrander-Stumpel*[1];
[1]*Maastricht University Medical Center, Maastricht, Netherlands,* [2]*Cedars Sinaï Medical Center, Los Angeles, CA, United States,* [3]*Leiden University Medical Center, Leiden, Netherlands,* [4]*Ghent University, Ghent, Belgium,* [5]*Adelante Zorggroep, Valkenburg, Netherlands,* [6]*VU Medical Center, Amsterdam, Netherlands.*

Ehlers-Danlos syndrome (EDS) is a clinically and genetically heterogeneous group of inherited connective-tissue disorders characterized by hypermobility, tissue fragility and skin abnormalities. Six subtypes have been characterized based on clinical features and molecular genetic abnormalities. The arthrochalasis type EDS (former type VIIa and VIIb) is characterized by bilateral congenital dislocation of the hips, severe generalized joint hypermobility with dislocations, muscular hypotonia and distinct dysmorphic features. Early diagnosis of arthrochalasis type EDS is of importance because of consequences for mobility in later life. However, the differential diagnosis may be difficult because of overlap with other hypermobility syndromes. We describe seven patients at different ages. Timing of diagnosis varied from antenatally to adult age. Genetic counselling is possible at the adult age.

Diagnosis was confirmed in all patients by biochemical studies or mutation analysis showing characteristic mutations in COL1A1 and COL1A2, resulting in skipping of exon 6, leading to the production of abnormal procollagen and defective collagen synthesis.

For physicians treating patients with EDS type VII achieving mobility for the patient is the greatest challenge. The prognosis for achieving independent walking may be poor due to recurrent dislocations of nearly all joints in severe cases. We stress the importance of a diagnosis at various ages.

P02.099**
Musculo-contractural Ehlers-Danlos syndrome (EDS type VIB): a new EDS-subtype caused by a defect in proteoglycan biosynthesis

F. Malfait[1], *D. Syx*[1], *P. Vlummens*[1], *S. Nampoothiri*[2], *A. De Paepe*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Amrita Institute of Medical Sciences and Research Center, Cochin, Kerala, India.*

Musculo-contractural Ehlers-Danlos syndrome (MC-EDS) is a recently described autosomal recessive form of EDS characterized by craniofacial abnormalities, congenital joint contractures, especially of fingers and toes, talipes equinovarus, tapering fingers and excessive palmar wrinkling, severe progressive muscle hypotonia and multi-systemic tissue fragility with ophtalmological, gastro-intestinal and genito-urinary manifestations, in addition to skin fragility, wound healing problems, bleeding diathesis and joint hyperlaxity. The condition is caused by homozygous mutations in CHST14, encoding dermatan-4-sulfotransferase 1 (D4ST-1). The clinical phenotype of MC-EDS strongly overlaps with that of adducted thumb-clubfoot syndrome (ATCS), and with a Japanese EDS-variant, “EDS Kosho type”, two conditions that were independently shown to be caused by CHST14 mutations. Detailed phenotypic analysis of the 20 patients reported with CHST14 mutations strongly suggests that these conditions form a single entity with multi-systemic, but age-dependent and variable phenotypic features, of which joint contractures and generalized muscle weakness are distinguishing features, hence the name “musculo-contractural EDS”.

Hitherto reported CHST14 mutations comprise six missense, two frameshift and one nonsense mutation, some of which were shown to result in loss of function of D4ST-1. This is a key enzyme in the biosynthesis of dermatan sulfate (DS), catalyzing 4-O-sulfation of N-acetyl-galactosamine. Loss of D4ST-1 activity results in the replacement of DS by chondroitin sulfate. The broad array of physiological events in which DS plays a role, including the correct assembly of collagen fibrils mediated by decorin, a DS proteoglycan, explains the multisystemic manifestations of this condition.

Hospital Universitario Virgen de la Arrixaca., Murcia, Spain,* [3]*Center for Medical Genetics. Ghent University Hospital. UZ Gent., Gent, Belgium.*

Introduction: Ehlers-Danlos syndrome (EDS) is a connective tissue disorder characterized by skin hyperextensibility, abnormal wound healing and joint hypermobility. Clinical and genetic heterogeneity is described. Classification of patients in the several subtypes is sometimes difficult. We report on a patient with Osteogenesis Imperfecta / Ehlers-Danlos phenotype (OI/ED) and COL1A1 gene mutation.

Clinical Report: The patient, a 6 years old boy, was referred at 17 months of age with clinical diagnosis of Osteogenesis imperfecta. Motor retardation, fractures, osteopenia, blue sclerae, macrocephaly, short stature and dysmorphic features. Physical examination revealed fine hyperextensible skin, abnormal healing, easy bruising, hyperextensible joints, lumbar kyphoscoliosis, pectus excavatum, long fingers and toes and inguinal herniae. Clinically suggestive of Ehlers Danlos syndrome. We started treatment with byphosphonates due to bone fragility. Biochemical collagen analysis in cultured fibroblasts was performed with identification of an extra band migrating above the type I collagen chain. Molecular analysis of COL1A1 gene revealed a de novo heterozygous mutation in exon 8 c.607G>T (p.Gly203Cys, Gly25Cys). These results support clinical diagnosis of combined OI / ED phenotype.

Discussion: A new mutation associated to OI / ED phenotype is described. This report extends the range of phenotypes caused by COL1A1 gene mutations. Consider treatment with byphosphonates in patient with Ehlers Danlos syndrome and bone fragility.

P02.101
Intragenic EHMT1 mutations in French patients with Kleefstra Syndrome

S. DRUNAT[1], *Y. Alembik*[2], *C. Baumann*[1], *M. Gérard*[1], *C. Mircher*[3], *M. Rio*[4], *S. Whalen*[5], *A. Verloes*[1];
[1]*Robert Debré University Hospital, AP-HP, Paris, France,* [2]*CHU Strasbourg, Hôpital de Hautepierre, Strasbourg, France,* [3]*Institut Jérôme Lejeune, Paris, France,* [4]*Necker University Hospital, AP-HP, Paris, France,* [5]*La Pitié-Salpêtrière University Hospital, AP-HP, Paris, France.*

The Kleefstra syndrome is one of the first and most common clinically recognisable telomeric syndrome characterized by intellectual disability, chidhood hypotonia and distinctive facial features. In addition, heart and urogenital defects, epilepsy and behavioural problems are also observed. The syndrome is either caused by a 9q34.3 submicroscopic deletion (75 %) or by intragenic euchromatin histone methyl transferase 1 (EHMT1) mutations leading to haploinsufficiency of the gene.

We evaluated 42 patients referred by clinical geneticists presenting with the core phenotype of the syndrome but no deletion identified by routine subtelomere or whole genome chromosome testing. The molecular analyses included a screen for small intragenic EHMT1 deletions by MLPA and direct sequencing of the 27 exons for point mutations identification.

In total, 9 intragenic mutations or deletions were found that are highly likely pathogenic. 4 small deletions were identified by MLPA. 5 mutations predicted to result in nonsense mediated mRNA decay were found by sequencing: 1 previously described nonsense change (p.Arg620X) and 4 novel frameshift mutations (p.Glu342fs, p.Glu187fs, p.Val1026fs, c.2018_2018 +3 del 4). De novo occurrence was confirmed when DNA from both parents were available. As previously described, mutations were spread all over the gene.

Frequently associated features reported in the Kleefstra syndrome such as obesity, congenital heart defect or epilepsy do not seem to be as frequent in our patients suggesting that genes, apart from EHMT1, included in larger deletions may be implicated in the phenotype.

P02.102
Copy number variations in patients with electrical status epilepticus in sleep

S. H. G. Kevelam[1], *F. E. Jansen*[2], *E. van Binsbergen*[1], *K. Braun*[2], *N. Verbeek*[1], *D. Lindhout*[1], *M. Poot*[1], *E. H. Brilstra*[1];
[1]*Department of Medical Genetics, University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*Department of Child Neurology, Rudolf Magnus Institute of Neuroscience, University Medical Centre Utrecht, Utrecht, Netherlands.*

Background: Electrical Status Epilepticus in Sleep (ESES) refers to an electroencephalographic pattern of continuous, subclinical sleep induced spikes-and-waves. ESES related epilepsy syndromes share an association of infrequent seizures, deficits in language or global cognitive functioning and behavioural problems. The aetiology is often unknown, but genetic risk factors have been implicated.

Aim of the study: To detect copy number variations (CNVs) in patients with ESES syndrome in order to identify possible underlying genetic risk factors.

Methods: We included a consecutive series of patients with ESES between January 2000 en August 2009, at the Paediatric Neurology outpatient Clinic of the University Medical Centre Utrecht. CNVs were identified by array comparative genomic hybridization. To gain more insight into the pathogenic contribution of the identified CNVs, we reviewed the literature, searched in databases for similar CNVs in patients and studied the function of the genes located within the CNVs. We compared the clinical characteristics of patients with CNVs and patients without CNVs

Results: We detected seven CNVs in four of the thirteen patients with ESES, which consisted of six novel gains and one loss, the recurrent 15q13.3 microdeletion. The copy number variant genes in two of these patients belonged to the cholinergic pathway. There were no differences in clinical characteristics between patients with CNVs and patients without CNVs.

Conclusion: Our data on CNVs in patients with ESES indicate that specific chromosomal loci and genes may be involved in the aetiology of ESES. In particular, our findings point towards putative alterations in the cholinergic pathway.

P02.103
Mutations in ENPP1 associated with a new phenotype including hypophosphatemic rickets, skin abnormalities and hearing loss

G. Baujat[1], *S. Hadj-Rabia*[2], *M. Le Merrer*[1], *B. Bader-Meunier*[3], *N. Chassaing*[4], *V. Couloigner*[5], *C. Gay*[6], *G. Guest*[7], *K. Lambot*[8], *A. Linglart*[9], *L. Martin*[10], *Y. Nitschke*[11], *F. Rutsch*[11];

Generalized arterial calcification of infancy (GACI) is an autosomal recessive disorder due to mutations in ENPP1 in most cases, and characterized by diffuse vascular and periarticular calcifications, frequently leading to death in early infancy. A few patients present with a milder phenotype and hypophosphatemic rickets. Pseudoxanthoma elasticum (PXE) is another autosomal recessive multisystem disorder characterized by ectopic mineralization and fragmentation of elastic fibers of connective tissue including skin, arteries, and the eye. Classic PXE results from mutations in the ABCC6 gene.

We report on two unrelated children with an unusual phenotypic overlap of GACI and PXE. They both presented with neonatal articular and vascular calcifications, with favourable evolution. Later in infancy, both patients developed abnormal mineralization in a number of organs, including ear ossicles, kidney, and eyes, associated with hypophosphatemic rickets. Angiomatous cutaneous lesions were noted in both patients. The older patient presented also with PXE skin lesions, confirmed by histology. In both patients presence of ENPP1 mutations, and absence of ABCC6 mutations was demonstrated.

This particular phenotype, overlapping between PXE and GACI appears to be associated with a better prognosis than the classical GACI with respect to vascular calcifications.

Since ABCC6 was recently discussed as the causative gene in a case of GACI without mutations in ENPP1, we demonstrate here that, conversely, ENPP1 may be involved in some cases of PXE in the absence of ABCC6 mutations. We conclude that ENPP1 and ABCC6 are probably involved in the same molecular pathway.

P02.104
Familial study of R217C mutation in Exon 7 of CHRNG gene in a case of multiple Pterygia Syndrome

A. Zuñiga, ***G. Pi****, Y. Bello, A. Guerrero;*
Hospital de la Ribera, Alzira (Valencia), Spain.

BACKGROUND: Escobar or multiple pterygia syndrome (OMIM 265000), a form of arthrogryposis multiplex congenital, is an autosomal recessive condition characterized by excessive webbing (pterygia), congenital contractures (arthrogryposis), and scoliosis. Congenital contractures are common and may be caused by reduced fetal movements due to myasthenia gravis. Hereditary causes of congenital myasthenic syndrome have also been identified, mostly mutations in subunits of nicotinergic acetylcholine receptor (AChR). The AChR is composed of five subunits; two alpha, one beta and one delta subunit are invariably present. The gamma subunit (CHRNG gene) is present before the 33rd wk of gestation in humans but is replaced by a subunit in the late fetal and perinatal period, thereby forming the adult AChR.

MATERIALS AND METHODS: Proband case was a four year old male. On clinical examination, the patient had all the characteristic features of multiple pterygium syndrome. He was of short stature, with flexion deformities of the wrists and hands and webbing across all flexion creases. Bilateral foot deformities were present with a right-sided rockerbottom foot deformity and a residual club foot on the left.

RESULTS AND CONCLUSIONS: Genetic study of CHRNG gene was performed, patient was carrier of R217C mutation in exon 7 (c.715C>T) in homozygosis. Study of other members of family detected 35 heterozygotic carriers and till three different familial pedigrees affected. CHRNG gene mutations have been identified in families with Escobar syndrome and showed that the trait is a congenital dysmorphology caused by the transient inactivation of the neuromuscular end plate.

P02.105
Submicroscopic 7q36.1-36.3 deletion causes multiple congenital eye anormalies, associated with short stature in a boy with normal development

A. Beleza-Meireles[1,2], *E. Matoso*[3], *R. Oliveira*[1], *C. F. Reis*[1], *J. B. Melo*[3], *E. D. Silva*[4], *I. M. Carreira*[3], *L. Ramos*[1];

[1]*Serviço de Genética - Hospital Pediátrico de Coimbra, Coimbra, Portugal,* [2]*School of Health Sciences, Aveiro University, Aveiro, Portugal,* [3]*Cytogenetics Laboratory, Institute of Medical Biology, Medical Faculty, Coimbra University, Coimbra, Portugal,* [4]*Department of Ophthalmology, Coimbra University Hospita, Coimbra, Portugal.*

The eye is a very complex structure that originates from constituents derived from a number of sources, such as the neuro- and surface ectoderm and the periocular mesenchyme, which receives contributions from both the neural crest and mesoderm lineages. Proper eye development requires many interacting proteins, such as PAX6 and SHH, which orchestrate a series of sequential inductions. Due to the complexity of eye development, it is not surprising that congenital eye abnormalities occur, particularly in multiple malformation syndromes.

We report the case of patient LG, a 14 year old boy, referred to the Medical Genetics clinic due to multiple congenital eye abnormalities (unilateral microphthalmia, bilateral microcornea, severe myopia, nystagmus, dysplasia of the optic disc with coloboma-like areas, vitreo-retinal degeneration), proportionate short stature, absence of the two maxillary central incisors and congenital unilateral vertical astragalus. Brain MRI scan, heart, abdominal and reno-pelvic ultrasound were normal, evidencing the absence of additional malformations. Furthermore, he has a normal psychomotor development.

The cytogenetic investigation detected a de novo submicroscopic deletion in terminal region of the long arm of chromosome 7 [46,XY,del(7)(q36.1-q36.3). ish 7qsubtel(VY JyRM2000X2). arr 7q36.2q36.3 (153206357-156133135)X1 dn). This region encompasses 10 genes reported in the OMIM morbid map, including SHH and MYP4, both implicated in eye development and function.

This report indicates a contiguous gene disorder, causing multiple congenital anomalies, particularly affecting the eye development, in the absence of developmental delay.

P02.106
A novel mutation in the APC gene in a patient with attenuated colonic polyposis and severe extra-colonic phenotype

S. Miccoli[1], *L. B. Amato*[1], *E. Polmpilii*[1], *L. Varesco*[2], *P. Baccarini*[3], *G. Tallini*[3], *D. Turchetti*[1];

[1]*U.O. Genetica Medica, Policlinico Sant'Orsola-Malpighi, Bologna, Italy,* [2]*S.S. Centro Tumori Ereditari, Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy,* [3]*Servizio di Anatomia, Istologia e Citologia Patologica, Ospedale Bellaria, Bologna, Italy.*

We describe a woman with no relevant clinical history until age 70, when she underwent right hemicolectomy for multiple colonic polyps. Pathology examination revealed 40 adenomas, one of which, showing cancer foci, tested negative for microsatellite instability. At age 76 the patient developed an ampullar adenoma and at age 77 she underwent surgery for lung adenocarcinoma (she is non-smoker with no other lung cancer risk factors). Family history was negative for polyposis but her father and brother died at a young age for stroke, while her niece died at age 40 for medulloblastoma. Search for germline mutations in polyposis genes detected the heterozygous mutation c.6156delG (p.L2052fs) in APC, whereas MYH was wild-type. The c.6156delG mutation was found in both duodenal adenoma and lung adenocarcinoma at the heterozygous state, excluding the loss of the wild-type allele in tumor tissue.

To our knowledge, the c.6156delG mutation has not been reported before. Its location at the 3' terminus of the gene may explain the attenuated colonic phenotype in this patient, consistently with the reported genotype-phenotype correlations, but such extracolonic manifestations were unexpected. However, although molecular analysis on tumor tissue failed to find LOH, several factors suggest that the APC mutation may be the cause of the neoplasms arisen in the family: i) 50% of patients with classic FAP develop ampullar adenomas; ii) adenocarcinoma of the lung has been reported in three patients with FAP; iii) APC mutations can cause Turcot syndrome, featured by the association of colonic polyposis with the rare adult-onset medulloblastoma.

P02.107
Floating-Harbor Syndrome: report on a case in a mother and daughter, further evidence of autosomal dominant inheritance

S. Arpin[1,2,3], *A. Afenjar*[2], *B. Dubern*[4], *A. Toutain*[1,3], *S. Cabrol*[5], *D. Héron*[2];

[1]*Service de Génétique,centre de référence «anomalies du développement et syndromes malformatifs» , Hôpital Bretonneau, Tours, France,* [2]*Département de Génétique et Cytogénétique et Centre de référence «déficiences intellectuelles de causes rares », Groupe Hospitalier Pitié-Salpêtrière, Paris, France,* [3]*Université François Rabelais, Tours, France,* [4]*Service de Gastro Entérologie et Nutrition Pédiatriques, Hôpital d'Enfants Armand Trousseau, Paris, France,* [5]*Explorations Fonctionnelles Endocriniennes, Hôpital d'Enfants Armand Trousseau, Paris, France.*

Floating-Harbor Syndrome (FHS) is a rare disorder characterized by the triad of proportionate short stature with delayed bone age, characteristic facial appearance and delayed speech development. The genetic basis of the syndrome is still unclear, most cases being sporadic. In the rare familial cases, three reports with either mother-daughter or mother-son transmission, fulfilling the diagnosis criteria of FHS, suggest an autosomal dominant inheritance pattern. This mode of transmission is also suggested by advanced paternal age in almost all sporadic cases. On the other hand, autosomal recessive inheritance has also been suggested in three pedigrees where the phenotype is less convincing. In two other reports, autosomal recessive inheritance seemed possible because of consanguinity although germinal mosaicism for an autosomal dominant gene mutation could not be excluded. We report on the fourth case in a mother and daughter, review the familial cases of the literature and suggest autosomal dominant inheritance for this syndrome.

P02.108
Search for a gene responsible for Floating-Harbor syndrome

E. Lopez[1], *P. Callier*[1,2], *V. Cormier-Daire*[3], *D. Lacombe*[4], *A. Moncla*[5], *A. Bottani*[6], *S. Lambert*[7], *L. Gueneau*[1], *L. Duplomb-Jego*[1], *A. Goldenberg*[8], *B. Doray*[9], *B. Aral*[7], *C. Thauvin-Robinet*[10], *L. Faivre*[1,10];

[1]*Université de Bourgogne, Dijon, France,* [2]*Cytogénétique, Dijon, France,* [3]*Génétique Médicale, Hôpital Necker Enfants Malades, Paris, France,* [4]*Génétique Médicale, CHU, Bordeaux, France,* [5]*Génétique Médicale, CHU, Marseille, France,* [6]*Génétique Médicale, Genève, Switzerland,* [7]*Biologie Moléculaire, CHU, Dijon, France,* [8]*Génétique Médicale, CHU, Rouen, France,* [9]*Génétique Médicale, CHU, Strasbourg, France,* [10]*Centre de Génétique, CHU, Dijon, France.*

Floating-Harbor syndrome (FHS) is characterised by characteristic facial dysmorphism, short stature with delayed bone age and expressive language delay. To date, the gene(s) responsible for FHS are unknown and the diagnosis is only made on the basis of the clinical phenotype. The majority of cases appeared to be sporadic but rare cases following autosomal dominant inheritance have been reported. We identified a 4.7 Mb *de novo* 12q14.3-q21.1 microdeletion in a patient with FHS and mental retardation. Pangenomic 244K array-CGH performed a series of twelve patients with FHS failed in identifying overlapping deletions. We hypothesized that FHS is caused by haploinsufficiency of one of the 19 genes or predictions comprised in the deletion found in our index patient. Since none of them appears as good candidate genes by their function, high-throughput sequencing approach of the region of interest was used in eight FHS patients. This method is based on the production of thousands or millions of sequences at once during the sequencing process. The analysis only revealed a nonsense variant in the exon 2 on the *TMEM19* gene in one patient, but segregation analysis showed that the mutation was inherited from his unaffected mother. This approach failed in identifying the gene responsible for FHS, and it can be explained by 3 reasons: i) our index patient could be a phenocopy of FHS; ii) the disease can be clinically heterogeneous since the diagnosis only relies on clinical features, iii) high genetic heterogeneity of the disease.

P02.109
A family with frontometaphyseal dysplasia in three generations

C. Yapijakis[1,2], *A. Vylliotis*[1], *E. Vairaktaris*[1];

[1]*University of Athens Medical School, Athens, Greece,* [2]*Cephalogenetics Center, Athens, Greece.*

Frontometaphyseal dysplasia (FMD, OMIM 305620) is a rare X-linked craniofacial genetic syndrome first described by Gorlin and Cohen in 1969. It is characterized by supraorbital hyperostosis, hypertelorism,

conductive hearing loss, downslanting palpebral fissures, anodontia or oligodontia, as well as generalized skeletal dysplasia which manifests with thickening of the calvarium, agenesis of the frontal, ethmoidal and sphenoidal sinuses together with bowing and undermodeling of the diaphyses and metaphyses of the tubular bones. FMD is caused by mutations in the FLNA gene which encodes the cytoskeletal protein filamin A that binds actin fibrils and participates in the modulation of the cytoskeleton. We describe here a Greek family with five FMD cases in three generations. Three brothers had typical severe manifestations of the syndrome, while their mother and maternal grandmother had less prominent signs. Genomic DNA was extracted from all patients, as well as from the normal father of the three male patients. All 48 exons of the FLNA gene including exon-intron boundaries were sequenced in one male proband and a single mutation (D253E) was revealed. The same mutation was found in all affected members of the family, both in hemizygous males and in heterozygous females.

P02.110
High prevalence of ectopic calcification in the Azores - Gitelman Syndrome as the cause for secondary Chondrocalcinosis

S. Sieuve de Menezes[1,2], *A. R. Couto*[1,2], *M. Soares*[1,2], *M. R. Santos*[1,2], *J. P. Pinheiro*[1,2], *S. Brum*[3], *J. Bruges-Armas*[1,2];
[1]*Hospital de Santo Espirito, SEEBMO, Angra do Heroísmo, Portugal,* [2]*Institute for Molecular and Cell Biology (IBMC), University of Porto, Porto, Portugal,* [3]*Hospital de Santo Espirito, Serviço de Nefrologia, Angra do Heroísmo, Portugal.*

Gitelman syndrome (GS) is an autosomal recessive inherited renal disorder, characterized by defective tubular reabsorption of sodium, potassium and magnesium, due to loss of function mutations of the *SLC12A3* gene. This syndrome leads to hypomagnesemia, hypokalaemia, mild hypotension, mild metabolic alkalosis and hyperreninemic hyperaldosteronism. It is thought that hypomagnesemia is the reason for the recurrent association of GS with Chondrocalcinosis (CC).

A 59 years-old Azorean patient with CC, hypomagnesemia and hypokalemia, was identified in the Rheumatic Diseases Clinic, Hospital de Santo Espírito, Azores, Portugal. The clinical diagnosis of GS was performed and, after informed consent, genomic DNA was extracted from peripheral blood cells. *SLC12A3* direct sequencing revealed three variants: a missense substitution in heterozygous state (c.296A-G, His99Arg), a synonymous heterozygous substitution (c.366A-G, Ala122Ala) and a homozygous missense substitution in exon 15 (Ser615Leu). Mutation in exon 15 has been previously described as a genetic cause for GS.

In geographic regions, such as the Terceira Island (Azores, Portugal), in which CC and enthesopathies are considered to be extremely prevalent, it is crucial to determine its genetic causes and to establish the differential diagnosis. The genetic cause for the secondary CC in this GS patient was identified. Further studies in family members of this patient will be needed in order to evaluate the segregation of hypomagnesemia and CC.

P02.111
Deletions of the GLI3 gene can be the frequent cause of Greig cephalopolysyndactyly and preaxial polydactyly type IV

A. Jamsheer[1,2], *A. Sowinska*[1,2], *A. Geppert*[3], *A. Latos-Bielenska*[1,2];
[1]*Center for Medical Genetics GENESIS, Poznan, Poland,* [2]*Department of Medical Genetics, University of Medical Sciences, Poznan, Poland,* [3]*Department of Neurology, University of Medical Sciences, Poznan, Poland.*

Greig cephalopolysyndactyly syndrome (GCPS) and isolated preaxial polydactyly type IV (PPIV) are rare autosomal dominant disorders, both caused by mutations in the GLI3 gene. GCPS is predominantly characterised by craniofacial anomalies (macrocephaly, high forehead with frontal bossing, hypertelorism), and limb malformations such as preaxial polydactyly type IV, syndactyly, and postaxial polydactyly type A or B. Other congenital abnormalities are less frequent. The syndrome exhibits high inter-individual and intra-familial clinical variability. Mutations in the GLI3 transcription factor gene can also cause Pallister-Hall syndrome, and isolated postaxial polydactyly type A and B. In this study we screened 11 probands (8 familial and 3 sporadic) with the clinical diagnosis of GCPS/PPIV by gene sequencing and found 8 novel and 1 previously reported heterozygous point mutations. Subsequently we performed MLPA (P179 MRC Holland Kit) to screen for intragenic copy number changes and demonstrated heterozygous deletions in the 2 remaining cases (18%). Although based on a small sample, our study shows that intragenic GLI3 deletions may account for a considerable proportion of GCPS/PPIV causative mutations. Therefore, we propose that MLPA or qPCR should be included into routine molecular diagnostic of the GLI3 gene, especially if the sequence analysis detects no pathogenic mutation.

P02.112
Goldenhar Syndome - report of three cases

M. Puiu, *S. Dumitriu, A. Chirita Emandi;*
University of Medicine &Pharmacy "V. Babes", Timisoara, Romania.

Goldenhar Syndrome (oculo-auriculo-vertebral dysplasia), is a rare congenital complex of abnormalities with various models of expressivity.

Matherial and methods: We present three male infants with Goldenhar syndrome from Romania. Results: All cases were diagnosed in their newborn period. There was no family history of facial syndromes or ocular condition. The children have normal anthropometric parameters (head circumference, birth length and weight) and abnormalities characteristic for the syndrome (consistent features of epibulbar dermiods, pre-auricular tags, and vertebral anomalies). Investigation and complex interdisciplinary consultations highlight the similar and different abnormalities present in the three cases. The severity of the syndrome is different for each case and consequently the management, evolution and prognosis will be different. Conclusions: Due to the fact that manifestations of Goldenhar syndrome can be similar to other diseases, to confirm the syndrome, genetic testing is a valuable tool to establish the diagnosis and allow appropriate genetic counseling.

P02.113**
Looking at Gorlin syndrome from the perspective of the cilia of hedgehog

S. C. E. H. Sallevelt[1], *E. B. Gómez García*[1,2];
[1]*Maastricht University Medical Center+, Maastricht, Netherlands,* [2]*Maastricht University, Maastricht, Netherlands.*

Gorlin syndrome (GS), also known as basal cell nevus syndrome, is an autosomal dominant disorder characterized by multi-organ developmental abnormalities, and neoplasms. In up to 85% of cases of GS, a mutation can be identified in the patched homolog 1 gene (*PTCH1*). *PTCH1* gene is a member of Sonic Hedgehog (SHH), an important signaling pathway of the cilia. PTCH1 is the SHH receptor and represses the SHH signaling through inhibition of Smoothend (Smo). Mutations in *PTCH1* render it unable to repress Smo which enters the primary cilia resulting in permanent activation of SHH signaling. So far, attempts to make genotype-phenotype associations in GS have not been successful. However, no one has looked at GS from the pathogenic perspective of a cilia abnormality. We provide evidence supported by research reports that the apparently unrelated phenotypic features of GS have a ciliary dysfunction as their common underlying mechanism. Support for this hypothesis includes firstly clinical overlap (cysts, hydrocephalus, medulloblastoma, skeletal abnormalities) between GS and other ciliopathies. Secondly, the important role of cilia in the development of the involved structures in GS (i.e. brain, skin, skeleton) and their malignant counterparts (basalioma, medulloblastoma). Furthermore, mutations in *SUFU*, a ciliary protein and a negative SHH regulator, have been found in sporadic medulloblastoma, as well as in germline in a family with GS. Also *SUFU* +/- mice have features of GS. The perspective of GS being a ciliopathy can be clinically relevant for treatment with drugs targeted to downstream components of the primary cilia.

P02.114
Problems of differentiation between Huntington and Hallervorden-Spatz disease

N. Galeeva, *E. Dadali, A. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Huntington disease (HD) is an autosomal dominant progressive neurodegenerative disorder with a distinct phenotype characterized by chorea, dystonia, incoordination, cognitive decline, and behavioral difficulties. In the classic form age of onset is between 30 and 40 years. Hallervorden-Spatz disease is an autosomal recessive disorder characterized by extrapyramidal movements, such as parkinsonism

and dystonia. In the classic form patients present within the first decade of life with rapidly progressing disease and loss of ambulation approximately 15 years later. In classic forms differentiation of this disorders is not difficult for physicians. But there is juvenile-onset Huntington disease (10% of all HD cases), typically defined as onset before age 20 years and the atypical form of Hallervorden-Spatz disease, when patients have onset in the second decade with slow progression and maintain independent ambulation after 15 years. In our practice there were two cases wrong diagnosis "Hallervorden-Spatz disease" when patient suffered from Huntington disease. Therefore we decided to draw attention of physicians for this problem. These disorders have overall symptoms such as dystonia, choreatic athetosis, dementia, ataxia, rigidity dysarthria, bradykinesia and only patient suffered from Hallervorden-Spatz disease have deformation of foot, primary pigmentary degeneration of retina, blepharospasm, tremor, spasticity, diphthongia. The main feature of Hallervorden-Spatz disease is the 'eye of the tiger' sign on brain MRI. The main confirmation of Huntington disease is expansion of repeat number more than 37 in IT15 gene. The main confirmation of Hallervorden-Spatz disease is presence mutations in the PANK2 gene.

P02.115
Hartsfield syndrome and Xq24 microduplication

R. Kosaki[1], *H. Okuno*[2], *C. Torii*[2], *K. Kosaki*[2];
[1]*Division of Medical Genetics, National Center for Child Health and Development Hospital, Tokyo, Japan,* [2]*Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan.*

The combination of holoprosencephaly and ectrodactyly was first described by Hartsfield et al in 1984. Fifteen cases have been reported to date and the condition is likely to represent a single genetic entity (Hartsfield syndrome). The genetic defect is yet to be unraveled. Based on the observation that male patients have preferentially been affected, X-linked recessive mode of transmission has been suggested for this condition. Yet, no candidate genes have been suggested on the X chromosome. We report a patient with a full-brown Hartsfield syndrome phenotype who had a microduplication at Xq24 that involved at least 5 genes: A Japanese boy had bilateral ectrodactyly of the hands, midline cleft lip with aplasia of premaxillary segment, cleft palate, a low nasal bridge and micropenis with undescended testes. A CT scan of the brain revealed lobar-type holoproencephary. Cleft lip and palate was repaired a age 2 years and ectrodactyly was repaired at age 3. He had multiple episodes of hyper natremia with serum sodium level as high as 194 mEq/l. His development was mildly delayed. His G-banded karyotype was normal. Array comparative genomic hybridization using the Whole Human Genome CGH array (Agilent) revealed a duplication of 0.3 Mb, on Xq24. The duplication has never been recognzied as benign copy number variation in various CNV databases. The duplication was derived from the unaffected mother who had random X-inactivation pattern. The fact that the X-inactivation pattern was not incompatible with the notion that the duplication could be pathogenic.

P02.116
A HPE-like phenotype and heterotaxy associated with a 1,3 Mb deletion encompassing the *GLI2* gene at 2q14.2

S. H. G. Kevelam[1], ***J. J. T. van Harssel***[1], *B. van der Zwaag*[1], *H. J. Smeets*[2], *A. D. C. Paulussen*[2], *K. D. Lichtenbelt*[1];
[1]*Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands.*

Loss-of-function mutations of *GLI2* are associated with holoprosencephaly (HPE)-features, including abnormal pituitary gland formation and/or function, craniofacial abnormalities, branchial arch anomalies and polydactyly. We report a patient carrying a 1,3 Mb submicroscopic deletion in 2q14.2, encompassing the *GLI2* gene. She presented with a HPE-like phenotype (bilateral cleft lip and palate and abnormal pituitary gland formation with panhypopituitarism),heterotaxy and normal psychomotor development. Submicroscopic deletions encompassing *GLI2* have not been reported so far. Large microscopically visible interstitial deletions spanning 2q14.2 are rare and have been reported sporadically in patients with multiple congenital anomalies and mental retardation. The clinical and molecular findings in our proband and her family are presented. Additionally, we review the features of previously reported index patients with a *GLI2* aberration (17 mutations and 7 large deletions spanning 2q14.2). With the report of this *GLI2* deletion we confirm that haploinsufficiency of *GLI2* is associated with HPE-like features. Comparable to what has been described in families with *GLI2* mutations, we observed an incomplete penetrance of the deletion in our family, illustrating the multifactorial etiology of HPE and HPE-like features. The deletion contains five other genes, including the *Epb4.1l5* gene. Based on observations in *Epb4.1l5* mutant mice embryo's, we argue that haploinsufficiency of *Epb4.1l5* might be the cause of the heterotaxy in our proband. A pathogenic effect of the *GLI2* deletion cannot be excluded. Finally, we conclude that, while other HPE-genes have been excluded, *GLI2* is still a candidate gene for the Holoprosencephaly-polydactyly syndrome, also known as Pseudotrisomy 13.

P02.117
Alobar holoprosencephaly in two sibs: deletion of chromosome 17

L. A. Ribeiro-Bicudo[1], *R. M. Zechi-Ceide*[1], *M. Guion-Almeida*[1], *A. Richieri-Costa*[1], *T. Rodrigues*[2], *A. C. V. Krepischi*[2], *C. Rosenberg*[2];
[1]*Hospital de Reabilitacao de Anomalias Craniofaciais, Bauru, Brazil,* [2]*Instituto de Biociencias, Universidade de São Paulo, São Paulo, Brazil.*

Most of the reported cases on HPE are sporadic, representing nonrandom chromosomal aberrations and environmental agents, however, familial cases are described in some mendelian genetic syndromes. HPE recurring in sibs has been also reported as part of the clinical spectrum of some well recognized autosomal or x-linked recessive syndromes such as the pseudotrissomy 13 syndrome, Genoa syndrome, Lambotte syndrome, Smith-Lemli-Opitz syndrome, among other less frequent. Mutation in genes such as SHH, GLI2, PTCH, TGIF, and SIX3 have been recently reported in patients with different types of HPE, in parents with minor anomalies, and in normal carrier parents with an autosomal dominant patter of inheritance. In the present report we describe two affected brothers with alobar HPE and one of them represent a case of recurrence in sibs with normal parents. Mutation screening for the genes SHH, GLI2, PTCH, TGIF, and SIX3 was carried out. No evidence of mutation was found. Then, aCGH analysis was carried out and a chromosome 17 deletion affecting the p12 band between 14052279 and 15102307 bp was found. The deficiency of this fragment has been associated to the hereditary neuropathy with liability to pressure palsies (HNPP). It is possible that the phenotype is associated to this chromosomal alteration. Genetics and clinical aspects involving the present family and recurrence risks involved are discussed.

P02.118
Duplication of TBX5 and TBX3 associated with Holt-Oram-Syndrome plus supernumerary mammary glands

M. Hempel[1,2], *N. Rivera-Brugués*[2], *C. Daumer-Haas*[3], *K. Hörtnagel*[3], *T. Meitinger*[1,2], *T. M. Strom*[1,2];
[1]*Institute of Human Genetics, Technische Universität München, Munich, Germany,* [2]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [3]*Pränatal-Medizin München, Munich, Germany.*

Loss of function mutations in TBX5 are associated with Holt-Oram-Syndrome (HOS), an autosomal dominant disease characterized by radial limb defects and heart defects. Loss of function mutations in TBX3 result in Ulna-Mammary-Syndrome (UMS), an autosomal dominant disorder associated with ulnar limb defects, hypoplasia of breasts, and dental abnormalities. Here we report on a German family in which a duplication of the two adjacent genes TBX5 and TBX3 was identified. Affected members in five generations suffered from mild hand anomalies, heart defects, and supernumerary mammary glands. The phenotype except accessory mammary glands resembled HOS. Sequencing of all TBX5 exons was performed with inconspicuous results. Using a SNP oligonucleotide array, duplication at 12p24.21 was detected extending 210 kb and encompassing exclusively the TBX5 and TBX3 genes. To our knowledge duplication of both TBX5 and TBX3 genes have never been described before. Previously published studies have shown that TBX5 gain of function mutations are associated with HOS with mild skeletal involvement. Based on this knowledge the mild hand malformations in the family described here are likely caused by duplication of the TBX5 gene. Taking into account that TBX3 loss of function mutations result in hyploplastic breasts development, supernumerary mammary glands observed

in our cases are likely caused by duplication of the TBX3 gene. We assume that duplication of TBX5 is associated with a HOS with milder skeletal involvement and duplication of TBX3 apparently leads to supernumerary mammary glands.

P02.119
Biallelic absence of TRMP1 may explain the retinopathy in patients with homozygous 15q13.3 microdeletions

A. Masurel-Paulet[1], *I. Drumare*[2], *M. Holder*[3], *J. Cuisset*[4], *L. Vallée*[4], *S. Defoort*[2], *B. Bourgois*[5], *P. Pernes*[6], *J. Cuvellier*[4], *J. Thevenon*[1], *C. Thauvin*[1], *L. Faivre*[1], *J. Andrieux*[7];

[1]*Centre de génétique et Centre de Référence Anomalies du développement et Syndrômes malformatifs, CHU, Dijon, France,* [2]*Service d' Ophtalmologie, CHRU, Lille, France,* [3]*Service de génétique clinique, Hôpital Jeanne de Flandre, CHRU, Lille, France,* [4]*Service de Neuropédiatrie, CHRU, Lille, France,* [5]*Service de Pédiatrie, CH, Roubaix, France,* [6]*Centre de soins Saint Exupery, Vendin le Vieil, France,* [7]*Laboratoire de génetique médicale, Hôpital Jeanne de Flandre, CHRU, Lille, France.*

The 15q13.3 heterozygous microdeletion is a new frequent recurrent microdeletion with high clinical variability and incomplete penetrance, with an average size of 1.5 Mb. Rare patients have been described in the literature with a homozygous microdeletion inherited from both parents. We describe 3 patients from a French cohort, aged 8 months to 6 years, including one sibship, with a 1.5 Mb homozygous microdeletion. The parents had mental retardation in one family only. They all had congenital blindness with a peculiar rod-cone dystrophy confirmed by electroretinography. The two oldest patients had convulsivant encephalopathy, major hypotonia, and one of them had choreoathetosis movements. Contrary to the heterozygous microdeletion, the homozygous 15q13.3 microdeletion displays an identifiable clinical phenotype. The neurological symptoms might be explained by homozygous deletion of CHRNA7. Taking into account another patient from the literature with a homozygous deletion not including TRPM1 in one allele and absent eye manifestations, we conclude that homozygous deletions of TRPM1 might be responsible of the retinopathy. This data is supported by the finding that homozygous mutations lead to congenital stationary night blindness. In conclusion, the association of retinopathy and convulsive encephalopathy should lead to the search of a 15q13.3 homozygous microdeletion.

P02.120
Interstitial duplication of HUWE1 supports the role of this gene in X-linked mental retardation.

V. M. Siu;

University of Western Ontario, London, ON, Canada.

Ubiqitin ligases have been implicated in various neurogenetic disorders, most notably Angelman Syndrome (UBE3A). The HUWE1 ubiquitin E ligase gene is an X-linked gene involved in the ubiquitination of proteins in the nervous system. It functions upstream of the N-Myc-DLL3-Notch pathway and plays a crucial role in regulating the balance between proliferation and differentiation of neural cells. Mutations in HUWE1 have been described in a family with Turner-type mental retardation associated with macrocephaly (OMIM #30706) and 2 families with nonsyndromic XLMR. As well, 6 unrelated families have been reported with various duplications of the Xp11.2 region, encompassing both HSD17B10 and HUWE1. We present a male child with severe MR, partial complex seizures, and moderate to profound sensorineural hearing impairment. He was nondysmorphic as a child, but at 15 years, had poor eye contact, with long narrow face and anterior maxillary overbite. MRI showed multiple hyperintensity foci on the T2 flare images with a large area involving the right temporal lobe. Array CGH demonstrated a microduplication involving the HUWE1 gene within cytogenetic band Xp 11.22. This represents a partial duplication of the gene with minimum size of 55 KB from exons 37 to 84 and maximum size of 99 KB including exons 24 to 84. His mother and 2 of his maternal half-sisters have the same duplication and mild learning disabilities. This case represents the first description of an interstitial duplication of HUWE1 and supports the implication of HUWE1 alterations in abnormal brain development and functioning.

P02.121
Comparison of prescreening methods and their effectiveness in diagnostic of hypertrophic cardiomyopathy

P. Vanickova[1], *V. Drimlova*[1], *J. Januska*[2], *M. Branny*[2], *P. Branny*[2], *E. Prusova*[1], *A. Boday*[1];

[1]*P&R Lab a.s., Novy Jicin, Czech Republic,* [2]*Hospital Podlesi, Trinec, Czech Republic.*

Familial hypertrophic cardiomyopathy (HCM) is characterized by progressive hypertrophy of left (sometimes also right) ventricle, diastolic dysfunction, heart failure and sudden death. HCM is heterogenic disease, penetrance is incomplete with variant expressivity. Heredity is autosomal dominant with frequency 1/500. Genetic heterogeneity is caused by mutations in approximately 12 genes that encode sarcomeric complex and others.

Mutations in 3 genes: *MYH7* (gene encodes heavy chain of β-myosin), *TNNT2* (gene encodes troponin T), and *MyBPC3* (gene encodes myosin binding protein C) cause 2/3 of all cases of HCM.

Because of the high frequency of disease and heterogeneity of HCM mutation analysis is extremely laborious and time-consuming. Neither the clinical phenotype is not guideline to genetic analysis, because there are no specific symptoms that would correlate with mutations in genes. The only option is to follow the frequency of mutations in the genes: MYH7, MYBPC3, TNNT2, TPM1, MYL2, MYL3, TNNI3 and others. We compare and discusse the sensitivity and specificity of SSCP, DGGE and heteroduplex analysis and we propose testing of patients with HCM. The results put further emphasis on the need for cooperation with cardiologist, clinical genetics and molecular genetics from diagnosis to interpretation the results of molecular genetic testing.

P02.122
Genetic diversity of Myosin-Binding Protein C (MyBPC3) gene in Russian patients with hypertrophic cardiomyopathy (HCM)

N. Ogorodnikova, *V. Dolotov, H. Mardanyan, A. Pirkova, E. Zaklyazminskaya; Russian Research Centre of Surgery named by Petrovski, Moscow, Russian Federation.*

Background: Primary HCM is an inherited cardiac disorder characterized by clinical and genetic heterogeneity. Mutations in the *MyBPC3* gene account for 20% of HCM cases and are usually associated with a favourable prognosis. Despite the good survival of *MyBPC3* mutation carriers, they may also be at risk of sudden cardiac death (SCD).

Methods: A panel of 30 patients with primary HCM was formed. We screened coding and adjacent intronic areas of the *MyBPC3* gene by direct sequencing in 4 patients. Patients had a medical examination, personal and family history was collected, physical examination, standard ECG, 24-hr HM and Echo-CG.

Results: Two known mutations (S217G, Q1233ter), 2 known HCM-associated polymorphisms (S236G, R326Q) and 2 new variants (c.2067+38 A>T, V449E) were found. One patient carried heterozygous variants R326Q, Q1233ter and c.2067+38 A>T, had early manifestation, fast progression and a positive SCD family history. Compound heterozygosity of Q1233ter and R326Q variants was previously described as associated with HCM but without SCD events. A patient with a mild form of HCM had a heterozygous S217G mutation shown previously as leading to both dilated cardiomyopathy (DCM) and HCM (with sudden infant death).

A carrier of the new V449E variant had a positive family history with SCD. A fourth patient with the HCM-associated polymorphism S236G, had mild HCM with late-onset at 45 y.o. Population analysis of unknown variants (c.2067+38 A>T, V449E), and genetic screening of HCM-associated genes will be further provided in this group of patients.

Conclusion: Genetic screening of HCM-related genes in HCM patients can be used for confirmation of diagnosis, clarifying personal and familial prognosis and genetic counseling.

Research was partly supported by grant 02740110783

P02.123
Regional distribution of mutations associated with hypertrophic cardiomyopathy in the Northwest of Spain

X. Fernández-Fernández[1], *M. Ortíz*[1], *R. Barriales-Villa*[1], *M. I. Rodríguez-García*[2], *L. Núñez*[3], *E. Veira*[1], *D. García*[1], *L. Cazón*[1], *E. Maneiro*[1], *M. Pérez*[1], *E. Álvarez*[1], *A. Castro-Beiras*[2], *L. Monserrat*[2];

[1]*Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña,*

Spain, [2]CHUAC. Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña, Spain, [3]Universida de A Coruña. Instituto de Investigaciones Biomédicas de A Coruña (INIBIC), La Coruña, Spain.

Background/objectives: Hypertrophic cardiomyopathy has been associated with more than 600 different mutations in sarcomeric genes. Several studies performed in reference centers have reported the presence of multiple families with the same mutation in a given geographic area. Our objective was to evaluate the potential founder effects in a regional population.

Methods: Analysis of the geographic origin of HCM families with mutations in sarcomeric genes identified in Galicia (Northwest Spain).

Results: We have identified 67 different mutations in 376 carriers of 136 apparently independent families (32 MYBPC3 mutations in 61 families, 26 MYH7 in 49 families, 4 TNNT2 in 8 families, 3 TNNI3 in 8 families, 1 TNNC1 in 1 family, and 1 ACTC mutation in 9 families). Forty-four of the 67 mutations (65%) had been previously described. Eighty-eight of the 136 families (65%) shared mutations with other families, and 58 of those 88 (68%) were repeated within the same or a bordering district, strongly suggesting a common origin. Twenty-four of the 67 different mutations appeared in more than one family: 4 were in 2 different families, 9 mutations in 3 families, 3 mutations in 4 families, and 1 mutation was repeated in 5,6, 7,8 and 9 families respectively.

Conclusions: Multiple families with the same mutations are frequent in our population. The knowledge about the geographic origin of the families in a regional setting may be useful to focus the genetic studies. The identification of a high proportion of previously described mutations in multiple families can improve our knowledge about genotype-phenotype correlations.

P02.124

Partial, homozygous deletion of *PREPL* and *C2orf34* on 2p21 in siblings with atypical hypotonia-cystinuria syndrome (HCS)

***D. Bartholdi**, R. Asadollahi, B. Oneda, A. Baumer, A. Rauch;*
Institute of Medical Genetics, Schwerzenbach, Switzerland.

Homozygous contiguous gene syndromes are rare. On 2p21, however, two overlapping homozygous contiguous gene syndromes have been described. The first syndrome, referred to as 2p21 deletion syndrome, is characterized by neonatal hypotonia, seizures, severe developmental delay, elevated serum lactate concentrations, poor feeding, growth retardation, facial dysmorphisms and cystinuria type I. The deletion affects at least four genes, PPM1B, SLC3A1, PREPL and C2orf34. The second syndrome, hypotonia-cystinuria syndrome (HCS, MIM606407) is characterized by infantile hypotonia, poor feeding, growth hormone deficiency, mild facial dysmorphism and cystinuria type I; affected individuals carry homozygous deletions encompassing the SLC3A1 and the PREPL gene. Cystinuria is due to the loss of the SLC3A1 gene.

We describe two siblings with a homozygous deletion of 83 kb encompassing exon 1 of the PREPL gene - implicated in both syndromes - and the first three exons of the C2orf34 gene - implicated in the 2p21 deletion syndrome. To our knowledge, this is the first homozygous deletion on 2p21 not disrupting the coding sequence of the SLC3A1 gene. The affected individuals display the classical symptoms of HCS such as severe muscular hypotonia in infancy and pronounced feeding difficulties with growth failure, but no cystinuria. They also show additional features such as cleft palate and genital abnormalities which have not been reported so far, neither in the 2p21 deletion syndrome nor in HCS. Our findings confirm that PREPL is the key gene in causing the complex growth and neuromuscular phenotype in HCS. The role of C2orf34 still remains to be determined.

P02.125

HLA Assessment in Romanian Children Associating IgA Deficiency

***O. Belei**[1], I. Simedrea[1], L. Tamas[2], O. Marginean[1], C. Daescu[1], T. Marcovici[1], M. Puiu[3];*
[1]First Pediatric Clinic, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [2]Biochemistry Department, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [3]Genetic Department, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Introduction:Selective IgA deficiency (IgAD) is a genetic disorder characterized by decreased or absent level of serum IgA. IgAD is 10 to 15 times more frequently in patients with celiac disease (CD) than in healthy subjects.IgAD has been associated with chromosomes 18,14 and 6.Certain MHC haplotypes have been associated with susceptibility to IgAD:HLA-A, B14, B8, DR3. Objective: The goal of this study was to assess the association between HLADQ and IgAD in Romanian children. Methods:From 122 celiac patients diagnosed between 2000 and 2010, 9 associated IgAD (diagnosis was IgG serology and histology based).A second study lot consisted in 10 IgAD children without autoimmune associations.The lot of control consisted in 20 healthy children.DQ2/DQ8 alleles were typed by PCR-SSP in all children. Results:Alleles distribution for children with CD and IgAD was:8 cases (89%) presented homozygous DQ2 haplotypes (DQA1*0501/DQB1*0201 and DQA1*0501/DQB1*0201) and one (11%) associated heterozygous DQ8 haplotype (DQA1*0301/DQB1*0302 and DQA1*0301/DQB1*0103).From the second lot IgA deficient without CD, 3children (30%) presented homozygousDQ2 haplotypes.From the contol lot, one healthy children (5%) associated DQ2homozygous alleles. HLA DQ2 homozygous haplotype was present in 58% of total IgAD patients comparing to 5% in controls (p<0,00012).We found a significant correlation between DQ2 homozygous haplotype and IgAD (r=0,62).Conclusions:Presence of HLA DQ2/DQ8 is mandatory but not sufficient for developing CD.Susceptibility to IgAD is associated with DQ2 alleles,but it is not equally in different populations.Differences in HLA association of IgAD reported by various studies suggest that multiple different genes within the MHC region might be involved in the pathogenesis of this immunodeficiency.

P02.126

Mental retardation, microcephaly and cerebellar dysplasia in a child with mosaic interstitial duplication 16q11.2-q12.1

***C. Vinkler**[1], A. Zerem[2], L. Ben-Sira[3], M. Michelson[1], T. Lerman-Sagie[2], D. Lev[1];*
[1]Institute of Clinical Genetics Wolfson Hospital, Holon, Israel, [2]Pediatric Neurology Unit Wolfson Hospital, Holon, Israel, [3]Radiology Department Ichilov Tel-Aviv Medical Center, Tel-Aviv, Israel.

Intersitial duplications in the long arm of chromosome 16 have been previously reported in a small number of patients. Whereas no distinct common dysmorphic features can be defined for these patients, they all had in common, mental retardation, speech delay and behavioral problems.

We describe a boy who presented with mental retardation, cerebellar signs and mild dysmorphic features who had an interstitial duplication of the long arm of chromosome 16.

This boy is the first child of unrelated parents of Ashkenazi origin. IUGR was noticed at 31w gestation and delivery was induced at 36 weeks due to reduced growth. His birth weight was 1,730 g. He had poor sucking and general psychomotor delay. On examination at the age of 4y, he had microcephally, high nasal bridge, deep set eyes, thin lips, and mild retrognatia. He had low muscle tone and wide-based gait due to clumsiness or ataxia. He used only 5 verbal words and communicated mainly with gestures and signs. Brain MRI revealed cerebellar cortical dysplasia. Large forth ventricle with mild elongated superior cerebellar peduncles and small vermis with atrophy of the inferior aspect were noted.

Microarray and FISH analysis detected a 3.3 Mb mosaic gain from 16q11.2-16q12.2 . and identified a marker chromosome in 17/30 metaphases cells examined. The parents had normal karyotypes.

This is the first report of cerebellar anomalies in a patient with partial trisomy 16q. More patients with an interstitial duplication of 16q11-q12 and brain imaging findings will help to further characterize the phenotype.

P02.127

Report of a Jacobsen syndrome with a mild facial dysmorphism, severe hearing impairment and trombocytopenia

***L. Cimbalistienė**, V. Dirsė, V. Kučinskas;*
Department of Human and Medical Genetics, Vilnius, Lithuania.

Jacobsen syndrome (JBS), also known as 11q deletion syndrome, is a rare syndrome with variable phenotypic expression. To date, over 200 cases of JBS have been described, with an estimated prevalence of 1:100000 birth. The most characteristic symptoms are short stature, craniofacial anomalies, congenital heart defects, visceral malformations, developmental delay and thrombocytopenia.

Case report. The proband, 11 months old boy was referred to our department due to suspected genetic disorder. He was born by Cesarean section after a full term pregnancy. His Apgar score was 10-10, birth weight 3000 g, height 50 cm and head circumference 36cm. At the age of 2 months he was hospitalized due to atopic dermatitis and severe foliculitis on the face. Laboratory investigations revealed a low platelet count. Ophthalmological and otolaryngologic evaluation revealed optical nerve subatrophy and severe hearing impairment. Clinical examination revealed short stature, macrocephaly, short neck, ocular hypertelorism, strabismus, epicanthal folds, slight retrognathia, abnormal palmar creases. There were no cardiac, genitourinary and renal anomalies. Cerebral MRI was normal. Slight delay in psychomotor development was noted. According clinical signs diagnosis of Jacobsen syndrome was considered.
FISH analysis using subtelomeric specific probes (ToTelVysion™) for all long and short arms of chromosomes have been performed. Subtelomeric FISH analysis has detected submicroscopic deletion at 11q25. Array CGH analysis for revealing the breakpoints and the size of the aberration is under the way. The present report emphasizes the importance of the FISH as rapid, precise and useful method in such cases with hearing impairment and trombocytopenia.

P02.128
A patient with features reminiscent of Johanson-Blizzard Syndrome and cortical malformations

*P. Accorsi[1], L. Giordano[1], V. Uliana[2], F. Forzano[2], L. Pinelli[1], G. Olioso[1], M. Zenker[3], E. Di Maria[2,4], **F. Faravelli**[2];*
[1]Pediatric Neuropsychiatric Division, Spedali Riuniti, Brescia, Italy, [2]Division of Medical Genetics, Galliera Hospital, Genova, Italy, [3]Institute of Human Genetics, University Hospital of Magdeburg, Magdeburg, Germany, [4]Dept. of Neuroscience Ophthalmology and Genetics, University of Genova, Genova, Italy.

Johanson-Blizzard syndrome (JBS; OMIM 243800) is a rare autosomal recessive syndrome, clinically characterised by distinctive facial features, with aplastic or hypoplastic alae nasi, and exocrine pancreatic insufficiency. The clinical spectrum of the disorder include others features as short stature, deafness, mental retardation, scalp defects, oligodontia, hypothyroidism, rectourogenital malformations, ocular abnormalities, heart defects and central nervous system anomalies. Mutations in the UBR1 gene (15q14-q21) are the only genetic cause of JBS known to date.
We describe a boy with a phenotype reminiscent of JBS, in particular facial features, abnormal hair pattern, micropenis and hypopituitarism, and no signs of exocrine pancreas insufficiency at 12 years of age. He also presented an ovalar skull defect (about 2 cm of maximum diameter) in the frontal bone, normal IQ at two cognitive evaluations (5 and 12 years of age) and cortical malformations (nodules of heterotopic gray matter, incomplete development of the right fronto-temporal operculum, dysplastic cortex and mild cerebellar atrophy). The parents reported a previous pregnancy with severe IUGR and hypertrophic cardiomyopathy. The molecular analysis of UBR1 gene did not identify mutations.
The proband could present either a novel condition partially overlapping with JBS, genetically distinct and characterized by a normal pancreatic function, or a variant of JBS phenotype.

P02.129
OFD VI syndrome with cerebellar malformations: clinical, radiological and molecular characterisation

***V. Darmency-Stamboul**[1], L. Burglen[2], N. Méjean[3], B. Franco[4], D. Rodriguez[5], D. Lacombe[6], I. Desguerres[7], V. Cormier-Daire[8], B. Doray[9], L. Pasquier[10], M. Gonzales[11], J. Dean[12], L. Faivre[1], T. Attié-Bitach[8], C. Thauvin-Robinet[1];*
[1]Centre de Génétique et Centre de Référence « Anomalies du Développement et Syndromes Malformatifs », Dijon, France, [2]Unité de génétique clinique et neurogénétique et Centre de Référence des Anomalies du cervelet CHU Armand Trousseau, Paris, France, [3]Hopital d'Enfants. Centre de Génétique et Centre de Référence « Anomalies du Développement et Syndromes Malformatifs », Dijon, France, [4]Telethon Institute TIGEM, Naples, Italy, [5]Service de Neuropédiatrie et Centre de Référence des Anomalies du cervelet, CHU Armand-Trousseau, Paris, France, [6]Service de Génétique et Centre de Référence Anomalies du Développement et Syndromes Malformatifs, Hôpital Pellegrin, Bordeaux, France, [7]Service de Neuropédiatrie, Hôpital Necker - Enfants Malades, Paris, France, [8]Département de Génétique, Hôpital Necker - Enfants Malades, Paris, France, [9]Service de cytogénétique, Strasbourg, France, [10]Service de génétique médicale, Rennes, France, [11]Service de génétique, CHU Armand-Trousseau, Paris, France, [12]Medical Genetics, Ashgrove House, Foresterhill, Aberdeen, United Kingdom.

The oral-facial-digital syndrome type VI (OFD VI) or Varadi syndrome (OMIM 277170) is characterized by the association of malformations of the face, oral cavity and extremities, and distinguished from the 12 other OFD syndromes by cerebellar and metacarpal abnormalities. Cerebellar malformation in OFD VI syndrome has recently been described as a molar tooth sign (MTS), including OFD VI syndrome among the « Joubert syndrome related disorders » (JSRD). We report on the clinical and radiological data of 9 OFD VI cases with normal *OFD1* analysis and molecular investigations of six genes implicated in JSRD. Among the nine collected cases, two were fetuses and 8/9 cases were female. All patients presented oral malformations, facial dysmorphism and distal abnormalities including mainly polydactyly (70%), 50% in hands and 70% in feet. All patients presented with neurological symptoms with mental retardation (5/5 cases), from moderate to severe impairment. Supratentorial abnormalities, brainstem malformations, cerebellar malformations with constant MTS and cystic dilatation of the posterior fossa were always present. In conclusion, the OFD VI syndrome defined by the association of OFD features and cerebellar malformations presents with constant MTS associated to constant brainstem and supratentorial malformation and could definitively be considered as JSRD and an additional ciliopathy. Six of the nine causative genes implicated in JBS and JSRD (*INPP5E; CORS2; TMEM67/MKS3; RPGRIP1L; ARL13B and CC2D2A)* were studied in 5/8 families but no pathogenic mutation was found. The responsible gene(s) probably interact(s) with *OFD1* gene and the JSRD genes.

P02.130
Severe Aortic Stenosis in a Child with Joubert Syndrome and Related Disorders (JSRD) - a Case Report and Review of Congenital Heart Defects Reported in the Human Ciliopathies

***N. Karp**, S. Blaser, L. Grosse-Wortmann, S. Bowdin;*
The Hospital for Sick Children, Toronto, ON, Canada.

We report a case of a 2 year-old boy with classical features of JSRD including oculomotor apraxia, postaxial polydactyly, episodes of rapid breathing and developmental delay. Magnetic resonance imaging demonstrated the pathognomonic "molar tooth sign". In addition, the child was also diagnosed with severe congenital aortic stenosis and underwent valvular balloon dilatation. The results of gene sequencing of the AHI, TMEM67, CEP 290 and NPHP1 were negative for causative mutation. We are in the process of testing several other genes, including CC2D2A, INPP5E, RPGRIPIL, ARL13B and TMEM216.
JSRD is one of a group of conditions known as 'ciliopathies', whose multi-organ involvement results from primary cilia dysfunction. Human ciliopathies present with distinct but overlapping phenotypes whose core features include retinal degeneration, cystic disease of the liver, pancreas and kidney, postaxial polydactyly and situs inversus. To date, there have not been other reported cases of aortic stenosis associated with JSRD. Indeed, cardiac screening is not currently recommended in the management guidelines for individuals suspected of having JSRD. We speculate that while the presence of congenital aortic stenosis in this child could be caused by an unrelated genetic mechanism, it could also represent a phenotypic overlap with another ciliopathy, the Bardet Biedl syndrome, in which aortic stenosis is present in about 38% of cases.
We also review the range of cardiac lesions reported to be present in all human diseases known to be ciliopathies, in order to assist with the investigation and management of individuals with a suspected or proven ciliopathy.

Neuroimaging, clinical and genetic analysis of novel and known congenital neurodevelopemental brain malformations followed by deep sequencing

***K. Kahrizi**[1], J. Jalal Shokouhi[2], M. Garshasbi[3], S. Abedini[1], M. Hosseini[1], M. Mohseni[1], L. nouri[1], F. Larti[1], S. Arzhangi[1], S. Banihashemi[1], A. Kuss[3], A. Tzschach[3], H. Ropers[3], H. Najmabadi[1];*
[1]Genetics Research Center, USWR, Tehran, Islamic Republic of Iran, [2]Jam-Jam Imaging Center, Tehran, Islamic Republic of Iran, [3]Max-Planck-Institute for

Molecular Genetics, Berlin, Germany.
Intellectual disability (ID) occurs as a symptom in heterogeneous groups of neurodevelopemental disorders.
Three of the most important contributions in understanding of the structural or functional brain defects are the capacity to perform detailed neuroimaging, the ability to perform highly advanced genomic testing and the accurate and professional characterization of the patients. Neuroimaging could provide more refined correlations between clinical and molecular evaluations, and could result in to the identification of genetic causes of nurodevelopemental brain diseases.
We have investigated one hundred mentally retarded patients clinically candidate for neurodevelopental brain malformations .Up to now we have performed neuroimaging for 60 families, which for some of them next generation sequencing have been recently done to identify genetic defects as well.
We could identify 15 families with cerebellar hypoplasia or atrophy, two families with Joubert syndrome type3 (with mutations in AHI1), two families with CP like syndrome and mutations in *AP4A1* as a recently identified syndrome and two families with spinocrebellar ataxia type 14 syndrome (with mutations in PRKCG).
Our findings suggest that more than thirty percent of autosomal recessive ID (ARID) families with neurologic symptoms suffer from different types of neurodevelopemental brain malformations.

P02.132
Microdeletion 10q23 and juvenile polyposis syndrome: a case report

T. Reimand[1,2,3], *O. Uibo*[2,4], *K. Luts*[5], *I. Talvik*[2,6], *O. Zilina*[1,7], *K. Muru*[1,2], *K. Õunap*[1,2];
[1]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [2]*Department of Pediatrics, University of Tartu, Tartu, Estonia,* [3]*Department of Obstetrics and Gynecology, University of Tartu, Tartu, Estonia,* [4]*Children's Clinic, Tartu University Hospital, Tartu, Estonia,* [5]*Tallinn Children`s Hospital, Tallinn, Estonia,* [6]*Children's Clinic, Tartu University Hospital, Tartu, Austria,* [7]*Department of Biotechnology, Institute of Cell and Molecular Biology, University of Tartu, Tartu, Estonia.*
Juvenile polyposis syndrome is a rare disease characterized by hamartomatous polyps in the gastrointestinal (GI) tract. For clinical diagnosis there has to be one of the three following findings: more than five juvenile polyps of the colorectum; multiple juvenile polyps throughout the GI tract; any number of juvenile polyps and a family history. Approximately 20% of individuals with JPS have mutations in *BMPR1A* and approximately 20% have mutations in *SMAD4*.
We describe a 4-year-old boy who was born with congenital heart defect (atrioventricular septal defect), macrocephaly and dysmorphic features. His karyotype from lymphocytes was normal (46,XY). According to his clinical picture (facial dysmophism, failure to thrive and heart anomaly) Noonan syndrome was clinically diagnosed at the age of 1 year although no mutations in *PTPN11* and *KRAS* genes was detected. At the same age the iron deficiency anaemia was diagnosed and in the second year of life he has blood in the stool. At the age of 4 years polyps were found all over the GI tract. His development was delayed, he was dysmorphic with macrocephaly (+4 SD), in MRT of the brain showed mild ventriculomegalia. There was a suspicion to 10q microdeletion according to his clinical picture. Whole-genome genotyping was performed, using the Illumina platforms and 5,1Mb deletion in the region 10q23.1-23.3 was found. This finding was confirmed also by quantitative PCR analysis. In 10q23.1-23.3 region both *BMPR1A* and *SMAD4* genes are located so the deletion is responsible to the polyposis of the patients.

P02.133
Extended genotype - phenotype correlation study in Kabuki syndrome patients comparing MLL2 mutation carriers vs. non-carriers

C. Schrander-Stumpel[1], *M. Blok*[2], *D. Tserpelis*[1], *C. Posma-Velter*[1], *C. Rusu*[3], *K. Devriendt*[4], *J. Schrander*[2], *Y. Detisch*[1], *B. Smeets*[1], *A. Stegmann*[1], *A. Paulussen*[1];

Kabuki syndrome (KS, MIM: 147920) is a clinically recognizable syndrome of multiple congenital anomalies and mental retardation affecting approximately 1:30,000 live births. Key features are a characteristic face, growth retardation, developmental delay and additional features such as hypodontia and persistent foetal fingertip pads. Recently, a gene causing KS was identified through exome sequencing, reporting de novo mutations in the histone methyl transferase (HMT) gene *MLL2* in 66% of 53 patients with Kabuki syndrome (Ng et al., Nat Genet.42(9):790-3, 2010). We confirmed the pathogenic significance of this gene in KS in our first published series, demonstrating 76% MLL2 mutations in 45 KS cases (Paulussen et al, Hum Mutat. 32(2), 2011). In another series of 31 patients, we identified 21 additional novel MLL2 mutations. Thus the combined mutation yield of Sanger-based MLL2 exon sequencing for both series is 55/76 = 72%, further supporting the major contribution of MLL2 mutations to the disease. We collected detailed clinical data of the 76 patients from both series (49 female, 27 male). Relevant clinical features were selected from the Dyscerne guidelines for KS (www.dyscerne.org) and interrogated using standardised questionnaires and checklists. Analysis focused on 7 clustered feature groups: facial, growth and development, cardiovascular, sensory (vision, speech, hearing), skeletal/orthopaedic malformations and accessory minor feautures. Statistical analysis using SPSS v12 was used to correlate (clustered) clinical features to MLL2 mutation carrier status We will present data from an extended pheno-genotype analysis, including the contribution of type-specific clustered mutations (i.e. nonsense, frame-shift, missense and splice-site).

P02.134
"Kabuki make-up syndrome" - characterization of rare findings of 2 new patients

N. Rumiantsava[1], *H. Iljina*[2], *I. Naumchik*[2], *R. Chmel*[2];
[1]*Republican Scientific and Practice Center, Minsk, Belarus,* [2]*Republican Scientific and Practice Center "Mother&Child", Minsk, Belarus.*
"Kabuki make-up" syndrome (KS, MIM 14792) is a clinically distinct MCA/MR disorder with uncertain inheritance (most cases are sporadic). The main diagnostic criteria are well-known, but a phenotypic spectrum of rare abnormalities have delineated. We present clinical pictures of 2 new unrelated patients and characterize rare features in comparison with literature. Patients were a single child of young healthy nonconsanguineous couples. Pregnancy, labor were unremarkable. Growth delay, mental retardation, craniofacial dysmorphisms, heart involvement, fingertip pads were common. Karyotype (GTG): 46,XX; 46,XY. Metabolic disorders, prenatal infections were excluded. Case 1: Girl, 2 years old, showed typical facial appearance, dysmorphic ears, preauricular fistulas, lower palpebra eversion, cleft palate, diaphragmatic hernia, heart defect (ASD,VSD). Case 2. 12 years old boy presented severe mental and speech delay, tetraparesis, brain cyst, large prominent malformed ears, hearing loss, arched eyebrows, long palpebral fissures, nystagmus, strabismus, bilateral coloboma of iris, chorioidea and optic nerves, myopia, cataracts, high palate, malocclusion of teeth, scoliosis, thorax deformation, flat feet. Heart defect (AVC, VSD, insufficiency of valves). At the time of counseling mother was pregnant and underwent to standard combined prenatal screening. No fetal malformations were detected. Families were reffered for genetic counseling due to affected child for diagnostics and prognoses. We have established KS (sporadic origin) based on association of characteristic facial features, growth and mental delay. Uncommon malformations were preauricular fistulas, cleft palate, diaphragmatic hernia (case 1), ophtalmological abnormalities, scoliosis (case 2). Rare signs could not influence for diagnostics if main criteria were found.

Kabuki syndrome (KS, MIM 147920) is a MCA-MR syndrome characterized by a facial gestalt, intellectual disability, visceral and skeletal malformations and, postnatal short stature with overweight.

An exome sequencing strategy recently identified *MLL2* as the disease-causing gene with heterozygous, *de novo* CDS mutations in about 70% of the patients fulfilling clinical diagnostic criteria.

Here we report the identification of an *MLL2* mutation in 80% of the cases from a series of 79 KS patients. All patients were sporadic except for one KS familial case with two sibs and their mother being affected. Mutations are spread throughout the gene with no hot-spot. Nonsense, frameshift ,splice site, Missense and in frame duplication/deletion mutations were found in 15 (23%), 27 (42%), 2 (3%) 18 (28%), and 2 (3%) patients respectively.

Phenotype/genotype correlations were investigated for intellectual disability, growth, seizure, cleft lip/palate, cardiac and renal malformations, endocrine disorders (GH deficiency and hyperinsulinism), and dysimmunity (immunoglobulin deficiency and auto-immune manifestations).We also compared patients with and without *MLL2* mutations in an attempt to delineate clinical, biological and skeletal features allowing to differentiating the 2 groups.

P02.136
A novel *de novo* splice-site mutation in MLL2 gene in a patient with Kabuki syndrome

E. Sarasola-Diez, C. Ruiz-Espinosa, M. Fernandez-Cuesta, J. Garcia, E. Achalanbaso, B. Santos, ***M. J. García-Barcina****;*
Hospital de Basurto, Bilbao, Spain.

Kabuki syndrome (KS, MIM# 147920) is a rare disorder characterized by developmental delay, distinctive facial features and short stature. Recently, Ng et al. identified mutations in MLL2 gene as causative of KS. Up to date, approximately 65 mutations have been described in MLL2 gene related to KS, being most of them truncating mutations with a *de novo* origin.

In this work, we describe the case of a 14 month old female patient referred to our Hospital in order to study her developmental delay and growth retardation. She presented microcephaly, ventricular septal defect, hypotonia and joint laxity, persistence of fetal finger pads and a sacral dimple. She showed facial features as arched eyebrows with sparseness of hairgrowth in the lateral half, long eyelashes, long palpebral fissures with an one third of the lower lid everted lateral, broad nasal tip and prominent ear lobes (anteverted and with simplified morphology). She also showed feeding difficulties and breast development from 3 months of age.

In order to confirm the clinical suspect of KS we performed complete sequencing of MLL2 gene. This genetic study revealed the presence of a splice site mutation, not previously reported in the literature. De novo origin of the mutation was confirmed due to its absence in patient's parents. Currently, RNA studies are being carried out to determine the causal mechanism of the mutation.

[1]Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany, [2]Insititute of Human Genetics, University of Cologne, Cologne, Germany, [3]Pediatric Genetics Unit, Department of Pediatrics, Hacettepe University Medical Faculty, Ankara, Turkey, [4]Institute of Human Genetics, University Hospital Essen, Essen, Germany, [5]Private Practice for Human Genetics, Erfurt, Germany, [6]Institute of Human Genetics, University of Lübeck, Lübeck, Germany.

Epigenetic control of developmental processes is a fascinating mechanism by which spatial and temporal expression of distinct genes and pathways is regulated. Alterations of epigenetic mechanisms have been mainly associated with the pathogenesis of cancer, but recently also with the occurrence of congenital malformation syndromes. An up-to-date example is the identification of *de novo* dominant mutations in the *MLL2* gene using a whole-exome sequencing strategy in patients with Kabuki syndrome. Kabuki syndrome is a classical, clinically well-known multiple congenital anomalies/mental retardation syndrome, mainly characterized by a distinct facial appearance in addition to e.g. developmental delay, short stature, persistent fingerpads, and urogenital tract anomalies. In our study, we sequenced all 54 coding exons of the *MLL2* gene in 34 patients with Kabuki syndrome. We identified eighteen distinct mutations in nineteen patients and twelve of thirteen tested *de novo*. Mutations included four nonsense mutations, two splice-site mutations, six small deletions or insertions, and six missense mutations. The mutations were located throughout the *MLL2* gene without a clustering in specific exons of the gene or domains of the protein. Interestingly, genotype-phenotype comparison indicated a higher frequency of specific symptoms in *MLL2*-positive cases. Mutation-negative patients were subsequently tested for mutations in 12 highly relevant functional candidate genes (e.g. *MLL1, ASC2, ASH2*, and *WDR5*) and we identified one alteration in *MLL1* with a yet unclear causative role. Our results indicate that *MLL2* is the major gene for Kabuki syndrome with a wide spectrum of *de novo* mutations and they provide evidence for further genetic heterogeneity.

P02.138
Is Hardikar syndrome distinct from Kabuki (Niikawa-Kuroki) syndrome? Report of a case with a novel mutation in the MLL2 gene.

I. Ejarque*[1], V. Uliana[1], F. Forzano[1], V. Viassolo[1], C. Marciano[1], G. Merla[2], L. Zelante[3], E. Di Maria[1,4], F. Faravelli[1];*
[1]Division of Medical Genetics, Galliera Hospital, Genova, Italy, [2]Laboratory of Medical Genetics, IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, [3]Medical Genetics Unit, IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, [4]Dept. of Neuroscience Ophthalmology and Genetics, University of Genova, Genova, Italy.

Kabuki syndrome (Niikawa-Kuroki syndrome) is characterised by distinctive facial features, skeletal anomalies, dermatoglyphic abnormalities, mental retardation, and growth deficiency. Recently, mutations in the MLL2 gene were identified as the genetic cause of Kabuki syndrome. Hardikar syndrome is a rare condition of unknown cause in which cleft lip and palate, patchy pigmentary retinopathy (''cat's paw'') and obstructive liver disease are associated.

We describe a patient with typical facial features of Kabuki syndrome who also developed a hepatoblastoma and retinal pigmentation anomaly cat's paw type. The pathogenic c.11119C>T nonsense mutation in the exon 39 of MLL2 was found. By comparing our patient's phenotype with the patients with Hardikar syndrome described to date, we focussed on the overlapping features of the two syndromes. As a conclusion, we suggest that Hardikar syndrome could be an extreme of the wide phenotypic spectrum of Kabuki syndrome.

P02.139
A case with Kallmann syndrome and ichthyosis: not always a contiguous gene syndrome

E. Trevisson*[1], A. Casarin[2], K. Ludwig[3], C. Daolio[2], L. Salviati[2];*
[1]Clinical Genetics, Department of Pediatrics, Univeristy of Padova, Padova, Italy, [2]Clinical Genetics, Department of Pediatrics, University Hospital, Padova, Padova, Italy, [3]Department of Medical Diagnostic Sciences & Special Therapies, Pathology Unit, Padova, Italy.

Kallmann syndrome consists of congenital, idiopathic hypogonadotropic hypogonadism and anosmia. The X-linked form is caused by mutations in the *KAL1* gene on chromosome Xp22.3. Some patients have larger deletions encompassing neighbouring genes and thus may present with other clinical features, such as X-linked ichthyosis (XLI), which results from steroid sulfatase deficiency due to loss of function mutations of the STS gene at Xp22.3.

We report a 9 year and 7 month old boy who was diagnosed with

ichthyosis and Kallmann syndrome on the basis of hypogonadotropic hypogonadism, left kidney agenesis and hyposmia. Close examination of the patient's family history revealed an apparently X-linked pattern of ichthyosis with three affected male relatives of the mother. On examination auxological parameters were normal. Skin appeared dry and scaly, particularly at limbs, ears, trunk and feet. His parents and younger brother were phenotypically normal, without detectable renal anomalies on ultarsounds.
Array-CGH analysis on peripheral blood lymphocytes detected a deletion of about 500 kilobases, involving the 5' region of the *KAL1* gene, but not the *STS* gene; the same deletion was then confirmed in the proband's mother. Quantitative PCR analysis of the *STS* transcript showed normal expression levels and sequencing of the whole coding region of the *STS* gene did not reveal any sequence variant.
Our excludes a potential positional effect of the genomic rearrangement on the expression of the *STS* gene and supports the hypothesis of additional loci for ichthyosis on the X chromosome.

P02.140
Lafora disease with a new inheritance

M. S. YILDIRIM[1], *M. BALASAR*[1], *E. TUNCEZ*[1], *B. O. GENC*[2], *M. C. AVUNDUK*[3], *A. G. ZAMANI*[1];
[1]*Selcuk University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*Selcuk University, Meram Medical Faculty, Department of Neurology, Konya, Turkey,* [3]*Selcuk University, Meram Medical Faculty, Department of Pathology, Konya, Turkey.*

A type of progressive myoclonic epilepsy called Lafora Disease (OMIM 254780) is a very rare autosomal recessive fatal genetic disorder caused by mutations in laforin gene or malin gene. It is described as starting in early adolescence as grandmal seizures and/or myoclonus and characterised by the presence of periodic acid-Schiff-positive staining intracellular inclusion bodies. We report a patient diagnosed as Lafora disease with a possibility of an autosomal dominant inheritance.
A 25 years old girl reffered from neurology clinic to genetic clinic for pedigree analysis who has myoclonic and grandmal tonic-clonic seizures started at age 15, dysarthria, ataxia, visual hallucinations and depression. Intracellular PAS positive polyglucosan inclusion bodies (Lafora bodies) has been showed in skin. Pedigree analysis revealed an autosomal dominant inheritance which is not described in literature before. Patient's parents aren't consanguineous. Her father, aunt and grandfather diagnosed as Lafore,too. So, we suggest that a new gene or mutation may cause Lafore in this family . Further studies will be done for highlighting the reason of this unexpected inheritance.

P02.141
Langdon-Down syndrome in a newborn from mother with epilepsy - Case report

D. Iacob[1], *M. Boia*[1], *C. Ilie*[1], *R. E. Iacob*[2], *A. Manea*[1], *M. Tira*[3];
[1]*University of Medicine and Pharmacy Timisoara, Timisoara, Romania,* [2]*Clinical Emergency County Hospital, Arad, Romania,* [3]*Clinical Emergency Hospital for Children "L. Turcanu', Timisoara, Romania.*

Introduction: Down syndrome is the most common and known chromosomal disorder.
This syndrome is characterized by mental retardation, facial dimorphism and other phenotype distinctive traits.
Many individuals with Down syndrome have also heart defects.
Objective: Describe a case of Down syndrome from mother with severe epilepsy under treatment.
Material and methods: Medical history: the patient is a 2.500 gram male newborn, GIV, PIV, delivered by cesarean section at 38 weeks of gestation; his 38-year-old mother is known with: Severe epilepsy partially controlled by medication - 4 seizures/month (she was treated throughout pregnancy); his father is 41-year-old.
Physical examination admission revealed: serious general condition, short neck, facial dismorphism: hypertelorism, upward slanting eyes, epicanthal folds, low set ears; perioral cyanosis; short hands; hypospadias; poor muscle tone, poor reflexes; systolic murmur grade III/VI.
Cytogenetic analysis showed 100% of 21 trisomy; karyotype: 47XY, +21
Imagistic examination
- Echocardiography: hypertrophic cardiomyopathy; atrial and ventricular septal defect; aortic stenosis and tricuspid insufficiency.
- transfontanelar ultrasound : hypoxic ischemic encephalopathy.
Results: During hospitalization evolution were wavy; gaining slowly in weight; abnormal development: the absence of sucking reflex (gavage feeding); poor muscle tone; he required antibiotics for respiratory problems, cardiologic and neurological treatment.
Conclusions: The prognosis is variable, depending on the types of complications.
Increased incidence of cardiac malformations requested cardiologic consult in every case because congenital heart disease is the major cause for early mortality.
The development and growth is usually delayed and often average height and developmental milestones are not reached.

P02.142
Laryngomalacia (OMIM 150280): unexpectedly high frequency in population

A. Y. Petrunitchev;
Saint-Petersburg medical academy of postgraduate studies, Saint-Petersburg, Russian Federation.

The diagnosis of laryngomalacia is based on endoscopic revealing of inspiratory collapse of laryngeal vestibule. Many investigators proved this disorder as the most common congenital malformation of upper airways. Despite this, no one medical geneticist reasonably regards this diagnosis as real genetic syndrome "laryngomalacia" (OMIM 150280). No data on frequency of this syndrome in population appeared to be found in world literature.
Complex investigation in three groups was performed: 369 children (1 to 38 months old) with congenital stridor (separation of genetic syndrome), 10 children with laryngomalacia and no surgical treatment (follow up more than 5 years), 300 adults with absence of laryngeal problems in anamnesis (assessment of laryngeal vestibule).
Identical findings, most close to genetic syndrome "laryngomalacia", were obtained in 77 cases of congenital stridor. They include typical stridor, inspiratory supraglottic collapse, anatomic anomalies of laryngeal vestibule, any of related pathology (gastroesophageal reflux, failure to thrive, obstructive sleep apnea, chokes), typical course, family character (the last was found just in 27 cases). All cases with prominent catarrhal changes, neurological problems, other congenital malformations of upper airway were excluded. Thereby, "laryngomalacia" (as syndrome) provides more than 40 % events of congenital stridor.
Ten cases of laryngomalacia were followed up till anatomic peculiarities of laryngeal vestibule became stable (children reached 7 to 9 years old) and tried to find the same changes in 300 healthy adults. It had been successful in 13 (4 %) cases, that represents minimal frequency of syndrome "laryngomalacia" in population.

P02.143
Leber Congenital Amaurosis (LCA): development of a comprehensive molecular genetic test panel using next-generation sequencing

F. Coppieters[1], *B. De Wilde*[1], *E. De Meester*[1], *S. Lefever*[1], *N. De Rocker*[1], *C. Van Cauwenbergh*[1], *F. Pattyn*[1], *B. P. Leroy*[1,2], *J. Vandesompele*[1], *E. De Baere*[1];
[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium.*

Leber Congenital Amaurosis (LCA) is associated with 16 genes, accounting for 70% of cases. Generally, genetic testing is limited to screening of a selected number of mutations and/or Sanger sequencing of a subset of genes. We aimed to design an accurate, fast and affordable molecular test for all known LCA genes using next-generation sequencing.
We developed a novel protocol consisting of qPCR, ligation, fragmentation, sequencing on an Illumina GAIIx, and data analysis by NextGENe. As a proof-of-concept, ten LCA patients were included, five of which had a known molecular defect.
Using in-house primer design, 375 amplicons were developed to cover 236 exons and intron-exon boundaries of 16 genes (*RD3*, *RPE65*, *CRB1*, *MERTK*, *IQCB1*, *LRAT*, *LCA5*, *TULP1*, *IMPDH1*, *CEP290*, *RPGRIP1*, *RDH12*, *SPATA7*, *AIPL1*, *GUCY2D* and *CRX*). Following amplification, ligation and shearing, amplicon pools were sequenced in one GAIIx lane (1x100bp, indexing). This yielded sufficient coverage for 93-95% of exons. In total, 104/107 previously identified variants were detected, including the known mutations in the positive controls. In addition, mutations were identified in 2/5 mutation-negative patients.

In conclusion, we developed a cost-efficient workflow for parallel sequencing of all known LCA genes, which enables sequencing of regions with variable length, such as exons, on a short-read sequencer. The flexibility of this approach allows easy expansion with other genes, providing an excellent basis for molecular testing of other retinal dystrophies. Finally, our protocol enables an early molecular diagnosis for LCA, which is essential with respect to reproductive issues, prognosis and eligibility to gene therapy.

P02.144
New primary mutations in Iranian LHON patients

A. Arastehkani[1], *V. Ghodsinejadkalahroudi*[1], *S. Dadgar*[1], *O. Aryani*[1], *M. Houshmand*[1,2];

[1]*Medical Genetic Dep. Special Medical Center, Tehran, Islamic Republic of Iran,* [2]*National Institute for Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.*

Leber Hereditary Optic Neuropathy (LHON) is a maternally inherited blinding disease caused by missense mutations in the mitochondrial genes that encode subunits of NADH dehydrogenase (complex 1 of respiratory chain), include MT-ND (1-6). It is characterized by bilateral, painless, subacute visual failure that develops during young adult life. Sequence analysis of the all ND genes was performed in 30 Iranian patients with clinical symptoms of LHON. The result showed that 20% only have primary mutations (3460G>A, 11778G>A, 14484T>C) while 17% just present secondary mutations (4216Y>H, 4917N>D,...) ,of which only 6% have both types of mutations. 50% of patients with primary mutations showed 11778G>A while 33% have 3460G>A and 16% present 14484T>C mutation. Also 17% of patients are lack of any mutations and even polymorphisms and finally 46% revealed new homoplasmic mutations (9949V>I, 13802T>I, 3893T>S) which were not reported before and not existed in LHON patients with primary or/ and secondary mutations. Because the mitochondrial genome contains a large number of apparently neutral polymorphisms that have little pathogenic significance, along with secondary homoplasmic mutations that do not have primary disease-causing effect, the pathogenic role of all newly discovered mutations must be rigorously established with familial assay, investigation of nuclear genes and evaluation of other diseases which have common symptoms with LHON . We believed that these new mutation may have primary effect in LHON.

P02.145
Molecular-clinical correlation in a family with a novel heteroplasmic Leigh syndrome missense mutation in the mitochondrial cytochrome c oxidase III gene

E. MKAOUAR-REBAI[1], *I. CHAMKHA*[1], *E. ELLOUZE*[2], *F. KAMMOUN*[2], *C. TRIKI*[2], *F. FAKHFAKH*[1];

[1]*Laboratoire de Genetique Moleculaire Humaine. Faculte de Medecine de Sfax, Sfax, Tunisia,* [2]*2. Service de Neurologie Infantile, C.H.U. Hédi Chaker de Sfax, Sfax, Tunisia.*

The clinical spectrum of mitochondrial disorders is extremely heterogeneous, affecting young and adult patients at any age, with involvement of a wide variety of tissues. More than 100 mitochondrial DNA (mtDNA) mutations have been described in association with different neurological disorders and with respiratory chain deficiency. Besides the most frequently reported mitochondrial tRNA mutations and deletions, pathogenic mutations affecting structural genes of mtDNA-encoded respiratory chain subunits, mainly cytochrome b and cytochrome c oxidase (COX) subunit genes, have been reported in association with various mitochondrial disorders such as Leigh syndrome. Cytochrome c oxidase is an essential component of the mitochondrial respiratory chain that catalyzes the reduction of molecular oxygen by reduced cytochrome c. In this study, the authors report the second mutation associated with Leigh syndrome in the blood and buccal mucosa of 2 affected members of a Tunisian family. It was a novel heteroplasmic missense mitochondrial mutation at nucleotide 9478 in the gene specifying subunit III of cytochrome c oxidase substituting the valine at position 91 to alanine in a highly conserved amino acid. It was found with a high mutant load in tissues derived from endoderm (buccal mucosa) and mesoderm (blood). However, it was nearly absent in tissue derived from ectoderm (hair follicles). It was absent in 120 healthy controls, and PolyPhen analysis showed that the hydropathy index changed from +1.276 to +0.242, and the number of structures of the 3D protein decreased from 39 to 32.

P02.146
Leigh syndrome in two Iranian sisters with mild phenotype with novel missense mutation in SURF1

h. soltani[1], *a. kariminejad*[1], *m. karimi*[1], *a. baradaranfar*[1], *b. bozorgmehr*[1], *m. garshasbi*[1], *h. hu*[2], *a. kuss*[2], *j. hoffer*[2], *h. ropers*[2], *a. tzschach*[2];

[1]*Kariminejad-Najmabadi Path. & Genetics Center, Tehran, Islamic Republic of Iran,* [2]*Max Planck Institute for Molecular Genetics, Human Molecular Genetics, Berlin, Germany.*

Leigh syndrome (LS) is a rare inherited neurometabolic disorder that affects the central nervous system. This rapidly progressive disorder usually occurs in infants while rarely in teenagers and adults. LS is a heterogeneous condition with at least 3major causes , each defferent modes of inheritance; X-linked, autosomal recessive and mitocondrial. SURF1 locus is identified to be affected in LS patients. Insertion/ delition and missense/ nonsense mutations in exons and splicing sites in introns have been detected in LS patients. Missense mutations have been reported to cause mild LS. Symptoms include hypotonia, ataxia, seizures, brain stem and basal ganglia dysfunction, spasticity and ophtalmoplegia. Generalized weakness and episodes of lactic acidosis may also be diagnosed.

We report a novel missense mutation in SURF1 locus (c.679T>C,W227R) in two iranian sisters ages 25 and 27 years old with ataxia (started from 3 years of age), disarthria, short stature and normal cognition. To the best of our knowledge they are the longest survivng LS patients.

P02.147
LMNA mutation in Hutchinson-Gliford progeroid syndrome in association with strokes

L. Gonzalez-Quereda[1], *J. Juan-Mateu*[1], *E. Verdura*[1], *V. Delgadillo*[2], *M. Rodriguez*[1], *M. Pineda*[2], *E. Tizzano*[1], *M. Baiget*[1], *P. Gallano*[1];

[1]*Genetics Dept. Hospital de la Santa Creu i Sant Pau, U-705 CIBERER, Barcelona, Spain,* [2]*Pediatric Neurology Dept. Hospital Sant Joan de Deu, Barcelona, Spain.*

Hutchinson-Gilford progeria syndrome is a very rare but well characterized genetic disorder that causes premature ageing. The clinical features affect growth, skeleton, body fat, skin, hair and the cardiovascular system. It is caused by mutations in *LMNA* gene, the most frequent being p.Gly608Gly (c.1824C>T) in exon 11.

Here we present a four-year-old HGPS patient presenting a heterozygous *LMNA* missense mutation in exon 2. This mutation is located far from the C-terminal region implicated in the posttranslational processing of prelamin A, but it lies within the rod domain of lamin A/C that represents a highly conserved domain specific to nuclear lamins. We hypothesize that this region could be involved in early and severe strokes in HGPS, as those presented by our patient. This is the first report of an HGPS patient with Maghrebian origin.

P02.148
Severe Lysosomal Storage Disease of Liver in del(1)(p36): A New Presentation

M. Haimi[1], *T. Iancu*[2], *L. Shaffer*[3], *A. Lerner*[4];

[1]*Children's Health center, Clalit Health services, Haifa, Israel,* [2]*Pediatric Research and Electron Microscopy Unit, Rappaport Faculty of Medicine ,Technion, Haifa, Israel,* [3]*Signature Genomic Laboratories,, Spokane, WA, United States,* [4]*Pediatric Gastroenterology and Nutrition Unit, Carmel Medical Center, Haifa, Israel.*

1p36 deletion is the most common terminal deletion syndrome with an estimated occurrence of 1:5000 live births. The deletion is of variable size. It usually involves less than 10 Mb in the 1pter-1p36.23 interval. Variability of the phenotype is partially related to the extent of the deletion. Some children with a 1p36 deletion were reported with obesity and hyperphagia, raising the question of possible phenotypic overlap with Prader-Willi syndrome. Correlation between presence of obesity and the size of the deletion has only be documented in one case. We report an 11-year-old girl with 1p36 deletion and the classical dysmorphological features. In late infancy, she developed an uncontrolled voracious appetite, overweight, truncal obesity and elevated serum transaminases. Liver biopsy disclosed severe steatosis. The hepatocytes contained accumulation of lipofuscins. Lipolysosomes were abnormally numerous and extremely enlarged. These features have not been previously reported in 1p36 deletion. Oligonucleotide-based microarray analysis showed a subtelomeric 2.2

Mb deletion at 1p36.33p36.32. This suggests that this chromosome segment is a critical region for obesity and hyperphagia. The accumulation in the liver with abnormal ultrastructure may be an additional feature of this form of syndromal obesity. 1p36 deletion syndrome should be considered in patients with obesity, hyperphagia and liver fat accumulation.

Mabry syndrome (hyperphosphatasia with developmental disability) was first described by Mabry et al. in 1970 a single family (OMIM#239300) [1970]. At first considered rare, our work to describe the disorder has led to recruitment of over twenty families world-wide. Descriptions of this cohort have resulted in the recognition of several other salient features of the disorder including: a characteristic facial dysmorphology (hypertelorism, a broad nasal bridge and a tented mouth); subtle hand bone abnormalities (variable shortening of middle and distal phalanges) and nerve abnormalities (plaques disrupting Schwann cells). Like many infantile metabolic storage disorders, seizures associated with Mabry syndrome have an onset in the first year of life. Persistently elevated serum alkaline phosphatase (ALP) levels are now known to be associated with abnormalities of the phosphoinositol glycan (PIG) anchor, which was found to be disrupted in eight of these families. Lysosomal storage material detected in patients with Mabry syndrome has been putatively identified as glycolipid material. As PIGV mutations have not been identified in all patients with a clinical diagnosis of Mabry syndrome, we describe this cohort. As twenty genes are integral to PIG anchor synthesis, PIGV mutations negative patients or those with vacuolar plaques may result from disruptions to other genes in the PIG anchor biosynthesis pathway. This work will assist in elucidating the inborn errors of metabolism that underlie Mabry syndrome.

P02.150
Identification of an additional putative Brunner syndrome family in Southern Sweden by means of genomic microarray analysis

T. Jonson[1], *M. Bidgoli*[1], *I. Sjöberg*[2], *M. Soller*[1], ***H. Ehrencrona***[1];

[1]*Dept of Clinical Genetics, Lund University, Lund, Sweden,* [2]*Dept of Pediatrics, Lund University Hospital, Lund, Sweden.*

We have identified a Swedish family with a partial deletion of the MAOA gene located on the X-chromosome. MAOA (monoamine oxidase A) is involved in the degradation of neurotransmitters. The detected deletion presumably leads to a complete lack of functional MAOA in male carriers.

The proband in the present study is a 13-year-old boy who was subjected to genomic microarray analysis using the Affymetrix Cytogenetics Whole-Genome 2.7M Array due to a history of behavioral problems including social interaction and slow learning. His intelligence has been classified within normal range, but he has a diagnosis of ADHD with symptoms in line with DAMP (deficit of attention, motor control and perception). He is obese with BMI 33,8. The proband also has a brother with a diagnosis of ADHD.

We detected a 1.2 Mb deletion on Xp11.3-p11.4 in the proband, including the first three exons of the gene MAOA as the only known gene. An identical deletion was detected in the boy's mother. Functional analyses and extended characterization of the family is ongoing.

This study describes the first kindred with an isolated functional abrogation of MAOA since 1993, when Brunner et al. reported a Dutch nondysmorphic kindred with borderline mental retardation, prominent behavioral disturbances and an inactivating point mutation in MAOA. The behavioral problems noted in our proband seems similar to the symptoms in the Dutch kindred. The subjects in the original family were not obese, but other studies have suggested an association between low MAOA activity and increased BMI.

P02.151
Marfan syndrome: role of inflammation in dilatation or dissection of the aorta

R. Zhuraev, *D. Zerbino;*

Lviv National Medical University after Danylo Halytski, Lviv, Ukraine.

Background. The primary cause of early death in untreated Marfan syndrome (MFS) patients is aortic dilatation and dissection. A defective gene causing MFS, FBN1, encodes for an extracellular matrix protein called fibrillin-1, a component of the elastic fiber system. The fibrillin-1 deficient mouse, an accepted model of MFS that recapitulates the cardiovascular phenotype, shows medial degeneration in the aortic wall that was surprisingly associated with inflammatory infiltrates prior to dilatation or dissection.

Methods. We examined 13 patients with MFS after aortic valve-replacing root operations. Full aortic segments and blood samples were collected from patients undergoing repair. Immunohistochemistry staining was performed using antibodies directed against markers of lymphocytes and macrophages.

Results. Immunohistochemisty demonstrated that the media and adventitia had increased numbers of T lymphocytes and macrophages, indicating the role of inflammation in the onset and progression dissection of the aorta. Macrophages were significantly increased in the aortic media with infiltrated aneurysms. CD3+ cells were localized in the media and surrounding the vasa vasorum in the adventitia. Transmural inflammation was associated with increased aortic external diameter, intimal thickening, preserved vascular smooth muscle cell density, and decreased matrix proteins. We found elevated level of TNF-α, IL-2, IL-6, IL-8 in 12 patients.

Conclusions. These results indicate that infiltration of inflammatory cells contributes to the pathogenesis of MFS. Immune mediated aortitis may contribute to pathogenesis of dilatation or dissection of the aorta in MFS formation involve inflammatory infiltrates in the aortic media. Superantigen-driven stimulation of T lymphocytes may contribute to the initial immune response.

McCune-Albright syndrome - Importance of active screening for complications

A. Chirita Emandi[1], *M. Puiu*[2], *I. Micle*[2];

[1]*„Louis Turcanu" Emergency Hospital for Children Timisoara, Timisoara, Romania,* [2]*„Victor Babes" University of Medicine and Pharmacy Timisoara, Timisoara, Romania.*

McCune-Albright syndrome (MAS) is classically defined by the clinical triad of fibrous dysplasia of bone, café-au-lait skin spots, and precocious puberty. MAS is a rare disease with estimated prevalence between 1/100,000 and 1/1,000,000. We present a case of a 9 year old girl who shows deformations of the hand bones, 2 café-au-lait skin spots and development of breast tissue. Her height and weight is normal for age, wihle the bone age is slightly advanced.The endocrinological examination showed elevated prolactin and estrogen, with other hormones in normal range. All other investigations are in normal range. GH (growth hormone) and prolactin excess are common (21%), but the signs and symptoms can be very subtle. Most GH secreting tumors are co-secretors of GH and prolactin, GH excess can worsen craniofacial bone disease and hyperprolactinemia can independently have an adverse affect on gonadal function. Consequently, it becomes important to assess prolactin level and have an oral glucose tolerance test to look for non-suppressible GH at least once, in order to make the diagnosis and treat.

Meier-Gorlin syndrome (MGS) is an autosomal recessive disorder characterized by microtia, patellar aplasia/hypoplasia and short stature. Additional common features encompass a characteristic facial appearance, lung and genitourinary malformations.

Recently, we identified mutations in five genes from the pre-replication complex, crucial in cell cycle progression and growth, in 23/38 (61%) individuals with MGS.

Here, we report on genotype-phenotype studies in this unique cohort (13 females, 10 males; age 3 months - 47 years). The triad of microtia, absent/hypoplastic patellae and short stature was observed in 60% of individuals. Microtia and short stature with normal patellae was seen in 15%; microtia and abnormal patellae without short stature in 15%; short stature only in 10%.

Intrauterine growth retardation was present in 76%, postnatal growth retardation in 86% and microcephaly in 50%. Compound heterozygous or homozygous mutations were detected in *ORC1* (39%), *ORC4* (13%), *ORC6* (13%), *CDT1* (31%) and *CDC6* (4%). Seventeen different mutations were identified: ten missense, three nonsense, two frameshift, two splice-site mutations.

Pre-replication complex mutations appear to be associated with a broader phenotypic spectrum than previously expected. No clear genotype-phenotype association was observed, although compound heterozygous frameshift mutations seem to give rise to a more severe phenotype compared to homozygous mutations, particularly in *ORC1* and *ORC4*. Homozygous missense mutations in *CDC6*, however, resulted in more severely impaired growth than compound heterozygous nonsense mutations in *CDT1*. Further studies in additional individuals are needed to substantiate these observations and to understand the role of the separate genes in normal and disrupted organ development.

P02.154

Audiological caracteristics of syndromic and nonsyndromic patients carrying mtDNA 3243A>G mutation

K. Iwanicka Pronicka[1], *A. Pollak*[1], *A. Skorka*[1,2], *U. Lechowicz*[1], *M. Rzeski*[1], *L. Korniszewski*[1], *R. Ploski*[2];
[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Medical University of Warsaw, Warsaw, Poland.*

Background: Patients harbouring the 3,243A>G mutation in tRNA leucine (UUR) gene (MTTL 1) frequently develop multisystemic disease, however they may present an isolated sensorineural hearing loss (SNHL).

Aim: To compare audiological parameters of syndromic and nonsyndromic patients carrying the 3,243A>G mutation.

Methods: Study group include 32 patients (16 probands) carrying the 3,243A>G mutation. We analysed DNA samples isolated from blood leukocytes, hair follicles, urinary sediments, buccal mucosa and nails of each patient.

Molecular search for the 3,243A>G mutation was performed on RealTime PCR using TaqMan Assay; a heteroplasmy level was assessed using PCR-RFLP analysis.

Results: Among 16 nonsyndromic patients (11 women), aged from 6 to 62 yrs; mean age 19 yrs postlingual, stable SNHL or normal hearing was frequently observed.

17 syndromic patients (10 women) aged from 12 to 75 yrs; mean age 39 yrs mainly present poslingual progressive SNHL or retrocochlear hearing loss. Tinnitus was reported by five, vertigo by six patients.

Maternal inheritance was revealed in all families but one.

Conclusions: Patients with postlingual isolated SNHL demonstrating maternal inheritance require a diagnosis for the 3243A>G mutation. Progressive postlingual SNHL in syndromic patients seems to be a good phenotypic marker of mitochondrial disorder.

P02.155

Evidence of germinal mosaicism associated with *MEN1* gene deletions: implications for genetic counseling

L. Dix[1], *O. Bonny*[2,3], *J. Blouin*[4], *M. Addor*[1], *F. P. Pralong*[5,6], *M. Matter*[7], *J. S. Beckmann*[1,8], *S. Giraud*[9], ***F. Fellmann***[1];
[1]*Service of Medical Genetics, CHUV, Lausanne, Switzerland,* [2]*Department of Internal Medicine, Service of Nephrology,CHUV, Lausanne, Switzerland,* [3]*DPT, UNIL, Lausanne, Switzerland,* [4]*Service of Genetic Medicine, HUG, Genève, Switzerland,* [5]*Service of Endocrinology, Diabetology and Metabolism, CHUV, Lausanne, Switzerland,* [6]*UNIL, Lausanne, Switzerland,* [7]*Department of General Surgery, CHUV, Lausanne, Switzerland,* [8]*Department of Medical Genetics, UNIL, Lausanne, Switzerland,* [9]*Hospices Civils, Lyon, France.*

Multiple endocrine neoplasia type 1 (MEN1) is an autosomal dominant disorder characterized by combinations of more than 20 endocrine and non-endocrine tumours. The penetrance is 95% by age 40 years. Germline *MEN1* mutations are identified in about 85% of individual with familial MEN1 syndrome, large deletions are rare. We report 2 families with MEN1 gene deletions and evidence of germinal mosaicism.

Family 1: MEN1 was diagnosed in a 30-y-o male. Family history was negative. *MEN1* sequence analysis failed to detect any mutation. Few years later, his 54-y-o father was referred for MEN1. Quantitative analysis of *MEN1* in the proband showed a heterozygous deletion of exons 2-10. Father's blood and saliva DNA analysis was repeatedly negative. The mutation was present in tumor sample. Predictive genetic testing in proband's siblings identified one 30-y-o carrier.

Family 2: MEN1 was diagnosed in two adolescent sisters. *MEN1* analysis failed to detect any mutation. Several years later, quantitative analysis of *MEN1* showed a heterozygous deletion of exons 1-6. At that time, family history revealed a paternal uncle was treated for HPT. Genetic analysis showed that he and the asymptomatic 45-y-o father carried the exons 1-6 *MEN1* deletion. QMPSF in their mother sample showed ratio compatible with mosaicism.

MEN1 somatic mutation is assumed in sporadic MEN1 cases with negative blood analysis. To our knowledge, we present the first evidence of germinal mosaicism in MEN1. In both cases, *MEN1* mutations are deletions events, associated with a lower penetrance. This observation raised questions regarding genetic counseling in MEN1 families.

P02.156
Approach to molecular screening in Polish patients with hearing loss

A. Pollak[1], *U. Lechowicz*[1], *M. Mueller-Malesinska*[1], *A. Skorka*[2], *M. Oldak*[3], *G. Kostrzewa*[4], *K. Iwanicka-Pronicka*[1], *L. Korniszewski*[1], *H. Skarzynski*[1], *R. Ploski*[4];
[1]*Institute of Phisiology and Pathology of Hearing, Warsaw, Poland,* [2]*II Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland,* [3]*Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland,* [4]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.*

Background: In European countries, about 2/1000 children suffer from severe congenital or prelingually hearing loss, another 1 / 300 children are born with a minor degree of hearing loss. Causes of hearing loss are complex and in most cases harbor a combination of genetic and environmental factors. It is assumed that approximately 60% of isolated cases of hearing loss are genetic. For this type of hearing loss most often are responsible mutations in GJB2 and GJB6 genes. The optimal diagnostic algorithm for this group of patients can reduce the cost of conducting effective research and genetic counseling.
Aims: The aim of the study was to present an algorithm of molecular investigations in patients with a suspicion of a genetic based hearing loss.
Materials: 6882 DNA samples retrieved from patients suffering from bilateral hearing loss prelingual and postlingual, varying in degree from mild to severe. Only non consanguineous patients (probands) were included for the analysis.
Methods: Mutliplex PCR test for 5 common Polish GJB2 mutations, direct sequencing of coding exon of GJB2 gene, rtPCR test for the presence of IVS1+1G>A mutation, AS-PCR for the detection of GJB6 D13S1830 deletion, real time PCR for the detection of MELAS 3243 A>G mutation.
Results: Molecular analysis, performed step by step, revealed presence of the two pathogenic mutations in a group of 720 among 4103 analyzed probands.
Conclusions: Application of the optimal algorithm of molecular tests can detect the cause of hearing impairment in about 18% of patients.

P02.157
Detection and assessment of mitochondrial DNA heteroplasmy in patients with MELAS disease

U. Lechowicz[1], *A. Pollak*[1], *K. Iwanicka-Pronicka*[1], *A. Skorka*[2], *M. Mueller-Malesinska*[1], *M. Franaszczyk*[3], *H. Skarzynski*[1], *R. Ploski*[3];
[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*II Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland,* [3]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.*

Mitochondrial encephalomyopathy, lactic acidosis and strokelike episodes -MELAS, is one of several mitochondrial diseases. Clinical features also may include: short stature, seizures, episodic vomiting, sensorineural hearing loss and others. Symptom onset can occur protean, also incomplete or milder phenotypes are recognized.
We studied 1478 Polish subject recruited from a consecutive cohort of 7000 treated at the Institute of Physiology and Pathology of Hearing between 2000 and 2010. Patients were unrelated and suffered from nonsyndromic, postlingual, bilateral sensorineural HI ranging from mild to profound. All individuals were previously tested for the presence of common GJB2/GJB6 mutations.
Searching for the mutation A3243G was performed using different molecular techniques (direct sequencing, RealTime TaqMan Assay, PCR-RFLP, dHPLC).
MELAS mutation was found in 15 unrelated patients. Tests were conducted also in their family members, among whom another 13 cases of MELAS were found.
Molecular tests were performed on DNA samples isolated from blood leukocytes, buccal swabs, hair follicles, urine sediment cells and nails. In our group of MELAS patients A3243G mutation ratio is significantly higher in urine than in blood and other type of material. Measurement of A3243G mutation ratio in urine is a non-invasive, convenient and rapid method with its diagnostic meaning superior to blood testing. Direct sequencing might not be sufficiently sensitive method for detecting A3243G mutation.

P02.158
Hereditary palmoplantar keratoderma and hearing loss with mutations in GJB2 gene - A case report

R. Pourová, *M. Malíková, M. Havlovicová, A. Křepelová;*
Dept. of Biology and Medical Genetics, Charles University in Prague, Second Medical Faculty and University Hospital Motol, Prague, Czech Republic.

Mutations in the *GJB2* gene, encoding Connexin-26, are the most common cause of nonsydromic hearing loss with autosomal recessive inheritance (DFNB1), but also cause autosomal dominant hearing loss - isolated (DFNA3) or syndromic (KID, HID, Vohwinkel and Bart-Pumphrey syndromes).
We present a Czech family where 3 members suffer from hearing loss (HL) and palmoplantar keratoderma (PK).
The proband is a 22 year-old boy who presents late-onset epilepsy in addition to HL and PK. Since the first year of age the proband has shown several squamous focuses on his hands, feet, knees, and elbows. The skin lesions are progressive and have been becoming psoriasis-like and ichtyosis-like in character. The HL was verified at the age of 4, with a strong indication that it is congenital. The epilepsy appeared at the age of 12, presenting itself as motoric seizures during sleep, and is well balanced with Valproic Acid monotherapy. There is no pathology on MRI brain scan.
Mother and sister of the proband suffer from HL and PK, but not epilepsy. Proband's father is deaf after early meningitis and has no skin problems. All grandparents are hearing well and without any skin lesions.
We found two *GJB2* gene mutations in our patient - p.Arg75Trp (c.223C>T) and p.Met34Thr (c.101T>C). The first mutation has already been described as a pathogenic dominant mutation; however, the role of the second one still remains unclear. With regards to the low-compliance of the family, all molecular-genetic analysis are not yet completed.
Supported by MZ0FNM2005, IGA NS 9913-4.

P02.159
Contributions about the incidence of hearing-speaking disorders in a population with mental deficiency

I. Tomulescu, *C. Pusta;*
University of Oradea, Oradea, Romania.

Deafness is determined in many cases by genetic causes. For example, it is estimated that one of 1000 children has hereditary deafness. In 50% of cases, is a genetic cause, but is important to mention that in different families can occur diverse types of inheritance. We investigated 596 children interned in Neurology and Psychiatry Clinical Hospital of Oradea between 1999 and 2001 period. The methods utilised were cytogenetic, clinical investigations, somatometrical, statistical, psychiatric investigation and hearing tests, too. There were realised family investigations and were constructed pedigrees. We recorded 50 cases of hearing-speaking disorders in studied population, which means a frequency of 8,39%. Eight cases (16%) of all cases recorded, have no mental deficiency associated. Over 10% of the cases with mental deficiency have hearing-speaking disorders. It were observed increased frequencies in groups with moderate and severe mental deficiency. The frequency of hearing-speaking disorders in group with severe mental deficiency could be more increased because of the young age of children, when they can't cooperate with the person who investigate them. Most of cases proceed from rural area, perhaps because of agglomeration of some mutant genes. We could assume an autosomal recessive or dominant inheritance. Also, we could assume an X-linked inheritance.

P02.160
Study about the incidence of the congenital bony abnormalities in a population with mental deficiency

C. Pusta, *I. Tomulescu;*
University of Oradea, Oradea, Romania.

It is known that genetic disorders cause mental disorders and malformative disorders, including bony abnormalities.The most frequent congenital bony disorders observed in the studied population are: congenital hip sprain, club foot, flat foot and vertebral column abnormalities. We investigated 596 children interned in Neurology and Psychiatry Clinical Hospital of Oradea between 1999 and 2001 period. In 596 children, 393 associated different levels of mental deficiency.

The methods utilised were cytogenetic, clinical, statistical, psychiatric investigation and were constructed pedigrees. We reported 81 cases of congenital bony disorders. In this total, 55 cases (67,9%) associated mental deficiency. In general, the frequency in rural has a meaningful increase than in urban. In studied population, 13 cases associated mild mental deficiency, 10 cases associated moderate level of mental retardation and 32 cases associated severe mental deficiency. Most of cases proceed from rural area. The most often is observed the congenital vertebral column disorders. The frequency is meaningfully increased in children group with severe mental deficiency. This result can be explained because of the existence of congenital bony abnormalities, such as common traits in chromosomal syndromes or other syndromes which cause plurimalformative phenotypes associated with mental deficiency.Cranial and facial dysmorphism has a frequency of 13%. This frequency is increased in the group of severe mental deficiency. These abnormalities could be caused by some genetic disorders which cause bony abnormalities, too. The explanation of these frequencies is the presence in the children group with associated mental deficiency of many genetic disorders which could cause congenital abnormalities.

aCGH has significantly improved the ability to identify cryptic chromosome rearrangements in patients with MR/MCA, dysmorphism, and behavioral abnormalities. We report on a 17-year-old patient with a Smith-Magenis syndrome-like phenotype, including mild intellectual impairment, hyperactivity, aggressiveness, and self-destructive behavior. Sleep disturbances and nocturnal cry have been noted from childhood. After an episode of seizures at 10 years, antiepileptic treatment was successfully initiated. No mutation or exonic deletion were found in RAI1. Using a clinical oligonucleotide aCGH, we have identified a unique ~ 317 kb hemizygous deletion at chromosome 10q24.32 harboring seven genes, including transcription factor PITX3 that is known to regulate the development of midbrain dopamine (DA) neurons together with other transcription factors. Pitx3-/- mice have a selective loss of dopaminergic neurons in the substantia nigra, leading to the significantly reduced DA levels in the nigrostriatal pathway and manifest anomalous striatum-dependent cognitive impairment and abnormal lens development. Heterozygous missense mutations in PITX3 have been reported in patients with dominant congenital cataract and anterior segment mesenchymal dysgenesis. Interestingly, no eye anomalies were found in our patient and analysis of neurotransmitters in his cerebrospinal fluid revealed undetectable level of L-DOPA and significantly decreased levels of catecholamine metabolites. Based on our data and the results of the experiments with dopamine agonists in the Pitx3 deficient mice, we suggest that the abnormal neurobehavioral phenotype in our patient, likely resulting from the decreased levels of dopamine, could be mitigated with tetrahydrobiopterin and/or L-DOPA.

P02.162
Detection of deletions and duplications that cause mental retardation by whole genome array CGH

D. Sunnetci[1], *N. Cine*[1], *B. Kara*[2], *S. Eren*[1], *B. Enguzel*[1], *H. Savli*[1];

[1]*Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey,* [2]*Department of Child Health and Diseases, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.*

Introduction: Mental retardation is one of the most common developmental disorder and its prevelance is known as %1-3 percentage of population. In the majority of mentally retarded individuals a specific cause can not be identified. Aim of this study was determining chromosomal aberrations in patients with mental retardation by scanning whole genome.

Materials and Methods: Peripheral blood samples were collected from 52 individuals between the ages of 0-18 with mental retardation regardless of gender. Genetic deletions/duplications were detected on DNA level using array-CGH method. Isolated gDNAs from peripheral blood samples were hybridized on CytoSure Syndrome Plus(v2) Microarray 4x44K microchips. Obtained data were analyzed using CytoSure Analysis Software v.2.0.8.

Results: Deletions and duplications with various sizes were detected in various regions of the genome on 38(73%) patients. No deletions/duplications were found on 14(27%) patients. Deletions/duplications with different sizes were found in different parts of the genome on 7(70%) of non-syndromic mental retardation patients, 22 (78.6%) of patients with mental retardation associated with dysmorphic findings, (87.5%) of patients with mental retardation accompanied by epilepsy and 2(33.3%) of patients with mental retardation associated with epilepsy and dysmorphism.

Conclusion: The diagnostic yield of array CGH in general population of individuals with mental retardation is at least twice as high as that of standart GTG-banded karyotyping and fluorescence in situ hybridization (FISH) in terms of high resolution. The limited ability to differentiate between inherited copy number variations (CNV) which cause abnormal phenotypes and rare variants unrelated to clinical alterations currently constitutes a limitation for guiding genetic counselling.

P02.163
Investigation of microdeletion syndromes by MLPA in Iranian patients with Mental Retardation

H. Loghmani Khouzani, *A. Kariminejad, R. Kariminejad, H. Imanian, H. Najmabadi;*

Kariminejad - Najmabadi Pathology & Genetic center, Tehran, Islamic Republic of Iran.

Mental Retardation (MR), defined as a state of developmental deficit, results in significant limitation of intellect and poor adaptation behavior. Karyotyping is a usual method for primary screening of MR patients, however, detection of small duplications and deletions require a more sensitive technique. Because of the large number of known genes involved in MR, mutation screening in all of them is not a feasible and cost effective approach. Multiplex Ligation-dependent Probe Amplification (MLPA) has the ability of relative quantification of several target DNA sequence in a single reaction by using specific probes for each target.

During the last year a total of 71 patients with dysmorphism and MR have been referred to us. Initially, all patients were clinically evaluated and karyotype analyses were performed. All of the patients had normal karyotypes. By using MLPA method, we investigated duplications and deletions for 21 different microdeletion syndromes by MRC-Holland kit. We identified 10 (~14%) aberrations as follow (table):

Syndrome	Williams	Miller-Dieker	Sotos	DiGeorge	Angelman	Others
Chromosomal region	7q11.23/ del	17p13.3/ del	5q35.3 / del	22q11.21/ del	15q12/ del	4p16.3/ dup
No. of Probes	3	2	2	3	4	2
No. of patients detected	3	3	1	1	1	1

Our MLPA results indicate a high degree of concordance between the clinical data, and the genotype. We suggest MLPA as a first screening method for patients suffering from MR with normal karyotypes. In the case, in which clinical findings was not completely compatible with the microdeletion syndrome detected by MLPA, array CGH was performed revealing a larger duplication/deletion in the critical region.

Key words: Mental Retardation, MLPA, Iran

Objective: To compare the spectrum of congenital anomalies (CA) and minor anomalies (MA) between mentally retarded/developmentally delayed (MR/DD) patients with clinically significant CNVs and MR/DD patients with normal molecular karyotyping results.
Methods: Molecular karyotyping using oligo arrayCGH and SNP microarrays was performed on 114 MR/DD patients with/without CA and dysmorphic features. Based on the molecular karyotyping results, patients were divided into two groups. Group A consisted of patients with clinically significant CNVs (N=16) while group B consisted of patients with normal molecular karyotyping results (N=98). CA and MA were coded using Eurocat Malformation coding guides.
Results and Discussion: CNS congenital anomalies occurred more often in group A versus group B (31% versus 11%, *P*=0.048). No significant differences were found between these two groups when analyzing the rate of CA in the organ systems included in other blocks of the XVII chapter (ICD-10 classification, Q00-Q99). Interestingly, patients with chromosomal rearrangements (group A) were more likely to have at least one MA (*P*=0.02) and had a significantly higher frequency of eye, ear, face and neck MA (Q10-Q18) compared to patients from group B (68.8% versus 38.8%, *P*=0.04). The increased rate of CA in the CNS and MA of the eye, ear, face and neck in MR/DD patients with clinically significant CNVs provides useful information for counseling and may aid in the identification of submicroscopic chromosomal rearrangements in other patients.
This research was funded by the European Union 7th Framework Programme [FP7/2007-2013] as part of the CHERISH project (www.cherishproject.eu, grant agreement n°223692).

P02.165
Clinical and molecular characterization of two cases with rare chromosomal microduplications

R. V. Vazharova[1], *I. M. Bradinova*[1], *S. Bichev*[1], *A. Savov*[1], *V. Bojinova*[2], *E. Simeonov*[3], *I. Kremensky*[1];
[1]*National genetic Laboratory, Sofia, Bulgaria,* [2]*USBALNP "Saint Naum", Sofia, Bulgaria,* [3]*University Hospital "Alexandrovska", Sofia, Bulgaria.*

After introduction of methods for molecular karyotiping many new microdeletions/ microduplications were characterized and their association with specific phenotypes recognized. We report two patients with chromosome duplications involving regions associated with common microdeletion syndromes. Among 90 patients affected with mental retardation (MR) / developmental delay (DD) screened by MLPA for common microdeletion syndroms and subtelomeric rearrangements two were found to carry small duplications - at 3q29 and 10p15 respectively. Both patients are ascertained because of MR and dysmorphism of unknown etiology. Both cases are sporadic. At age of 13 years patient with 3q29 duplication presents mild MR, microcephaly and dysmorphism. Patient with duplication of 10p15 was refereed to our department at age of 18 months because of DD and epilepsy. After initial cytogenetic and metabolic investigations MLPA was performed using consecutively kits P245, P70 and P36 (MRC Holland). Duplications were detected with at least two of the used kits. Chromosomal rearrangements were further characterized using arrayCGH. Phenotypes of our patients share similarities with cases reported recently by other investigators.
Contiguous gene syndromes involving small chromosome microduplications are typically less frequently reported than their microdeletions counterparts. Although these rearrangements can arise from a common mechanism involving nonallelic homologous recombination, microduplication syndroms are usually less commonly recognized, possibly due to their milder and more variable phenotype and technical limitations of routine cytogenetics. Methods for molecular karyotiping are invaluable in clarifying the etiology of MR/DD and the approach of "reverse phenotypics" broadens our understanding of human genome architecture and functioning.

P02.166
Fryns mesomelic dysplasia: a new familial case

A. Toutain[1,2,3], *B. de Courtivron*[4], *C. Bonnard*[4,2];
[1]*Service de Génétique, Centre Hospitalo-Universitaire, Tours, France,* [2]*Université François Rabelais, Tours, France,* [3]*INSERM U930, Tours, France,* [4]*Service de Chirurgie Orthopédique Pédiatrique, Centre Hospitalo-Universitaire, Tours, France.*

Mesomelic dysplasias are a heterogeneous group of inherited skeletal dysplasias among which Leri-Weill dyschondrosteosis caused by SHOX haploinsufficiency and its homozygous form, Langer mesomelic dysplasia, are the most frequent and best known. In addition to Kantaputra dysplasia, an autosomal dominant form caused by duplications of the *HOXD* locus on chromosome 2q, various unclassified forms of unknown cause, mostly with a unique phenotype in single families, have been reported. In these observations, mesomelic dysplasia of the upper limbs was associated with involvement of the lower limbs and in most cases with other skeletal problems. However, in 1988, Fryns et *al.*, described a female patient and her father presenting with bilateral mesomelic dysplasia of the upper limbs without any other features. In 2005, Mégarbané et *al.* reported a similar clinical picture in a boy whose father, interestingly, had unilateral involvement. In both families, the patients had severe developmental abnormality of the ulna, which was extremely short and thick, associated with marked radial bowing, and resulting in a severely shortened and angulated forearm with ulnar deviation of the hand but with no Madelung deformity. The tibiae and fibulae were completely normal and the patients had normal stature.
We report a female patient and her similarly affected father who have exactly the same phenotype with mesomelic dysplasia confined to the upper limbs. This new family adds further arguments to the existence of a separate condition, probably autosomal dominant, consisting of mesomelic dysplasia of the upper limbs as the unique feature.

P02.167
New recessive syndrome of microcephaly, cerebellar hypoplasia, and congenital heart conduction defect

M. S. Zaki[1], *G. M. H. Abdel Salam*[1], *S. N. Saleem*[2], *W. B. Dobyns*[3], *M. Y. Issa*[1], *S. Sattar*[4], *J. G. Gleeson*[5];
[1]*Clinical Genetics Department, National Research Centre, Dokki, Cairo, Egypt,* [2]*Radiology Department, Cairo University, Cairo, Egypt,* [3]*Clinical Genetics Department, National Research Centre, Seattle, WA, United States,* [4]*Clinical Genetics Department, National Research CentreNeurogenetics Laboratory, Howard Hughes Medical Institute, Department of Neurosciences, University of California, San Diego, CA, United States,* [5]*Neurogenetics Laboratory, Howard Hughes Medical Institute, Department of Neurosciences, University of California, San Diego, CA, United States.*

We identified a two-branch consanguineous family in which 4 affected members (3 females and one male) presented with constitutive growth delay, severe psychomotor retardation, microcephaly, cerebellar hypoplasia, and second degree heart block. They also shared distinct facial features and similar appearance of their hands and feet. Childhood-onset insulin-dependent diabetes mellitus developed in one affected child around the age of 9. Molecular analysis excluded mutations in *PTF1A* locus and *EIF2AK3* gene being pathogenetics for insulin-dependent diabetes mellitus with cerebellar agenesis or microcephaly, respectively. To our knowledge, this phenotype does not meet diagnostic criteria of any known condition, and thus suggests a unique clinical entity of autosomal recessive mode of inheritance.
Key Words:
Microcephaly, insulin-dependent diabetes, cerebellar hypoplasia, mental retardation, heart block

P02.168
Septo-optic dysplasia: a new manifestation of microdeletion 22q11.2?

L. Gwanmesia[1], *S. Gimelli*[1], *S. E. Antonarakis*[1,2], *A. Bottani*[1], *F. Béna*[1];
[1]*Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland,* [2]*Department of Genetic Medicine and Development, University of*

Geneva Medical School, Geneva, Switzerland.

22q11.2 microdeletion is a well known entity affecting potentially almost any organ and with more than 180 signs described. We report a female patient with a seemingly new manifestation, namely septo-optic dysplasia.

She was seen for genetic counseling at the age of 24 years because of mental handicap, short stature and visual impairment. Pregnancy and delivery were uneventful. Birth growth parameters were at P90. Nystagmus was present since birth and severe amblyopia diagnosed in infancy. Motor development was delayed, with walking at 5 years. Puberty was uneventful with menarche at 12 years and regular menstrual cycles. Complete growth hormone deficiency was diagnosed at 20 years and brain MRI showed septo-optic dysplasia with agenesis of the anterior pituitary. At examination, the patient was overanxious and talkative. Height was 139 cm (-4.4 SD), weight 44 kg (-1.5 SD) and OFC 52 cm (-2.5 SD). Erratic nystagmus, divergent left strabismus, broad neck and slender fingers were noted.

As the phenotype was not evocative of a known syndrome, array-CGH (Agilent 244k) was performed and showed, surprisingly, a classical 3 Mb *de novo* heterozygous 22q11.22 microdeletion, confirmed by FISH. To the best of our knowledge, septo-optic dysplasia has not been previously reported in microdeletion 22q11.2. Whether this is a new and rare finding associated with this deletion or the chance occurrence of two separate conditions (a frequent deletion on the one hand, and, on the other hand, a mutation in a gene such as *HESX1* causing in itself the dysplasia) cannot be answered at present.

P02.169

Subtelomeric study of the patients with developmental delay, dysmorphy and/or congenital anomalies of unexplained etiology

N. Maksimovic[1], *T. Damnjanovic*[1], *G. Cuturilo*[2], *V. Kostic*[3], *V. Dobricic*[3], *T. Varljen*[4], *B. Jekic*[1], *L. Lukovic*[1], *I. Novakovic*[1];

[1]*Institute of Human Genetics, School of Medicine, Belgrade, Serbia,* [2]*University Children's Hospital, Belgrade, Serbia,* [3]*Institute of Neurology, Clinical Center of Serbia, Belgrade, Serbia,* [4]*Institute of Legal Medicine, Belgrade, Serbia.*

Submicrosopic chromosomal rearrangements involving the subtelomeric regions are considered to be a significant cause of idiopathic mental retardations (MR). Their prevalence is about 5.2%, depending on the preselection criteria. Because of the small size of involved segments, these aberrations are undetectable by conventional banding techniques. Subtelomeric regions can be screened by multiplex ligation-dependent probe amplification (MLPA). We have studied a series of 60 unrelated patients with MR and normal results of GTG-banded chromosomes. Subtelomeric assays using MLPA with SALSA P036-E1 and P070-B1 kits were performed.

The MLPA screening revealed subtelomeric chromosome aberrations in three cases(5%).

Case 1: A 3- year-old girl, born from healthy unrelated parents, with growth retardation, facial dysmorphism, microcephaly, syndactily, tumor hepatis and severe mental retardation. Deletion of 1p and duplication 12q has been detected.

Case 2: A 28- month-old girl, born from healthy unrelated parents, with severe growth retardation of prenatal onset, mental retardation, mild facial dysmorphism, epilepsy and hemiparesis. Deletion of 4p has been detected.

Case 3: A 28- month-old girl, born from healthy unrelated parents, with craniostenosis, facial dysmorphism, microcephaly and moderate mental retardation. Deletion of 9p and duplication of 15q have been detected.

Parents of the patients with disclosed subtelomeric aberrations were also tested in order to clarify the origin of aberrations. In all cases de novo origin was confirmed.

These results demonstrated that MLPA may be very useful tool in order to approach genetic diagnosis of mentally retarded patients.

Clinical characteristics of patients are not always related to specific syndromes. Array comparative genomic hybridisation (aCGH) is used to detect small copy number changes within the genome that are not always visible by conventional karyotyping. We analysed with aCGH (Agilent 244K & 4x140K), 253 patients with various degrees of MR, DD, dysmorphic features and/or single or multiple congenital abnormalities, normal previous conventional karyotype and negative genetic tests (FRAX, RETT, single FISH or metabolic screens). Clinically significant submicroscopic imbalances were detected in 92 (~30%) patients. The high percentage of positive patients is probably due to the strict criteria of patient selection. Some patients presented with more than one aberration relevant to their phenotype. A total of eleven aberrations were detected on the X chromosome regarding

genes related to MR/ DD. Array CGH has proven a powerful tool for the identification of novel chromosomal syndromes, for more accurate prognosis and phenotype-genotype correlations.

P02.171
A novel deletion at 3q13.31-22.1 causes dysmorphia and multiple congenital malformations.

A. Materna-Kiryluk[1,2,3], *S. Sanna-Cherchi*[4], *K. Burgess*[4], *K. Kiryluk*[4], *A. G. Gharavi*[4];

[1]*Departments of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland,* [2]*Polish Registry of Congenital Malformations (PRCM), Poznan, Poland,* [3]*Center for Medical Genetics GENESIS, Poznan, Poland,* [4]*Division of Nephrology, Department of Medicine, Columbia University, New York, NY, United States.*

We describe a 14-year-old Polish girl with dysmorphic features and multiple congenital malformations, who carries de novo heterozygous deletion of 15Mb at 3q13.31-22. The child's clinical presentation included mental retardation, epilepsy, myopia, hypothyroidism, and hypotonia. The dysmorphic features included: macrostomia, narrow left palpebral fissure, right auricular tags, short stature, scoliosis, contraction of the left forearm and left hand phalangeal hypoplasia, absent radial bones, hypoplastic thumbs, left clubfoot varus, and prominent clitoris. Moreover, the child demonstrated the following congenital malformations: right renal agenesis, grade IV left vesicoureteral reflux, left thyroid lobe aplasia, patent ductus arteriosus, and hypoplasia of corpus callosum. The karyotype was 46XX. We performed a genome-wide analysis of copy number variants using the Illumina 610-Quad array. We identified a large deletion of 14,960,554 bp at the 3q13.31-22.1 locus that was absent in public databases and >15,000 controls. The deletion was confirmed by qPCR and SNP genotyping, and was absent in both parents, indicating a de novo event. These data provide strong support for pathogenicity.

P02.172
Autosomal dominant natal teeth with selective tooth agenesis

J. M. Graham[1], *N. Kramer*[1], *V. Funari*[1], *O. Klein*[2], *K. Seidel*[2], *P. Kantaputra*[3], *K. Taylor*[1];

[1]*Cedars Sinai Medical Center, Los Angeles, CA, United States,* [2]*University of California, San Francisco, CA, United States,* [3]*Chiang Mai University, Chiang Mai, Thailand.*

We report a 5-generation family with multiple natal teeth and selective tooth agenesis segregating in an autosomal dominant fashion. Natal teeth are usually a sporadic isolated finding in an otherwise normal infant, and familial occurrence is uncommon. Selective tooth agenesis is usually genetic and not associated with natal teeth. In affected persons in the family we report, at least 6-8 natal teeth are usually present at birth, and this is followed by selective tooth agenesis that results in absence of as many as 16 permanent teeth. Natal teeth with hypodontia occurs in some ectodermal dysplasia syndromes. In the family we report, natal teeth with selective tooth agenesis did not include ectodermal dysplasia or any other problem. DNA from 28 family members was analyzed on the Illumina OMNI-express chip using 733,120 SNPs and mapped to an approximately 2Mb segment on chromosome 1q36.11 with LOD score 2.97 at 23.8 Mb to 25.8 MB (GRCh37/hg19; MERLIN). By dividing the pedigree into three 3-generation families, a region of association was found located between LOC284632 and GRHL3 (parenTDT, p=0.005 for rs11249039, rs11249045, or rs7526505). GRHL3 is a gene expressed exclusively in surface ectoderm in drosophila, where it plays an essential role in cuticle formation. Expression of the murine Grhl3 gene is evident in ectodermally derived tissues, including the oral epithelium. We speculate that variation in the regulation of this gene may play a role in the phenotype we describe in this family.

P02.173
Nemaline myopathy caused by mutations in the nebulin gene may present as a distal myopathy

V. Lehtokari[1], *K. Pelin*[2], *A. Herczegfalvi*[3], *V. Karcagi*[4], *J. Pouget*[5], *J. Franques*[5], *J. F. Pellissier*[6], *D. Figarella-Branger*[6], *M. von der Hagen*[7], *A. Huebner*[7], *B. Schoser*[8], *H. Lochmüller*[9], *C. Wallgren-Pettersson*[1];

[1]*The Folkhälsan Institute of Genetics and University of Helsinki, Helsinki, Finland,* [2]*Department of Biosciences, Division of Genetics, University of Helsinki, Helsinki, Finland,* [3]*Department of Paediatric Neurology, Heim Pal Hospital, Budapest, Hungary,* [4]*Department of Molecular Genetics and Diagnostics, NIEH, Budapest, Hungary,* [5]*Reference centre of neuromuscular pathologies and ALS, Hôpital La Timone, Marseille, France,* [6]*Service d'Anatomie Pathologique et de Neuropathologie, Hôpital La Timone, Marseille, France,* [7]*University Children's Hospital, Technical University Dresden, Dresden, Germany,* [8]*Friedrich-Baur-Institut, Department of Neurology, Ludwig Maximilians University, Munich, Germany,* [9]*Institute of Human Genetics, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Congenital myopathies are a group of disorders characterised by muscle weakness due to abnormalities in muscle fibres, disturbing their normal function. The muscle biopsy usually also shows abnormal structures, such as protein aggregates. Mutations in the nebulin gene (*NEB*) are the main cause of autosomal recessive nemaline myopathy (NM), with clinical presentations ranging from mild to severe proximal muscle weakness and protein aggregates, nemaline bodies, seen in the muscle fibres. At present over 130 NM-causing *NEB* mutations have been identified in more than 110 families. In addition to mutations causing NM, compound heterozygous mutations in *NEB* have been identified causing core-rod myopathy (CRM) in one patient, and homozygous missense mutations in *NEB* causing distal myopathy with no or almost no nemaline bodies in four different Finnish families. It was concluded that perhaps the presence of two missense mutations in *NEB* would lead to distal myopathy, while more disruptive compound heterozygous mutations would cause NM or CRM. Recently, however, we have identified four different compound heterozygous *NEB* mutations, only one of which is a missense mutation, in three non-Finnish patients in two unrelated families with distal myopathy and nemaline bodies in their muscle biopies. One of the mutations has previously been identified in one family with the severe form of NM. We conclude that NM and distal myopathy caused by *NEB* mutations form a clinical and histological continuum. NM should be considered as a differential diagnosis in patients presenting with an early-onset, predominantly distal myopathy.

P02.174
Molecular investigation of neonatal hypotonia : 27 floppy infants

D. H'mida, *I. Fekih, S. Trabelsi, S. Sassi, A. Msakni, M. Gribaa, S. Mougou, A. Saad;*

Unit of Cytogenetic, Biology of Reproduction and Molecular Genetic, SOUSSE, Tunisia.

The neonatal hypotonia is the call sign of many diseases of the newborn and infant. Taking into account the diseases covered by a molecular diagnosis certainty and with neonatal hypotonia as a major clinical sign, we are interested in three neurological disorders: Prader Willi Syndrome (PWS), spinal muscular atrophy type I (AMSI), and myotonic dystrophy type 1 (DM1).

The aim of our work is to establish a molecular diagnosis strategy of neonatal hypotonia with neurological origin (SPW, AMSI, and DM1).

Our study was performed in 27 newborns referred to our laboratory for neonatal hypotonia. We carried the diagnosis of PWS by both MS-MLPA techniques and TP-PCR, for AMSI we have deployed the technique of PCR-RFLP, for the DM1, both techniques of TP-PCR and QMPSF were used. Patients without clinical suspicion of predilection were investigated with all these techniques.

The PWS diagnosis was confirmed in only one patient. Among 17 patients with AMSI suspicion this diagnosis was confirmed for only 7. For the remaining 19 patients none of the 3 molecular diagnostics (AMSI, DM1 and SPW) could be confirmed and etiology of neonatal hypotonia is to unveil.

Our work provides clinicians a strategy for the diagnosis of neonatal hypotonia. However this strategy remains incomplete and a multitude of other etiologies will have to be explored.

P02.175
Nijmegen breakage syndrome in siblings with atypical cardiac involvement

G. Doros[1], *M. Gafencu*[1], *A. Popoiu*[1], *M. Bataneant*[1], *A. But*[2], *A. Botiz*[2], *M. Puiu*[1];

[1]*III rd Pediatric Clinic, University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Louis Turcanu - Emergency Children Hospital, Timisoara, Romania.*

Background: Nijmegen breakage syndrome (NBS) is a rare autosomal recessive congenital disorder, caused by a mutation in the *NBS* gene, located on chromosome 8q21.

Aim: To present two siblings with NBS, a boy 8 yrs old and a girl 3

yrs old, detected because of progressive microcephaly and recurrent sino-pulmonary infections. The boy was born with a severe cyanotic congenital heart defect (CHD).
Material and methods: We performed clinical, cardiology, neurology, ultrasound and genetic examination on both patients, followed by complex laboratory investigations.
Results: The patients have a distinctive facial appearance, microcephaly, short stature, recurrent infections and multiple splenic tumours. The sister also has convergent strabismus of the right eye, right palpebral ptosis, areas of skin hypopigmentation, and severe IgA immunodeficiency. She was treated with intravenous immunoglobulin. The boy has CHD with double outlet right ventricle, ventricular septal defect, inefficient pulmonary artery banding, severe pulmonary artery hypertension, NYHA III cardiac failure, cachexia, severe thrombocytopenia, severe motor delay, low mental retardation, and cellular immunodeficiency. A paravertebral T8-T9 tumour was detected in the boy. He was treated for heart failure. Thrombocytopenia is a contraindication for treatment of pulmonary arterial hypertension. Splenic tumours and paravetebral tumour have to be investigated. Genetic tests are in progress for both, looking for mutation, and colony survival assay. Parents have Slavic origin.
Conclusions: NBS is rare in siblings and needs to be diagnosed because of immunodeficiency that has to be treated, because of radiation sensitivity, which means radiation exposure must be avoided, and a strong predisposition to lymphoid malignancy, which has to be sought. CHD is a particular association.

P02.176
NIPBL gene mutation analyses among 70 Polish CdLS patients

J. Limon[1], *A. Kuzniacka*[1], *J. Wierzba*[2], *M. Malinowska*[1], *M. Ratajska*[1], *M. Brzeskwiniewicz*[1];
[1]*Department of Biology and Genetics, Medical University of Gdansk, Gdansk, Poland,* [2]*Department of Paediatrics, Medical University of Gdansk, Gdansk, Poland.*

Cornelia de Lange Syndrome (CdLS) (MIM 122470) is a rare dominantly inherited multisystem disorder, characterised by a typical but variable phenotype, which includes developmental delay, characteristic facial features, pre- and post-natal growth retardation and limb abnormalities. About 50-60% of cases of CdLS are caused by mutations in one of three genes, mainly in a regulator of cohesion - NIPBL, and less frequently in two building the cohesin ring - SMC1 and SMC3. Cohesin is involved in control chromosome segregation during cell divisions and also in double strand break repair and/or transcriptional regulation. We screened 32 patients with the CdLS classical phenotype and 38 with mild phenotype for NIPBL point mutations, using a combination of denaturing high-performance liquid chromatography and direct sequencing. We identified 26 different NIPBL sequence variants. Eight of them were frame shift (exclusively present in the classical type), 15 were missense and three splice mutations resulting in exon skipping. Moreover, within the group of patients without identifiable point mutations, we performed an MLPA analysis and detected two heterozygous deletions of the entire NIPBL gene, confirmed by aCGH. In our group, NIPBL point mutations account for 37% of CdLS patients. Large rearrangements were detected only twice, which explains only 7% of all detected mutations. These findings are in agreement with other published data.

P02.177
The phenotypic variability in Noonan syndrome - Clinical consideration on two new cases diagnosed in neonatal period

E. V. Gorduza[1], *M. Stamatin*[1], *L. I. Butnariu*[2], *S. Ghironte*[3], *A. Petrariu*[3], *M. Volosciuc*[4], *E. E. Braha*[2], *G. Iliev*[3], *L. Caba*[1], *R. Popescu*[1], *M. Panzaru*[1], *C. Rusu*[1];
[1]*University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania,* [2]*University of Medicine and Pharmacy, Iasi, Romania,* [3]*"Cuza Voda" Obstetrical Hospital, Iasi, Romania,* [4]*"Sf. Maria" Children Hospital, Iasi, Romania.*

Noonan Syndrome (NS) is a common autosomal dominant disorder that affects both sexes. The main features are congenital heart defect, short stature, learning problems, pectus excavatum, impaired blood clotting, webbed neck, and a facial dysmorphism. The incidence is 1/1,000- 1/2,500 newborn. The range and severity of features can vary greatly in patients with NS, and thus the diagnosis is often delayed. We present two cases of NS in newborns with clinical features that attest the phenotypic variability of disease. Case 1: girl, born at term, APGAR 7, first child of an apparently healthy couple; clinical examination: dysmorphic face with: hypertelorism, down-slanting eyes, small and upturned nose, low set and backward rotated ears, short and webbed neck, muscular hypotonia, without any type of cardiac problems. The clinical examination of the mother indicated a phenotype of NS with short stature, mild mental retardation, short and webbed neck, facial dysmorphism, without cardiac problems. Case 2: girl, born premature at 35 weeks, APGAR 5, after a pregnancy complicated with polyhidramnios detected at 22 weeks, 2nd children of a healthy couple; clinical examination: generalized lymphoedema, dysmorphic face with hypertelorism, small and upturned nose, short palpebral fissures, short and webbed neck, thoracic hypoplasia, and cardiac anomalies: pulmonary valvular stenosis, and ventricular septal defect, hepatomegalia. Unfortunately, the girl dies at 2 days after delivery. In both cases the karyotype was normal: 46,XX and we have not had the opportunity for molecular diagnosis. Our cases confirm the phenotypic variability in NS and the importance of clinical examination.

P02.178
A patient with hyperactivity, speech delay and dysmorphic features associated with a deletion of the *NRXN1* gene at 2p16.3 and a 10q22.3q23.1 duplication

K. Konska[1], *G. Annerén*[1,2], *M. Ingstedt*[3], *A. Thuresson*[1];
[1]*Clinical Genetics, Uppsala University Children's Hospital, Uppsala, Sweden,* [2]*Dept of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [3]*Dept of Paediatrics, Västerås Medical Centre Hospital, Västerås, Sweden.*

We report on a 7 years old boy with hyperactivity, concentration difficulties, speech delay and discrete dysmorphic features. The patient is the third child to non-consanguineous parents. A sister is healthy and a twin brother has suspected attention deficit disorder (ADD). The mother has a family history of ADD, autism spectrum disorder and mild mental retardation.
Micro-array analysis of the proband revealed a 174 kb deletion at 2p16.3 inherited from the healthy father and a 508 kb duplication at 10q22.3q23.1 inherited from the mother. The deletion comprises the *NRXN1* gene but no other coding sequences. *NRXN1* has previously been associated with autism spectrum disorders and the deletion can, in part, explain the neuropsychiatric features of the boy. Furthermore *NRXN1* gene variants may segregate with a reduced penetrance[1] explaining the inheritance from a healthy father. The maternal family history and the complex phenotype in the boy, including dysmorphisms, made us also consider the maternally inherited duplication. The duplication spans 5 genes; *ANXA1, CTSLL6, MAT1A, PLAC9* and *SFTPD*. The gene product of *ANXA1* has been implemented as a central player in the anti-inflammatory and neuroprotective role of microglia[2]. *MAT1A* is the only gene that is sensitive to haplo-insufficiency and MAT deficiency can lead to neurological abnormalities, including brain demyelination[3]. Studies are ongoing to further investigate the phenotype of the proband and the genotypes of additional family members.

P02.179
A 10.46 Mb 12p11.1-12.1 interstitial deletion coincident with a 0.19 Mb *NRXN1* deletion detected by array CGH in a girl with scoliosis and autism

Y. Soysal[1], *J. Vermeesch*[2], *N. Ardeshir Davani*[2], *K. Hekimler*[1], *N. İmirzalıoğlu*[1];
[1]*Afyon Kocatepe University, Afyonkarahisar, Turkey,* [2]*Center for Human Genetics, University Hospital, Catholic University of Leuven, Leuven, Belgium.*

We present a 12-year-old girl with de novo karyotype 46,XX,del(12)(p11.1p12.1). Array CGH revealed in addition to a 10.466 Mb interstitial deletion on 12p11.1→12p12.1 a 0.191 Mb deletion on 2p16.3. The girl presented with mild facial dysmorphism consisting of microcephaly, hypertelorism, downslanting palpebral fissures, strabismus, broad nasal base, bulbous nose, short philtrum, micro/retrognathia, irregular tooth arrangement, phalangeal deformity in distal phalanges of hands, 5th finger camptodactyly, brachydactyly in feet, history of joint hypermobility and scoliosis. She was considered to have mild to moderate mental retardation and ascertained for an autism spectrum disorder. Interstitial deletions of short arm of chromosome 12 are rarely reported whereas point mutations and deletions of *NRXN1* which is located on chromosome 2p16.3 are associated with autism spectrum

disorders. In this article we present and discuss the phenotypic consequences of a patient who was effected by deletions of two different chromosomal regions.

P02.180
Three uncommon cases of OAVS

C. Barone, E. Gitto, A. Salpietro, S. Aversa, V. Ferraù, C. Cuppari, P. Vicchio, S. Meduri, M. Caruso, D. C. Salpietro, S. Briuglia, ***A. Talenti****;*
Department of Pediatric Science Policlinico Messina, Messina, Italy.

Oculo-auriculo-vertebral spectrum (OAVS) is a heterogeneous condition results from a defect of blastogenesis involving abnormal development of facial structures derived from the first and second branchial arches with in same cases cardiac, vertebral and CNS defects.

We describe three uncommon newborns' case with OAVS. First is a male with OAVS and severe caudal regression: the clinical features were marked right hemifacial microsomia, hypoplasia of the right mandibular ramus and right external ear with atresic external auditory canal and ossicles agenesia; "frog-like" appearance of the lower extremities, flexed knees due to bilateral popliteal pterigium and equinovarus deformity of bilateral feet. Abdomen US showed crossed renal ectopia, lower spine X-rays revealed absence of vertebra below D12 level, spine and brain RMI showed the spinal cord terminated at D6 level and corpus callosum hypoplasia. The association between OAVS and caudal regression is a typical manifestations of the axial mesodermal dysplasia complex.

The second is a female with OAVS and left labial cleft: the clinical features were left hemifacial microsomia, microtia, left labial cleft and dysmorphic right ear implanted in mandibular region.

The third is a female with OAVS and anterior cervical meningocele: the clinical features were left hemifacial microsomia, hypoplasia of the left mandibular ramus and reduced motility of the tongue due to a functional deficit of hypoglossal nerve and anterior cervical meningocele.

So the management of OAVS requires a multidisciplinary approach to provide the most appropriate treatment even more if, as in our cases, typical manifestations are associated with other specific malformations.

P02.181
Association of mitochondrial disorders with oxidative stress in obsessive compulsive disorder

N. Orhan*[1], C. I. Kucukali[1], U. Cakir[2], N. Arican[3], M. Aydin[1];*
[1]Department of Neuroscience, Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey, [2]Department of Biochemistry, Eyup State Hospital, Istanbul, Turkey, [3]Department of Forensic Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Obsessive compulsive disorder (OCD) is a common psychiatric disorder defined by the presence of obsessive thoughts and repetitive compulsive actions. The mutations or polymorphic variants in mitochondrial DNA-encoded genes or nuclear genes result in oxidative stress, which has recently been associated with various psychiatric disorders. In order to understand the association of mitochondrial disorders with oxidative stress in OCD, we examined genetic variants of MnSOD and UCP-2 antioxidant genes, whose product imported into mitochondrion, and MDA and GSH, markers of oxidative stress. The study sample comprised 102 patients with OCD and 104 healthy controls. For MnSOD, the frequencies of CT (Ala/Val) genotype ($p<0.01$) in patients were significantly lower than those of controls. However, CC (Ala/Ala) genotype was significantly more frequent in patients than controls ($p<0.05$). For UCP-2 (I/D), the frequencies of ID genotype ($p<0.01$) and I allele ($p<0.05$) were lower in patients as compared with controls. In contrast, DD genotype was more prevalent in patients than controls ($p<0.01$). While serum GSH was significantly depleted ($p<0.0001$), serum MDA was significantly elevated in patients compared with controls ($p<0.0001$). MDA levels were significantly elevated in subjects with DD genotype of UCP-2 (I/D) ($p<0.05$) and CC genotype of MnSOD ($p<0.05$) as compared with II or ID and TT or CT genotype, respectively. MDA levels in patients carrying CC ($p<0.05$) or CT ($p<0.05$) genotype were significantly higher than those of carrying TT genotype. In conclusion, CC genotype of MnSOD or DD genotype of UCP-2 might result in mitochondrial disorders by increasing oxidative stress in OCD.

P02.182
Oculoauriculovertebral spectrum: 1.34 Mb duplication in 14q23.1 in a family with autosomal dominant inheritance

M. Ballesta-Martínez*[1], V. López-González[1], D. Calvo-Martínez[1], L. Armengol-Dulcet[2], E. Guillen-Navarro[3];*
[1]Hospital Universitario VIrgen de la Arrixaca, Murcia, Spain, [2]Quantitative Genomic Medicine Laboratories, Barcelona, Spain, [3]Hospital Universitario Virgen de la Arrixaca, Murcia, Spain.

Introduction: Oculoauriculo vertebral spectrum or OAVS (OMIM 164210) is a clinically and genetically heterogeneous congenital disorder involving developmental defects of first and second branchial arch derivatives. Main features are unilateral/bilateral ear anomalies (anotia, microtia, preauricular tags, pits), hemifacial microsomia, ocular defects and vertebral malformations. Other features are cleft lip and/or palate, cardiac, cerebral , renal malformations and mental retardation. Diverse chromosomal abnormalities have been associated with OAVS (trisomies/monosomies).

Clinical Report: We report a 31 year old patient, with clinical diagnosis of Treacher Collins syndrome and several affected family members suggestive of autosomal dominant inheritance. Normal pregnancy and delivery. No gestational diabetes, uterine malformations, toxic environment. Physical examination: Long narrow face, bilateral preauricular pits and tags, left anotia, agenesis of middle and inner left ear, micrognatia, macrostomia, high arched palate. Length: 167 cm, PC: 55 cm. Normal cardiological evaluation. Spine Xray: dorsolumbar scoliosis. No vertebral defects. Father: right macrostomia. No hearing defect. Born with preauricular tags. Other 4 family members with preauricular tags, and macrostomia; suggestive of autosomal dominant inheritance. High density array-CGH was performed: 1,34 Mb duplication at 14q23.1.

Discussion: This is the second report of a 14q23 duplication in OAVS with autosomal dominant inheritance (previous description with a 11.79 Mb duplication at 14q22.3-23.3 with 4.38 Mb deletion at 13q21.31-q21.32: complex rearrangement). We discuss clinical heterogeneity as well as support the fact that 14q23 is a candidate region for OAVS phenotype. Our case narrows down the candidate region to 1,34 Mb, including SIX1 and SIX6 genes.

P02.183
Novel pathogen mutation in TYR gene in an Iranian patient with Oculocutaneous Albinism Type I(OCAI)

V. Ghodsinejadkalahroudi*, A. Arastehkani, O. Aryani, M. Houshmand;*
Medical Genetic Dep. Special Medical Center, Tehran, Islamic Republic of Iran.

Oculocutaneous albinism (OCA) is a severe genetic disorder characterized by reduced or absent biosynthesis of melanin pigment in melanocytes of the skin, hair follicle, and eye. Type I OCA results from deficient activity of melanocyte tyrosinase, a copper containing enzyme that catalyzes the first two steps in the melanin biosynthetic pathway. In classic, type IA OCA tyrosinase activity and melanin biosynthesis are entirely absent, and in type IB OCA tyrosinase activity and melanin production are greatly reduced. Types IA and IB OCA were result from allelic mutations of the tyrosinase gene.

In This study a patient with clinical phenotype of OCA I and her parents were investigated for mutations in TYR gene by PCR and sequencing method. This patient was homozygote for c: 89 T → A mutation that changes amino acid Cysteine to Serine while her parents were heterozygous for this mutation. This mutation was not reported previously and was not found in healthy controls and literatures. We believed that this mutation may have effect in patient phenotype.

P02.184
Oesophageal atresia with tracheoesophageal fistula, anal atresia and thumbs hypoplasia in a patient with a de novo gain in 17q12 detected by genome wide SNP array analysis.

R. Smigiel*[1], C. Marcelis[2], D. Patkowski[3], N. de Leeuw[2], K. Mascianica[3], M. Sasiadek[1], H. Brunner[2];*
[1]Genetic Department Wroclaw Medical University, Poland, Wroclaw, Poland, [2]Department of Human Genetics, University Medical Center, Nijmegen, Netherlands, [3]Pediatric Surgery and Urology Department, Wroclaw Medical University, Poland, Wroclaw, Poland.

Oesophageal atresia (OA) and tracheoesophageal fistula (TOF) are foregut malformations with a heterogeneous etiology. OA/TOF may occur as an isolated anomaly or as part of a syndrome. Several

syndromes have OA/TOF as a clinical feature. The best known is the VACTERL association that is seen in 10-30% of OA/TOF. Chromosomal anomalies have been reported in 6-10% of OA/TOF, but no single specific chromosomal defect has been confirmed as a main etiological factor. Several genes have been implicated in cases of syndromic OA/TOF. It is thought that a combination of genetic and environmental factors play a role in the etiology of OA/TOF.
We report a male infant, born at 33 weeks of gestation with IUGR presenting the combination of multiple congenital defects (OA/TOF, anal atresia, thumbs hypoplasia, tracheomalacia, sacral bone defect, cryptorchidism) resembling VATER association. Follow-up examination showed psychomotor and somatic retardation. Genotype analysis revealed a normal male karyotype and absence of subtelomeric imbalances. Genome wide 250k SNP array analysis showed a 1.4Mb gain in 17q12. This gain appeared to have occurred de novo (normal result in the patient's parents) and is likely to explain the clinical picture of this patient.
Recently, aberrations of this 17q12 region that is flanked by low-copy repeats have been described by Nagamani et al. in patients with renal defects, epilepsy, brain abnormalities and intellectual disability. Among these patients, one presented with OA/TOF and vertebral defect.
We propose to consider a role for selected genes in the 17q12 region in the development of OA/TOF.

P02.185
GLI3 is rarely implicated in OFD syndrome with midline abnormalities

M. Avila[1], *B. Aral*[2], *P. Callier*[3], *N. Gigot*[2], *M. Payet*[3], *C. Ragon*[3], *J. Thevenon*[1], *L. Pasquier*[4], *E. Lopez*[1], *A. Goldenberg*[5], *C. Baumann*[6], *V. Cormier*[7], *S. Marlin*[8], *A. Masurel*[1], *F. Huet*[9], *T. Attié-Bitach*[7], *L. Faivre*[1], *C. Thauvin-Robinet*[1];

Oral-facial-digital (OFD) syndromes represent a heterogeneous group of clinical entity characterized by the association of malformations of the face, oral cavity and extremities. Thirteen subtypes have been currently distinguished, characterized by specific extra-OFD features. Only the *OFD1* gene has been identified in the OFD type I and mutations in the *CORS2* gene in two patients with an OFD type VI. Recently, 6 mutations within the *GLI3* gene, responsible for Greig cephalopolysyndactyly and Pallister-Hall syndrome (PHS), have been reported in some cases (6/21 cases, 29%) who presented features of OFD syndrome associated to midline abnormalities. Five of the 6 mutations were similar in position within *GLI3* to other mutations that have been described in PHS. We report the results of *GLI3* sequencing analysis in 8 cases with OFD syndrome and midline abnormalities, including pituitary gland deficit (5/8 cases) with pituitary stalk interruption (3/5 cases), hypothalamic hamartoma (HH) (1/8 cases), corpus callosum agenesis (1/8 cases) and imperforate anus (1/8 cases). No *GLI3* mutation was identified. The difference between our cohort and the previous published results could be explained by the frequent HH (4/6 cases) in the previous published data and the rare prevalence (1/8 cases) in our cohort. When pooling with the previous studies, the frequency of *GLI3* mutations in OFD syndromes with midline abnormalities is 21%, and 36% if a HH is associated. In conclusion, further studies are required in order to evaluate the implication of the *GLI3* gene in OFD phenotype with midline abnormalities.

P02.186
A novel mutation in SALL4 causes Okihiro Syndrome with mainly skeletal involvement

S. Uhrig[1], *C. Rotky-Fast*[2], *D. Horn*[3], *F. Laccone*[4];
[1]Institute of Human Genetics, Graz, Austria, [2]Department of Paediatrics, Graz, Austria, [3]Institute of Medical Genetics, Charité, Berlin, Germany, [4]Institute of of Medical Genetics, Vienna, Austria.

Okihiro syndrome (Duane-Radial Ray syndrome; DRRS) is an autosomal dominant condition characterized by upper limbs anomalies (radial ray defects), improper eye movements (Duane anomaly), and congenital bilateral non-progressive sensorineural and/or conductive hearing loss. Other less consistent deformities include anal, renal, cardiac, ear, and foot malformations. This disease results from of a mutation in the SALL4 gene, a human gene related to the developmental regulator spalt (sal) of Drosophila melanogaster. SALL4 mutations may also cause Acro-Renal-Ocular syndrome (AROS), which is characterized by radial ray malformations, renal abnormalities, ocular coloboma, and Duane anomaly. The majority of the mutations are truncating point mutations, which are expected to result in nonsense-mediated mRNA decay and are considered to cause the phenotype via haploinsufficiency. The only truncating mutation predicted to escape nonsense-mediated mRNA decay is associated with extensive clinical variability and severe hemifacial microsomia in one member of a large family.The only missense mutation identified so far is predicted to cause an increase of DNA binding capacity and is associated with central midline defects [Kolhase J, GeneReviews 2008]. Here we present an Austrian family with four members affected by Okihiro syndrome, in which we have identified a novel SALL4 mutation in exon 2 leading to an in frame deletion **c.694_696delACC (p.T232del)**. Family members had varying degrees of radial ray malformation and facial characteristics without Duane anomaly, but no hearing loss, nor malformation of other organs. This is the first report of an in frame deletion of SALL4 that causes Okihiro syndrome.

P02.187
A diagnosis of X-linked Opitz G/BBB syndrome by array-CGH in a boy and a girl

M. C. Maiburg, *E. van Binsbergen, E. H. Brilstra, P. A. Terhal;*
University Medical Center Utrecht, Utrecht, Netherlands.

X-linked Opitz G/BBB syndrome (OS) is characterized by facial dysmorphisms, laryngo-tracheo-esophageal and genitourinary abnormalities with mental retardation in 50% of (male) patients. *MID1* analysis detects mutations, deletions or insertions in 15-45% of males clinically diagnosed with OS. We report a male and female patient in whom the diagnosis of OS was either confirmed or suggested by array-CGH.
A girl with severe mental retardation had facial dysmorphisms including hypertelorism. Additional abnormalities included laryngotracheomalacia, tracheo-esophageal fistula, and absent puberty. Sequencing of *MID1* revealed no mutations. However, array-CGH showed a deletion in Xp22.2p22.32, including *MID1*, as well as *KAL1*, *STS* and *OA1*. X-inactivation studies are pending. Female carriers of a *MID1* mutation usually manifest only hypertelorism. A few male cases with a deletion of the entire *MID1*-gene have been reported, but to our knowledge this is the first female patient with a *MID1* deletion.
A boy presented with cryptorchidism, kidney cysts, glottic web, heart defect and thin corpus callosum. Dysmorphic features included hypertelorism, dysplastic ears and a midline defect of his upper lip. Array-CGH revealed two duplications in Xp22.2, with one of the breakpoints mapping within the *MID1*-gene and therefore possibly disrupting it. Mate-pair analysis could provide insight into the structure of *MID1* in this patient. One patient with OS due to a duplication of the first exon of *MID1* has been reported in the literature.
These cases illustrate that there can be a role for array-CGH in the diagnosis of OS and show an example of full OS in a female patient.

P02.188
Large duplication of the MID1 gene in a patient with Opitz GBBB syndrome

S. Rajaei, L. Lovmar, A. Erlandsson, J. Rundberg, ***M. Stefanova****;*
Department of Clinical Genetics, Sahlgrenska University Hospital, Gothenburg, Sweden.

Opitz GBBB syndrome (OS, MIM145410 and MIM300000) is a congenital midline malformation syndrome characterized by hypertelorism, hypospadias, cleft lip/palate, laryngotracheoesophageal abnormalities, imperforate anus and developmental delay. The X-linked form is caused by a large variety of mutations in the MID1 gene. They involve point mutations, small sized (less than 1kb) insertions, deletions and duplications.
Here we report a maternally inherited duplication involving part of MID1 gene, minimum 37kb in size, in a 2-months-old-boy with Opitz

syndrome. The patient presented with feeding and swallowing difficulties and following features: brachycephaly, large fontanel, pronounced hypertelorism, shallow orbits, alternated divergent strabismus, broad flat base of the nose, mid-cleft of the tongue, short fraenulum, high palate and posteriorly rotated ears. Laryngooesophagofibroscopy and X-ray failed to detect laryngotracheoesophageal abnormalities. SNPs array analysis (Affymetrix 250k NspI) detected a 37-176kb duplication which involves exon 1 of MID1 gene (NM_000381.2) and spans between base pair X:10415285-10451959 (NCBI36/hg 18). The aberration and its maternal origin were confirmed by MLPA. Patients' mother showed subtle clinical features, such as feeding difficulties in the infancy, hypertelorism and shallow orbits. Variable clinical features of OS presented also maternal grandfather, his sister and her son. All affected family members have normal intelligence.
This report defines a novel type of genetic defect in patients with X-linked OS that is undetectable by the classical sequence analysis on the DNA level. Further studies for larger duplications/deletions of the MID1 gene on patients with a clinical diagnosis Opitz syndrome may be appropriate and could confirm the molecular diagnosis.

P02.189
De novo R304W mutation in the P63 gene associated with variable expressivity of the EEC syndrome

A. Singer[1], *J. McGrath*[2], *C. Vinkler*[3];
[1]*Genetic Institute, Ashkelon, Israel,* [2]*St John's Institute of Dermatology Guy's Hospital, London, United Kingdom,* [3]*Genetic Institute Wolfson Medical Center, Holon, Israel.*

Mutations in the transcription factor gene p63 is associated with several syndromes each including various combinations of limb malformations ectodermal dysplasia and orofacial clefting. Ectrodactyly, ectodermal, clefting (EEC, OMIM 604292) is the prototype of these syndromes. Most patients present with all three components.
We present a case with mutation in p63 and no limb involvement The proband is a 7 years old boy who was born at term to unrelated parents of Jewish origin. He had cleft lip and palate which as well as lacrimal duct stenosis which were corrected. He has spars thin and pale hair. He has hypodontia with 17 teeth missing. On his back there are hyperpigmented lesions. No abnormality was noted in his hands feet or nails. He has no abnormal sweating, no hearing impairment or kidney abnormality. He has no developmental problems.
A diagnosis of EEC syndrome was suspected. Screening for mutations in the p63 gene revealed an R304W mutation, known to be a disease causing mutation in this syndrome. The parents do not carry this mutation.
Even though ectrodactyly is a hallmark in EEC syndrome and is found in the vast majority of the patients, it should be included in the differential diagnosis when the other two major components exist (i.e. ectodermal and clefting). Lack of involvement of the limbs in this boy may be due to other genes affecting the expression of the mutated p63 in this case pointing at a more complex mechanism for the mild phenotype in this boy.

P02.190
A boy with intranasal hamartomatous polyp and pericallosal lipoma further expands Pai syndrome phenotype.

D. J. Lederer, *P. Lefesvre, C. Verellen-Dumoulin;*
Center For Human Genetic, IPG, Charleroi (Gosselies), Belgium.

Pai syndrome is characterized by mild hypertelorism, midline cleft lip, nasal and facial polyps, pericallosal lipoma, ocular anomalies and normal neuropsychologic development.
We describe an 8 years old child presenting with congenital nasal hamartomatous polyp and peri-callosal lipoma. The association of these two extremely rare findings in the same patient is highly suggestive of Pai syndrome. Thirty patients with Pai syndrome are described in the literature. Nasal polyp is a constant feature in Pai syndrome patients described so far. Peri-callosal lipoma was present in all but one patients screened with brain MRI. Another common feature is midline cleft lip described in 26/30 patients. In view of this case and literature review, we suggest as minimal clinical criteria for Pai syndrome: congenital midline nasal polyp, peri-callosal lipoma and/or midline cleft lip. Furthermore, our patient expands the phenotype of Pai syndrome with some atypical findings such as bucco-lingual dyspraxia, true tracheal bronchus, sacral dimple and hypospadias.

P02.191
Study of allelic variants in patients with neuropathic pain from Salamanca (Spain)

M. López[1], *P. Armero*[1], *Á. Paula*[1], *J. Santos*[2], *L. San Norberto*[2,3], *C. Muriel*[2,3], *R. González-Sarmiento*[1];
[1]*Unidad de Medicina Molecular-Departamento de Medicina. Universidad de Salamanca, Salamanca, Spain,* [2]*Unidad del Dolor. Servicio de Anestesia. Hospital Clínico de Salamanca., Salamanca, Spain,* [3]*Cátedra Extraordinaria del Dolor. Fundación Grünenthal. Universidad de Salamanca., Salamanca, Spain.*

Introduction
Perception of pain is a complex process which implies multiple biochemical pathways together with unknown processes of cortical integration. The existence of individual differences in the response to painful stimuli suggest that genetic factors can be involved in its modulation. The aim of our study was to investigate the genetic variation of 25 genes involved in different pathways of pain in patients from Salamanca (Spain), diagnosed with neuropathic pain.
Methods
Genomic DNA was extracted from peripheral blood leukocytes by standard techniques. We selected 29 non-synonymus SNPs. Studies were performed using TaqMan probes (Applied biosystems) for the analysis of the polimorphisms in the following genes: IL6, IL4, IL1B, NOS, eNOS, nNOS, TRPV, GSTM1, GSTT1, GSTP1, CYP2D6, COMT, PTGS2, HTR2A, SLLC6A4, OPRD, OPRM, OPRK, CNR1, DRD2, GABRA1, GABRA6, PPARG, EDN1, BDNF and CHRNA5.
Statistical analysis was performed comparing the different allelic variants of the genes in subgruopus of patients: patients with a VAS below and over 50.
Results and conclusion
Preliminary analysis has shown significant differences ($p<0.05$) comparing both groups of patients in the IL1B and PTGS2 genes. Il1B is an important mediator of the inflammatory response, involved in a variety of cellular activities, including cell proliferation, differentiation, and apoptosis. PTGS2 is the key enzyme in biosynthesis of the prostanoids, regulated by specific stimulatory events, suggesting that it is responsible for the prostanoid biosynthesis involved in inflammation and mitogenesis.
This results support the hypothesis that polymorphisms in genes involved in different pathways could be asociated with increased susceptibility to suffer pain.

P02.192
INew mutation of ARX gene as a cause of Partington syndrome.

M. Simandlová[1], *A. Křepelová*[1], *D. Novotná*[1], *H. Bémová*[2], *J. Kraus*[2], *T. Mařík*[1], *M. Havlovicová*[1];
[1]*UBLG, FN Motol, V úvalu 84, P5, Prague, Czech Republic,* [2]*Dpt of Pediatric Neurology , FN Motol, V úvalu 84, P5, Prague, Czech Republic.*

Infantile spasms, mental retardation, autism, and dystonia represent disabling diseases for which little etiologic information is available. Mutations in the Aristaless related homeobox gene (ARX) have been found in patients with these conditions .Aristaless related homeobox (ARX) is a transcription factor containing highly conserved octapeptide, homeobox, acidic, and aristaless domains, as well as four polyA tracts.. The most common mutation, the c.428_451dup, is associated with a wide spectrum of phenotypes, ranging from the most severe West syndrome to Partington syndrome (MR and hand dystonia), and even nonsyndromic X-linked mental retardation (NS-XLMR). Here, we report the boy with clinical manifestation of Partington syndrome (PS) , where the mutation of poly A tract is slightly different: c.426_458 dup. The boy presents with brachial dystonia, ataxia and severe mental retardation- typical symptomps of PS. .
Mutations in the homeobox gene, ARX, cause a diverse spectrum of disease that includes cognitive impairment, epilepsy, and in another group of patients severe cortical malformations. Although the precise prevalence of ARX mutations is unclear, ARX may rival Fragile X as a cause of mental retardation and epilepsy in males.
The work was supported by the grant MZOFNM2005

Bilateral persistent hyperplastic primary vitreous - case report

T. Marcovici[1,2], *I. Simedrea*[1,2], *O. Marginean*[1,2], *L. Olariu*[1,2], *O. Belei*[1,2], *C. Daescu*[1,2], *D. Chiru*[1,2], *A. Militaru*[1,2], *M. Puiu*[1,2];
[1]*"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,*

[2]"Louis Turcanu" Children's Emergency Hospital, Timisoara, Romania.
Background: Persistent hyperplastic primary vitreous (PHPV) is a rare congenital condition due to failure of regression of the embryological, primary vitreous and hyaloid vasculature. It typically presents unilaterally (90%) without associated systemic findings. Between the three variants of PHPV(anterior, posterior or a combination of anterior and posterior presentations) the last one is the most commonly seen. The patient usually has microophthalmia, leukocoria and reduced vision. Cataract and anomalies of the anterior chamber angle are present. Accompanying retinal lesions (detachment, dysplasia) may be seen. Other complications in PHPV are : amblyopia; strabismus; loss of vision; glaucoma.The treatment is surgical and the procedures depend on the clinical presentation. Early surgical rehabilitation may facilitate a better visual outcome. Material and methods: We present a 3 years old girl with visual impairment and moderate psychomotor delay. She is the product of an uncomplicated full-term pregnancy. In her mother's family are present some cases of cataract and strabismus. Full evaluation (history, clinical exam, biological and imagistic tests, ophthalmological, neurological and genetic evaluation, audiometry) was done. Results: Bilateral strabismus, enophtalmia, amblyopia and cataract were noticed. Ocular ultrasonography revealed bilateral persistent hyperplastic primary vitreous. No hearing impairment was identified. Patient's family disagrees with surgical eye procedures (vitrectomy). Conclusions: The visual prognosis is poor in this case because it is a bilateral complicated presentation of PHPV. The delay of the surgical rehabilitation would lead to irreversible amblyopia, even loss of vision. Genetic and family counseling, ophthalmological and neurological follow up are mandatory.

P02.194

Variation of clinical expression in family with Pfeiffer syndrome caused by p.P252R mutation in FGFR1 gene

A. Jakubiuk-Tomaszuk[1,2], *R. Leśniewicz*[3], *W. Sobaniec*[1], *R. Posmyk*[4];
[1]*Department of Pediatric Neurology and Rehabilitation, Medical University of Bialystok, Bialystok, Poland,* [2]*Department of Clinical Genetics, Podlaskie Center of Clinical Genetics, Bialystok, Poland, Poland, Poland,* [3]*Department of Gynecological Endocrinology, Medical University of Bialystok, Bialystok, Poland,* [4]*Department of Clinical Genetics, Podlaskie Center of Clinical Genetics, Bialystok, Poland, Bialystok, Poland.*
Pfeiffer syndrome (OMIM#101600) is a genetic disorder which belongs to craniofacial dysostosis group, inherited autosomal dominant with change in clinical expression. It affects about 1 in 100,000 live-births. Typical features include: premature fusion of certain bones of the skull (craniosynostosis), maxillary hypoplasia and digital abnormalities of the hands and feet. This condition can be caused by heterozygous mutations in either fibroblast growth factor receptor gene type 1 or 2 (*FGFR1* or *FGFR2*). *FGFR1* mutations often result in less severe craniofacial involvement and abnormalities of the limbs.
The family of three members (father, his son and daughter) affected by Pfeiffer syndrome has been reported. Father demonstrated brachycephaly, hypertelorism, midfacial hypoplasia, stiff and broad thumbs, 2rd and 3rd toe syndactyly, very broad, flat, medially deviated great toes and normally developed intelligence. Son during examination showed severe mental retardation without ability of speaking, total 2rd to 4rd syndactyly toes at both feet, slightly medially deviated great toes and he did not express craniosynostosis features. In case of daughter insignificant signs of stiff thumbs, slight, partial 2rd and 3rd toes syndactyly without craniosynostosis features and normal intelligence were reported. In affected family we showed p.P252R mutation in *FGFR1* gene.

Pitt Hopkins syndrome (PHS, MIM#610954) patients present with severe intellectual disability with no speech, typical facial gestalt and hyperventilation episodes. In 2007, TCF4 was indentified as the disease causing gene with de novo heterozygous mutations or deletions. Since, about 60 patients have been reported.
Here, we report a novel series of 30 patients diagnosed with PHS and refine the neurological and morphological phenotype.
Within a two years period we identified heterozygous de novo TCF4 gene mutations or deletions in 30 patients with severe intellectual disability and the PHS facial gestalt. All patients were clinically revaluated with special attention to neurological presentation, with films whenever possible, and available brain-MRIs were reviewed.
All our patients had severe intellectual disabilities with no speech. Twenty-seven have facial features typical for the syndrome. A majority of the patients presents stereotypic movements (arm flapping, rapid movement of fingers, hand nibbling or rubbing and head rotation) and restless movements increasing with anxiety and excitation. Hyperventilation is frequent and often triggered by anxiety or excitement. Epilepsy and microcephaly are very inconstant findings. Cerebral MRI shows minor morphological changes only.
PHS is not rare among patients with severe intellectual deficiency. We report the clinical features of 30 PHS patients, with special emphasis on the neurological phenotype and key diagnostic features in the Rett-like group of patients. Genotype-phenotype correlation will also be discussed.

P02.196

Mutation analysis of the NPHS2 gene with the direct DNA sequencing method in Russian children with steroid-resistant nephritic syndrome.

V. Kornienko[1], *A. Tsygin*[1], *A. Asanov*[1,2], *V. Pinelis*[1];
[1]*Scientific center for children's Health, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical Universit, Moscow, Russian Federation.*
The NPHS2 gene encodes podocin protein, which plays an important role in glomerular ultrafiltration and controlling slit membrane permeability. Podocin is a raft associated component of the glomerular membrane where it is localized at the insertion of the slit-diaphragm. It was known that mutations of an NPHS2 can determine specificity of treatment for children with nephrotic syndrome (NS). In Russian patients with steroid-resistant nephrotic syndrome (SRNS) mutations of the NPHS2 gene have remained mainly unknown. The aim of present study was to screen for podocin mutations in Russian children with SRNS. There were 61 patients with SRNS and 15 age-matched healthy children. Mean age at onset of proteinuria was 6,3±4,8 years. Mutation analysis was performed in eight exons of the NPHS2 gene using the direct DNA sequencing method. We identified mutations and polymorphism variants in the NPHS2 gene: rs3738423 (S96S), rs61747728 (R229Q), rs1410592 (A318A), rs3818587 (L346L), rs1410592 (A318A), IVS3+1507 C>T, IVS3+1460 C>T, IVS7+7 A>G, IVS7+1078 G>C. First discovered in the Russian patients the

polymorphism IVS7+7 A>G (N.Poltavetz) was also represented in our SRNS patients. We revealed two new mutations I255T and V338L. It is known that R229Q polymorphism associates with the SRNS in different ethnic groups. In our study frequency of R229Q polymorphism in children with SRNS have met in two times often than in the healthy group. The frequencies of other polymorphisms was approximately the same in both groups. Thus the detected NPHS2 gene polymorphisms in our patients must be borne in mind when choosing therapy of SRNS.

P02.197
Two cases of Pontocerebellar Hypoplasia Type 2: clinical, neuroradiological and molecular genetical findings

A. Bier[1], *C. Finetti*[2], *H. Böhrer-Rabel*[3], *S. Reif*[1], *J. Plaschke*[1], *F. R. Kreuz*[1], *S. Krüger*[1];

[1]*Gemeinschaftspraxis für Humangenetik, Dresden, Germany,* [2]*Klinikum Duisburg Klinik für Kinder- und Jugendmedizin Abteilung für Neuropädiatrie, Duisburg, Germany,* [3]*genetikum, Neu-Ulm, Germany.*

Pontocerebellar hypoplasias (PCH) are rare autosomal recessive neurodegenerative disorders which are characterised by severe mental and motor impairments, hypoplasia of the cerebellum and ventral pons, microcephaly, and variable degrees of cortical atrophy. PCH are subdivided into six types (PCH1 to PCH6), of which PCH2 is most common accounting for about 90% of all PCH cases.

PCH2 is characterised by progressive microcephaly from birth combined with extrapyramidal dyskinesia, lack of voluntary motor or mental development, severe chorea, and frequently epilepsy. It is caused by biallelic mutations in *TSEN54*, whereby a homozygous c.919G>T (p.Ala307Ser) mutation has been identified in approximately 90% of PCH2 cases. This mutation is thought to be a founder mutation descending of a single couple that lived in the seventeenth century in Volendam, The Netherlands. Most children die before age ten years, although survival beyond age 20 has been reported. Typical findings in PCH2 in cerebral Magnetic Resonance Imaging (cMRI) are, beyond ventral pontine atrophy/hypotrophy, cerebellar hypoplasia whereby the cerebellar hemispheres are more affected than cerebellar vermis with a relative sparing of the flocculi. These cMRI features were termed as dragonfly-like cerebellar pattern and recognised as pathognomic for *TSEN54* mutations.

Here we report on two female patients aged 9 months and 13 years, respectively. Both children were born by non consanguineous parents of German descent. After an uneventful pregnancy and birth, they developed neurological signs resembling to PCH. Cranial MRI displayed typical pattern of PCH2. Sequencing of *TSEN54* revealed homozygousity for the *TSEN54* c.919G>T mutation in both patients.

P02.198
Psychological and behavioral profile of Romanian Prader Willi patients

C. Rusu[1], *E. Braha*[1], *M. Volosciuc*[2], *V. Gorduza*[1], *C. Skrypnyk*[3], *V. Plaiasu*[4], *C. Badiu*[5], *A. Szekely*[6], *M. Puiu*[7], *D. Dan*[6];

[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Sf Maria Children's Hospital, Iasi, Romania,* [3]*University of Medicine, Oradea, Romania,* [4]*Institute for Child and Mother Protection, Bucharest, Romania,* [5]*University of Medicine and Pharmacy, Bucharest, Romania,* [6]*Prader Willi Association, Zalau, Romania,* [7]*University of Medicine and Pharmacy, Timisoara, Romania.*

Prader Willi syndrome (PWS) is a complex disorder that includes prenatal/neonatal central hypotonia, poor suck and infantile failure-to-thrive, characteristic facial appearance,

developmental delay, childhood onset obesity, short stature, hypogonadism and a characteristic behavior disorder.

We have studied the 57 patients registered with Romanian Prader Willi Association in order to appreciate the psychological and behavioral profile. The major aims of this study were to identify specific behavioral patterns and early ways to improve developmental delay and behavioral problems, for the benefit of patient and family. Criteria studied included concordance of the different developmental fields (motor/language/cognitive), severity of developmental delay, personality (stubbornness, preferences, communication, manipulation, selfmutilation etc) and evolution of personality characteristics in time, memory and functioning, sleep problems and how do they influence behavior, evolution of hypotonia in time. After a global analysis, the cases have been grouped according to the genetic defect and all these parameters have been compared.

Statistics for all these criteria will be provided, as well as a comprehensive model for the investigation, education and therapy offered to a child diagnosed with PWS, in order to reduce major psychological and behavioral problems. Particularities found will be underlined.

In conclusion, we have analyzed the psychological and behavioral profile of 57 cases diagnosed with PWS. Based on this, we have elaborated a model of investigation, education and therapy in order to optimize the recovery of the psychological problems that these patients are facing.

P02.199
Prader-Willi/ Angelman syndromes: different molecular approaches.

A. Botezatu[1], *A. Cosmin*[2], *N. Cucu*[2], *M. Puiu*[3], *C. C. Diaconu*[1], *I. V. Iancu*[1], *G. Anton*[1];

[1]*Institute of Virology "St.S.Nicolau", Bucharest, Romania,* [2]*University of Bucharest, Faculty of Biology, Bucharest, Romania,* [3]*University of Medicine and Pharmacy "V.Babes", Timisoara, Romania.*

Prader-Willi (PWS) and Angelman (AS) syndromes are distinct neurogenetic disorders, caused by chromosomal deletions, uniparental disomy or loss of the imprinted gene expression in 15q11-13 region. While PWS occurs from a lack of the paternally expressed gene contribution, AS originates from a lack of the maternally expressed gene expression in the region, specifically *UBE3A*.

The aim of the study was to evaluate the clinical diagnosis using different comparative molecular methods.

The study group consisted in 14 children (age 2-10 years) presumptively diagnosed with PWS and one case with AS at UMF Timisoara- Pediatric Hospital and 10 normal patients (control).

DNA and RNA samples were isolated from white cell blood. For MS-PCR 700ng of DNA was sodium bisufite treated. RNA samples were reverstranscribed with Access Quick Kit (Promega). Epigenetic changes at SNRPN gene locus were evaluated with MS-PCR technique. Two non-imprinted genes expression (NIPA1 and OCA2) was evaluated by qReal-Time PCR for identification of deletions type 1,2,3. SALSA MS-MLPA kit ME028 was used to detect copy number changes and to analyze CpG islands methylation of the 15q11 region. 4/14 children presented deletions type 1,2,3 and 6/14 display imprinting defect (all PWS). In children with 15q11-13 deletions, no or poor NIPA1, OCA2 gene expression was found, depending on deletion type. The deletions was confirmed in FISH and MLPA analysis thus recommending NIPA1 and OCA2 gene expression as an alternate method for deletions investigation.

P02.200
The oro-maxillo-facial anomalies in patients with Prader Willi syndrome: a survey of 13 cases

E. Braha[1], *C. Rusu*[1], *V. Gorduza*[1], *M. Volosciuc*[2], *C. Skrypnyk*[3], *D. Dan*[4], *M. Puiu*[5];

[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Pediatric Hospital, Iasi, Romania,* [3]*University of Medicine and Pharmacy, Oradea, Romania,* [4]*Asociaţia Prader Willi din România, Zalau, Romania,* [5]*University of Medicine and Pharmacy, Timisoara, Romania.*

Prader Willi syndrome PWS is a chromosomal microdeletion or disomy disorder due to deletion or maternal disomy 15q11-13. It is characterized by severe neonatal hypotonia, childhood-onset hyperphagia and obesity, short stature, facial dysmorphy (narrow bifrontal diameter, almond-shaped palpebral fissures, down turned mouth), hypogonadism, mental retardation and anomalies of the oral region.

The purpose of this report is to evaluate carefully the patients with PWS and to describe the oro-maxillo-facial anomalies.

We followed 13 PWS patients (age range 26 years- 5 years 8 months; 8 girls, 4 boys) in Centres for Medical Genetics Iasi and Timisoara: dysmorphologic and clinical examination, dietetic and GH treatment history, cognitive function and behavior problems, oral and radiologic exam, reviewed all the laboratory studies.

All the patients presented characteristic facial features, thick saliva, speech articulation defects, 2 patients had microstoma, 1 with microdontia, 5 with malloclusion, 5 with enamel dysplasia, and 9 patients presented multiple dental caries (erosive and pour oral hygiene, bruxism).

PWS is frequent associated with oro-maxillo-facial anomalies and typically dysmorphic face. Clinical proper management is essential for a favorable oral health status.

P02.201
Early death in an infant diagnosed with Prader-Willi syndrome

M. Stoian[1], *V. Belengeanu*[1], *S. Farcas*[1], *N. Andreescu*[1], *M. Puiu*[1], *M. Boia*[2];
[1]*University of Medicine and Pharmacy, Department of Medical Genetics, Timisoara, Romania,* [2]*University of Medicine and Pharmacy, Department of Neonatology, Timisoara, Romania.*

Prader-Willi syndrome (PWS), a disorder with severe implications in child pathology marked by hypotonia in neonate period and obesity after the age of two years may have fatal evolution. The death causes may vary according to patient's age and also depend of the initiation of growth hormone therapy. We report the history of a PWS case with early death. The male infant delivered by caesarian section with low birth parameters, due to breech presentation, presented hypotonia, but no feeding difficulties. The clinical examination revealed: high forehead, slight upslanting palpebral fissures, low nasal bridge, microretrognathia, short neck and cryptorchidia. Conventional cytogenetic analysis was performed and the karyotype was normal. Due to hypotonia hormonal profile was evaluated: FT3, FT4, and TSH indicating congenital hypothyroidism defined later as transitory. At age of 7 months the persistent hypotonia, imposed the microdeletion FISH analysis with SNRPN probe for the Prader-Willy syndrome, which confirmed the diagnosis. Echocardiography revealed hypoxic hypertrophic cardiomyopathy with atrial septal defect. In evolution metabolic disturbances were identified with high levels of cholesterol, glycemia and GPT. The investigation of gonadotrophins sexual hormones indicated high levels of LH and low levels of FSH and testosterone. The patient was admitted several times due to recurrent episodes de bronchiolitis and pneumonia and at the age of eight months died due to cardio respiratory failure. For the next pregnancy the parents agreed to prenatal diagnosis although the recurrence risk is only 1-2% due microdeletion etiology of the case.

P02.202
Diagnosis in Prader-Willi Syndrome by methylation test in Brazil

C. L. A. Paiva, *C. R. Rocha, L. A. Agostinho, E. Paradela, A. S. Figueiredo, R. P. Alvarenga, S. R. dos Santos;*
Universidade Federal do Estado do Rio de Janeiro (UNIRIO), Rio de Janeiro, Brazil.

PWS is caused by loss of paternal contribution of genes located on chromosome 15 (15q11-13). Most of patients show obesity and mental disability. Holms *et al. (1993)* proposed the criteria for its clinical diagnosis. These criteria were revised by Gunay-Aygun *et al*. (2001) aiming to define criteria for selecting patients who should undergo molecular testing. The aim of this work was to identify PWS in 34 Brazilian patients with putative diagnosis, and to verify whether the molecular results were compatible with the clinical diagnosis based on Holms and Gunay-Aygun's criteria. The patients were sent to the Genetics Outpatient Clinic of HUGG by different clinicians. They were reassessed and had the methylation test done. The method employed McrBC endonuclease that digests the site 5'...Pu^{m}C(N40-3000) Pu^{m}C...3' of exon-1 of *SNRPN* gene (methylated only in normal chromosomes of maternal origin). Amplification of exon-1 *SNRPN* gene was achieved by PCR with *SNRPN* primers. The amplicons were detected by 3% agarose gel if the SPW region of paternal origin was normal. This method can detect SPW caused by deletion or abnormal methylation on chromosome 15 of paternal origin, as well as by maternal uniparental disomy. Out of 34 patients, 23 were judged clinically by Holms criteria and 29 were offered the molecular test based on Gunay-Aygun. We found 8 patients with a molecular result compatible with PWS. Therefore, PWS is best diagnosed clinically by experienced clinicians backed by DNA analysis. The diagnosis should be done as early as possible for appropriate counselling and dietary management initiation.

P02.203
Estimation of prevalence of malformation syndrome by population-based birth defects monitoring system in Japan

K. Kurosawa[1], *K. Enomoto*[1], *N. Furuya*[1], *A. Ishikawa*[1], *M. Tominaga*[1], *T. Wada*[1], *M. Masuno*[2], *Y. Kuroki*[2];
[1]*Kanagawa Children's Medical Center, Yokohama, Japan,* [2]*Kawasaki University of Medical Welfare, Kurashiki, Japan.*

Multiple malformation syndromes are recognized by characteristic anomalies and need specialized medical cares. For the study of genetic diseases, epidemiology plays a central role in public health, improvement, and disease prevention. However, evaluation and ascertainment of the incidence of these disorders is limited because of difficulties of diagnosis and rarity in general population. To elucidate the incidence of malformation syndromes, we used data from population-based monitoring system and genetic clinic of highly specialized children's hospital in the same prefecture. KAMP is one of the population-based birth defects monitoring program operating from 1981 in Kanagawa Prefecture, Japan. It covers a half of total births, 40,000 annually. During the study period, the annual number of patients with Down syndrome in the genetic clinic has been correlated with the prevalence in the KAMP. These results suggested the hypothesis that other recognizable malformation syndromes may visit the clinic with the same ratio. According to the known prevalence of Down syndrome (1/800), we calculated the incidence of the recognizable malformation syndromes. The estimation indicated that the incidence of Costello syndrome is 1/60,000-120,000 births, CHARGE syndrome 1/30,000 births, Rubinstein-Taybi syndrome 1/50,000-60,000 births, Young-Simpson syndrome 1/100,000 births, and ATR-X syndrome 1/60,000 male births respectively. Although the syndromes are very rare, the total number of diseases is high and has large impacts on the public health. This methodology may be successfully applied to other malformation syndromes.

P02.204
Dopamine gene receptors expression in psoriatic patients

M. Mohammadian[1], *G. Ahangari*[1], *H. Mortazavi*[2], *R. Torabi*[1], *S. Ghasemi*[1];
[1]*Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran,* [2]*Department of Dermatology, Razi hospital, Tehran university of medical science,, Tehran, Islamic Republic of Iran.*

Dopamine plays roles as a neurotransmitter and neuromodulator with functions in brain and peripheral tissues. Dopamine receptor (DRD) subtypes are related to depression and also have been shown to be present in certain cells of the immune system. There are some evidences that suggest that DRD subtypes are responsible for high lymphocyte activation in psoriasis. Psoriasis is a proliferative and inflammatory disease. There are at least five subtypes of DRDs, D1, D2, D3, D4, and D5. The D1 and D5 receptors are members of the D1-like family of DRDs, whereas the D2, D3 and D4 receptors are members of the D2-like family. The aim of this study is evaluation of DRD (3,5) genes expression in psoriatic patients in comparison with normal individuals by Real Time PCR.
The PBMC was separated from whole blood by Ficoll-hypaque. The total cellular RNA was extracted and the cDNA was synthesized. This process was followed by real-time PCR using primer pairs specific for DRD mRNA and beta-actin as internal control. Results show relative overexpression of DRD3 gene has significant changes between two groups, but we could not find significant changes between two groups for DRD5 gene. Considering these results the present study has shown a change in DRD3 gene expression in PBMC of psoriasis patients. Due to this data, we conclude that significant increased expression of DRD3 gene may has an important role in psoriasis.

P02.205
PTEN-Associated Macrocephaly/Autism Syndrome

M. Havlovicová, *P. Vasovčák, A. Křepelová, M. Simandlová, Z. Sedláček;*
Institute of Biology and Medical Genetics, 2nd Medical School, Charles University and Faculty Hospit, Prague, Czech Republic.

There is a strong genetic component to autism spectrum disorders (ASDs) but due to significant genetic heterogeneity individual genetic abnormalities contribute a small percentage to overall total.
PTEN hamartoma tumour syndrome (PHTS) is a heterogeneous group of disorders (Cowden syndrome, Bannayan-Riley-Ruvalcaba

syndrome, Proteus syndrome and Proteus-like syndrome) characterized by germline mutations in the PTEN gene and an increased risk of different tumours.
Previous studies have proved PTEN mutations in a portion of individuals with ASDs and macrocephaly that do not exhibit features of PHTS.
From a group of patients currently genetically investigated in our institute we have selected 21 children with a head circumference range from 2.0 to 4.8 standard deviations above the mean for the PTEN mutation analysis. Three novel (p.Asp331ThrfsX11, p.Thr321GlnfsX23, p.Glu242X) and one known germline mutation (p.Pro246Leu) have been found in four (19%) of 21 probands.
Our data support former findings that PTEN mutations are relatively frequent in children with ASDs and macrocephaly and therefore PTEN gene testing should be considered in such patients. The gene findings may impact on assessment of the recurrence risk as well as medical management of early cancer prevention.
The work was supported by the grant MZOFNM2005 and CHERISH

P02.206
Absence of influence of gender and BMPR2 mutation type on clinical phenotypes of pulmonary arterial hypertension

B. GIRERD[1,2], *D. MONTANI*[1,2], *M. EYRIES*[3], *A. YAICI*[1,2], *B. SZTRYMF*[1,2], *F. COULET*[3], *O. SITBON*[1,2], *G. SIMONNEAU*[1,2], *F. SOUBRIER*[3], *M. HUMBERT*[1,2];
[1]*Service de Pneumologie, Hôpital Antoine Béclère, Clamart, France,* [2]*Inserm U999, Centre Chirurgical Marie-Lannelongue, Le Plessis-Robinson, France,* [3]*Groupe Hospitalier Pitié-Salpétrière, Paris, France.*

Background: Previous studies indicate that patients with pulmonary arterial hypertension (PAH) carrying a mutation in the bone morphogenetic protein receptor type 2 (BMPR2) gene, develop the disease 10 years earlier than non-carriers, and have a more severe hemodynamic compromise at diagnosis.
Methods: We reviewed data from all patients with PAH considered as idiopathic and patients with a family history of PAH who underwent genetic counseling. We compared clinical, functional, and hemodynamic characteristics between carriers and non-carriers of a BMPR2 mutation, according to gender or BMPR2 mutation type.
Results: PAH patients carrying a BMPR2 mutation (n=115) were significantly younger at diagnosis than non-carriers (n=267) (35.8±15.4 and 47.5±16.2 respectively, p<0.0001). The presence of a BMPR2 mutation was associated with a younger age at diagnosis in females (36.4±14.9 in BMPR2 mutation carriers and 47.4±15.8 in non-carriers, p<0.0001), and males (34.6±16.8 in BMPR2 mutation carriers and 47.8±17.1 in non-carriers, p<0.0001). BMPR2 mutation carriers had a more severe hemodynamic compromise at diagnosis, but this was not influenced by gender. No differences in survival and time to death or lung transplantation were found in male and female PAH patients carrying a BMPR2 mutation. No differences were observed in clinical outcomes according to the type of BMPR2 mutations (missense, truncating, large rearrangement or splice defect).
Conclusion: When compared to non-carriers, BMPR2 mutation carriers from the French PAH network are younger at diagnosis and present with a more severe hemodynamic compromise, irrespective of gender. Moreover, BMPR2 mutation type had no influence on clinical phenotypes in our patient population.

P02.207
UPK3A and FGF7 mutation analysis in Dutch renal adysplasia patients provides further evidence for the role of UPK3A in congenital anomalies of the kidneys and urinary tract (CAKUT) pathogenesis

A. M. van Eerde[1], *K. Y. Renkema*[2], *K. Duran*[1], *E. van Riel*[1], *R. B. van der Luijt*[1], *W. F. Feitz*[3], *E. M. H. F. Bongers*[2], *C. Marcelis*[2], *M. R. Lilien*[4], *T. P. V. M. de Jong*[5,6], *C. G. F. de Kovel*[1], *N. V. A. M. Knoers*[1,2], *J. C. Giltay*[1];
[1]*Department of Medical Genetics, University Medical Center, Utrecht, the Netherlands, Utrecht, Netherlands,* [2]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Department of Urology, Pediatric Urology Centre, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [4]*Department of Pediatric Nephrology, University Medical Center Utrecht, Utrecht, Netherlands,* [5]*Pediatric Renal Center, University Medical Center Utrecht, Utrecht, Netherlands,* [6]*Pediatric Renal Center, Academic Medical Center Amsterdam, Amsterdam, Netherlands.*

Renal adysplasia is part of the spectrum of congenital anomalies of the kidney and urinary tract (CAKUT) that forms a major cause of end-stage renal disease in children. Little is known about the origin of renal dysplasia, though it is anticipated that genetic and environmental factors are involved. There is a role for genes expressed during early nephrogenesis in CAKUT etiology. In this study, two genes, uroplakin 3A (UPK3A) and fibroblast growth factor 7 (FGF7), were screened for variants in a phenotypically diverse cohort of 19 Dutch renal adysplasia patients. Four novel, inherited, UPK3A mutations were identified in 3/19 (16%) patients with unilateral multicystic dysplastic kidney. The mutations - c.356T>C (p.Ile119Thr), c.418G>A (p.Gly140Arg), c.450C>A (p.Gly150Gly) and c.545G>A (p.Trp182X) - were not described before and not observed in 96 control chromosomes. As c.418G>A was detected in a patient with VACTERL association (Vertebral defects, Anal atresia or stenosis, Cardiac defects, Tracheo-Esophageal fistula, Radial defects and Renal anomalies, Limb defects), 25 additional DNA samples of VACTERL cases were screened; no mutations in UPK3A were detected. In FGF7, no likely pathogenic mutations were detected. This is the first time a stop-mutation in UPK3A is reported. All UPK3A mutations published so far were reviewed and in silico analyses are presented. This study revealed novel UPK3A mutations strengthening the position of variants in UPK3A in the etiology of renal adysplasia.

P02.208
The low penetrance of retinoblastoma for the V654L mutation in RB1 gene

C. Hung[1,2], *S. Lin*[3,4], *C. Lee*[4], ***Y. Su***[1,2,3];
[1]*Graduate Institute of Clinical Genomics, National Taiwan University College of Medicine, Taipei, Taiwan,* [2]*Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan,* [3]*Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan,* [4]*Department of Obstetrics and Gynecology, National Taiwan University Hospital, Taipei, Taiwan.*

Background
Retinoblastoma is caused by compound heterozygosity or homozygosity of retinoblastoma gene (*RB1*) mutations. In germlinal retinoblastoma, mutations in *RB1* gene predispose increase cancer risk during development and segregates as an autosomal dominant trait with high penetrance (90%).
Methods
In this study, we screened 30 family members from a certain families using high resolution melting assay (HRM) and DNA direct sequencing. We evaluate the phenotype and penetrance of a germ-line mutation of *RB1 gene* in a large Taiwanese family.
Results
The molecular analysis and clinical details of this family showed phenotypic variability associated with certain V654L mutation in exon 19 of *RB1* gene in 11 individuals. The phenotype varies from asymptomatic to unilateral tumor. Only 4 individuals (2 males and 2 females) developed unilateral retinoblastoma, which results in calculated low penetrance of 36% (4/11). In particular, none of them relatives in this family exhibited the variable severity and bilateral retinoblastoma.
ConclusionsThe diseased-eye ratio (DER) for this family was 0.36, lower than current estimates. This suggests that the *RB1* V654L mutation was itself insufficient to develop the retinoblastoma.

P02.209
A case of bilateral retinoblastoma with later development of a jaw osteosarcoma as a second primary malignant tumor

F. F. Cionca[1], *L. Cionca*[2], *C. Nastasia*[2], *C. Ardeleanu*[1];
[1]*"Victor Babes" National Institute for Research and Development in Pathology and Biomedical Sciences, Bucharest, Romania,* [2]*"Prof. Dr. Dan Teodorescu" Clinical Hospital of Oro-Maxilo-Facial Surgery, Bucharest, Romania.*

Introduction
Retinoblastoma represents a rare type of eye malignant tumor that usually develops in early childhood in the retina. Most cases present inactivating mutations in the RB1 gene, located on chromosome 13q14, a tumor suppressor gene which regulates the cell growth. 40 % of all retinoblastomas are germinal, concerning all bilateral forms and 15% of the unilateral ones. The mutation in the RB1 gene is inherited in a autosomal dominant pattern, with a high penetrance rate. Patients

with this form have an increased risk of developing second site primary malignant tumors, including osteosarcoma , pinealoblastoma, Ewing sarcoma, leukaemia, lymphoma, epithelial or brain tumors. Genetic counseling and analysis are indicated for every patient, including an anticipation examination schedule for testing and direct and indirect molecular tests.

Case presentation

A 17 years old female presented with a large, unilateral tumor located on the right upper jaw. From her antecedents we mention: she was born at full term, by normal vaginal delivery, she had developmental milestones adequate for the age. At the age of three she was operated and then chemo and radio treated for bilateral retinoblastoma. Family history for retinoblastoma was negative (including a brother and a sister). The upper maxilla tumor was histopathologically diagnosed as a osteosarcoma.

Conclusion

The patient presented bilateral retinoblastoma in childhood, caused by germline mutation of the RB1 gene, surgical, chemo and radio treated, with an increased risk of developing second site primary malignant tumors, which explains the later development of a jaw osteosarcoma in her case.

P02.210
Novel triple deletion of the MECP2 gene in atypical Rett syndrome patient

I. Sansović, *I. Barišić, K. Dumić;*
Children's Hospital Zagreb, Clinical Hospital Center Sisters of Mercy, Zagreb, Croatia.

Rett syndrome (RTT) is an X-linked dominant neurodevelopmental disorder with variable clinical presentation. About 75-90% patients with classical and 40% with variant RTT have heterozygous mutation in the X-linked MECP2 gene. We report on a 5.5 year old girl with a novel C-terminal MECP2 triple deletion and atypical clinical presentation. The girl was born at term after an uneventful pregnancy. Her development was slow from birth. She started sitting at the age of 12 months and walking at the age of 18 months. By the age of 1 year she acquired several words, thereafter speech deteriorated. Postnatal deceleration of head growth was not present. She was evaluated at the age of 2 years and 8 months due to moderate global developmental delay and behavioural problems (aggressiveness, hyperactivity, screaming and laughing spells and impaired social interaction). At that time her height was 95.5cm (+1SD), weight 18.5kg (+2.5SD), head circumference 50cm (+1SD). On follow up no progression of mental deterioration was observed. Her gait is only mildly disturbed, she is able to walk unsupported, purposeful hand use is preserved, with only occasional stereotypic movements. DNA bidirectional sequencing of MECP2 coding exons revealed de novo triple deletion in C-terminal region of MECP2 gene - c. [1021_1037del17; 1057_1089del33; 1162_1179del18,] not previously described. Result was confirmed with MLPA analysis. The variability of the clinical presentation of RTT emphasizes the need of the molecular analysis of MECP2 gene in all girls with developmental delay.

P02.211
The age related changes of phenotype in boy with ring chromosome 15 and del(15)(q26.2-qter) together with dup(15)(q26.1) .

A. T. Midro[1], *B. Panasiuk*[1], *M. Gogiel*[1], *O. Zuffardi*[2];
[1]*Department of Clinical Genetic Medical University Bialystok Poland, Bialystok, Poland,* [2]*. Biologia Generale e Genetica Medica, Universite di Pavia, Italy, Pavia, Italy.*

In case of ring chromosomes occurring in karyotype the monosomy of the terminal long arm of ring chromosome and mitotic ring instability are taking into consideration as a explanation of peculiar morphologic and behavioral phenotype. Recently inv dup del rearrangements have been described in some of ring chromosomes which may influenced phenotype. We present natural history of 26-years old of boy with developmental delay, short stature and peculiar morphological phenotype and late onset diabetes mellitus type 2. The ring chromosome 15 in his karyotype were detected using GTG and RBG banding techniques. The loss of chromosome material from short and long arm of chromosome 15 leading to monosomy 15q26.2→qter were confirmed by FISH using IGF1R probe (Posejdon). The analysis performed by array-CGH technique with resolution of about 60 kb (kit 105K AGILENT) has revealed: a duplication of about 6.7 Mb of the long arm of a chromosome 15 [dup(15)(q26.1)], with proximal breakpoint falling between 88,860 Mb (normal) end 88,885 Mb (duplicated) and a deletion of about 4.8 Mb of the long arm of a chromosome 15 [del(15)(q26.2→qter)] with proximal breakpoint between 88,885 Mb (duplicated) and 95,606 Mb (deleted). Phenotype -genotype correlation changing with the age was evaluated using dysmorphological protocol of Stengel-Rutkowski et al for quantitative phenotype evaluation of boy for each from 4 periods of development separately and differences have been observed.

P02.212
Rubinstein-Taybi syndrome: case report

M. O. Mkheidze, ***E. S. Shabanova****;*
Medical Academy for Postgraduate Studies, St.Petersburg, Russian Federation.

Rubinstein-Taybi syndrome (RSTS; MIM180849) is a congenital disease characterized by postnatal growth deficiency, microcephaly, specific facial characteristics, broad thumbs and big toes, and mental retardation. Estimated prevalence of RSTS is 1 per 10,000 live births. It occurs generally sporadic, and can be caused by a microdeletion of chromosome 16p13.3, or by mutations in CREB or EP300 genes. Here we reported on 6 years old girl with multiple congenital anomalies and mental retardation. Proband was born premature at 35-36 weeks of seventh pregnancy complicated with anemia, threatened miscarriages at 10-12, 29-30 and 34-35 weeks of gestation. She was the second child of non-consanguineous parents. At birth her father was 25 years aged. Her mother 27 years aged suffered from thyroid enlargement, chronic urogenital infection and had a professional contact with industrial hazards. Proband's birth weight was 1950g and length was 42 cm. At 6 yr her weight was 10,000g, her length 68cm, chest circumference 51cm, head circumference 49cm. Clinical findings of the proband 6 yr aged included mental retardation and speech difficulties, facial abnormalities (down-slanting palpebral fissures, highly arched eyebrows, ptosis, epicanthal folds, strabismus, OD with atypical cataract, hypermetropia of high degree, astigmatism, OS with hypermetropia of average degree and astigmatism, prominent beaked nose, hypoplastic maxilla with narrow palate, malformed ears), digit abnormalities (broad great toes and thumbs, broadness of other fingers, persistent fetal finger pads, syndactyly), cardiac symptoms (tricuspid regurgitation, incomplete right bundle-branch block, premature ventricular repolarization). X-ray examination of upper extremity showed marked malformation of hand bones.

P02.213
Clinical and molecular analyses in a series of 28 patients carrying a pathogenic *SALL4* mutation

Introduction. We report on a series of 28 patients, 16 probands and 12 relatives, presenting with heterozygous *SALL4* mutations on chromosome 20q13.13-q13.2.

Patients. Sixteen probands were initially referred for Okihiro syndrome

(7/16), or other overlapping phenotypes such as Holt-Oram (8/16) or Townes-Brocks (1/16) syndromes. After clinical expertise, final considered diagnoses were Okihiro (11) and Holt-Oram (5) syndromes.
Methods. The clinical and molecular characteristics were analyzed in order to identify genotype-phenotype correlations. Clinical details were obtained from the referent practitioners. Direct sequencing of the complete *SALL4* coding region and quantitative real time PCR were performed. After identification of the causal mutation or deletion, 12 affected relatives were also tested.
Results. We identified 100% radial ray malformations (28/28), 39% Duane anomalies (11/28), 28.5% renal anomalies (8/28), 25% heart defects (7/28), 21% growth-retardation (6/28), 14% deafness (4/28), 11% scoliosis (3/28) and 11% gastrointestinal abnormalities (3/28). Most of the patients carry either a frameshift mutation or a deletion in *SALL4* within exons 2 (68%: 19/28) and 3 (21%: 6/28). Two patients were mutated in exon 4, and 1 presented a complete *SALL4* deletion. Thirteen mutations had never been reported previously.
Discussion. We confirm in this large series that *SALL4* mutations cause a range of variable phenotypes, including Okihiro and Holt-Oram syndromes. These results suggest that all patients presenting with a radial ray malformation should be referred to an ophthalmologist and tested for *SALL4* if an anomaly was to be identified. The clinical characteristics are more precisely defined but genotype-phenotype correlations are not yet obvious.

P02.214
Role of the SCN1A gene in the pathogenesis of familiar febrile seizures and GEFS+

V. Sansoni[1], *D. Grioni*[2], *S. Redaelli*[3], *L. Dalprà*[3], *R. Combi*[1];
[1]*Dept of Biotechnology and Biosciences, University of Milano Bicocca, Milano, Italy,* [2]*Infantile Neuropsychiatry Clinic, San Gerardo Hospital, Monza, Italy,* [3]*Dept of Neurosciences and Biomedical Technologies, University of Milano Bicocca, Milano, Italy.*

Febrile seizures (FS) are epileptic phenomena occurring in course of fever in children with an age ranging from 6 months to 6 years old. FS are the most common type of epilepsy in childhood, with an incidence rate of 2-14%. If febrile seizures persist after six years old, they are considered as an epileptic syndrome named GEFS+, a rare familiar disease that arises as FS and progresses to generalized epilepsy in adults. GEFS+ presents an extremely heterogeneous spectrum of epileptic phenotypes whose acuteness varies from mild to severe.
It is well known that the gene coding the α-1 sodium channel subunit (SCN1A) is mutated in GEFS+ patients; moreover it has been recently suggested as a possible susceptibility locus for FS. We investigated the involvement of SCN1A in a group of GEFS+ and FS families by means of mutation analysis. The study indentified two missense mutations (R542Q and T297I) in highly conserved regions of the channel together with several known SNPs. The R542Q is a de novo mutation already known to be associated with both autism and myoclonic epilepsy, while the T297I, previously associated with SMEI, was identified in all affected members of a family showing FS.
Functional studies aimed at evaluating the effect of these mutations on the physiological properties of the channel are currently in progress. Preliminary results suggest that these variations can compromise the functionality of the protein altering the activation/inactivation properties of the channel.

P02.215
New genetic variation (Y87C) in SCN5A gene in patient with asymptomatic Brugada syndrome

A. G. Shestak, *E. I. Gutovskaya, E. V. Zaklyazminskaya;*
Russian Research Center of Surgery RAMS, Moscow, Russian Federation.

Background: Mutations in the cardiac sodium channel gene (SCN5A) have been identified in people with Brugada syndrome, which causes idiopathic ventricular fibrillation and sudden cardiac death (SCD).
Methods: We have screened coding and contiguous intronic areas of SCN5A gene by DNA sequencing in asymptomatic patient, who was examined in our Centre. He has been observed by physical examination, standard ECG, 24-h Holter monitoring and Echo-CG.
Results: Asymptomatic male patient (46 y.o.) with spontaneous Brugada syndrome type 1 characterized ECG-pattern BrS 1 revealed during planned examination. There were no syncopes, ventricular fibrillation episode, but his son (23 y.o.) also had ECG-pattern BrS 1. There were no observations of sudden cardiac death and heart diseases in this family.
A single nucleotide substitution of A to G at nucleotide position 260 changed the coding sense of exon 2 of the SCN5A from tyrosine to cysteine (Y87C) was found.
Conclusion: We recently identified the Y87C variation by DNA sequencing of SCN5A, which have not been previously described.
A new variation may be associated with the risk of sudden cardiac death. Population analysis of ethnically-matched controls will be perfomed.
This work was partly supported by grant N°02740110783.

P02.216
Screening of BSCL2 in Spanish patients with spastic paraparesis and motor neuropathies.

B. Quintáns[1,2], *S. Piñeiro*[3], *P. Blanco-Arias*[3,2], *J. Pardo*[4], *J. M. Prieto*[4], *S. I. Pascual-Pascual*[5], *A. Ordoñez-Ugalde*[2], *I. Sanz*[6], *A. Rojo*[7], *P. Suárez-Gil*[8], *Á. Carracedo*[2,3], *M. J. Sobrido*[3,2];
[1]*Hospital Clínico Universitario, Santiago de Compostela, Spain,* [2]*Grupo de Medicina Xenómica, Universidade de Santiago de Compostela, CIBERER-Instituto de Salud Carlos III, Santiago de Compostela, Spain,* [3]*Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain,* [4]*Servicio de Neurología, Hospital Clínico Universitario, Santiago de Compostela, Spain,* [5]*Servicio de Neuropediatría, Hospital Universitario La Paz, Madrid, Spain,* [6]*Servicio de Neurología, Hospital Universitario La Paz, Madrid, Spain,* [7]*Servicio de Neurología, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain,* [8]*Servicio de Neurología, Complejo Hospitalario Universitario de Pontevedra, Pontevedra, Spain.*

BACKGROUND: While recessive mutations in Seipin/BSCL2 cause Berardinelli-Seip lipodystrophy, dominant gain-of-toxic-function mutations affect upper and lower motor neurons, causing Silver syndrome (SS), hereditary spastic paraplegia (HSP-SPG17), distal hereditary motor neuropathy (dHMN) and Charcot-Marie-Tooth disease type 2 (CMT2). p.N88S and p.S90L in the glycosylation site are the only mutations identified in neurologic seipinopathies, however screening was generally limited to the canonical 398 aa seipin isoform. A longer isoform of 462 aa has been proposed but its role remains unknown.
AIMS: To investigate the contribution of BSCL2 to HSP and motor neuropathies.
METHODS: Sequencing the whole coding region of the large BSCL2 isoform (NM_001130702.1; NP_001124174.1) in: a) 106 cases of spastic paraplegia without mutations in spastin and atlastin; b) 10 patients with peripheral neuropathy and pyramidal signs without mutations in other CMT genes. Sequence variations were checked in 180 control individuals.
RESULTS: One family with the p.N152S (p.N88S in short isoform) mutation showed manifestation spectrum from pure-HSP to SS and pyramidal signs without subjective symptoms. One family with the p.S154L (p.S90L) mutation presented pure HSP, CMT2 or dHMN. Seven new BSCL2 sequence variations were detected (4 missense, one in-frame deletion, two intronic).
CONCLUSIONS: Seipin mutations account for at least 1% of spastic paraparesis and 10% of motor neuropathies with pyramidal signs in our series. Variable expression within a given kindred is the rule, difficulting diagnostic awareness. The role of BSCL2 isoforms in the nervous system, as well as the functional effect of sequence variants in motor neuron disorders remains to be elucidated.

Finlay-Marks syndrome, or Scalp-Ear-Nipple (SEN) syndrome (MIM ID %181270) is a very rare Autosomal Dominant disorder, first described in 1978 by Finlay and Marks in a family with 10 affected individuals over five generations. The clinical diagnosis is based on the occurrence of scalp defects, dysplastic ears, and absent or rudimentary nipples and breasts. Urinary tract malformations and/or disfunctions, and diabetes,

were reported in three cases.
We report the follow-up study in the affected one of two dyzygotic female twins, since the age of 2 years and during 36 years. The periodical clinical evaluation, with the recurrent, diagnostic, laboratory and instrumental tests, in order to follow the natural history, revealed a progressive number of additional features. Normal intelligence and behaviour, and the characteristic phenotype confirm the data reported in the very few cases of the literature. The patient was submitted to surgery correction of the congenital bald nodules over the scalp, reduction of the hypertelorism, correction of the prominent and dysplastic ears, and correction of the bilateral athelia and amastia. Unilateral renal hypoplasia, identified by ultrasounds at age 5 years is now associated with severe renal hypertension. Normal 46,XX constitutional karyotype and normal CGH array. By using a battery of polymorphic DNA markers we confirmed the DZ twinning.

Missense heterozygous mutations in SET binding protein 1 gene (SETBP1) have been recently demonstrated to cause Schinzel-Giedion syndrome (SGS, MIM #269150). SGS is characterised by severe mental retardation, distinctive facial features, and multiple congenital malformations abnormalities (skeletal anomalies, hearth defects, genitourinary and renal malformations) (Hoischen et al, 2010). More recently, some authors describes two patients with *de novo* chromosomal microdeletions in 18q12.3 and SETBP1 haploinsufficiency. The patients shows a milder phenotype distinct from SGS and characterised by moderate developmental delay and peculiar facial features including prominent forehead, sparse eyebrows, mild ptosis (Filges et al, 2010). Both patients exhibit expressive speech impairment. Here, we describe a patient with an apparently balanced *de novo* translocation t(2;18)(q24;q21) and mild mental retardation, peculiar facial features and expressive language impairment in presence of conserved receptive language skills. Oligo array-CGH analysis revealed the presence of a cryptic interstitial deletion of about 372 Kb. The microdeletion is located near the breakpoint region at 18q12.3 and causes the disruption of SETBP1 gene. The patient here described shows a significant phenotypic overlap with the previously reported patients with SETBP1 haploinsufficiency. All these patients differ significantly from the Schinzel-Giedion syndrome. The fundamental phenotypic feature of our patient and of the previously described two patients is the discrepancy between expressive and receptive language abilities, suggesting an essential role of SETB1 in expressive speech development. Functional studies will be necessary to unravel the exact function of this gene.

P02.219
A Large Turkish Setleis Syndrome Family

***R. O. Rosti**[1], Z. O. Uyguner[2], S. Pehlivan[1], M. Bekerecioglu[3];*
[1]Gaziantep University Medical Biology and Genetics Department, Gaziantep, Turkey, [2]Istanbul University Istanbul Medical Faculty Department ofMedical Genetics, Istanbul, Turkey, [3]Gaziantep University Plastic and Reconstructive Surgery Department, Gaziantep, Turkey.

Focal facial dermal dysplasias (FFDDs) are a group of rare ectodermal disorders characterized by bitemporal scar-like lesions that resemble forceps marks and additional facial findings that give an aged-leonine appearance. Three subtypes have been delineated based on clinical features. Lately, it has been found that homozygous nonsense mutations in TWIST2 cause type III FFDD, or Setleis syndrome.
We describe a Setleis syndrome family of Turkish origin in which there are three affected sibs born to a first degree cousin marriage. Detailed clinical features and pedigree will be included along with detailed imagery of characteristic facial findings. Mutational analysis are under way for TWIST2. These mutational data will be shared in the poster as well.

P02.220
Autosomal recessive form of Severe Combined Immune Deficiency Disease as the predominant pattern in Iranian patients

***M. Malek**, M. Houshmand;*
Special Medical Center. Genetic Laboratory, Tehran, Islamic Republic of Iran.

Introduction : Severe Combined Immune Deficiency (SCID) is a rare syndrome which can show an X-linked or autosomal recessive inheritance pattern. World-wide investigations showed nearly 48% X-linked inheritance, caused by mutations of the IL-2 receptor. This form of SCID is characteristically $T^-/NK^-/B^+$. On the other hand many genes are involved in the autosomal recessive form. The aim of this study was to determine the inheritance pattern of SCID among affected families in Iran.
Methods: Genomic DNA of 20 unrelated male patients with T^-B^+ clinical symptoms of SCID was purified from peripheral blood. PCR and sequencing of the *IL2RG* gene was performed in patients to find out if they harbour any mutation.
Results: Because the patients were considered to have T^-B^+ SCID , we analyzed the *IL2RG* gene of the patients for mutations by direct genomic sequencing. The X-linked mode of inheritance was not detected in any patient. The *IL2RG* gene of all the patients was normal, suggesting an autosomal mode of inheritance of SCID.
Discussion: About 48% of SCID patients worldwide are reported to have IL2RG deficiency, but our preliminary result shows that the autosomal recessive pattern is predominant in Iranian SCID patients. The high frequency of consanguineous marriage makes it less likely that isolated cases of SCID are caused by *IL2RG* mutations. However, this conclusion is based on only a small number of patients. This is a pilot study and much more investigation is needed to clarify which gene is most frequently causative in Iranian patients.

Molecular karyotyping identifies CNVs in individuals with short stature

***D. Zahnleiter**[1], U. Trautmann[1], A. B. Ekici[1], D. Wieczorek[2], A. Reis[1], H. Doerr[3], A. Rauch[4], C. T. Thiel[1];*
[1]Institute of Human Genetics, Erlangen, Germany, [2]Institute of Human Genetics, Essen, Germany, [3]Department of Pediatrics and Adolescent Medicine, Erlangen, Germany, [4]Institute of Medical Genetics, Schwerzenbach-Zurich, Switzerland.

Shortness of stature is one of the most common concerns in genetic counselling. Overall, 3 % of the population present with a body height below -2 SD score (SDS). In about 80% of cases (idiopathic short stature) the underlying cause remains unknown.
To identify novel genetic causes of growth retardation we performed molecular karyotyping in 105 individuals with idiopathic short stature. We found a total of 3,787 aberrations with an average of 36 copy number changes per individual. To rule out copy number polymorphisms, a screening of all identified CNVs was carried out against an independent control cohort of 820 healthy individuals.
To narrow down our search for potential pathogenic CNVs, we analysed all remaining 1,499 aberrations based on their gene content. A total of 46 CNVs (27 duplications, 19 deletions) in 34 patients were retained for follow-up. Inheritance of 30 CNVs (2 *de novo*, 14 maternally and 14 paternally inherited) could be verified in 23 families. After re-evaluating the parental growth phenotypes, 10 CNVs (2 de novo, 6 maternally and 2 paternally inherited) in 9 families, including 5 duplications and 5 deletions, were scored as potentially pathogenic. These CNVs cover a range of 34 to 14,229 kb in size with only one aberration smaller than 100 kb.This is the first report of a systematic approach using molecular karyotyping to identify novel genetic causes of shortness of stature. We identified individual potentially pathogenic CNVs in 9% of affected individuals, supporting a “rare variant - frequent disease” hypothesis.

P02.222
SHOX gene polymorphic variants and their association with isolated short stature

*K. Hirschfeldova, V. Kebrdlova, R. Solc, M. Florianova, P. Lnenicka, J. Stekrova, R. Mihalova, A. Baxova, **M. Florianova**;*
Institute of Biology and Medical Genetics, 1st FM and GTH, Charles University

in Prague, Prague, Czech Republic.
Mutations or deletions affecting production of the short stature homeobox-containing gene (SHOX) are responsible for a small portion of cases with isolated short stature (ISS). We were interested if *SHOX* gene polymorphic variants predispose for the ISS phenotype.
Our sample was made of 43 unrelated probands in charge of the Department of Medical Genetics (GTH and 1stFM, Charles University in Prague). Study inclusion criteria were the presence of short stature (-2,0 SD) in combination with at least one of following symptoms: disproportionate stature, cubitus valgus, short forearm, bowing of forearm, muscular hypertrophy, or dislocation of ulna (at elbow). A population sample of 96 individuals was used to compare the frequencies. DNA sequencing was done of *SHOX* gene exons 1 (including promotor), 2, 3, 4, 5 and coding parts of exons 6a and 6b.
Overall, eleven polymorphic variants (promoter, exon 1, exon 2, and exon 6b) were detected and one unique mutation in exon 6a. Four polymorphisms were already described in the SHOX database (SHOX @ http://www.hd-lovd.uni-hd.de/). Three promoter polymorphism and one sequence variant from the exon 1 are in a strong linkage. There was no statistically significant difference in rare allele frequencies between ISS group and population sample.
Our study indicates that *SHOX* gene polymorphic variants are not significantly associated with isolated short stature.
This work was supported by Grant No. IGAMZCR NS/ 10327-3/2009.

P02.223
Duplication of pseudoautosomal region 1 and *SHOX* gene could be linked with characteristic phenotype

***K. Dumic**, L. Morozin-Pohovski, I. Barisic;*
Childrens University Hospital Zagreb, University Clinical Centre "Sisters of Mercy", Zagreb, Croatia.
The reports on duplications of *SHOX* gene and pseudoautosomal region 1 (PAR 1) are scarce and thus the information on the possible phenotypic consequences is lacking. We report on five new patients from two families with large duplication of SHOX gene and downstream PAR 1 region. All of them were of normal or even short stature, with no signs of skeletal deformities or Mayer-Rokitansky-Kuster-Hauser type I syndrome. However all patients had a distinct phenotype, characterized with dysmorphic facial features (deep set eyes, high forehead, retrognathia), developmental delay/mental retardation, speech delay and stereotypic mouth movements which segregated with duplication of *SHOX* gene and PAR 1 in both families.
So far, data on only 4 patients with large duplications of both *SHOX* gene and PAR 1 downstream of the *SHOX* gene have been published. In three of them mental retardation and dysmorphic features similar to those observed in our patients were described.
Analysis of the size and position of duplications indicates that the ~50 kb large region of overlap between 626 kb and 678 kb, located in the PAR 1 could be responsible for the distinctive phenotype. It is very likely that duplications of *SHOX* gene and PAR 1, which still hasn't been completely sequenced, are under-ascertained. With increasing application of molecular cytogenetic methods like MLPA, more patients with large duplication of the *SHOX* gene and PAR 1 or isolated PAR 1 will be eventually discovered delineating phenotypic consequences in more details.

P02.224
Brachydactyly: a rare complication of sickle cell anaemia

***D. G. M. Bosch**, C. A. van Nieuwenhoven, A. J. M. Hoogeboom;*
Erasmus MC Rotterdam, Rotterdam, Netherlands.
We present a 17 year old woman with acquired brachydactyly. The left hand showed a short metacarpal, proximal phalanx and mid phalanx of the fourth digit. There is also a deformation of the proximal phalanx. The right hand showed shortening of the third and fourth metacarpals. The pattern of the skeletal involvement did not fit with the known congenital brachydactyly groups. She was known with sickle cell anaemia and she endured dactylitis in childhood. In 40% of the cases with HbSS, the first clinical manifestation is dactylitis, also known as hand-foot syndrome. Dactylitis in sickle cell anaemia is the result of vaso-occlusion and infarction of the bone. In rare cases infarctions of the epiphyses result in an asymmetric brachydactyly, like in our case.

P02.225
11p15 familial duplication causing Silver-Russell syndrome in the daughter and Beckwith-Wiedemann syndrome in the mother.

***R. Teek**[1], T. Kahre[1,2], K. Muru[1,2], O. Zhilina[1,3], P. Mee[4], K. Õunap[1,2];*
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, [2]Department of Pediatrics, University of Tartu, Tartu, Estonia, [3]3Department of Biotechnology, Institute of Cell and Molecular Biology, University of Tartu, Tartu, Estonia, [4]United Laboratories, Tartu University Hospital, Tartu, Estonia.
Silver-Russell syndrome (SRS) is a clinically and genetically heterogeneous disorder characterized by severe intrauterine and postnatal growth retardation. Beckwith-Wiedemann syndrome (BWS) is defined by overgrowth, hemihyperplasia and an increased risk of childhood tumors. It is known that SRS and BWS are both resulted by methylation defects in chromosomal region 11p15. Most of cases SRS and BWS are sporadic but some familial cases are also reported. We report here a familial case, where daughter has SRS and her mother BWS caused by duplication in 11p15 chromosomal region.
The proband was consulted by geneticist at the neonatal age due to dysproportionate intrauterine and postnatal growth retardation and dysmorphic features typical to SRS. We performed the chromosomal microarray analysis (CMA) of the child and found ~1.3-Mb size duplication in chromosomal region 11p15.5. CMA analysis of her parents revealed that the duplication is inherited from her mother, who has the same duplication at the region 11p15.5. Patients' mother has overgrowth since the birth and clinical features of BWS. The further investigations of grandparents are in work.
SRS and BWS have been linked with a variety of epigenetic and genetic defects affecting a cluster of imprinted genes at chromosome 11p15.5. More than 50% BWS patients have aberrant methylation patterns in 11p15. In SRS patients were found hypomethylation patterns in up to 63%; 11p15 duplication in maternal material was found in only 1-2%. There is previously only one report in the literature about 11p15 duplication resulted in SRS and BWS phenotype in single family.

Molecular investigations of Polish patients with Silver-Russell syndrome

***A. Tańska**[1], E. Ciara[1], A. Marczak-Hałupka[2], M. Kugaudo[1], M. Kalina[3], D. Jurkiewicz[1], M. Borucka-Mankiewicz[1], P. Kowalski[1], S. Łuczak[1], M. Pelc[1], D. Piekutowska-Abramczuk[1], J. Trubicka[1], M. Krajewska-Walasek[1], K. Chrzanowska[1];*
[1]Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland, [2]Genetic Out-patient Clinic, Regional Institute for Mother, Child and Adolescent Care, Katowice, Poland, [3]Department of Pediatrics, Endocrinology and Diabetes, Medical University of Silesia, Katowice, Poland.
Silver-Russell syndrome (SRS) is a clinically and genetically heterogeneous syndrome characterized by intrauterine growth restriction, body asymmetry, relative macrocephaly and a typical triangular face. SRS is caused by epigenetic dysregulation of the imprinted genes controlled by two Imprinting Centers Regions: ICR1 and ICR2 located on chromosome 11p15.5. Hypomethylation of ICR1 is found in ~40% of patients with SRS. In addition, hypomethylation of other imprinted loci can be detected in ~7% of ICR1 hypomethylation carriers. Moreover, 5-10% of SRS individuals have epigenetic alterations due to maternal uniparental disomy of chromosome 7 (mUPD7).
We analyzed 87 patients with clinical diagnosis of SRS. We examined the methylation profile of the ICR1 by MS-MLPA analysis and mUPD7 by STR analysis for chromosome 7. We confirmed hypomethylation of ICR1 in 31 individuals. Interestingly, 2 of these patients were monozygotic twins with both ICR1 and ICR2 hypomethylation. STR analysis carried out on patients without detected hypomethylation of ICR1 revealed mUPD7 in 8 patients. We demonstrated maternal hetero-, isodisomy and a mixture of hetero- and isodisomy. Applied molecular techniques enabled us to confirm clinical diagnosis of SRS in ~45% of patients. The cause of almost half of SRS cases is still unknown. It is hypothesized that other imprinted loci and molecular factors can be involved in SRS etiology. Our findings concerning ICR1 and ICR2 hypomethylation are consistent with the assumption.
The study was supported by the Polish Ministry of Science and Higher Education (grant No NN 407 285339).

P02.227

Molecular karyotyping is indicated in growth-retarded patients with SRS features

S. Spengler[1], *M. Begemann*[1], *M. Baudis*[2], *B. Denecke*[3], *B. Schulze*[4], *C. Spaich*[5], *P. Kroisel*[6], *T. Eggermann*[1];
[1]*Institute of Human Genetics, RWTH University Hospital Aachen, Aachen, Germany,* [2]*Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland,* [3]*IZKF Aachen, RWTH University Hospital Aachen, Aachen, Germany,* [4]*Practice of Human Genetics, Hannover, Germany,* [5]*Institute of Clinical Genetics, Stuttgart, Germany,* [6]*Institute of Human Genetics, Graz, Austria.*

Silver-Russell syndrome (SRS) is a congenital disorder characterized by severe growth retardation, relative macrocephaly, a triangular face and asymmetry. The clinical spectrum is broad and the diagnosis is rather subjective. In nearly half of patients (epi)genetic alterations can be detected: >38 % show a hypomethylation of the imprinting control region 1 in 11p15; 10 % carry maternal uniparental disomy of chromosome 7 (upd(7)mat). Besides conventional cytogenetic findings recently submicroscopic chromosomal imbalances have been reported in single cases.To determine the relevance of submicroscopic imbalances for the aetiology of the SRS, we performed molecular karyotyping of 39 patients referred as SRS without 11p15 (epi) mutations and upd(7)mat using the Affymetrix SNP Array 6.0. In three patients probably pathogenic de-novo imbalances were identified: a 5.4 Mb microdeletion in 15q26 including *IGF1R*, a 2.5 Mb microdeletion of the DiGeorge region and a 9.1 Mb duplication in Xq26. In further 18 patients we detected a total of 26 different, so far unregistered copy number alterations (CNAs): up to now, 15 were determined to be probably apathogenic rare familial CNVs; for three CNAs a de-novo origin was discovered. To our current knowledge it is unclear whether they are causative for the patients' clinical features. In summary, in three of 39 (7,7%) patients pathogenic de-novo imbalances were detected. In further three patients the pathogenic significance of the CNAs remains unclear. In conclusion, submicroscopic chromosomal imbalances significantly contribute to the mutational spectrum of the SRS. Therefore molecular karyotyping is indicated in idiopathic patients with SRS features.

A Simpson-Golabi-Behmel patient with severe neonatal liver involvement

B. Demeer[1], *G. Morin*[1], *D. Djeddi*[2], *G. Jedraszak*[1], *F. Lacaille*[3], *M. Raynaud*[4], *J. Micheli*[5], *F. Amram*[1], *R. Rhazlane*[6], *S. Lanta*[7], *M. Mathieu*[1];
[1]*Genetics department, CHU Amiens, Amiens, France,* [2]*Pediatrical gastroenterology unit , CHU Amiens, Amiens, France,* [3]*Pediatrical gastroenterology department, Necker Enfants Malades hospital, Paris, France,* [4]*Molecular genetics department, CHU Tours, Tours, France,* [5]*Pediatrical oncology and haematology unit, CHU Amiens, Amiens, France,* [6]*Paediatrics department, CHU Amiens, Amiens, France,* [7]*Gynaecology and Obstetrics department, CHU Amiens, Amiens, France.*

Patient prenatal period was marked by the discovery, on the 22 gestation weeks (GW) ultrasound of an hydramnios and fetal macrosomia (biparietal diameter and abdominal circumference >97 percentile). There was no gestational diabetes, and no fetal caryotype was performed. At 27 GW, a bilateral nephromegaly without pyelocaliectasis was found. A close ultrasound follow-up till the end of the pregnancy showed a stability of the ultrasound signs.

The patient was delivered by ceasarean section at 38 GW, and birth parameters were : weight : 4kg105, height 52cm and OFC 37cm. On examination, he had hypotonia, feeding difficulties and was icteric. He also presented facial dysmorphism with coarse features, hypertelorism, anteverted nares and macrostomia. Three abdominal supernumerary nipples and a abdominal diastasis recti were noted. Extremities were normal. No neonatal hypoglycemia was noted. Abdominal ultrasounds confirmed the bilateral nephromegaly, and then showed an hepatomegaly at 2 weeks of age. Blood tests showed a hepatic cholestasis and jaundice.

At the age of 6 weeks, because of worsening of cholestasis, persistent jaundice and difficulties displaying the biliary ducts on CT scan, a liver biopsy was performed. It showed no biliary atresia, but found a significant proliferation, portal fibrosis and cholestasis.

The study of the *GPC3* gene found a single base deletion in the exon 7, confirming the diagnosis of Simpson-Golabi-Behmel syndrome (SGBS).

Apart from the visceromegaly, neonatal liver involvement is very rarely associated to the SGBS. We will precisely describe this case, especially the hepatic data, and compare it to the literature.

P02.229

Expanding the Phenotype of Spondyloepiphyseal Dysplasia-Brachydactyly and Distinctive Speech syndrome in patients of Diverse Ethnic Backgrounds

A. Guerin[1], *L. Dupuis*[1], *L. Fishman-Shapiro*[1], *B. Alman*[1], *C. Le Goff*[2], *V. Cormier-Daire*[3,2], *R. Mendoza-Londono*[1];
[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*Hôpital Necker, Paris, France,* [3]*Paris Descartes University, Paris, France.*

Spondyloepiphyseal Dysplasia-Brachydactyly and Distinctive Speech dysplasia (SED-BDS, MIM 611717) is characterized by postnatal short stature, brachydactyly, platyspondyly, facial dysmorphisms, delayed epiphyseal ossification and characteristic voice. Only a few cases have been described and the molecular etiology is uncertain. We present two unrelated individuals who share clinical and radiological features of SED-BDS and compare them with other conditions with similar phenotypes.

Patient 1 was born to a non-consanguineous Chinese couple. At 13 years of age he had severe short stature with height below the third centile. Dysmorphic features included upslanting palpebral fissures, mildly coarse face and brachydactyly. He has a high pitched hoarse voice were noted. Skeletal survey showed platyspondyly, metaphyseal irregularity and delayed bone age. Patient 2 was born a non-consanguineous Ghanian couple. He was diagnosed with congenital heart disease in infancy. At 7 years of age his height was below the third centile and had round face, brachydactyly and hoarse voice. Skeletal survey showed shortening of long bones with brachydactyly.

SED-BDS is a recently described skeletal dysplasia. Conditions that must be considered in the differential include acromicric and geleophysic dysplasias. Mutations in *ADAMTSL2* have been identified in some patients with geleophysic dysplasia and is thought to interact with TGF-β, which is important for cell proliferation, migration, differentiation, and survival. As these conditions have clinical and radiological overlap distinguishing between them can be a challenge. Molecular studies of *ADAMTSL2* in our patients are underway to further investigate the molecular defect underlying these disorders.

P02.230

Extense spanish pedigree affected of SMN1 gene deletion diagnosed by MLPA

A. Zuñiga, ***I. Pitarch****, Y. Bello, A. Guerrero;*
Hospital de la Ribera, Alzira (Valencia), Spain.

BACKGROUND: Spinal muscular atrophy (OMIM 253300) refers to a group of autosomal recessive neuromuscular disorders characterized by degeneration of the anterior horn cells of the spinal cord, leading to symmetrical muscle weakness and atrophy. SMA is the second most common lethal, autosomal recessive disease in Caucasians after cystic fibrosis. More than 95% of SMA patients show homozygous deletion of at least exon 7 of the telomeric *SMN1* gene. SMA carriers can be identified by the presence of only a single copy of *SMN1* exon 7.

MATERIAL AND METHODS: We report a three month-old infant who was hospitalized because she refused to eat. Clinical examination revealed an alert infant with weakness of all four limbs, hypotonia and absent deep tendon reflexes. Serum creatine kinase and liver enzyme studies were normal. Electrophysiological studies revealed reduced compound muscle action potential amplitudes (CMAPs). Distal latencies, F-waves latencies, and sensory nerve action potentials (SNAPs) were normal. Magnetic resonance imaging of the brain and spine was appropriate for age. A genetic test detected a complete deletion of the *SMN1* gene by MLPA. Members of the family were studied in order to detect carriers of the *SMN1* deletion.

RESULTS AND CONCLUSIONS: Genetic study of a *SMN1* deletion was performed in 21 members of both sides of the family. In the paternal family, a deletion was confirmed affecting *SMN1* and the *BIRC* gene, which is located close to *SMN1*. In the maternal family, the deletion was confined to the *SMN1* gene. We detected 16 heterozygous carriers for this deletion and proper genetic counseling was offered.

P02.231

A patient with short stature, microcephaly and mental retardation associated with 5q35.2 duplication reciprocal to the common Sotos syndrome deletion

O. Zilina[1], *A. Kurg*[1], *K. Õunap*[2,3];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Department of Pediatrics, University of Tartu, Tartu, Estonia,* [3]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia.*

The higher-order architecture of the human genome has been shown to predispose to structural rearrangements that are frequent cause of human diseases. Recombination- and replication-based mechanisms have been described to generate genomic rearrangements. The mechanism responsible for the vast majority of common-sized recurrent rearrangements is nonallelic homologous recombination (NAHR) between region-specific low-copy repeats (LCRs). This mechanism assumes that recombination between the same pair of directly oriented LCRs could result either in deletion or reciprocal duplication. So far, only a few duplications reciprocal to the recurrent deletions associated with different syndromes (e.g. Williams-Beuren and Smith-Magenis syndrome) have been described.

Here we present a patient with 5q35.2 duplication of the Sotos syndrome critical region. The Sotos syndrome is characterized by childhood overgrowth, learning disability and distinctive facial appearance, and is caused by *NSD1* gene defects (point mutations, partial gene deletions and 5q35 microdeletions). Clinical evaluation of the patient at 13 years revealed short stature (-4SD), microcephaly (-3.5SD), dysmorphic face, bradydactyly, cone shape epiphyses, delayed bone age, and mental retardation. A 2-Mb duplication at 5q35.2 (5:174950741-176979615 (NCBI36)) was detected applying HumanCytoSNP-12 BeadChip (Illumina Inc.) analysis. So far, only two patients with duplications reciprocal to the Sotos common deletion have been reported, with phenotypes very similar to that observed in our patient. Thereby, our patient supports the hypothesis that *NSD1* plays a role in regulation of somatic growth in humans, and gene's dosage reduction or increase may lead to reversed phenotypes. More patients and further investigations are needed to reveal the exact mechanisms.

P02.232

Cutis laxa associated with Sotos syndrome: a clinical and molecular puzzle.

O. M. Vanakker[1], *H. Verhelst*[2], *B. Menten*[1], *P. Verloo*[2], *R. Van Coster*[2], ***A. De Paepe***[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Paediatric Neurology, Ghent University Hospital, Ghent, Belgium.*

Introduction. Cutis laxa, characterized by fragmentation of elastic fibres, has been associated with several syndromic phenotypes with heterogeneous mode of inheritance. Besides the skin symptoms, related systemic features are diverse, including skeletal, pulmonary, cardiovascular and metabolic symptoms.

Results & discussion. The first child of healthy non-consanguineous parents is presented, born at 38 weeks' gestation. During pregnancy, an isolated unilateral hydronephrosis was detected. At birth, dysmorphic features were noted, including macrocephaly with sparse frontal hair, a pointed chin and low-set, posteriorly rotated ears. In addition, redundant skin folds in the neck, hands and lower limbs were present. Skin biopsy confirmed the diagnosis of cutis laxa. Soon after birth, he developed episodes of hypoglycaemia. Radiographies revealed an advanced bone age (4.5 months for 5 weeks of age) and advanced bone maturation.

The phenotype of this patient showed resemblance to Costello syndrome. However, these patients do not have advanced bone age and maturation. Micro-array analysis revealed a 5q35.2q35.3 deletion, compatible with Sotos syndrome. Cutis laxa is however not a classic feature. Three cases of alleged Sotos syndrome with cutis laxa have been previously reported; however, contrary to our patient, neither advanced bone age nor hypoglycaemia were present.

Conclusion. The phenotype of our patient does not fully comply with the Sotos with cutis laxa syndrome. This might suggest that this patient harbours a second mutation in the deleted 5q35 region which may explain the presence of cutis laxa.

P02.233

Intrafamilial variability in a large kindred with SVAS and an *ELN* mutation

M. Gonçalves-Rocha[1], *S. Magalhães*[1], *C. Cruz*[2], *R. El Malti*[3], *E. Dias*[4], *P. Bouvagnet*[3];
[1]*Unidade de Genética Médica - Departamento de Genética, Centro de Genética Médica JM, INSA,IP, Porto, Portugal,* [2]*Cardiologia – Unidade de Medicina, Hospital São João, EPE, Porto, Portugal,* [3]*Laboratoire de Cardiogénétique Moléculaire, Centre de Biologie et Pathologie Est, Hospices Civils de Lyon, Lyon, France,* [4]*Cardiologia Pediátrica – Unidade da Mulher e da Criança, Hospital São João, EPE, Porto, Portugal.*

Supra Valvular Aortic Stenosis (SVAS; MIM ID #185500) has an incidence of 1/20 000 live births and is associated with mutations in elastin gene (*ELN*). SVAS can occur sporadically, as a dominant trait or as a part of Williams-Beuren syndrome (WBS). WBS is characterized by developmental delay, particular psychological phenotype and dysmorphic features, and is caused by a microdeletion ~1,5Mb at 7q11.23 which encompasses *ELN* and at least other 24 genes.

We report on a large family with 17 affected members spanning 4 generations with variable phenotypic presentation with isolated or a combination of several major arteries stenosis, namely: SVAS, common pulmonary stenosis or peripheric pulmonary stenosis. No developmental delay, particular psychological phenotype or dysmorphic features of WBS were present in any of the affected individuals.

ELN exons and intron-exon boundaries were amplified by PCR and mutation screening was performed by High Resolution Melting (HRM). Exons showing an abnormal amplification profile or with frequent SNPs were sequenced. After testing 18 coding exons, a heterozygous transversion G>T was found at position 34 (c.34C>T) changing the Glycine at position 12 to a stop codon (p.Gly12X). This nonsense mutation is presumably responsible for haploinsufficiency as often observed in *ELN* mutations in SVAS.

Remaining affected members are currently being investigated for the mutation what will expectably confirm segregation within this family.

This report underlines the clinical intrafamilial variability of *ELN* mutations and highlights the importance of cascade screening enabling a proper genetic counseling.

P02.234

A six year old boy with Temple syndrome due to segmental maternal uniparental disomy 14 and clinical features of Prader Willi syndrome

K. Platzer[1], *I. Stefanova*[1], *K. Buiting*[2], *S. Purmann*[1], *G. Gillessen-Kaesbach*[1];
[1]*Institut für Humangenetik, Universität zu Lübeck, Lübeck, Germany,* [2]*Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany.*

Temple syndrome is associated with a recognizable phenotype consisting of pre- and postnatal growth retardation, neonatal hypotonia, feeding problems and precocious puberty. The molecular cause of Temple syndrome comprises a deficiency of imprinted gene expression in the paternal chromosome region 14q32 due to maternal uniparental disomy 14 (upd(14)mat), an epimutation or deletion on the paternal allele. Chromosome 14 contains an imprinted gene cluster, which is regulated by a differentially methylated region (IG-DMR) between the genes *DLK1* and *GTL2*.

We report on a six year old boy with severe neonatal hypotonia and feeding difficulties, followed by hyperphagia with onset during his third year of life with absence of satiety and leading to obesity. Additional features were short stature, small hands and feet, delayed psychomotor development, sleep apnea and fever attacks. His phenotype was strongly suggestive for Prader Willi syndrome, but methylation analysis of the 15q11-q13 region revealed no abnormalities. Considering Temple syndrome as an important differential diagnosis we consequently performed methylation analysis of the 14q32 region, which revealed lack of the paternal band. Further analysis with microsatellite markers and SNPs detected a segmental upd(14)mat of the 14q32 region in our patient.

To our knowledge, there are no reported patients with a segmental upd(14)mat of the 14q32 region so far. We provide a review of the literature on patients with Temple syndrome and discuss on the phenotype genotype correlation.

P02.235
Partial tetrasomy 14 associated with multiple malformations

J. Winberg[1], *K. Lagerstedt Robinson*[1], *A. Liedén*[1], *B. Anderlid*[2], *C. Graff*[3], *A. Nordenskjöld*[4], *A. Nordgren*[1], *P. Gustavsson*[1];
[1]*Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden,* [2]*Department Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden,* [3]*Department of Neurobiology, Care Sciences and Society, Karolinska Institute, Stockholm, Sweden,* [4]*Department of Woman and Child Health, Karolinska Institute, Stockholm, Sweden.*

We report a 6-year-old girl with multiple malformations including bilateral cleft lip and palate, coloboma and craniosynostosis. The girl also suffers from severe mental retardation, seizures and gastrointestinal dysfunction. In addition she has a mitochondrial defect with reduced function of complex I and III of the respiratory chain. An abnormal karyotype was identified showing an extra marker chromosome. The marker chromosome was identified in all cells in both peripheral blood lymphocytes and cultured fibroblasts whereas parental chromosomes were normal. Array-based comparative genomic hybridization (CGH) revealed tetrasomy for proximal 14q corresponding to a 14,6 Mb region on 14q11.2q13.2 spanning more than 60 known genes. To determine the origin of the marker chromosome we analyzed polymorphic markers using quantitative fluorescent PCR (QF-PCR). The results from the QF-PCR indicate formation of the marker chromosome in maternal meiosis. Partial tetrasomy 14q has previously been reported in four cases, however, this is the first described non-mosaic case not resulting in early lethality.

P02.236
The incidence and morbidity of congenital thoraco - abdominal wall defects

M. C. Popoiu[1], *V. L. David*[2], *A. V. Popoiu*[1], *M. Puiu*[1], *G. F. Brad*[2], *A. Timofte*[3], *P. Fuicu*[1], *E. S. Boia*[1];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*Emergency Children's Hospital "Louis Turcanu", Timisoara, Romania,* [3]*Municipal Hospital, Timisoara, Romania.*

Background: Congenital abdominal and thoracic wall defects remain a source of significant morbidity and mortality, despite the advances in neonatal and pediatric surgical care. The abdominal wall is much more often involved in congenital birth defects than the thoracic wall, which are more severe and have dismal outcomes more often. Material and methods: This is a 4 years period analysis of the entire cases of congenital thoracic and abdominal wall defects admitted to the pediatric surgery department of our hospital. Results: There were six cases of gastroschisis, two omphaloceles, one sternal cleft and one case of ectopia cordis. Surgical repair was performed in emergency conditions for all gastroschisis and omphalocels with good outcomes. Postoperative complications were: intestinal adhesions after one case of gastroschisis repair and rezidual eventration after omphalocele closure, considered with no significant influence over the final outcomes. For ectopia cordis surgical covering was performed but, unfortunately the patient died 24 hours after surgery. No surgical treatment was necessary for the sternal cleft. Conclusions: Although the prenatal diagnosis is accessible, there are many cases diagnosed after birth. This study helps to bring together the most recent epidemiological data regarding outcomes and interventions for thoracic-abdominal wall defects and to compare the epidemiology of such kind of malformations in different regions of the country.

P02.237
Three Tumor Necrosis Factor promoter polymorphisms in Romanian patients with Sjogren's syndrome - Results from a pilot-study

R. Sfrent-Cornateanu, *D. Opris, O. Popa, C. Bara, R. Ionescu;*
Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Sjögren's Syndrome (SS) is an autoimmune disorder which affects exocrine glands. Tumor Necrosis Factor alpha (TNF-α) contributes to the physiopathology of autoimmune diseases including SS. The -857C/T, -308G/A and -238G/A polymorphisms of TNF-α gene demonstrated their influence on the susceptibility and clinical phenotype of autoimmune diseases.
We aimed to investigate the influence of these three TNF-α polymorphisms on the susceptibility and clinical phenotype of primary Sjögren's syndrome in Romanian patients.
We assessed 141 Romanian subjects (37 primary SS patients and 104 healthy unrelated matched controls) for all three polymorphisms. TNF-α -857C/T (rs1799724), -308 G/A (rs1800629) and -238G/A (rs 361525) polymorphisms were genotyped by Real Time PCR (Taqman SNP Genotyping Assays C_2215707_10, C_7514879_10 and C_11918223_10 respectively, Applied Biosystems, USA). Association tests for each SNP were performed using SPSS 12.0 (T student test) and p values ≤0.05 were considered significant.
The Hardy-Weinberg equilibrium assessed using Chi-square test was respected in all studied groups for all polymorphisms.
The frequencies of minor alleles -857T, -308A and -238A, were similar in primary SS patients and controls (0.21/0,16/0.09 and 0.18/0,15/0.04 respectively). Primary SS patients carriers of A allele (-238G/A) seems to have less digestive (t= 2,95) and systemic (t=1,4) manifestations than G carriers. The primary SS patients carriers of T allele (-857C/T) seems to have more xerophthalmia (t=2,8) and xerostomia (t=3,04) than C allele carriers.
Conclusion: TNF-α polymorphisms (-857C/T and -238G/A) seems to influence clinical manifestations. The three polymorphisms of TNF-α does not influence susceptibility to SS. These results should be confirmed on larger patients cohort.

P02.238
Unusual family advice causes Turner-like syndrome

M. A. Soylemez*;*
Marmara University Medical School, Istanbul, Turkey.

Objective: To recognize long term use of high potency steroids from an early age as a potential cause of iatrogenic Cushing Syndrome (CS) and Turner-like symptoms.
Case Presentation: A 16 year old teenage girl was referred from her gynecologist with diagnosis of Turner syndrome (TS). The most consistent features of TS are short stature and premature ovarian failure. She had initially presented for follow up of amenorrhea about 8 weeks prior to referral and was noted to have short stature (<3.p) at a hospital. Upon presentation to our clinic, she was noted to have a round plethoric face, supraclavicular/dorsocervical fat pads, centripetal obesity and short stature. Lab tests showed ACTH 15pg/mL (6-46pg/mL) and 8 a.m cortisol of 0.3mcg/dL (6-30mcg/dL). TSH, LH, FSH, and prolactin were normal. Chromosomal analysis revealed a 46,XX karyotype. Iatrogenic and factitious Cushing Syndrome was investigated. Further discussion with the patient and her family revealed oral use of 0.75 mg/day dexamethasone for 12 years. The patient is a 16 year-old teenage girl who had begun to take high dose deksamethasone by the advice of her family at the age of four. She continued to use the steroid so far.
Conclusions: Oral intake of high dose steroid at the beginning of the childhood can cause iatrogenic CS and Turner-like symptoms. An inspection is not enough searching for the right diagnosis of genetic syndromes. We recommend a careful patient history and a detailed physical examination in terms of Turner syndrome and other genetic diseases.

P02.239
Unbalanced chromosomal translocation 3;5 in child with dysmorphic features and developmental delay. Case report.

D. Locmele, *Z. Krumina, G. Kalnberza, A. Dzalbs;*
State Medical Genetic Clinic, Riga, Latvia.

We report a clinical case of a unbalanced translocation between 3p and 5q chromosome terminal regions which results in 3rd chromosome short arm subtelomeric region deletion and 5th chromosome long arm subtelomeric region trisomy.
Consulted for the first time at the age 4y6m due to speech delay and changed behavior. Anamnesis: boy was born from 5th pregnancy, 3rd delivery to 38 years old mother from nonconsanguinous marriage. During first trimester mother had flu. Delivery on 38/39th week of gestation, birth weight 2360g, length 49cm. He had poor weight gain during 1st year of life, he started to walk at the age of 1y4m. He had one episode of seizures at the age 4y 5m. Speech- he use less than 10 words. Hearing test has not been performed.
Investigation: height 96cm (<<3rd percentile), weight 14kg (3rd pc), OFC 46.6cm (<<3rd pc), 6.5cm, 3rd finger 4.5cm. Dysmorphic features: deformed skull, almond shaped eyes, small mouth, irregular tooth placement, smooth philtrum, over folded helix, fetal pads, changed

dermatoglyphics in left hand, unilateral cryptorchism. Behavior: comes to sit in lap and wants to kiss during consultation, puts hair and dog fur into mouth, touches himself, no toilet training.
There was performed a karyotyping and FISH for subtelomeric region. Result: 46,xy.ish der(3)t(3;5)(pter-;qter+). Karyotyping was performed to both parents and father is a carrier of balanced translocation with result- 46,xy,t(3;5)(p26;q32~33).

P02.240
Clinical expression of an inherited unbalanced translocation in Chromosome 6

B. B. Ganguly[1], *V. Kadam*[2], *N. N. Kadam*[3];
[1]*MGM Centre for Genetic Research & Diagnosis, Navi Mumbai, India,* [2]*MGM's Medical College, Navi Mumbai, India,* [3]*MGM's New Bombay Hospital, Navi Mumbai, India.*

Congenital malformation in newborns is the first visible expression of major chromosomal alterations followed by growth and mental retardation and systemic complications. The unbalanced rearrangements are not common; however, have significant clinical expression. The parental balanced translocation produces unbalanced chromosome, which is eventually transmitted to next generation through fertilization of gametes carrying the derivative chromosome. The carriers of balanced rearrangements mostly do not have recognizable phenotypic expression. We report a family comprising of healthy and non-consanguineous young parents and their primi newborn severely affected with multiple congenital anomalies and systemic disorders. Conventional G-banding analysis of somatic chromosomes identified a balanced translocation, t(6;10)(p23;q24) in mother and an unbalanced rearrangement, der(6),t(6:10)(p23;q24)mat in the child. The child has inherited a derivative chromosome 6 with partial deletion of 6 (p23-pter) and partial trisomy 10(q24-qter), which has obviously resulted in fusion of genes of two different chromosomes. The prominent phenotypic features of del(6p), including high forehead, flat nasal bridge, agenesis of left year, atrio septal defect (ASD), craniosynostosis and growth retardation were overlapping with specific Axenfeld-Reiger -, Larsen - and Ritscher-Sinzel/3-C syndromes; however, lacking in ocular anomalies, skeletal laxity or cerebellar malformation. Therefore, this report rules out the isolated effect of del(6p23) or trisomy 10(q24) on distinct previously reported syndromes and proposes the combined effect of unbalanced chromosomal alteration.

P02.241
Paternal uniparental disomy (UPD) 14 is an important cause of infantile hypotonia in a South African cohort

K. E. Kuhn, F. Essop, ***A. Krause****;*
Division of Human Genetics, NHLS and School of Pathology, the University of the Witwatersrand, Johannesburg, South Africa.

Paternal and maternal uniparental disomy (UPD) for chromosome 14 are associated with two distinct phenotypes, accounted for by two oppositely imprinted genes on chromosome14, *DLK1* (paternally expressed) and *MEG3* (maternally expressed). Maternal UPD 14 is characterised by intrauterine growth retardation, hypotonia at birth, short stature, small hands and feet, scoliosis, mild developmental delay, early childhood obesity and precocious puberty, a phenotype overlapping with Prader-Willi syndrome (PWS). Paternal UPD (14) is reportedly less common, more severe and is characterised by severe neonatal respiratory problems, hypotonia, abdominal muscular defects, skeletal anomalies, and characteristic facies.
The study aimed to determine the frequency of UPD14 in 238 patients who were referred for PWS (86 patients) or SMA (152 patients) testing and who tested negative for the requested disease. Patients were sub classified into an infantile hypotonia group and a childhood PWS phenotype group. Genomic DNA was modified with a bisulfite modification kit. Multiplex methylation PCR of the modified DNA was used to determine whether UPD14 was present. Thirteen (5.5%) patients tested positive for paternal UPD14, while no patients tested positive for maternal UPD14. All paternal UPD 14 patients were from the hypotonic infants group. Further clinical and molecular analysis is in progress.
Paternal UPD14 which is reported to be rare was identified in a significant number of infants (<1 yr) referred for PWS and/or SMA testing, suggesting that neonatal and infantile hypotonia is a significant feature. UPD 14 analysis should be included in the routine genetic workup of patients with infantile hypotonia.

P02.242***
Wang syndrome- Four new cases each with a different underlying molecular mechanism

A. Dixit[1], *S. Naik*[2,3], *D. Mackay*[2,3], *K. Low*[4], *P. Fleming*[5], *W. van Hensbergen*[6], *M. Lever*[2,3], *R. L. Poole*[2,3], *H. Bullman*[2,3], *S. Smithson*[4], *I. K. Temple*[2,3], *M. Suri*[1];
[1]*Department of Clinical Genetics, Nottingham City Hospital, Nottingham, United Kingdom,* [2]*Division of Human Genetics, Faculty of Medicine, University of Southampton,, Southampton, United Kingdom,* [3]*Wessex Genetics Service, Southampton University Hospitals NHS Trust, Southampton, United Kingdom,* [4]*Department of Clinical Genetics, St Michael's Hospital, Bristol, Bristol, United Kingdom,* [5]*St Michael's Hospital, Bristol, Bristol, United Kingdom,* [6]*Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background
Wang syndrome is the eponym for paternal uniparental disomy for chromosome 14 (UPD14pat). Affected children present with polyhydramnios, narrow thorax with characteristic coat-hanger ribs, hypotonia, abdominal wall defects, high birth weight but poor postnatal growth, developmental delay, and typical facial dysmorphism including prominent, hisute forehead, elongated philtrum, micrognathia, short neck and mild joint contractures. We report four new cases of Wang syndrome with different underlying molecular mechanisms.
Report
Polyhydramnios and relatively increased abdominal circumference were noted during pregnancy in all cases. All patients showed characteristic chest x-ray and clinical features of Wang syndrome in the neonatal period. Methylation-specific PCR of the 14q32.2 differentially methylated region (DMR) showed only a methylated (paternal) product in all cases.
Case 1: Male child with an epimutation at maternally inherited 14q32.2 DMR.
Case 2: Female infant with segmental UPDpat for the 14q32.2 region.
Case 3: Male infant with a de novo microdeletion of the 14q32.2 DMR on his maternally inherited chromosome 14.
Case 4: Female infant with isodisomy for paternal chromosome 14.
Conclusion
These cases demonstrate that Wang syndrome is a clinically recognisable phenotype with typical radiological findings. Further studies are required to delineate the long-term prognosis and correlate this to the underlying molecular mechanism.

P02.243
Van Maldergem syndrome - a report of the first male patient and expansion of the clinical spectrum.

N. Tyshchenko[1], *K. Hackmann*[1], *D. Müller*[1], *A. Rump*[1], *E. Schrock*[1], *S. Tinschert*[1], *T. M. Neuhann*[1,2];
[1]*Institut für Klinische Genetik, TU Dresden, Dresden, Germany,* [2]*Medizinisches Genetisches Zentrum, Munich, Germany.*

Two unrelated female patients with a combination of mental retardation, hypotonia, distinctive combination of minor facial anomalies with telecanthus, epicanthus, broad flat nose, large mouth with an everted lower lip, small dysplastic ears, finger camptodactyly, and joint hyperlaxity were described by van Maldergem et al (1992) and Zampino et al (1994).
We report on the first male patient with the proposed diagnosis of van Maldergem syndrome. His parents are first cousins.
At the age of 4 years the boy presented severe developmental delay, talipes equinovarus, genital abnormalities, finger camptodactyly with interdigital webbing, joint laxity and a dysmorphic facies. The medical history was significant for pharyngeal instability requiring the placement of a tracheostomy tube and an inquinal hernia. He showed bilateral epicanthus, telecanthus, short palpebral fissures, broad flat nasal bridge, dental malocclusion, bilateral microtia. Due to severe feeding difficulties permanent tube feeding is required. The combination of the specific facial features with camptodactyly, interdigital webbing, joint laxity and developmental delay lead to the working diagnosis of van Maldergem syndrome. Metabolic tests and chromosomal analysis were normal. Array-CGH (Agilent 2x400K) revealed two parental CNVs, which are not listed as polymorphisms but might contribute to the patient's phenotype. Taking together, the report of the third patient with van Maldergem syndrome adds new features to the clinical spectrum such as male genital malformations, hernia, pharyngeal instability and severe feeding difficulty.

P02.244
A case of adult-onset vanishing white matter disease with *EIF2B3* gene mutations

Y. Ohnuki[1], *A. Kondo*[1], *T. Yanagimachi*[1], *T. Matsukawa*[2], *S. Izumi*[1], *S. Takagi*[1];
[1]*Tokai University School of Medicine, Kanagawa, Japan,* [2]*Tokyo University, Tokyo, Japan.*

Leukoencephalopathy with vanishing white matter (VWM) is a rare neurological disease associated with gene defects in *EIF2B1-5*. It is an autosomal recessive disorder with spasticity, cerebellar ataxia, and a relatively mild mental impairment. In most reported cases, *EIF2B5* mutations were identified. This is the first report of a patient with adult-onset VWM associated with mutation in *EIF2B3*.

A 31-year-old woman with progressive ataxic gait was referred. At age 20, an MRI study had shown diffuse leukoencephalopathy in the absence of any clinical neurologic signs. Five years later, headache and sensory disturbance appeared. At age 28, amenorrhea and ataxic gait appeared. All laboratory investigations, including evaluation of blood lactate and pyruvate,α-galactosidase and arylsulfatase A, were normal. Genetic study confirmed the diagnosis, revealing that the patient was homozygous for the novel T80A mutation in *EIF2B3*. By age 31, she has become bed-ridden.

P02.245
Waardenburg syndrome: Intrafamilial clinical variability in a 4-generation family.

I. M. Furquim, *A. C. de Paula;*
Hospital Municipal da Crianca e Adolescente, Guarulhos, Brazil.

Waardenburg syndrome (WS) is a rare syndrome with estimated prevalence of 2-3/100,000 in the general population within the Netherlands. Main features include facial dysmorphisms and congenital deafness. WS is classified into several forms based on whether dystopia canthorum is present (WS1) or absent (WS2), and whether upper limb defects (WS3) or Hirschsprung disease (WS4) are present. WS1 exhibits autosomal dominant inheritance with complete penetrance and variable expressivity. Mutations in PAX3 gene are responsible for WS1 phenotype. The index case is a 4-year-old female, first child of a young non-consanguineous couple, presented with displacement of the medial canthi, heterochromia iridis, white forelock and bilateral congenital sensorineural hearing loss. Her family history, however, showed other 06 affected relatives with different features of WS1.The purpose of this report is to describe the clinical variability among the affected members of this family. Molecular analysis is important to confirm the diagnosis and may help determining genotype-phenotype correlations.

P02.246
Knockouts of the murine ortholog of the atypical Williams-Beuren tyrosine-protein kinase gene Baz1b present cardiac and circadian rhythm impairments

G. Didelot[1], *C. Berthonneche*[2], *G. Ricard*[1], *Y. Emmeneger*[1], *P. Franken*[1], *T. Pedrazzini*[2], *A. Reymond*[1];
[1]*Center for Integrative Genomics, Lausanne, Switzerland,* [2]*Cardiovascular Assessment Facility, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

The Williams-Beuren syndrome (WBS) is a multisystem disorder caused by the hemizygosity of 25 genes, five of which encode transcription factors or chromatin remodeler. Modest perturbations in the dosage of the latter might substantially alter the expression of multiple target genes. Hence these genes are prime candidates to play a role in the phenotype of the patients.

To address the physiological and molecular role of one of these genes, the Bromodomain Adjacent to Zinc finger 1b gene (*BAZ1B*), *in vivo*, we ablated by transposable element insertion the expression of its ortholog in mice. Almost all *Baz1b*$^{-/-}$ embryos (97%) die a few hours after birth. The rare survivors do not present any of the craniofacial abnormalities previously identified in knockouts of the murine orthologs of other genes of the WBS interval. They are, however, smaller in size than their control littermates and present a smaller heart with larger ventricular walls. Noticeably, this abnormal heart appears to be associated with an increased cardiac function as measured by the percentage of blood ejected with each contraction. This translates in a significant increase in nighttime activity and sleep perturbation. We are currently characterizing histologically the heart of *Baz1b*$^{-/-}$ embryos.

Potential candidates genes for these multiple phenotypes have been identified by chromatin immunoprecipitation with antibodies raised against the BAZ1B unusual tyrosine-kinase.

Pyrroline-5-carboxylate reductase 1 deficiency leads to a complex clinical phenotype; Report of 6 patients

A. Kariminejad[1], *R. Kretz*[2], *B. Bozorgmehr*[1], *M. Rohrbach*[2], *I. Hausser*[3], *A. Baumer*[4], *M. Baumgartner*[5], *C. Giunta*[2], *J. Häberle*[2], *M. H. Kariminejad*[1];
[1]*Kariminejad Najmabadi Pathology and Genetics Center, Tehran, Islamic Republic of Iran,* [2]*Kinderspital Zurich, Division of Metabolism, Zurich, Switzerland,* [3]*Electron Microscopic Laboratory, Dermatological Department and EM Core Facility, University Heidelberg, Heidelberg, Germany,* [4]*Institut für Medizinische Genetik, Switzerland, Switzerland,* [5]*Kinderspital Zurich, Division of Metabolism, Switzerland, Switzerland.*

Wrinkly skin syndrome is a heterogeneous condition characterized by cutis laxa, wrinkly skin over hands and feet, progeroid appearance, visible veins over thorax, congenital hip dislocation with or without mental retardation. Loss of function mutations in the ATP6V0A2 gene and mutation in the gene encoding pyrroline-5-carboxylate synthetase (ALDH18A1; 138250), has been reported in some patients diagnosed with wrinkly skin syndorme.

Recently, mutations in *PYCR1* were described in patients with similar features (Guernsey et al. 2009; Reversade et al. 2009). The pathophysiological basis appears to be an impaired mitochondrial function leading to developmental defects through increased apoptosis. Here, we describe six patients with clinical manifestations of a wrinkly skin disorder. The patients all have distinct facial features comprising of thin triangular face, loss of adipose tissue, and thin pointed nose. Additional features are IUGR, short stature, wrinkling over dorsum of hand and feet, visible veins over chest, hyperextensible joints (mostly of fingers and toes), congenital hip dislocation, loss of muscle bulk. The age ranges from 4 months to 55 years. Three of the patients from a large consanguineous family did not have mental retardation while the remaining three patients from 3 separate families had mental and or developmental delay. Mutation analysis revealed the presence of disease-causing variants in *PYCR1*. Light- and electron microscopy investigations showed alterations of collagen and elastic fibres compatible with the involvement of collagen and elastin in the pathophysiological mechanism.

P02.248
Giant congenital melanocytic nevi mistaken for neurofibromatosis type 1

K. E. Stuurman, *C. J. Dommering;*
Department of clinical genetics, VU University Medical Center, Amsterdam, Netherlands.

An 80-year old developmentally normal male was referred to our department with a clinical diagnosis of neurofibromatosis type 1. The patient was born with numerous diffuse lenticular erythematous and brownish firm papules covering his entire body. The papules differed in size from several millimeters to one giant plaque covering almost his entire back. At the age of one year, part of this lesion was removed from his neck in order to allow better movement of his head. Over the years two more papules were removed. Removed papules did not grow back. His medical history showed basal cell carcinoma which was diagnosed on two occasions. He had an otherwise unremarkable medical and family history. His two sons and grandson were reported not to be affected by this disorder. Upon examination, no freckling, café-au-lait spots or Lisch noduli were noted and testing of the *NF1*-gene did not reveal a mutation. Array CGH was normal. Pathology results showed that the skin lesions were nevi naevocellulares, fitting the diagnosis of giant congenital melanocytic nevi (GCMN). GCMN are disfiguring lesions, consisting of cutaneous melanocytes. These GCMN, presenting at birth and covering minimally 2% of the total body surface area, are uncommon and have an estimated prevalence of one in 20.000 in live born children. GCMN usually occur sporadically, but familial cases have been described. The genetic background however remains unknown. To our knowledge this is the first time a case with such an extensive and unusual presentation of GCMN is described.

P02.249
Identification of a WWOX germinal mutation in a Spanish family without diagnosed cancer: insights into its supposed tumour suppressor function

J. Gardenyes[1], *Ó. Abad*[1], *P. Fàbregas*[1], *R. Ciordia*[2], *M. A. López-Arizteguí*[3], *V. Volpini*[1], *B. Campos*[1];
[1]*Center for Molecular Genetic Diagnosis (CDGM) - IDIBELL, L'Hospitalet de Llobregat, Spain,* [2]*Servicio de Neurología, Hospital de Cruces, Barakaldo, Spain,* [3]*Servicio de Genética, Hospital de Cruces, Barakaldo, Spain.*

The WW domain-containing oxidoreductase (*WWOX*) gene is located at 16q23.3-q24.1, within the fragile site FRA16D. It has nine exons and an open reading frame of 1,245 bp, encoding a 414 amino acids protein.

In the last few years, considerable amount of data has shown that *WWOX* participates in a number of cellular processes including growth, differentiation and apoptosis. Moreover, inactivation of *WWOX* has been observed in a variety of human malignancies, and targeted deletion of one allele of *Wwox* in mice causes increased spontaneous and chemically induced tumour incidence, including lymphomas, lung papillary carcinomas, liver tumours, and gastric squamous cell carcinomas. Altogether, these data indicate that *WWOX* is a tumour suppressor and that inactivation of one allele is sufficient for tumourigenesis.

Here we report the identification of a *WWOX* germline mutation in a 52-years-old female with psoriasis and an extradural mass (neurogenic tumour versus hemangiopericytoma or meningioma were considered as differential diagnosis), who was referred to our laboratory for molecular testing of Neurofibromatosis 1. The mutation consists in a 48.6 kb deletion and a 14 bp insertion, resulting in exclusion of exons 6-8 from the mature transcript. The same mutation was detected in the proband's father and two siblings, without diagnosed cancer.

Our findings show that inherited mutations in *WWOX* gene do not lead to a high predisposition to develop malignancies, as could be expected from mouse models and other reported data. Future identification of more families with germinal mutations in *WWOX* will allow clinicians to define its associated phenotype.

P02.250
Maternally inherited duplication Xq11.1-Xq13.1 in a boy with craniosynostosis, mild mental retardation and facial dysmorphism

C. Rigon[1], *K. Ludwig*[2], *A. Casarin*[1], *E. Trevisson*[1], *L. Salviati*[1];
[1]*Clinical Genetics, Department of Pediatrics, University Hospital, Padova, Italy,* [2]*Department of Medical Diagnostic Sciences & Special Therapies, Pathology Unit; University of Padova, Padova, Italy.*

Partial duplications involving the long arm of chromosome X have been reported as causing mental retardation and multiple malformations. Although data regarding these specific chromosomal anomalies in males are limited and duplication extensions are variable, a clear pattern of characteristic features, including short stature, developmental delay, cryptorchidism, restricted joint mobility and cranio-facial dysmorphisms has been identified.

We report the case of a 14 year old male patient with craniosynostosis, mild mental retardation, facial dysmorphisms and non specific polyarthritis. Chromosomal analysis on peripheral blood lymphocytes showed a normal male karyotype. Array-CGH, MLPA and quantitative PCR analysis revealed a duplication of approximately 5.9MB on the long arm of the X chromosome, subsequently identified in the proband's mother and grandmother.

As far as we know this is a unique rearrangement as there are no previous reports about a Xq11.1-Xq13.1 duplication. Among the 35 duplicated genes, *EDA* appeared to be the best candidate to explain at least some of the phenotypic peculiarities in our patient being the only gene known to have been associated to a gain of function phenotype in mice. It encodes ectodysplasin, a TNF- family protein required for normal morphogenesis and differentiation of several ectodermal organs. We therefore analysed the levels of *EDA* transcript and some of its downstream interactors by quantitative PCR.

Our data showed marked hyperexpression of *EDA*, supporting its role in determining, at least partially, the phenotype of our patient. Dosage sensitive genes as cause of the phenotype of our patient will then be discussed.

P02.251
A case of Zimmemann-Laband syndrome with supernumerary phalanx

Y. Capri[1,2], *C. Baumann*[1], *A. Aboura*[3], *S. Drunat*[4], *A. Verloes*[1,2], *L. Perrin-Sabourin*[1];
[1]*Clinical genetic, CHU Robert Debre, Paris, France,* [2]*University of medecine, Paris 7 Diderot, Paris, France,* [3]*Cytogenetic, CHU Robert Debre, Paris, France,* [4]*Molecular genetic, CHU Robert Debre, Paris, France.*

Zimmermann-Laband syndrome (MIM 135500) is the association of gingival fibromatosis, aplasic or hypoplasic nails, skeletal anomalies, hypertrichosis and facial dysmorphism. Occasionally, patient can display mental retardation, hepatosplenomegaly, mild hearing loss and supernumerary teeth. Molecular basis is still unknown but pattern of inheritance is more likely autosomal dominant.

We report on a 7 year-old girl with the hallmark of Zimmermann-Laband syndrome and particular distal phalanges. A large spectrum of phalangeal abnormalities could be seen such as classical hypoplastic but also epiphyseal hypertrophy, bi-partita or supernumerary phalanx. We discuss the spectrum of skeletal anomalies in this syndrome. In fact, if gingival and oral findings are frequently and well described, skeletal aspects of this disease are less known.

Cytogenetic exploration and CGH-array have been practiced on this patient's blood sample and results will be discussed.

P02.252
Clinical spectrum of heritable disorders connective tissue in Russian cohort patients

V. A. Rumyantseva, *O. M. Bogopolskaya O.M., E. R. Charchyan, E. V. Zaklyazminskaya;*
Petrovsky Russian Research Centre of Surgery RAMS, Moscow, Russian Federation.

Background: Heritable disorders of connective tissue (HDCT) often predispose patients to aortic aneurysm and acute aortic dissection. Forms of HDCT caused by mutations in the *TGFBR1* or *TGFBR2* genes have a severe prognosis due to the high risk of aortic rupture.

Patients and Methods: We performed clinical and genealogical examination of patients undergoing surgical repair of aortic root dilation/aneurysm and their relatives. Personal and family history were collected, and clinical examination (standard and 24-hour Holter ECG, EchoCG, Dopplerography, chest radiography) and genetic analysis were performed.

Results: We examined 66 index patients and relatives (mean age 33 y.o., range 4 to 64 y.o.) with HDCT symptoms (57% male). A positive family history was detected in 21%. A significant number of patients (77%) required operation because of large vessel aneurysm and/or valvular insufficiency. The phenotypic spectrum within the HDCT group was as follows: Loeys-Dietz Syndrome 5%, Marfan Syndrome 16%, Ehlers-Danlos Syndrome type IV 14%, Ehlers-Danlos Syndrome type VI 4%, TAAD 26%, functional valvular insufficiency 11%, aneurysms of large vessels 7%, MASS phenotype 3%, non-differentiated HDCT 14%. The overwhelming majority of patients had had cardiac arrhythmias. Mutation screening in the *TGFBR1* and *TGFBR2* genes is in progress now.

Conclusion: Correct molecular confirmation in families with HDCT is required to identify probands at high risk for aortic dissection. Even in the absence of identified mutations causing HDCT, we recommend standardized examinations of first-degree relatives in affected families. Prophylactic aortic root replacement should be considered for patients at risk.

This work supported by grants from Russian Ministry of Education and Science 02.740.11.0783.

P02.253
A case with Noonan syndrome and renal hypoplasia

C. Daescu[1,2], *I. Maris*[1,2], *I. Simedrea*[1,2], *O. Marginean*[1,2], *M. Puiu*[1,2], *T. Marcovici*[1,2], *O. Belei*[1,2], *A. Militaru*[1,2], *R. Stroescu*[1,2], *C. Duncescu*[2];
[1]*„Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*"Louis Turcanu" Emergency Hospital for Children, Timisoara, Romania.*

Introduction: Noonan syndrome comprises an unusual facies and multiple malformations, including congenital heart disease. Aim: To present the case of a boy with Noonan syndrome and right renal hypoplasia. Material and Methods: 19 months old B.M., of male gender, was referred to our department for a urinary tract infection. We

based our diagnosis on clinical features and imaging studies. Results: During the physical we noted the following features: micrognathia, low-set posteriorly rotated ears, hypertelorism, down-slanting palpebral fissures, epicanthal folds, proptosis, strabismus, dental malocclusion, short neck with low posterior hairline, shield chest, pectus excavatus, brachydactyly, blunt fingertips, retractile left testis. Furthermore, the child had a short stature. The neurologic consult found a mild motor delay. The cardiac ultrasound showed aortic regurgitation and obstructive hypertrophic cardiomyopathy. We performed an abdominal ultrasound which revealed right renal hypoplasia. The audiologic and ophthalmologic examinations were unremarkable at this time, but the child will require ongoing follow-up. Discussion: Renal anomalies are present in 10% of patients and are not usually clinically significant. In this case, a condition associated with this anomaly led to the proper diagnosis. Conclusion: Although described for the first time almost 50 years ago, Noonan syndrome can still reveal itself in unusual circumstances.

Deafness- associated DFNB599 gene (Pejvakin) mutations in Sistsn va Bluchestan province.

m. abolhasani[1], *E. Farrokhi*[1], *M. Taher zadeh*[1], *f. azadegan*[1], *A. Asgari*[1], *D. Farhood*[2], *S. Raisi*[1], *Z. Noeparast*[3], *G. Bani Talebi*[1], *M. Hashem Zadeh*[1];
[1]*Cellular and Molecular Reserch Center, shahrekord, Islamic Republic of Iran,* [2]*Genetic Clinic, Tehran, Islamic Republic of Iran,* [3]*Walf Organization, Tehran, Islamic Republic of Iran.*

Background and aim: Hearing loss is a common disorder affecting millions of individuals worldwide with opproximately 1 in 1000 newborns. A novel gene, DFNB59 encods Pejvakin has been recently shown to cause neural deafness. The aim of this study was to determine the frequency of DFNB59 gene mutations in 93 deaf pupils in Sistsn va Bluchestan province.
Methods: We investigated the frequency of DFNB59 gene mutations in the coding regions (exons 2-7) of the gene.
DNA was extracted following the standard phenol chloroform procedure, the frequency of DFNB59 gene mutations was investigated using PCR-SSCP /HA strategy.
Results: No pathogenic variant was detected in samples studied. However, one polymorphism including 793C>G was determined in 3 of 93 (3.2%) subject examined.
Conclusion: The results of this study showed no associated between DFNB59 gene mutations and hearing loss in Sistan va Baluchestan province.

New mutation in Notch3 gene of CADASIL in Iranian patients

M. Balali, *o. Aryani, S. Saber, M. Houshmand;*
special meddical center, tehran, Islamic Republic of Iran.

Cerebral autosomal dominant arteriopathy with sub cortical infarcts and leukoencephalopathy (CADASIL (is an inherited cerebrovascular disease due to mutations of the Notch3 gene at the chromosome locus 19p13. The clinical spectrum includes recurrent ischemic episodes, cognitive
Deficits, migraine and psychiatric disorders. MRI reveals extensive cerebral white matter lesions
And sub cortical infarcts. Notch 3 gene, encodes a transmembrane receptor and contains 33 exons. The mutation responsible for CADASIL are located within the extracellular domain of Notch 3, with strong clustering within exon 3 and 4 in more than 70% of patients.
In this study DNA was extracted from a patient suspected to CADASIL with clinical manifestations. Exon 3 and 4 of Notch 3 gene was amplified by PCR. After sequencing we found a c.347A>T mutation in exon 4 0f Notch 3 gene .This mutation alters Aspartic acid to Valine..

J02.03
The first case of diagnostics mucopolysaccharidosis type III in Novosibirsk region.

A. R. Shorina[1], *V. A. Makasheva*[1], *N. V. Ganina*[2], *N. P. Fedoruk*[3];
[1]*Novosibirsk Regional Children's Clinical Psychoneurological Dispensary, Novosibirsk, Russian Federation,* [2]*State Novosibirsk Regional Clinical Hospital, Novosibirsk, Russian Federation,* [3]*Paediatric Departament, Urgent Children's Municipal Hospital 3, Novosibirsk, Russian Federation.*

We report a case of diagnosis of Sanfilippo syndrome, the first in the territory of the Novosibirsk region. The diagnosis was made at a medicogenetic consultation at a children's psychoneurological dispensary. The proband, a girl of five years, was observed by the psychiatrist with a diagnosis of serious mental retardation (F72).
Psychoneurological features were prominent. In development of the child there was a retrogression of mental functions with a crushing defeat of intelligence, speech and communication functions, disturbances of behaviour with excitation and aggression. A lack of skills of self-care becomes perceptible. Craniofacial dysmorphism and signs of an osteal dysostosis were expressed moderately. The neurologic status: a lower spastic paraparesis, Babinsky positive signs, disturbance of gait and coordination, a divergent squint.
Functional examination showed CT signs of hydrocephaly, signs of an intracranial hypertension; a thickening of the cusps of the mitral valve, a sinus arrhythmia and episodes of transient sinuatrial blockade.
The clinical diagnosis has been confirmed in the laboratory of hereditary diseases of metabolism of the RAMS Research Center for Medical Genetics (Moscow). In the *SGSH* gene the mutation p.R74C was identified. Distinctive features of the present case are absence of the cramps characteristic of the classical variant of MPS III, neurosensory deafness and diarrhoea. It is possible to assume that this is related to the early diagnosis of disease.

Pierre Robin Syndrome - Evolution and Prognostic at Distance

M. Boia, *E. S. Boia, A. Manea, D. Iacob;*
University of Medicine and Pharmacy V. Babes, Timisoara, Romania.

Introduction: Pierre Robin syndrome is a rare condition in current medical practice, with an incidence of 1/8500-1/30000.
Clinical diagnosis is easily accomplished in the presence of typical associated malformations.
Objectives: We present the case of a newborn with Pierre Robin syndrome associated with omphalocele in major form.
Material and method: A premature newborn, gestational age 35 weeks, female, from a pathological pregnancy, presented at birth with a major omphalocele, requiring rapid surgical intervention. The particular phenotype with severe micrognathia, cleft palate, glossoptosis associated with stuck sternum and intraventricular septal defect easily suggested the clinical diagnosis.
Results: Low birth weight, early surgical intervention, cardiac malformation, associated respiratory distress and abdominal wall defect made a difficult clinical evolution. There were no karyotypic abnormalities. Progress was difficult due to feeding difficulties and recurrent respiratory infections that led to weight loss and prolonged hospitalizations.
Conclusions: 1. Clinical diagnosis of Pierre Robin syndrome is easily effected. 2. Even though severe associated malformations were present there were no karyotypic abnormalities.
3. The long-term prognosis is good through treatment and management by a multidisciplinary team.

Prevalence of the A1555G, A3243G and A7445G mitochondrial mutations in non-syndromic hearing impairment in Khuzestan province of the Iran

G. Banitalebi[1], *M. MOntazerozohori*[1], *E. Farokhi*[1], *M. Abolhasani*[1], *S. Reisi*[1], *F. Azadegan*[1], *Z. Ataii*[2], *H. Majed*[1], *S. Keshavarz*[3], *M. Hashemzadeh*[1], *A. Hosseinipor*[4];
[1]*cellular and molecolar reaserch center, Shahrekord, Islamic Republic of Iran,* [2]*cellular and molecolar reaserch center of Iran univercity, Tehran, Islamic Republic of Iran,* [3]*department of Exeptional children,Ministry of Education and Training, Shahrekord, Islamic Republic of Iran,* [4]*Dept of Exeptional children, Ministry of Education and Training, Shahrekord, Islamic Republic of Iran.*

Background and aime: Hearing impairment (HI) is one of the most prevalent sensorineural handicaps that occurs 1 in 1000 at new born. More than 50 nuclear genes have been shown to be involved in nonsyndromic HI, but mitochondrial mutations might also cause HI.Mitochondrial mutations are present in 0-2% hereditary hearing impairment .In the present study, we investigated three common mutation of the mtDNA molecule among 62 subject with non syndromic hearing impairment in Khuzestan province of the Iran.

Method: Individual's DNA was extracted using standard phenole-chloroform method. We screened known mtDNA mutations (A1555G, A3243G and A7445G) by PCR-RFLP procedure. Finally, the mutations were found confirmed by direct sequencing.
Results: A1555G and A3243G mutations were not found in our study. However, mutations screening by PCR-RFLP technique and direct sequencing revealed a known A7445C mutation and an unknown G3316A mutation in two hearing impaired patients with frequency of 3.2%.**Conclusion:** we concluded that contribution of mitochondrial mutations in hearing impaired patients in Khuzestan province can be importantly. Then testing for mutation in mtDNA should be considered only when other frequent deafness causing mutations have been excluded.

J02.06
Hereditary hearing loss and consanguinity

M. Khaleghian[1], *C. Azimi*[1], *Z. Safari*[2], *A. Fathpour*[1];
[1]*Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Young Researchers Club, Varamin-Pishva Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Many of the patients which referred to the departments of otolaryngology are suffering from some sort of hearing loss. Hearing problem usually place stress upon interpersonal relationships, social isolation, and even sadness and depression.The most of the hearing loss is hereditary and follow autosomal recessive pattern of inheritance. Therefore, the frequency of hearing loss is more among those populations which consanguineous marriage is an old tradition.
The aim of this study was to find out the frequency of hearing loss among the consanguineous marriages.
We investigated all the pedigrees of patients which referred to our Department for genetic counseling during the last three years. We found 206 pedigrees with some sort of otolaryngology disorders, and out of them 157 pedigrees were with consanguineous marriages. Among these 157 pedigrees, 496 cases were the result of consanguineous marriages, and 219 patients were affected with otolaryngology disorders, Therefore, these 219 cases were studied according to consanguineous and non-consanguineous marriages, kind and degree of relationship of their parents, patterns of inheritance, and sex, by using SPSS software. Out of 496 cases, 115 patients (23.2%) revealed total deafness, and 53 patients (10.7%) exhibited partial hearing loss.
Our results showed that, on the whole, there is a relationship between hearing loss and consanguinity, and the most affected individuals have consanguineous parents.

J02.07
Investigation of thyroid Transcription Factor-1 and TSH Receptor genes variant in Iranian children with congenital hypothyroidism

F. Fattahi[1], *F. Mahjoubi*[1], *M. Hashemipour*[2];
[1]*nigeb, Tehran, Islamic Republic of Iran,* [2]*Isfahan Endocrine & Metabolism Research Center, Isfahan University of, Isfahan, Islamic Republic of Iran.*

Congenital hypothyroidism(CH) is a metabolic disorder which occurs in 1:3000 or 1:4000 live births. The patients may suffer from thyroid gland dysgenesis or dyshormongensis. Thyroid dysgenesis (TD) may be caused by mutations in Thyroid Transcription Factor1 (TTF-1) or TSH Receptor (TSHR) genes. This study was aimed to analyze TTF-1 and TSHR (exons 5 and 7) genes in Iranian CH patients. Blood samples were collected from the 30 patients and family members in EDTA supplemented vacutainers. Informed consent was obtained from parents or guardian of patients. Genomic DNA from each individual was extracted using a QIAamp Blood Kit (QIAGEN) according to the manufacturer's instructions. The final concentration of extracted DNA was adjusted to a 50 ng/µl to develop the assay. Mutations in TTF1 and TSHR genes were investigated by PCR-SSCP followed by direct sequencing. In this presentation our data regarding TTF1 and TSHR genes mutations screening will be presented and the correlation between each mutation and clinical manifestation will be discussed.

J02.08
A case of Noonan syndrome

V. L. David[1], *M. C. Popoiu*[2], *M. Puiu*[2], *V. Trestianu*[1], *A. V. Popoiu*[2], *P. Fuicu*[2], *F. Horhat*[2], *A. Timofte*[3], *G. F. Brad*[1], *E. S. Boia*[2];
[1]*Emergency Children's Hospital "Louis Turcanu", Timisoara, Romania,* [2]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [3]*Municipal Hospital, Timisoara, Romania.*

Background: Noonan syndrome (NS) is a sporadic or inherited developmental disorder with an incidence of one in 1.000-2.500 children. Clinical manifestations of NS include a typical dysmorphic appearance, congenital heart defects, short stature, skeletal malformations like scoliosis and chest malformations, cryptorchidism, eye abnormalities and various degrees of cognitive deficits. NS is genetically heterogeneous, recent discoveries revealed a disorder of upregulated RAS-MAPK signaling. Case report: A 12 years old male child was admitted to the Department of Pediatric Surgery of our hospital for multiple musculoskeletal deformities: severe scoliosis with a 400 Cobb angle, funnel chest, bilateral flat feet, joint laxity, and curved thumbs. In addition the child had bilateral cryptorchidism, micrognathia, astigmatism and mental retardation. A management strategy was developed for each type of pathological dysfunctions: for scoliosis we preferred brace correction using Cheneau brace; for cryptorchidism a surgical intervention was scheduled; for astigmatism optical correction was recommended, for mental retardation intervention programs and individualized education strategies were proposed and for short stature therapy with growth hormone was consider. The opportunity of intervention for other problems like: the deformity of the chest, foot and thumbs is still in debate, a balance between risks and benefits being considered. Conclusion: Multidisciplinary treatment is the key to success in managing children with Noonan syndrome and the pediatric surgeon play an important position to lead the health team.

J02.09
Diagnostic and therapeutic management of a case with myelomeningocele in the context of a complex plurimalformative syndrome

A. Manea[1], *M. Boia*[1], *C. Ilie*[1], *D. Iacob*[1], *I. Ursache*[2];
[1]*University of Medicine and Pharmacy Timisoara, Timisoara, Romania,* [2]*Clinical Emergenc Hopital for Children "L. Turcanu', Timisoara, Romania.*

Myelomeningocele is a complex congenital spinal cord anomaly (the most severe form of spina bifida, localized mainly thoracic-lumbar 85%, also thoracic 10%, cervical 5%) that causes various degrees of myelodisplasia. In the context of plurimalformative syndrome, it is most commonly associated with hydrocephaly. The diagnosis is set clinic and imagistic.
Aim: presentation of diagnostic and therapeutic management of a case with thoracic-lumbar myelomeninocele with closed medullar area, in plurimalformative circumstances.
Material and method: we present the case of a newborn, gestational age 37 weeks, birth weight 2000g, APGAR 8, cranial presentation, from an unmonitored pregnancy, pregnant 1 para 1, with cytomegalovirus infection, prolonged jaundice, anemia, admitted in our service 4 days after birth. Clinic: spina bifida with exulceration at thoracic-lumbar level, flaccid paraplegia, bilateral varus equin, short neck, cranial perimeter in evolution.
Results and discussions: Due to malformative associations interdisciplinary exams were performed: ophthalmic, cardiologic (atrial septal defect), neurosurgical, transfontanellar ultrasound (dilated lateral ventricles, absence of corpus callosum), MRI for cervical, thoracic, lumbar spine and head (widening of lateral ventricles, absence of septum pellucidum, lumbar-sacral spine rotated in axis and right lateral, lumbar disraphia with myelomeningocele 1/3.7cm, malrotated kidneys), There were no modifications of cariotype.
Conclusions: 1. Due to malformative association interdisciplinary team cooperation was important especially for ventricle - peritoneal drainage and surgical cure of mielomeningocele. 2. There were no modifications of cariotype, the only modification was the cytomegalovirus infection. 3. Genetic consult and antenatal diagnosis can lead to a favorable prognostic of mielomeningocele and minimal further complications.

J02.10
A woman with 45,X/46,XY karyotype and clinical features of Turner syndrome

F. Mortezapour[1], *M. Rahnama*[1], *F. Nasiri*[1], *F. Manoochehri*[1], *F. Mahjoubi*[2], *R. Torabi*[2];
[1]*Iranian Blood Transfusion Organization Reasearch center, Tehran, Islamic Republic of Iran,* [2]*Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.*

45,X/46,XY mosaics have a wide spectrum of phenotypic appearances such as female or ambiguous external genitalia with bilateral streak gonads or asymmetrical gonadal differentiation. They also have an increased risk of developing gonadoblastoma, and a minority of them are masculinized.Structural X chromosome abnormalities are thought to occur as a result of breakages in the X chromosome with subsequent reunion of X chromosome sequences.

Here we report a 31-year-old woman referred to our laboratory due to infertility. The patient has irregular menstrual cycle. There was a familial history of infertility in her family. Chromosome analysis revealed mos45,X[22]/46,XY[8] karyotype. The clinical features of this case will be discussed and compared with the published cases.

P03.001
Intra-familial variable expression of a recurrent 16p13.11 deletion: a severe phenotype associated with a second genomic event.

K. Schlade-Bartusiak[1,2], *M. Van Allen*[3], *L. Brown*[1,2], *P. Eydoux*[1,2];
[1]*Cytogenetics Laboratory, BC Children's Hospital, Vancouver, BC, Canada,* [2]*Department of Pathology, University of British Columbia, Vancouver, BC, Canada,* [3]*Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada.*

Genomic disorders are recurrent microrearrangement syndromes that arise through non-allelic homologous recombination mediated by segmental duplications (SD). Over 20 novel genomic disorders have been described in recent years. Recurrent microdeletions at 16p13.11 span 1.5 - 3 Mb and are located between three sets of SD-associated breakpoints (BP1-BP2-BP3). There are no clear phenotypic differences between BP1 - BP2 and BP1 - BP3 deletions. The 16p13.11 deletion is associated with a broad spectrum of neurocognitive diseases, including autism, intellectual disability, epilepsy and schizophrenia, as well as skeletal and cardiac malformations. It is characterized by a high phenotypic variability, with some carriers having a normal phenotype.

Here we report a family with a father and two daughters carrying a 16p13.11 deletion (BP1-BP3), as determined by Affymetrix 6.0 SNP array. The oldest daughter has speech delay. The youngest daughter presented at birth with failure to thrive, congenital heart defect and features of oto-palato-digital syndrome. In addition to the 16p13.11 deletion, she carries a 7.5 Mb deletion at 10q22.3-q23.2. This deletion is a recurrent, SD-associated, genomic disorder, which has been previously reported in 7 unrelated patients with developmental delay and congenital abnormalities.

This is the first report of coexistence of a 16p13.11 deletion with an additional imbalance, causing a severe phenotype. Additional large imbalances have been previously observed in 25% of patients with 16p11.2 and 16p12.1 deletions, and were proposed to be responsible for the phenotypic variability of 16p rearrangements. Interestingly, the additional imbalance at 10q22.3-23.2 in our patient is also a recurrent genomic disorder.

P03.002
Genomic rearrangement dup(18p)/del(18q) studied by SNP-array, MLPA and BAC-FISH techniques

L. D. Kulikowski[1], *S. S. Takeno*[2], *A. R. Dutra*[2], *D. M. Christofolini*[2], *S. I. N. Belangero*[2], *F. T. S. Bellucco*[2], *A. J. S. Duarte*[1], *D. Brunoni*[2], *M. Melaragno*[2];
[1]*Department of Pathology, LIM 03, Universidade de São Paulo, Brazil, São Paulo, Brazil,* [2]*Department of Morphology and Genetics, Universidade Federal de São Paulo, Brazil, São Paulo, Brazil.*

Partial duplication-deletion of the short and long arms of chromosome 18 has been rarely reported in literature with few cases including molecular cytogenetic studies. We describe a 18-month-old boy with severe growth deficiency pre-and post-natal, microcephaly, dysmorphic features, epilepsy and intense hypotonia. The 18q deletion was first detected by G-banding karyotype and appeared to be a small deletion. Molecular techniques, including whole genomic array, multiplex-ligation probe amplification (MLPA) and fluorescence in situ hybridization (FISH) with BAC probes were required in order to better define the rearrangement, to determine the breakpoints and to better delineate the genotype/phenotype correlation. The Cytogenetics Whole-Genome 2.7M Array (Affymetrix) showed a result arr 18p11.3 2p11.22(234,125-9,782,925)x3, 18q21.2 q23(50,293,625-76,084,580) x1 dn. Thus, the patient presented a 9.6 Mb duplication, from 18p11.32 to 18p11.22, and a 25.8 Mb deletion, from 18q21.2 to 18q23. MLPA with subtelomeric probes revealed three copies of 18 psubtel and one copy of 18 qsubtel. FISH technique using RP11-113J12 and RP11-231N16 probes confirmed the results, since these probes were in upside down order. Thus, the duplication/deletion rearrangement probably originated due to an abnormal meiotic recombination within a pericentric inversion. The deleted and duplicated regions encompass genes whose imbalances contributed to the severe phenotype in the patient. These data highlight the fact that concomitant deletions associated with inverted duplications are more frequent than classical cytogenetic methods alone have been able to identify. Furthermore, our results show the usefulness of high-resolution molecular cytogenetic analysis both in the delineation of chromosome rearrangements and in clinical diagnosis.

P03.003
Familial 1q21.1 microduplication associated with cardiomyopathy and absent pulmonary valve

J. M. A. Verhagen[1], *D. N. M. Papatsonis*[2], *E. W. M. Grijseels*[1], *R. R. de Krijger*[1], *N. de Leeuw*[3], *M. W. Wessels*[1];
[1]*Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Amphia Hospital, Breda, Netherlands,* [3]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Introduction: The chromosome region 1q21.1 contains several low-copy repeats which makes this region susceptible for cytogenetic rearrangements. These rearrangements are associated with abnormal head size, mental retardation, autism and congenital anomalies. Most often, microdeletions and -duplications of 1q21.1 occur *de novo*. We describe a large family with a 1q21.1 microduplication.

Methods & Results: The proband is the first child of non-consanguineous Dutch parents. Prenatal ultrasound revealed an enlarged heart with a ventricular septal defect and wide aortic and pulmonary arteries. After pregnancy termination, external morphologic examination demonstrated a proportioned fetus with a round face, hypertelorism and short palpebral fissures. Autopsy showed a grossly enlarged heart, perimembranous ventricular septal defect, absent pulmonary valve, dysplastic tricuspid valve, persistent left superior vena cava and abnormally wide and thickened wall of the ascending aorta. Genome wide SNP array analysis on DNA from cultured amniocytes revealed a 1q21.1 microduplication of 2.2 Mb. This microduplication was also found in the mother, who presented with mild mental retardation. Subsequently, this rearrangement was detected in 9 family members. All displayed dysmorphic features including hypertelorism and macrocephaly. Normal development was present in most 1q21.1 microduplication carriers.

Discussion: Congenital heart malformations have been reported in 4/26 patients with 1q21 duplication from two large cohorts [Mefford 2008, Brunetti-Pierri 2008], including ventricular septal defects and univentricular heart. *GJA5* and *PRKAB2* are good candidate genes for the cardiac defects observed in these patients.

Conclusion: Our description of this unique 3-generation family underlines the incomplete penetrance and extreme phenotypic variability of 1q21.1 microduplications.

P03.004
Congenital heart defects in a novel recurrent 22q11.2 deletion syndrome harboring the genes *CRKL* and *MAPK1*

J. Breckpot[1], *B. Thienpont*[2], *L. Tranchevent*[3], *J. R. Vermeesch*[1], *M. Gewillig*[4], *Y. Moreau*[3], *K. Devriendt*[1];
[1]*Center for Human Genetics, University Hospitals Leuven, Leuven, Belgium,* [2]*Laboratory of Molecular Signalling and Laboratory of Developmental Genetics and Imprinting; Babraham Research Campus, Cambridge, United Kingdom,* [3]*Bioinformatics Group, Department of Electrical Engineering, ESAT-SCD, Katholieke Universiteit Leuven, Leuven, Belgium,* [4]*Department of Pediatric Cardiology, University Hospitals Leuven, Leuven, Belgium.*

The proximal region of the long arm of chromosome 22 contains eight low copy repeats (LCR), known as LCR22s. Non-allelic homologous recombination (NAHR) between these recombination substrates explains the existence of recurrent rearrangements within the 22q11.2 region, and the high prevalence of *de novo* events. The most common recombination event occurs between LCR22-2 and LCR22-4, and gives rise to a 3.0 Mb deletion, associated with DiGeorge syndrome.

We report on a novel recurrent 22q11.2 deletion syndrome in a 14-months-old girl with a common arterial trunk, growth delay and mild dysmorphic features. She presented a normal development. The current deletion spans LCR22-4, the distal part of the common 22q11.2 deletion syndrome and the proximal part of the distal 22q11 deletion syndrome. This deletion did not occur by NAHR between any of the major LCR22s. However, by means of extended long template PCR the proximal and distal breakpoint containing regions were found to coincide with a 3.7 kb block of 97% homology between 19,351,886-19,355,637 and 20,799,044-20,802,748. We believe that these homologous regions served as recombination substrates for this novel 22q11.2 deletion.

An identical deletion was described recently in a normally developing girl with imperforate anus and multiple septal defects (Ogilvie *et al.,* 2009). Interestingly, both cases presented with a congenital heart defect (CHD) and growth delay, but no developmental delay. Automated gene prioritization, based on ENDEAVOUR technology (Aerts *et al.,* 2006), was applied to identify candidate genes for CHD within this region. The highest ranking genes were *CRKL* and *MAPK1*.

Many patients referred for psychomotor retardation (PMR), dysmorphic features and/or congenital anomalies are predicted to have cytogenetic imbalances, which can not be identified by conventional methods. We present here genetic study on an 18 years old male investigated for severe mental retardation associated with dismorphic features, limb anomalies, cadiac and renal malformations. Conventional cytogenetics: abnormal chromosome 2, with additional material on the long arm, add(2q). The banding pattern of abnormal chromosome suggested that the additional segment 2q belongs to telomeric short arm, or telomeric long arm of chromosome 4. WCP4 probe was used and hybridized to the additional region of derivative chromosome 2. For differentiation, in addition a telomeric 4p probe was used, which did not hybridise to the segment attached to the long arm of the derivative chromosome 2. We concluded that the additional material of chromosome 2 belongs to chromosome 4. To delineate correctly the region implicated in the chromosomal rearrangement aCGH analysis (105A Oligo Microarray Kit) was performed and revealed a 7.5 Mb deletion on 2q37.3 and a 29 Mb duplication on 4q32-4q35.2. We compared the clinical features of our patient with other cases described in the literature and we found more than 60 cases of 2q37 terminal deletion reported with features ranging from developmental delay, mental retardation, dysmorphism, autism, cardiac or renal abnormalities. The chromosomal bands 4q32-q35 was associated with PMR, axial hypotonia, multiple congenital anomalies and hand/foot malformation. The aCGH analysis is a useful method for the detection and characterization of chromosomal rearrangements.

P03.006
2q34-qter duplication in a patient with developmental delay

A. Rashidi-Nezhad[1,2], *S. M. Akrami*[1], *N. Parvaneh*[3], *F. Farzanfar*[4], *C. Azimi*[4], *A. Reymond*[2];
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Science, Tehran, Islamic Republic of Iran,* [2]*Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland,* [3]*Department of Pediatrics, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Science, Tehran, Islamic Republic of Iran.*

Patients with 2q3 duplication syndrome show variable developmental delay, facial and visceral anomalies. The 2q34-qter duplication is apparently crucial in determining the phenotype, as shown by seven previously reported cases of 2q34-qter duplications.

We present a 10 months boy with developmental delay, growth retardation, hearing problem, facial and non-facial minor anomalies. He was born to a 30 years old mother with a history of recurrent fertility problems. She went through 3 spontaneous abortions, 2 of her children died at 8 days and 4 months as a result of water loss or hypotonia and cleft palate, respectively, and now she has one healthy boy. Karyotype analysis of the proband showed an additional segment of unknown origin on 4q35. Karyotyping of both parents showed that the mother carries a balanced translocation t(2;4)(q34;q35) and identified 2q34-qter as the origin of the additional segment.

The proband has a round face with high forehead, broad nasal bridge, high arched palate, macrostomy, long philtrum, thin upper lip, ear pit and flat occiput, confirming the importance of the distal region of HSA2 in the 2q3 duplication phenotype. Other findings include shawl scrotum with undescendent and hypoplastic testes, bilateral simian creases, clinodactyly with short fifth finger, hyperflexible joints, hypotonia, growth retardation, slow developmental motor function, and mild ventriculomegally in brain CT scan. Notably, none of the major congenital anomalies, such as congenital heart disease or urinary tract malformations found in more proximal duplications, are present suggesting a critical region from band 2q31 to q34.

P03.007
5q35.2 → ter deletion in a patient with craniofacial feature of sotos syndrome and growth retardation

A. Rajaee*, K. Najafi, G. Abbassi, H. Loghmani Khouzani, B. Bozorgmehr, A. Moshtagh, H. Najmabadi, R. Kariminejad, A. Kariminejad;*
Kariminejad-Najmabadi Path. & Genetics Center, Tehran, Islamic Republic of Iran.

Sotos Syndrome (SoS) is a congenital disorder characterized by excessive growth, typical craniofacial features, and various degrees of developmental retardation. Mutation of NSD1 (nuclear receptor SET-domain-containing protein) located at 5q35.3 are responsible for most cases. We present a 2 1/2-year-old girl in this study with unusual phenotype including macrocephaly, prominent and wide forehead, coarse face, hypertelorism, wide mouth, prominent jaw, premature eruption of teeth, low-set ears, hypotonia, hallux valgus, wrinkled skin, hearing loss, developmental delay and growth retardation (height and weight below the 3rd percentile) . Based on the clinical findings chromosomal study and Multiple Ligation Dependent Probe Amplification (MLPA) was requested with suspicion of Sotos syndrome. MLPA showed microdeletion at q35.3 which is associated with Sotos syndrome. Karyotyping confirmed deletion of long arm of chromosome 5 (q35.2 and the segment distal to this band. Since our patient had additional findings and differences compared to Sotos syndrome namely coarse features, wrinkled skin, hyperextensibility of joints, mainly in digits, growth retardation, while Sotos patients have excessive growth (>97th centile) array comparative genomic hybridization (aCGH) was performed showing a 0.5 Mb deletion in 5q35.2◊ ter with maximum,174416712 and minimum,174837769 breakpoint boundaries. The additional findings are most probably related to deletion of adjacent genes to NSD1.

P03.008
Characterization of a case with an atypical deletion 8p23.1

B. Hernández-Charro, *R. C. Narvaiza Martínez, A. Bengoa Alonso, M. Artigas López, A. Pérez-Juana del Casal, M. A. Ramos-Arroyo;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

Distal deletions of chromosome 8p are associated with congenital heart defects. Other features include microcephaly, mental retardation and facial anomalies. *GATA4* has been involved in the heart defects and, the *TNKS* in the behavioural problems and learning disabilities. The region between them, including *MSRA* and *SOX7*, has been suggested to play a critical role in microcephaly and facial dysmorphism.
Some cases share a commonly deleted region of ~6Mb with breakpoints clustering in the same regions (low copy repeats 8p-OR-REPD and 8p-OR-REPP). However, there are exceptional cases with larger or smaller deletions with variable phenotype so, it is necessary to investigate the precise deleted region in atypical cases, to define the minimal critical region.
We report a 3 year-old non dysmorphic girl with microcephaly, speech and developmental delay and normal cardiac evaluation. Karyotype showed a *de novo* del(8)(p23). FISH and MLPA confirmed a terminal deletion between 10.2 and 11 Mb involving *TNKS* and *MSRA*, but not including the GATA4 region (TelVysion 8 Vysis, P036 telomere, P096 MR2 and P311 congenital heart disease, MRC-Holland).
Although the patient presents a larger deletion than previously reported, she presents less features, therefore it is important to test which specific genes are deleted. On one hand, *GATA4* was not deleted as we expected. On the other hand and as it has been proposed, *MSRA* deletion could explain microcephaly in our case but other specific molecular analysis (aCGH) will be performed to find out if *SOX7* is present, explaining the absence of facial dysmorphism.

P03.009
Molecular cytogenetic analysis of 8p23.1 deletion associated with moderate mental retardation without heart defect

H. Ben khelifa[1], *N. Soyah*[2], *H. Hannechi*[1], *S. Mougou*[1], *I. Ben Abdallah*[1], *H. Elghezal*[1], *A. Saad*[1];
[1]*Laboratory of cytogenetics,molecular genetics and reproductive biology - Farhat Hached hospital, sousse, Tunisia,* [2]*Department of pediatrics- Farhat Hached hospital, sousse, Tunisia.*

To date more than 50 cases of interstitial or terminal 8p23.1 deletions have been reported. This aberration is especially prone to various genomic rearrangements mainly because of the existence of the two olfactory receptor gene clusters (REPD and REPP) which is associated with a spectrum of anomalies that can include congenital heart malformations and congenital diaphragmatic hernia (CDH).
We report on a 5-year-old boy with psychomotor delay, moderate mental retardation, hypotony, vertebral anomalies, and dysmorphic features without heart malformations nor any overlapping features of Cornelia de Lange syndrome (CdLS).
Using Array comparative genomic hybridization (CGH array) on a 44K resolution, we identified an interstitial deletion of 1,181,530 pb in 8p23.1: arr 8p23.1 (8,229,404 - 9,410,934) X1. Fluorescence in situ hybridization (FISH) analysis confirmed the deletion using RP11-429B7 probe.
The mental retardation presented by our case seems to be associated to genes haploinsuffiency included in the 8p deletion. This deletion includes TNKS gene, known as a candidate gene for CdLS, supporting other studies invalidating TNKS in CdLS. In addition, the absence of cardiac malformations often associated with the 8p deletions could be explained by the retention of SOX7 and GATA4 genes, known for their major role in cardiac development. Even though, further studies based on the high-resolution characterization of additional cases are needed to establish more clearly the role of the discussed candidate genes in carriers of 8p23.1 deletions.

P03.010
Molecular characterization of a complex rearrangement associated with an apparently balanced translocation

A. Bengoa Alonso, *B. Hernández-Charro, R. Narvaiza Martínez, A. Pérez-Juana Del Casal, M. Artigas López, M. Ramos-Arroyo;*
COMPLEJO HOSPITALARIO DE NAVARRA, PAMPLONA, Spain.

We report on a 42 year-old male with moderate mental retardation, facial dysmorphic features and skeletal anomalies, carrier of a complex chromosome rearrangement, consisting of a reciprocal translocation plus a deletion detected by conventional karyotype: 46,XY,t(3;13)(q26.2;q22),del(6)(q15q21). FISH analysis with subtelomeric probes confirmed the translocation. Further studies with array-CGH analysis (Agilent, 180K) demonstrated the presence of several copy number variants, including a duplication on chromosome 3, two deletions on chromosome 6, and a deletion on chromosome 13: arr 3q26.1(163,992,703-164,108,151) x3, 6q13q14.1(75,314,285-76,187,164)x1, 6q14.1(80,785,392-80,911,216)x1, 13q31.3(89,597,407-90,636,021)x1.
Deleted regions on chromosome 6 were 873Kb and 126Kb in size, and were separated by a 4.6Mb normal region. The deletion included 4 genes, one of which (COL12A1) is a known candidate gene for connective tissue pathology and is probably involved in the kyphosis and foot deformities seen in our patient.
The small size of the 6q deletion (~1Mb) and the presence of copy number variations on both chromosomes 3 and 13, suggest the existence of a more complex rearrangement than the one previously described. Therefore additional analyses should be done to unravel the nature of this rearrangement.
This study provides further evidence that cryptic genomic imbalances are common in patients with apparently balanced translocations and abnormal phenotypes, and emphasizes the importance of using high resolution genome-wide analysis to characterize complex rearrangements.

P03.011
A 2p16.1 deletion in a boy with MR/MCA syndrome detected by MLPA

I. M. Bradinova, *R. Vazharova, S. Bichev, A. Savov, I. Kremensky;*
National genetic laboratory, Sofia, Bulgaria.

Chromosomal abnormalities are a common cause of mental retardation / multiple congenital anomalies. The advent of new technologies for molecular cytogenetics such as FISH, MLPA, array CGH has dramatically increased the number of novel microdeletions and microduplications associated with a wide range of clinical phenotypes of a relative stable and distinctive MCA/MR syndromes.
We report a 5 months old boy with developmental delay, failure to thrive, severe hypotonia, hypoplastic genitalia (micropenis, cryptorchism), syndactily 4-5 of the left hand and facial dysmorphic features, including brachycephaly, strabismus, short and narrow palpebral fissures.
Routine cytogenetic studies at amniocentesis and postnatally (300-400 band level) were normal.
MLPA, performed using kit P245 (MRC Holland), detected deletion of the loci FANCL, 2p16.1 and REL, 2p16.1 and follow-up studies by arrayCGH were performed.Despite the early age our patient presents some of the characteristic feature of the 2p15-16.1 microdeletion syndrome. The clinical follow up of the patient and the determination of the deletion size by additional molecular techniques (array CGH, FISH etc.) will contribute to the further delineation of the syndrome phenotype and the underlying genes since a few cases are described up to now.

P03.012
A *de novo* 1.8 Mb 17q21.33 microdeletion detected by SNP-CGH in patient with mental retardation and dysmorphic features

V. Dirsė[1,2], *J. Kasnauskienė*[1,2], *A. Utkus*[1,2], *E. Preikšaitienė*[1,2], *Ž. Čiuladaitė*[1,2], *K. Männik*[3], *A. Kurg*[3], *V. Kučinskas*[1,2];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Centre for Medical Genetics at Vilnius University Hospital Santariškių Clinics, Vilnius, Lithuania,* [3]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.*

We report 16 years old male presenting with mild mental retardation and dysmorphic features (slight shortness of stature, poor weight gain, long face, beaked nose, thick lower lip, micrognathia, malocclusion of teeth and clinodactyly of the 5th fingers). The boy was born to healthy, non-consanguineous Lithuanian couple after a normal pregnancy in a normal delivery. His older half brother was healthy. The proband had a normal motor development, but language development was severly retarded. Karyotyping of peripheral blood cells revealed an inconspicuous karyotype. Analysis of patient genomic DNA by Illumina whole-genome genotyping (Infinium HD) assay using HumanCytoSNP-12 BeadChip revealed an interstition 1.8 Mb deletion of 17q21.33. FISH analysis

of patient and both parents confirmed the microdeletion as *de novo*. Among 23 genes in deleted region, haploinsufficiency of *CACNA1G* and *CA10* genes can play crucial role in developmental delay. Both of genes are involved in brain development and neurological processes. The *CACNA1G* gene, which predominantly is expressed in brain, encodes voltage-dependent calcium channels which are thought to be involved in neuronal oscillations and resonance, pacemaking activity in central neurons, neurotransmission. The *CA10* gene encodes the protein which is acatalytic member of the alfa-carbonic anhydrase subgroup and is thought to play significant role in the central nervous system, especially in brain development. Based on this information the reported *de novo* deleted region is considered as pathogenic.
The research leading to these results is funded by the European Community's Seventh Framework Programme [FP7/2007-2013] under grant agreement n° 223692, CHERISH project.

P03.013
Recurrence of a 19p13 duplication by a familial intrachromosomal insertional translocation

***C. Orellana**, S. Monfort, M. Roselló, S. Mayo, S. Oltra, F. Martínez;*
Hospital Universitario La Fe, Valencia, Spain.

Introduction: the occurrence of pure 19p13 duplication in two first grade cousins led us to investigate the presence of an insertional translocation. Intrachromosomal insertional translocation was found in at least three generations. Three mentally retarded cases and multiple abortions in the family were found.

Material and methods: whole genome array-CGH was performed on Agilent oligo-chip 44K. Microsatellite markers and MLPA were used to confirm the array-CGH findings. FISH using BAC probes were used to locate and confirm the insertional translocation.

Results: in a series of 200 patients with mental retardation associated with congenital anomalies, we found one patient with an interstitial duplication in 19p13. Initially it was thought that this change had arisen de novo because the duplication was not present in the parents of the index case. However, the appearance of another case with the same duplication in the family made us suspect the presence of an insertional translocation. This was confirmed by FISH with region-specific probes.

Discussion: Insertional translocations can be much more common than initially thought. Therefore, following the detection of a pure duplication or deletion that causes disease in a patient, it should be characterized by FISH in order to offer adequate genetic counselling.

P03.014
De novo deletion 10p14 in patient with mental retardation, speech impairment and hypothyroidism

***J. Kasnauskiene**[1], Ž. Čiuladaitė[1], E. Preikšaitienė[1], J. Hettinger[2], P. C. Patsalis[2], V. Kučinskas[1];*
[1]Vilnius University, Department of Human and Medical Genetics, Vilnius, Lithuania, [2]The Cyprus Institute of Neurology and Genetics, Department of Cytogenetics and Genomics, Nicosia, Cyprus.

The use of array CGH for clinical testing of patients with mental retardation/ developmental delay and/or congenital anomalies has provided a possibility to identify novel recognizable microdeletion/ microduplication syndromes, as well as to expand the phenotype. Additional report of smaller chromosomal rearrangements, allow to establish more accurate phenotype-genotype correlation or single genes impact to the phenotype. Microdeletion of 10p14-15 is characterized by HDR or DGS2 syndromes. We report on 11years old boy carrying 2.77 Mb interstitial deletion at 10p14, with mild mental retardation, speech impairment, hypotonia, hypoplastic corpus callosum, hypothyroidism with good respond to levothyroxin therapy, hypermetropia, syndactyly, dysmorphic features (narrow forehead, round face, simple ears, small nose). 2.77 Mb deletion was detected by Agilent 105K oligo-array genome hybridization and involves the genomic region between 8,255,605 and 11,023,139 base pairs on chromosome 10 (NCBI build 37.2). This deletion is one of the smallest from previously reported, involving only two genes (*SFTA1P1* and *LOC254312)*. We do not observe symptoms of HDR or DGS2 syndromes. Besides MR and speech impairment (characteristic for other patients with deletion in 10p15), our case is associated with few distinct features, as brain structure abnormalities and thyroid hypofunction. As adjacent region (10p15) contains many genes and is related with MR and speech impairment, the possibility of disruption of regulatory sequences by downstream deletion should be considered.
The research leading to these results is funded by the Research Council of Lithuania National Scientific Programme Chronic Noninfection Diseases (PROGENET project, No. LIG-1007).

P03.015
Molecular cytogenetic studies of 1p36 deletion syndrome in children with mental retardation and congenital malformations

***I. A. Demidova**[1,2,3], S. G. Vorsanova[1,2,3], A. D. Kolotii[1], Y. B. Yurov[2,1,3], I. Y. Iourov[2,1];*
[1]Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia, Moscow, Russian Federation, [2]National Research Center of Mental Health, RAMS, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation.

Deletions of 1p36 are associated with a common microdeletion syndrome affecting one in 5000 live borns. Diagnosis of 1p36 deletion represents a challenge for cytogeneticists inasmuch as these deletions are hardly visible by classical cytogenetic techniques. The solution is the application of FISH or array CGH. However, the former shows only loss of a small chromosomal region, whereas the latter is expensive for numerous laboratories around the world. To avoid significant expenses, we have tested whether high-resolution CGH (HR-CGH) can be used for diagnosis of 1p36 deletion syndrome. Cytogenetic studies of 3500 children with mental retardation and congenital malformations allowed to identify the deletion in one case only. Additional analysis of 100 cases non-randomly selected according to phenotypical manifestations by HR-CGH provided for detection of three other 1p36 deletions: del(1)(p36.1p36.3), del(1)(p36.13p36.21), del(1)(p36.22p36.23). Array CGH analysis has confirmed data obtained. Deletion sizes varied from 4.4 Mb to 12 Mb and encompassed regions previously reported to be involved in 1p36 deletion syndrome. It is noteworthy that one case demonstrated multiple chromosome abnormalities: constitutional 47,XXY and mosaic 12p tetrasomy in addition to 1p36 deletion. Phenotypic manifestations were similar to those usually observed in 1p36 deletions, being, however, insufficient for the clinical diagnosis of the syndrome. Our data shows that HR-CGH can be used for diagnosis of 1p36 deletion syndrome (prescreening before array-CGH application). Finally, we have demonstrated 1p36 deletion to occur as frequent as 1/875 in a clinical population of children with mental retardation and congenital malformations inhabiting Central Russia.

P03.016
Overlapping microdeletions in 15q22.1-q22.2 in two patients with intellectual disability - characterization of the critical region using the DECIPHER database

***A. M. Zink**[1], E. Wohlleber[1], R. Cohn[2], R. C. Betz[1], W. Kleffmann[1], J. A. Lee[1,3], M. J. V. Hoffer[4], M. H. Breuning[4], C. Ruivenkamp[4], E. Lisi[2], H. Engels[1];*
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]McKusick-Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD, United States, [3]Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany, [4]Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.

Here, we report two patients with intellectual disability (ID) and de novo microdeletions in 15q22.1-q22.2 detected by molecular karyotyping. The smallest region of overlap (SRO) of the two microdeletions contained 26 genes, 8 of which are listed in OMIM.

Patient 1, a 14 1/2 year old boy presented with moderate ID, slightly disproportional growth retardation, truncal obesity, strabismus and mild facial dysmorphisms. His IQ at the age of 6 8/12 years was 55-60. After an initial speech delay, his language skills at the age of 14 1/2 years were significantly better in comparison to his IQ.

Patient 2, a 6 1/2 year old male, was identified in the DECIPHER database. He presented with mild global developmental retardation, muscular hypotonia, uncoordinated movements, joint hypermobility, and mild dysmorphisms.

Molecular karyotyping detected de novo microdeletions in 15q22.1-q22.2 of 5.3 Mb and 5.5 Mb with an SRO of 4.97 Mb and 8 OMIM genes. However, the critical region could be reduced tentatively by the deletion in a third DECIPHER patient without ID, obesity, muscular hypotonia or dysmorphisms. His deletion overlaps the proximal 1.87 Mb of the SRO of patient 1 and 2, narrowing down the critical region to 3.09 Mb and 11 genes. Only two of the three remaining

OMIM genes are promising candidate genes for ID: VPS13C which is highly expressed in the central nervous system and RORA (retinoic acid receptor) which is involved in neuronal development and may also cause the muscular phenotype of patient 2 since it interacts with MYOD.

P03.017
SNP-array analysis in 64 Polish patients with intellectual disability - first results of the CHERISH project

S. Dębicki[1,2], *M. Badura-Stronka*[1,2], *B. Budny*[1], *M. Wiśniewska*[1,2], *R. Glazar*[2], *A. Materna-Kiryluk*[2], *A. Jamsheer*[1,2], *E. Bonora*[3], *P. Magini*[3], *K. Männik*[4], *C. Graziano*[3], *A. Kurg*[4], *A. Latos-Bieleńska*[1,2];

[1]*Department of Medical Genetics Poznań University of Medical Sciences, Poland, Poznań, Poland,* [2]*Center for Medical Genetics GENESIS, Poznań, Poland,* [3]*U.O. Genetica Medica, University of Bologna, Bologna, Italy,* [4]*Institute of Molecular and Cell Biology University of Tartu, Tartu, Estonia.*

The CHERISH consortium was established in 2009 with the main goal of developping a standardized approach to genetic tests in patients with intellectual disability (ID) in Eastern European and Central Asiatic countries.

In recent years, 239 Polish families of well clinically characterized patients with idiopathic ID have been included in the CHERISH study. Preliminary analysis (karyotype, *FMR1* molecular test, metabolic investigation) was followed by MLPA screening for microdeletions/microduplications and subtelomeric rearrangements. In patients with normal results or with complex chromosomal rearrangements search for cryptic chromosome rearrangements was carried out through array-CGH or SNP array analysis in partner laboratories in Bologna and Tartu.

The authors present results of SNP array in 64 investigated individuals. The size of structural aberrations with potential clinical significance found in 10 out of 64 investigated individuals varied from 800 Kb to 23 Mb.

These data demonstrate that SNP array analysis is necessary to tie complex karyotypes to phenotypes of patients with ID and that cooperation on the European level is crucial to achieve diagnostic standards in ID.

This research is funded by the European Community's 7th FP [FP7/2007-2013] under grant agreement n° 223692, CHERISH project.

P03.018
A patient with a 7 Mb de novo 2p12p13.3 deletion associated to cerebral anomalies, muscular hypotonia and dysmorphisms

F. Forzano[1], *M. Malacarne*[2], *V. Uliana*[1], *V. Viassolo*[1], *I. Moroni*[3], *C. Marciano*[1], *C. Viaggi*[2], *D. Coviello*[2], *M. Pierluigi*[2], *E. Di Maria*[1,4], *F. Faravelli*[1];

[1]*Division of Medical Genetics, Galliera Hospital, Genova, Italy,* [2]*Laboratory of Genetics, Galliera Hospital, Genova, Italy,* [3]*Division of Child Neurology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [4]*Dept. of Neuroscience Ophthalmology and Genetics, University of Genova,, Genova, Italy.*

We describe a patient with moderate mental retardation, atrial septal defect type II, epilepsy and peculiar facial features. Brain MRI revealed hypoplasia of the cerebellar vermis and widespread dilatation of cerebral sulci and fissures. The neurological examination revealed hypotonia, ataxia and dysmetria.

Array-CGH with an average resolution of about 75-100 Kb showed a 7 Mb de novo 2p12p13.3 deletion. The rearrangement includes 75 genes, 10 of which are known disease gene. Five patients with del2p11.2p13, detected with traditional cytogenetic analysis, have been reported in literature and overlapping with the deletion reported. The deletion present in our case also overlaps with three cases reported in DECIPHER database and identified with molecular cytogenetic analysis: a case with a smaller deletion, 780 kb, in region 2p13.3p13.2 and two cases with wider duplication, a 25.17 Mb duplication in region 2p16.2p12 and a 12.13 Mb duplication in region 2p13.3p12.

We discuss the phenotype of the patient, the overlap with other cases reported to date and the possible genotype-phenotype correlation.

P03.019
Array genomic hybridization characterization of an interstitial 2q36 deletion

S. Mougou-Zerelli[1], *H. Ben khélifa*[1], *h. hannechi*[1], *n. soyah*[2], *S. Dimassi*[3], *h. Elghezal*[1], *A. Saad*[1];

[1]*Department of Cytogenetics, Reproductive Biology and Molecular Biology Hospital Farhat Hached, Sousse, Tunisia, Sousse, Tunisia,* [2]*departement of pediatry- Farhat hached hospital, Sousse, Tunisia,* [3]*DDepartment of Cytogenetics, Reproductive Biology and Molecular Biology Hospital Farhat Hached, Sousse, Tunisia, Sousse, Tunisia.*

Interstitial 2q36 deletion is a rare event. Less than 10 patients have been reported with interstitial deletions involving this region. Patients carrying this deletion exhibit mental retardation usually severe. This aberration involves at least three genes known for their role in the developing nervous system.

We report here, the case of a 9 years old boy from non consanguineous couple and with familial severe mental retardation, language delay, epilepsy and mild facial dysmorphism. Conventional cytogenetic analysis was performed on the peripheral blood lymphocytes at 450-550 RHG banding showed a little asymmetry on the terminal chromosome 2q. Using array comparative genomic hybridization (CGH array Agilent 44K), we identified an interstitial deletion of 2(q36.3-q37.2) of 8,06Mb: arr2q36.3 (227,508,858- 235,569,556)X1.

This chromosomal aberration carries at least 24 genes, 3 genes are mainly involved in mental retardation: SLC19A3 (Solute Carrier family 19 member 3), DNER (Delta and Notch-like EGF-related receptor) and TRIP12 (Thyroid hormone receptor- interacting 12). All are involving in the nervous system developing. Besides mental retardation, other clinical disorders such as renal cysts, congenital abnormalities could be associated to this anomaly but this phenotypic spectrum depends on the deletion size and so the deleted genes. Therefore, further studies are needed to establish more clearly the effect of 2q deletion especially on the mental status

P03.020
Mendelian molecular cytogenetics in familial microcephaly: the Leuven's experience

E. Chabchoub[1], *K. Ballon*[2], *N. Gielissen*[2], *A. Raaijmakers*[2], *J. R. Vermeesch*[1], *P. Decock*[2], *J. P. Fryns*[1];

[1]*Centre for Human Genetics - University Hospital Gasthuisberg, Leuven, Belgium,* [2]*Centre for developmental disorders - University Hospital Gasthuisberg, Leuven, Belgium.*

Microcephaly is an important neurologic sign and represents a frequent reason for reference to neuropediatric and neurogenetic clinics. Microcephaly is usually defined as an occipitofrontal circumference (OFC) more than 2 standard deviations (SDs) below the mean for age and gender. Microcephaly may result from any event disturbing the initial stages of brain development and can be associated with more than 450 syndromes listed in the London Dysmorphology Database. Coexistent neurologic disorders include intellectual disability (50%), epilepsy (40%), ophthalmologic manifestations (20%-50%) and cerebral palsy (20%). A genetic etiology is found in 15,5% to 53,3%.

We applied high-resolution molecular cytogenetics using BAC and oligonucleotide-based array comparative genomic hybridization (aCGH) (successively the 1 Mb resolution BAC aCGH and the 32k BAC aCGH (The Sanger Institute-UK) and the OGT CytoSure ISCA 180k DNA oligoarray set (OGT, UK)) to investigate the genetic bases of microcephaly in familial cases referred between 2007 and 2010, to the genetics and pediatric neurology clinics of the University of Leuven for developmental delay and multiple congenital anomalies.

We identified 2 novel loci for microcephaly in 2 families investigated for primary microcephaly and intellectual disability associated with, respectively, a 3,7 Mb del(1q43) and a 6,25 Mb dup(4q13). Both were inherited from affected mothers and maternal grand-mothers. In addition, we mapped two familial microcephalies to the boundaries of the 16p11 (180 kb) and 16p12 loci (670 kb). Candidate genes are prioritized and genotype-phenotype correlations will be discussed together with the genetic counseling in these heterogeneous and challenging clinical conditions.

P03.021
Array CGH detection of genomic/chromosomal rearrangements in children with mental retardation and congenital malformations: the first Russian experience

I. Y. Iourov[1,2], *S. G. Vorsanova*[2,1,3], *O. S. Kurinnaia*[2,1], *A. P. Silvanovich*[1], *N. L. Gorbachevskaya*[3], *Y. B. Yurov*[1,2,3];

[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

Array CGH has become one of the most popular molecular cytogenetic techniques for diagnosing genomic and chromosomal disorders. However, this powerful approach has never been systematically applied to Russian cohorts of children with mental retardation and congenital malformations. Here, we present an array CGH study of 30 children with mental retardation and congenital malformations non-randomly selected according to clinical and cytogenetic data. We were able to detect genomic/chromosomal rearrangements in 14 cases (47%). These were additional chromosome X with 1p36 deletion and mosaic isochromosome 12p; del(3)(p21.32p21.33); del(4)(p16.1pter)/dup(8)(p23.1pter); del(7)(q36.2qter); del(9)(q34.2q34.3)/del(21)(q22.3q22.3); del(10)(q26.2q26.3); dup(10)(q25.2qter)/del(13)(q33.3qter); r(11)(p15.5q24.1)(loss of 11q24.1qter); dup(19)(p13.3pter); del(19)(q13.12q13.13); del(20)(q11.21q11.21); del(X)(p22.2pter)/dup(3)(p22.3pter); dup(X)(q28qter); del(Y)(q11.223q11.223). Size of the rearrangements varied from 1.2Mb to 36.3Mb. Clinically relevant CNVs were detected in 9 cases (30%). Pathological value of CNVs was assessed by bioinformatic assays using gene expression and proteome (interactome/reactome) meta-analysis by Gene Expression Omnibus, BioGPS, Cytoscape 2.8.0 and Pathway Commons. One case exhibited constitutional genomic instability manifested as multiple deletions and duplications (size: from 1Mb to 2.5Mb). To date, similar cases have not been reported in the available literature. These results generally agree with those of previous array CGH cohort studies, showing, however, previously unreported genomic rearrangements in mental retardation and a higher incidence of clinically relevant CNVs. Moreover, we found the application of bioinformatic assays to be valuable for proper interpretation of array CGH data. Finally, to the best our knowledge, this communication represents the first reported array CGH study of a clinical cohort of children with mental retardation and congenital malformations in Russia.

P03.022
12p13.33 microdeletion syndrome: redefining the associated clinical phenotype

J. THEVENON[1], *F. Mugneret*[2], *P. Callier*[3], *A. David*[4], *J. Andrieux*[5], *B. Delobel*[5], *S. Sukno*[5], *A. Mosca*[3], *N. Marle*[3], *D. Sanlaville*[6], *D. Minot*[1], *A. Masurel-Paulet*[1], *L. Gaunt*[7], *C. Thauvin-Robinet*[1], *J. Clayton-Smith*[7], *L. Faivre*[1];

[1]*Centre de référence maladies rares, Dijon, France,* [2]*cytogénétique, Dijon, France,* [3]*Cytogénétique, Dijon, France,* [4]*Centre de génétique, Nantes, France,* [5]*Hopital Jeanne de Flandres, Lille, France,* [6]*Laboratoire de Cytogénétique, Lyon, France,* [7]*Genetic Medicine, Manchester, United Kingdom.*

Subtelomeric rearrangement associated with developemental disabilities detection rate represents 5% of the etiologies. Sub-telomeric or interstitial deletions of less than 5 Mb involving chromosome 12p13.33 is one the least frequently deleted region. Only 5 patients diagnosed with FISH telomere analysis or array-CGH have been reported. The most phenotypic manifestation of this microdeletion seems to be speech delay associated with autism spectrum disorders (ASD) phenotype. Two of them were inherited from an apparently healthy parent, suggesting variable expressivity and incomplete penetrance.

A French collaboration together with a search in the Decipher database permitted to gather 6 novel patients (4 probands) with a 12p13.33 subtelomeric or interstitial rearrangement identified by high resolution array-CGH to further delineate this rare microdeletional syndrome. Speech delay was found in 5/6 patients, with dysarthry in 3/6, mental retardation in 4/6 patients, ASD phenotype in 3/6 patients, mild non-specific dysmorphism (3/6) with prominent ear lobes in 2/6 patients, normal growth parameters with macrocephaly in 1/6 patient and microcephaly in 1/6. Variable expressivity or incomplete penetrance was found in both familial cases. The clinical and molecular data of this group of patients were compared to the other observations of the literature. The ELKS/ERC1 gene is found in the commonly deleted region, and appears as a good candidate for speech delay.

These results reinforce the hypothesis that the 12p13.33 subtelomeric or interstitial deletions can be responsible of a variable phenotyope ranging from normal developpement, speech delay, to mental retardation and ASD.

P03.023
First familial case of partial 3p trisomy and Xp monosomy resulting from a maternal translocation characterized by array CGH

O. S. Kurinnaia[1,2], *S. G. Vorsanova*[2,1,3], *V. Y. Voinova*[2,3], *A. K. Beresheva*[2,1], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2];

[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

Partial trisomy of 3p is an uncommon chromosome abnormality usually produced by an unbalanced translocation and characterized by recognizable patterns of malformation. Here, we report on two sisters presenting with mental, growth and psychomotor retardation, seizures, pectus excavatum and square facieses with prominent cheeks who exhibited 46,X,add(X)(?::p?22->qter),16qh- karyotype after G-banding karyotyping. Array CGH analysis with Spectral Chip allowing genome scan at 0.3-1Mb resolution has demonstrated duplication of 3pter->p22.3 spanning 36.3 Mb and deletion of Xpter->Xp22.2 spanning 6.4 Mb resulted from an unbalanced translocation t(X;3). Cytogenetic evaluations of parents have shown a presumably balanced translocation between chromosomes X and 3 in mother. Therefore, partial 3p trisomy and Xp monosomy in the index cases have resulted from a maternal translocation. *In silico* analysis of rearranged chromosomal regions has shown that 3p duplication involves 285 genes (107 genes are indexed in OMIM) whereas Xp deletion involves 50 genes (22 genes are indexed in OMIM). Additionally, copy number variations (CNVs) located on 9q12, 10q11.22, 15q11.2 and 15q26.3 were detected. However, these CNVs are likely to be benign, taking into account data obtained by bioinformatic analysis (meta-analysis of gene expression) and by comparison with previously reported benign CNVs indexed in genome variation databases. Although there are no fewer than 30 reports on similar chromosomal abnormalities, to our knowledge there are no descriptions of array CGH analysis of partial 3p trisomy in the available literature. Therefore, these are the first cases of partial 3p trisomy addressed by high-resolution molecular cytogenetic technique of array CGH.

P03.024
Molecular cytogenetic and bioinformatic studies identify loss of *LIMBR1* and *MNX1* as a cause of lumbosacral dysgenesis: array CGH, FISH and gene expression meta-analysis in two independent unbalanced terminal rearrangements of 7q

S. G. Vorsanova[1,2,3], *I. Y. Iourov*[2,1], *V. Y. Voinova*[1,3], *O. S. Kurinnaia*[1,2], *A. D. Kolotii*[1], *Y. B. Yurov*[2,1,3];

[1]*Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia, Moscow, Russian Federation,* [2]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

Previously, cytogenetic analyses of terminal 7q imbalances have suggested that loss of 7q36 can lead to lumbar or sacral dysgenesis/agenesis. However, apart from reports on *MNX1* mutations in Currarino syndrome (partial sacrum absence and anorectal anomalies), intrinsic causes of lumbosacral dysgenesis associated with genetic defects within the terminal part of chromosome 7q have not been established. Here, we present molecular cytogenetic and bioinformatic analyses of two cases of terminal 7q loss. The first case is an unbalanced translocation t(7q;21q)(q34;q22.13) reported previously (Vorsanova et al., 2008), whereas the second one is a deletion of 7q36 both featured by characteristic facial dysmorphisms, mental retardation, lumbosacral dysgenesis. Using array CGH and FISH, we have narrowed the region of chromosome 7 - 7q36.2q36.3 (from ~152Mb to ~158Mb) - associated with common phenotypic features in these two cases. To identify genes associated with lumbosacral dysgenesis, we have further studied the deleted region by gene expression meta-analysis using Gene Expression Omnibus and BioGPS. Comparative analysis

of expression profiles of 45 genes located within the aforementioned chromosomal region in fetal and postnatal tissues have indicated that two genes *LIMBR1* and *MNX1* are the most likely candidates for lubosacral dysgenesis. Taking into account that *LIMBR1* is involved in bone morphogenesis and mutations in *MNX1* are likely to lead to sacral agenesis, we have concluded that loss of *LIMBR1* and *MNX1* causes lumbosacral dysgenesis. Finally, array CGH genome screening in combination with gene expression meta-analysis seems to represent a powerful approach for identification of genetic causes of diseases.

P03.025
Molecular karyotyping identified pathogenic CNVs in 3 patients with developmental delay and/or multiple congenital anomalies

S. P. Hadjidekova[1], *D. M. Avdjieva-Tzavella*[2], *B. B. Rukova*[1], *D. V. Nesheva*[1], *I. I. Dimova*[1], *R. S. Tincheva*[2], *D. I. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University-Sofia, Sofia, Bulgaria,* [2]*Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria.*

Oligo array-CGH was applied in 3 patients with developmental delay and multiple congenital anomalies in order to unravel the underlying genetic abnormalities. We have used BlueGnome CytoChip oligo 2X105K microarray, v1.1, with 35kbp backbone resolution. All abnormal results were confirmed with fluorescence in situ hybridization (FISH).
In one of the patient with karyotype 46,XY,inv(9)(p11q13) array CGH revealed duplication of (8)(q24.13q24.3) region involving 22764514bp and deletion of (9)(p24.3p22.2) region encompassing 18023616bp. It was initially assumed that the patient's imbalances are de novo, but the subsequent examination of the proband's family and the fine analysis of the FISH results revealed that it comes to familial reciprocal translocation between the chromosome 8 and the inverted chromosome 9. The second patient was with blurred karyotype - 46,XY,add(15q),add(18)(p11.2). Array CGH detected two pathogenic CNVs - dup(18)(p11.22p11.21) spanning 5479842bp and dup(6)(q16.1q21) with 21333134bp involved. The FISH validation highlighted the chromosomal rearrangement: it comes to insertion of the duplicated region of chromosome 6 in the long arm of chromosome 15 and partial trisomy 18p. The karyotype of the third patient was normal - 46,XX. The molecular karyotyping identified deletion of 12978687bp in (6)(q25.3q27) region and duplication in (10)(q25.2q26.3) region involving 21360000bp.
This study proves that array-CGH is a powerful method to identified genomic imbalances not detected at the level of GTG banded karyotype analysis. Furthermore, it shows that for provide correct diagnosis, one molecular cytogenetic method is not enough, although some of them (i.e. array CGH) have high-resolution capability.

P03.026
Investigation of Subtelomeric Chromosome Abnormalities in 50 patients with Idiopathic Mental Retardation and its comparison with 50 Control Normal Cases

F. Behjati[1], *K. Kahrizi*[1], *S. Ghasemi-Firouzabadi*[1], *M. Najafi*[1], *B. Ebrahimi Zadeh*[1], *M. Mohseni*[1], *Z. Hadipour*[2], *F. Hadipour*[2], *S. Banihashemi*[1], *S. Arzhangi*[1], *K. Jalalvand*[1], *I. Bahman*[1], *R. Pazhoomand*[1], *H. Najmabadi*[1];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics & Sarem Cell Research Center, Sarem Women's Hospital, Tehran, Islamic Republic of Iran.*

Mental Retardation (MR) has heterogeneous etiology mostly with genetic causes. It has been shown that 4-12% of idiopathic MR have subtelomeric rearrangements using MLPA technique. In this study, using MLPA technique, the subtelomeric abnormalities were investigated in 50 patients with idiopathic MR with or without dysmorphism, with non consanguineous parents as well as 50 normal people. All the patients had normal karyotypes and were negative for fragile-X. The patients were first screened with one MLPA kit, P036-E1. The abnormal cases were re-checked using a different set of MLPA kit, P070-A2. All the controls were normal for the subtelomeric regions. However, four patients (8%), using both P036 and p070 kits, had abnormal results. In this study, the abnormalities were duplication of subtelomeric region of long arm of chromosome 19, duplication of subtelomeric region of short arm of chromosome X/Y, duplication of subtelomeric region of short arm of chromosome 6/deletion of subtelomeric region of long arm of chromosome 10, and duplication of subtelomeric region of short arm of chromosome 19/deletion of subtelomeric region of long arm of chromosome 22. MLPA studies using both kits were carried out on the parents. Only the case with dup X/Yp was inherited from the mother. The other three patients had normal results for the parents. Therefore these abnormalities are pathogenic. FISH investigation on the parents in order to see whether the abnormalities are inherited or not are pending. Genetic counseling and prenatal diagnosis will be recommended to the affected families.

P03.027
Use of SNP-array in a cohort of Armenian children with mental retardation

D. Babikyan[1], *S. Midyan*[1], *K. Männik*[2], *S. Parkel*[2], *A. Hovhannisyan*[1], *H. Mkrtchyan*[1], *A. Gasparyan*[1], *A. Kurg*[2], *T. Sarkisian*[1];
[1]*Center of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [2]*Institute of Molecular and Cell Biology, Tartu, Estonia.*

The genetic diagnostics of mental retardation (MR) is difficult to establish and presently many cases remain undiagnosed and unexplained. Over the last few years, rearrangements below the detection level of conventional karyotyping have been proved to contribute significantly to the cause of MR. The implementation of SNP-array has enabled the high resolution analysis of copy number variants (CNVs) as duplications/deletions and uniparental disomy (UPD).
Here we report use of the SNP-array analysis for the first time in an Armenian cohort of 95 children with MR who had no visible cytogenetic abnormalities ascertained by standard karyotyping as well as microdeletion/microduplication, and subtelomeric abnormalities determined by FISH. We applied InfiniumHD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc.). Obtained data were analyzed with Illumina GenomeStudio and QuantiSNP software. Most of the detected CNVs have already been reported in the Database of Genomic Variants or recurrently present in our cohort. Recurrent microdeletion syndromes and UPD-associated syndromes were detected in nine cases (9.5%). Furthermore, 7 rare de novo CNVs (<5Mb) considered to be clinically relevant as well as 7 aberrations (>5Mb) also of potential clinical significance were discovered in syndromic and non-syndromic cases (16.8%) in chromosome regions, including 2p21-2p16.2, 6q22.1-6q22.32, 9q22.33-9q31.2, 10q26.11-10q26.3, 12q21.2-12q21.32, and 14q23.1-14q24.3. The majority of CNVs encompass several genes for which genotype-phenotype correlations have to be delineated.
Thus, in addition to its clinical diagnostic use in unexplained MRs, the introduction of SNP-array has facilitated identification of novel microdeletion/microduplication regions and corresponding disease genes.
Supported by FP7-CHERISH project 223692.

P03.028
Identification of two unrelated families with mentally retarded children extends the phenotypic spectrum of 15q25 deletions

M. Hančárová, *T. Mařiková, M. Malíková, J. Drábová, Z. Zmítková, D. Novotná, M. Vlčková, Z. Sedláček;*
Department Of Biology And Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.

Microarrays can considerably contribute to the identification of novel microdeletion and microduplication syndromes. Deletions of 15q25.2-q25.3 have recently been associated with autism and schizophrenia in 3 patients. We report additional patients with these deletions from 2 unrelated families identified primarily due to mental retardation (MR). One patient is a 5 year old boy affected with high functioning autism, mild MR, obesity and speech delay. The second case is a 4 year old boy suffering from mild MR, microcephaly, speech delay and chorioretinitis. Karyotyping revealed a normal karyotype in both patients. SNP array analysis (Illumina HumanCytoSNP-12) demonstrated in both cases identical ~800 kb deletions of 15q25.2-q25.3 (chr15:82.7-83.5Mb (hg18)) flanked by low-copy repeats (LCRs). The deletions are adjacent to recurrent 15q25.2 deletions associated with congenital diaphragmatic hernia, cognitive deficits and Diamond-Blackfan anemia which are also flanked by LCRs. Chromosome 15q25.2-q25.3 has been predicted to be a hotspot for rearrangements based on its genomic architecture predisposing

to non-allelic homologous recombination. The region deleted in our patients encompasses 9 protein-coding genes, of which at least 3 are good candidates for the phenotypes observed. The ZNF592 gene product plays a role in the regulation of genes involved in brain development, the PDE8A gene is involved in learning and memory, and the NMB gene is associated with body weight regulation and obesity. The data currently available on the 15q25.2-q25.3 deletions suggest that they may represent another aberration from the growing list of genetic defects predisposing to neuropsychiatric phenotypes. Supported by CHERISH (EC FP7 223692) and MZOFNM2005.

Molecular karyotyping of children with idiopathic mental retardation and/or dysmorphic features in Slovenian population

D. Krgović[1], *A. Zagorac*[1], *N. Marčun Varda*[2], *B. Zagradišnik*[1], *A. Erjavec Škerget*[1], *Š. Stangler Herodež*[1], *N. Kokalj-Vokač*[1,3];
[1]*Laboratory of Medical Genetics, University Medical Centre Maribor, Maribor, Slovenia,* [2]*Department of Paediatrics, University Medical Centre Maribor, Maribor, Slovenia,* [3]*Medical Faculty Maribor, University of Maribor, Maribor, Slovenia.*

Molecular karyotyping has become important tool for detecting chromosomal aberrations, which are overlooked with standard cytogenetic methods. Recently, it was proposed that arrayCGH should become first choice when unexplained developmental delay or congenital anomalies are involved.

Therefore, arrayCGH analysis of children with idiopathic mental retardation and/or dysmorphic features was performed to evaluate the importance of this diagnostic test in our laboratory. A series of karyotypically normal patients without subtelomeric abnormalities were included. In total, copy number variations (CNVs) in almost 45,5% of analysed patients were detected. CNVs with potential clinical significance were found in 18% of patients. Among them, 11% had aberration in regions with known microdeletion syndromes. In all cases, aberrations were causative for patients condition, therefore, they were determined to be pathogenic. Additionally, 7% of CNVs were characterized as probably pathogenic, based on their size and position. One male patient showed ~1,1 Mb duplication in region Xq21.32, and one female patient had ~2,3 Mb duplication in 8q23.1. Two additional patients had smaller deletions in 11q22.3 and 20q13.33 respectively. In 5,5% of patients, CNVs were identified as probably benign, based on their inheritance pattern. In the rest of the patients, aberrations were marked as variants of uncertain clinical significance. Further investigations should be carried out in these cases.

To conclude, diagnostic yield in our study was considerably higher (18%) than estimated average (~11%), due to the selected choice of patient. Nevertheless, we stress the importance of this test and emphasize the need of much bigger studies in Slovenian population.

P03.030
Epilepsy as a leading symptom in patients with mental retardation and chromosomal microdeletions/-duplications

A. Spreiz[1], *K. Rostasy*[2], *C. Fauth*[1], *G. Utermann*[1], *J. Zschocke*[1], *D. Kotzot*[1], *E. Haberlandt*[2];
[1]*Division for Human Genetics, Medical University of Innsbruck, Innsbruck, Austria,* [2]*Clinical Department of Pediatrics IV, Medical University of Innsbruck, Innsbruck, Austria.*

Epilepsy is defined as a chronic disorder of the brain, the occurrence of at least one epileptic seizure, and its neurobiological, cognitive, psychological, and social consequences, and is a common finding in chromosomal rearrangements detected by conventional karyotyping. Only few aberrations show a constant pattern of seizures. So, impairment of a single gene but also combined deleterious effects of several genes were assumed to be causative.

Here, we investigated 39 children with various patterns of epileptic seizures, mental retardation, and minor dysmorphisms and their healthy parents with the Illumina® Infinium Human1M-DuoV3 array to find *de novo* microrearrangements carrying epilepsy related genes. In four patients without any malformations or major dysmorphisms we found most likely causative *de novo* CNVs, i.e. deletions in 1q41q42.12 (3.3Mb), 19p13.2 (832kb), and Xq24 (165kb), and a two-part duplication in 17p13.2 (263kb) and 17p13.1 (464kb). One of the aberrations carries only one gene, which might be responsible for generalized tonic-clonic and myoclonic seizures and moderate developmental delay in the 4-year-old child. In four additional patients phenotypical consequences of the found *de novo* aberrations (deletions in 1q25.1 (71kb) and 19q13.43 (24kb) and duplications in 12q13.13 (116kb) and 15q25.1 (61kb)) cannot be excluded. Further clarification is in progress.

In total, the finding of causative chromosomal microrearrangements in a minimum of four out of 39 patients (10 %) with epilepsy and mental retardation but without major malformations shows again the power of DNA-arrays to find new disease-related genes and further expands the clinical indication for DNA-array investigations.

P03.031
A complex 21q deletion: molecular characterization marker chromosome by array-CGH.

E. Mansilla[1], *S. García-Miñaur*[1], *E. Vallespín*[1], *R. Rodriguez*[2], *J. Nevado*[1], *F. García-Santiago*[1], *N. Muñoz*[3], *M. de Torres*[1], *P. Lapunzina*[1], *M. Mori*[1];
[1]*Hospital Universitario la Paz.INGEMM.IdiPaz. CIBERER, Madrid, Spain,* [2]*Servicio de Fisiopatología Fetal Hospital Universitario la Paz., Madrid, Spain,* [3]*Servicio de Pediatria Hospital Infanta Leonor, Madrid, Spain.*

Introduction: Partial deletions of 21q are rare and these patients display a highly variable phenotype depending on size and position of the deletion. Proximal and distal deletions are associated with a milder phenotype, whereas deletions involving 31.2-36 Mb have a more severe phenotype.

Case report: We report a female four month old. During pregnancy a retarded growth intrauterine was detected. She was born in week 35 with a low birth weight for gestational age. At clinical examination mycrocephaly and dysmorphic features were noted including: mid-face hypoplasia, anteverted nares, retrognathia, hypertelorism, prominent eyes, broad base to nose and bulbous nasal tip and high palate.

The patient was hypertonic, ophthalmological and hearing examination showed strabismus and hypoacusia.

Magnetic resonance imaging revealed hypoplasia of corpus callosum and wide ventricles.

Results: Chromosome analysis showed a marker chromosome, the karyotype were reported as 46,XX,-21,+mar. A custom made array based on Agilent Technologies, called **KaryoArray®**, revealed two separate deleted segments: deletion 1 with a size of 21.65 Mb in 21q11.2-q22.12, and deletion 2 with a size of 4.04 in 21q22.2-q22.3. Extensive FISH analysis was performed on metaphase to validate the array-CGH results.

We review the literature and discussed about possible candidate genes.

P03.032
High frequency of genomic imbalances detected by array-CGH in patients with syndromic developmental eye anomalies

Developmental eye anomalies (DEA) encompass a spectrum of severe structural defects of the eye caused by the disruption of the smooth process of ocular morphogenesis. With a birth prevalence of approximately 1 in 3,000-4,000, DEA are considered to account for at least 25% of childhood visual impairment worldwide. There are up to 400 different chromosome aberrations described associated to DEA in the various dysmorphology databases. The exact frequency

of chromosomal deletions and duplications causing DEA is unknown. With the advent of whole genome array-CGH analysis, the number especially of interstitial genomic imbalances increased dramatically.
Seventy patients with unexplained DEA associated to another congenital malformation or mental retardation were analyzed using oligonucleotide arrays (Agilent).
In 4 patients, clinically relevant deletions encompassing genes already known to be involved in eye development (FOXC1 and OTX2) were identified. In 4 other patients pathogenic deletions not classically associated to DEA were found: del(17)(p13.3p13.3), del(10)(p14p15.3) and del(16)(p11.2p11.2). The pathogenicity of 11 additional copy number variation (6 duplications and 5 deletions) is discussed. Altered segments ranged in size from 0.11 to 5.57 Mb. These results show that array-CGH provides a high diagnostic yield in patients with DEA syndromes and point to novel chromosomal regions associated with these conditions. Besides their importance for diagnosis and genetic counselling, these data may pave the way to the search of genes involved in eye development.

P03.033
Microdeletion of the Down syndrome critical region and duplication of the terminal section of chromosome 21 in a child with a distinct morphological phenotype

B. Pabst[1], *D. Gonzalez-Fassrainer*[1], *D. Steinemann*[2], *K. Miller*[1], *M. Stuhrmann*[1], *J. Schmidtke*[1], *M. Arslan-Kirchner*[1];
[1]*Institute of Human Genetics, Hannover Medical School, Hannover, Germany,* [2]*Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover, Germany.*

We report on a child with a de novo combined interstitial deletion of 21q22.12-q22.3 and duplication of the terminal region of chromosome 21.
The patient is the 7th child of healthy parents. Birth weight and length were within a normal range, head circumference was below the 3rd percentile. Myocardial hypertrophy without clinical impact was detected, a finding that decreased over the years. At the age of 3 years and 10 months, microcephaly persists and weight and length are under the 3rd percentile. The boy presented with several dysmorphic features, e.g. brachycephaly with bitemporal narrowing, dysplastic, cup-shaped ears, hypertelorism, micropenis. There are feeding difficulties and regurgitations. He has a global developmental delay, especially speech development is impaired. There are an autistic-like manner and phases of behaviour problems with restlessness and laughter-attacks.
Molecular cytogenetic analysis of the subtelomeric regions identified a secondary signal of the chromosome 21 subtelomere probe on the distal short arm of one chromosome 21. An additional interstitial deletion was detected with a probe specific for the Down critical region and other region specific probes. The deletion encompasses 6.5 Mb distal to RUNX1 and the duplication 4.85 Mb as determined by tiling array-CGH analysis. STR marker analysis revealed that both the deletion and the insertion originate from the same parent. Both parents showed normal karyotypes.
Several of the clinical features reported in the patient can be assigned to the interstitial deletion of 21q whereas behavioural troubles described in the present case are not commonly mentioned.

P03.034
A first report of an unstably transmitted familial complex chromosome rearrangement

E. van Binsbergen, *R. Hochstenbach, J. Giltay, M. Swinkels;*
University Medical Center Utrecht, Utrecht, Netherlands.

Complex chromosome rearrangements (CCRs) are rare structural aberrations involving three or more breakpoints on two or more chromosomes. CCRs are classified as type I when they contain four or fewer breakpoints, or type II, when they contain more than four breakpoints. About one third of all CCRs are familial. Transmittance of such a CCR results either in non-disjunction at meiosis or is stably passed on to the next generation. Here we present a case of a phenotypically normal mother with a type II CCR involving chromosomes 1, 3 and 5 that gave birth to a phenotypically abnormal son. The boy presented with hypotonia and mild facial dysmorphisms. At the age of three he was severely mentally retarded, hypotonic and there were feeding disorders. Conventional karyotyping revealed the same CCR as previously was found in the mother. However, by use of array-CGH and FISH we discovered that during transmission of the CCR, a de novo deletion and duplication were evoked on two of the breakpoints by a mechanism of inversion/duplication on one of the derivative chromosomes. This is the first presented case of this mechanism in a structurally abnormal chromosome. Furthermore with this case we demonstrate the importance of breakpoint analysis in CCRs and stress that genetic counseling of a familial CCR is not straightforward.

P03.035
Clinical molecular karyotyping: an overview of 560 array experiments using 180k Agilent array.

A. M. Polstra, *K. Huijsdens, M. Bagnaij, M. Berens, A. Mul, N. Nibbering, J. Rozendaal, A. C. Knegt;*
Academic Medical Centre, Amsterdam, Netherlands.

Array-based comparative genomic hybridization has become an indispensable tool in the detection of submicroscopic chromosomal aberrations in patients with multiple congenital anomalies and/or idiopathic mental retardation (MCA/MR). Once introduced into the diagnostics, it is gradually replacing karyotyping. It is now the first diagnostic tool of choice for patients with mental retardation and or multiple congenital abnormalities at the AMC in Amsterdam. Since the introduction of array CGH different resolutions have been used. For over a year now we have been using the 180k Agilent array in the diagnostics. An overview will be given. We have processed over 560 experiments consistent of both index (n=385) and family members (n=184) so far. Of the index patients almost 40% warranted additional testing of the parents or other family members to clarify the meaning of the aberrations that were found. We present a summery of our result to date, such as diagnostic yield, type of aberrations, size, number of aberrant probes and parental origin. An overview such as this is important as they may warrant change in the way the array data are analysed and interpreted.

P03.036
Interstitial deletion 13q: case report

M. Quintanilla[1], *A. Gómez*[1], *I. Onsurbe*[2], *E. Balmaseda*[3], *G. M. Varo*[1], *L. Navarro*[1];
[1]*Unidad de Genética Clínica. Servicio de Análisis Clínicos. Complejo Hospitalario Universitario de Albacete., Albacete, Spain,* [2]*Neurología Pediátrica. Complejo Hospitalario Universitario de Albacete, Albacete, Spain,* [3]*Gastroenterología Pediátrica. Complejo Hospitalario Universitario de Albacete, Albacete, Spain.*

Chromosome 13q deletion is associated with varying phenotypes, which seem to depend on the location of the deleted segment. The most common clinical features are mental and growth retardation, malformations of brain, eye, kidney or heart, craniofacial dysmorphy and various congenital defects.
We report a 4 years old boy, patient of Neuropediatrics. Controlled pregnancy with threat of miscarriage in the second quarter. Birth weight: 3.100 g. He walked between 17 and 18 months and he didn´t crawl. He presents poor suck and swallowing reflex, bronchial hyperreactivity, hypotonia, hypertransaminemia, shy behaviour, and psychomotor and growth retardation. He has congenital absence of gallbladder and atopic dermatitis.
Conventional cytogenetic analysis using G-banding revealed a de *novo* 46,XY,del(13)(q?21q?31) karyotype. Whole Chromosome Paint (WCP) DNA FISH probe of chromosome 13 showed one pair of acrocentrics hybridized. 244K array-CGH characterization of chromosome 13q identified an 15.4 Mb deletion in 13q21.31-q22.3.
To date, there is still no consensus on possible correlations between the monosomy of distinct 13q regions and specific clinical features. Since 13q21 is a region with very few genes, deletion of band 13q22 is probably responsible of the patient´s phenotype.

P03.037
Genetic instabilities in the ataxia-telangiectasia brain: evidence for a neuroprotective effect of non-malignant genome/chromosome instability

Y. B. Yurov[1,2,3], *S. G. Vorsanova*[2,1,3], *T. Liehr*[4], *M. K. Tagirova*[1], *I. Y. Iourov*[1,2];
[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia,*

Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation, [4]Institute of Human Genetics and Anthropology, Jena, Germany.

Ataxia-telangiectasia is a chromosome instability (CIN) syndrome caused by ATM mutations associated with DNA damage and repair defects. The role of CIN in this neurodegenerative disorder is incompletely understood. Molecular cytogenetic analysis allowed us identification of a dramatic increase in aneuploidy in the AT brain (Iourov er al., 2009). Additionally, degenerating cerebellum exhibited non-random breaks of interphase chromosomes and dramatically increased chromosome 7-, 14- and X-specific aneuploidy. CIN more severely affects the cerebellum than the cerebrum. Paradoxically, AT patients' longevity has positively correlated with CIN rates in the cerebellum. To solve this paradox we propose two alternative hypotheses: (1) overproduction of immature neural cells with unrealized chromosome breaks and aneuploidy takes place exclusively during early brain development, and chromosomally aberrant cells might be resistant to apoptotic clearance throughout ontogeny and, therefore, survive; (2) an age-dependent increase of the percentage of chromosomally defective cells could be explained by abnormal adult neurogenesis in the degenerating cerebellum during brain aging. Therefore, we have to admit that adult neurogenesis can occur in the diseased AT cerebellum. We suggest the longer the lifetime of AT individuals the bigger amount of immature neuron-like cells is accumulated in the degenerating cerebellum. The persistence and age-dependent accumulation of neural cells with chromosome breaks during ontogeny (even immature and chromosomally abnormal) could protect the diseased cerebellum against dramatic cell loss and, therefore, partially prevents the progression of neurodegeneration with possible neuroprotective effect. Finally, CIN represents an important genetic phenomenon mediating variety of cellular processes leading to neurodegeneration in brain.

P03.038
Identification of chromosome abnormalities in screening of a family with manic depression and psoriasis; predisposition to aneuploidy

B. Demirbek[1], *O. Demirhan*[2], *N. Inandiklioglu*[2], *I. Uslu*[2], *M. Izmirli*[3], *S. Cetiner*[4];
[1]Psychiatric and Neurolojic Disease Hospital, Adana, Turkey, [2]Department of Medical Biology, Faculty of Medicine, Cukurova University, Adana, Turkey, [3]Department of Medical Biology, Faculty of Medicine, Bezmialem University, Istanbul, Turkey, [4]Central Laboratory of Balcalı Hospital, Faculty of Medicine, Cukurova University, Adana, Turkey.

Manic depression (MD) is a severe psychiatric disorder that affects approximately %1 of the world's population. The etiology of MD is presently unknown, but epidemiological studies of families, twins and adoptions have consistently supported a genetic base. Some studies have supported the presence of autosomal dominant major loci. In this study, we aimed at detect the relationships between chromosomal aberrations (CAs) and immunological markers and MD. We used the cell cultivation and conventional G-banding. Random and non-random imbalances CAs were found in %51, %25 and %7-11 of cells. We found numerical abnormalities of chromosomes 8, 15, 21, 22, X and Y. However, structural aberrations consisted of duplications, deletions and translocations, with a focus on: loci on del(1)(q12-q23), del(1)(q21.1-q24), del(1)(q21.1-q23), del(10)(p11.2-pter), der(2) t(2;4)(p25;p12), t(2;22)(p14;p13), t(19;Y)? and dup(10)(q26). The susceptibility genes of MD may be located on these loci. Numerical sex CAs included 4(%4.6) with 45,X, 3(%4,3) with 47,XXY, and 4(%5,8) with structural chromosome X; del(X)(q13); del(X)(p11-pter) del(X)(q21.3) and inv(Y)(q11.2). The other characteristic finding was the presence of marker chromosome. The percentage of CD2+, CD4+ and CD8+ lymphocytes of the father were significantly higher, whereas CD4+ lymphocytes were decreased in the mather. The percentage of CD4 level of the son were decreased, whereas CD8+ lymphocytes were higher. These results may suggest that and MD have a significant impact on both genetic and immunological parameters, and continuing anti-inflammatory state in the family and this process may explain the cause of MD.

P03.039
Cytogenetic evaluation in congenital Blepharophimosis ptosis epicanthus inversus syndrome patients

Y. Kumar[1], *M. Kumar*[2], *B. Chawla*[3], *R. Dada*[2];
[1]Dr. RP Centre for Ophthalmic Sciences, All India Institute of Medical Sciences, New Delhi, India, [2]Lab for Molecular Reproduction and Genetics, All India Institute of Medical Sciences, New Delhi, India, [3]Dr. RP Centre for Ophthalmic Sciences, All India Institute of Medical Sciences, New Delhi, India.

BPES is a rare eye genetic disorder which either occurs sporadically or familial. BPES is a genetic disorder which generally displays an autosomal dominant inheritance pattern. The purpose of this study is to identify chromosomal abnormalities in patients with congenital BPES. It has been shown that penetrance is 100% in type I when the transmission is by males only and 96.5% in type II in which transmission occurs through both sexes. In this study 20 sporadic and 3 familial cases of congenital BPES were enrolled for cytogenetic analysis. In all familial cases pedigree showed autosomal dominant pattern of inheritance. Disease information and all medical records were reviewed. Peripheral blood was collected and lymphocyte cultures were set up for chromosomal analysis. 20 metaphases were analyzed using GTG banding. Review of reported cases concluded that locus for eyelid development is situated at the interface of long arm of chromosome 3. Various reports linked the deletions (3q21, 3q22, 3q23, 3q24, 3q25) and translocations [t(3:7)(q26-qter:q+), t(X:3)(p22:q21), t(3:8)(q23:p22.1)] to the BPES. Thus cytogenetically different deletions and translocations of chromosome 3 have been described in patients with BPES. Deletions of 3q24-25 and 3q26.3 regions were found in two familial cases. We also found 3q-ter, 3q24-25 and 3q26-qter region deletions in three sporadic cases. 3qter region deletion found in 2 cases has been already been linked to the BPES. Theses finding may represent a severe manifestation of the disease. BPES is a heterogeneous entity, and evaluation and counseling of affected individuals should be undertaken with caution.

P03.040
Breakpoint characterization in a patient with a complex rearrangement of chromosome 7 including a dup(7)(q22.1q32.2) and an inv(7)(q31.31q31.33)

A. Frühmesser[1], *M. Erdel*[1,2], *H. Duba*[1,3], *C. Fauth*[1], *G. Utermann*[1], *J. Zschocke*[1], *D. Kotzot*[1];
[1]Division for Human Genetics, Innsbruck Medical University, Innsbruck, Austria, [2]Laboratory for Molecular Biology and Tumorcytogenetics, Department of Internal Medicine, Hospital of the Sisters of Charity Linz, Linz, Austria, [3]Department for Human Genetics, General Women and Children Hospital, Linz, Austria.

For the understanding of the impact of small chromosomal rearrangements, the knowledge of the exact breakpoint-position is important, but breakpoint characterization on the base pair level is rare to find in the literature. However, by high resolution CGH- or SNP-arrays it is possible to localize the breakpoint region to a size that can be detected by simple PCR techniques. Here, we report on the breakpoint characterization of a *de novo* 46,XY,der(7)(pter->q31.33::q31.31->q22.1::q32.2->q31.33::q31.31->q32.2::q32.2->qter) karyotype in a 12-year-old boy with multiple congenital anomalies and mental retardation.

The size and the breakpoints of the duplication were narrowed with the Illumina® Infinium HD HumanOmni1-Quad v1.0 BeadChip, which covers more than 1 million SNPs, between rs17720576 (98.616.657 bp) and rs10275844 (98.621.315 bp) and rs10954272 (130.296.528 bp) and rs6467310 (130.313.744 bp), respectively. So, the size of the duplication as a whole is about 31,7 Mb. Breakpoint-spanning long-range PCR revealed a PCR product of approximately 18 kb. Sequencing of this product is in progress and should identify the duplication breakpoints on the base pair level.

The distal breakpoint of the inversion which is about 25 Mb in size was narrowed by fluorescence in situ hybridization (FISH) with the breakpoint-spanning probe RP11-111J7 (BlueGnome®, Cambridge, UK) between 117.631.652 bp and 117.790.729 bp. Fine-mapping of the proximal breakpoint of the inversion by FISH is in progress.

In conclusion, combination of FISH and high-resolution CGH- or SNP-arrays allows narrowing the breakpoints in complex chromosome rearrangements more easily than previously applied techniques. This could be important for a better genotype-phenotype correlation.

P03.041
Recurrence of cat-eye syndrome secondary to parental somatic mosaicism

*G. Morin[1], S. Kanafani[2], K. Braun[3], G. Jedraszak[1], J. Andrieux[4], H. Copin[2], **M. Mathieu**[1];*
[1]Clinical Genetics and Oncogenetics, Amiens, France, [2]Cytogenetics Laboratory, Amiens, France, [3]Paediatric Endocrinology, Amiens, France, [4]Jeanne de Flandres Hospital, Lille, France.

We report on the observation of 2 brothers presenting the association of an anal atresia, preauriculat tags and growth hormone deficiency. Their ophthalmologic examination was normal. Their father was asymptomatic. Their mother presented bilateral preauricular pit. But she had no history of anal atresia or short stature. On blood karyotype, the 2 boys had a supernumerary marker of the chromosome 22 on all the analysed cells. Their father had normal blood karyotype. Their mother presented only on few lymphocytes the same supernumerary marker.

This observation is original if we consider the recurrence secondary to parental somatic mosaicism. The growth hormone deficiency is also an unusual feature of this disease.

P03.042
Chromosomal imbalance detected by aCGH in a female with obesity and schizoaffective disturbance

V. Belengeanu[1], *M. Stoian[1], N. Andreescu[1], S. Farcas[1], E. Frengen[2];*
[1]University of Medicine and Pharmacy, Department of Medical Genetics, Timisoara, Romania, [2]University of Oslo, Department of Medical Genetics, Oslo, Norway.

We present a 29 years old female with androgynous body evaluated for epimenorrhagia. At examination the patient showed minor anomalies in facial appearance: almond shaped eyed, abnormal aspect of the inner angle of the eyebrows, arched like upper lip. Her height was 168 cm, weight-117 kg, body mass index-41.45, head circumference-58 cm. Other findings were mental retardation, square hands with brachydactyly.

Developmental milestones were delayed, with sitting at 24 months and walking at 4 years, babbling at the age of 5 years. At the age of 18, the patient's behaviour showed cyclic maniacal changes, needing psychiatric assessment. Endocrinlogic markers for pituitary gland and cortisol were within the normal values.

Cytogenetic analysis showed a normal 46,XX karyotype. Due to morbid obesity, FISH analysis using Prader-Willi/Angelman syndrome probe was done, but the result was negative. Subsequently, because of the psychiatric disturbances we suspected a possible genomic imbalance and aCGH was performed (244k). Several duplications or deletions of very small size with poor gene regions were detected on chromosomes 11p, 10q, 19q and 21q. A small duplication containing several genes was detected on 22q13.33 region. For the genes in this region we did not find any correlations with the phenotype of our patient but rather would fit into manifestations for SHANK3 gene located in the same chromosomal region but further towards the telomere. Also a small duplication of 16-33 kb involving LHX4 gene was identified on chromosome 1q25.3, but clinical and the investigations do not sustain Machinis syndrome determined by LHX4 gene mutations.

P03.043
Chromosomal analysis in 1450 couples with reproductive disorders

***R. Talwar**, S. K. S. Vats, M. K. Verma, A. Singh, C. Singh;*
Super Religare Laboratories (SRL), Gurgaon, India.

Most reproductive disorders have underlying chromosomal imbalance as a major cause for spontaneous pregnancy loss, infertility and childhood disability thereby, contributing significantly to the genetic burden on society. The diagnosis of chromosomal anomalies is made by karyotyping of GTG banded chromosome preparations obtained from whole blood. In the present study, conventional cytogenetic analysis was conducted in peripheral blood samples from 1450 couples with history of spontaneous abortions, mainly in the first trimester and infertility. Cytogenetic analysis revealed chromosomal abnormalities in 585 cases. Balanced reciprocal translocations were observed in 262 cases while Robertsonian translocations were observed in 11 cases. Apart from this, inversions in chromosomes 3, 17, X, Y and deletion of X chromosome was also observed. Novel cytogenetic anomalies like t(4;12), t(7;16) and t(1;9;10) were also observed that have not yet been reported in literature, to the best of our knowledge.. Some cases revealed heteromorphic variants in chromosome 1 (n=96) and 9 (n=102). The detection of these novel chromosomal anomalies reiterates the importance of conducting cytogenetic analysis in couples with history of reproductive failure.

P03.044
Gene Expression Profiling of Karyotypically Normal, Trisomy 12 and XXY Human Embryonic Stem Cells

*H. Seol[1], H. kim[1,2], J. Baek[1], N. Song[1], K. Kwon[1], **S. Oh**[1,2], S. Ku[1,2], S. Kim[1,2], S. Moon[1,2], Y. Choi[1,2];*
[1]IRMP, MRC, Seoul National University, Seoul, Korea, Republic of, [2]OB&GY, Seoul National University College of Medicine, Seoul, Korea, Republic of.

Human embryonic stem cells (hESCs) are well known to have the ability to proliferate unlimitedly and to differentiate into all cell types. Recently, a number of reports have been published in which chromosomal abnormalities has been observed in hESCs. We analyzed gene expression profiles of normal cell lines (SNUhES3: S3 and SNUhES4: S4), two variants of SNUhES3 (trisomy 12: S3v12 and XXY: S3vX), and one variant of SNUhES4 (trisomy 12: S4v12) using the Illumina HumanRef-6 BeadChip including 48,095 probe sets to find epigenetic difference between normal cells and chromosome variants. Gene expression patterns were showed that 55 genes were up-regulated and 28 genes were down-regulated in S3v12 to compare with S3 and 98 up-regulated genes and 75 down-regulated genes were identified in S3vX. Also, 87 genes were up-regulated and 61 genes were down-regulated in S4v12 to compare with S4. In particularly, three genes, PUS7L (synthetase), INHBE (growth factor) and PKIB (kinase inhibitor), were up-regulated and two genes, ERG1 (KRAB box transcription factor) and GALNT9 (glycosyltransferase) were down-regulated in S3v12, S4v12 and S3vX compared to normal hESC lines. Gene expression profiling in variant hESC lines with trisomy 12 or XXY chromosome as well as normal hESC lines may provide insights to the development of research field for cell differentiation and clinical approach such as cell replacement therapy.

This research was supported by a grant (SC-1150) from Stem Cell Research Center of the 21st Century Frontier Research Program funded by the Ministry of Education, Science and Technology, Republic of Korea.

Novel and known chromosomal imbalances associated with congenital heart defects found by screening with a SNP-array

E. Piñero[1], *F. García Algas[2], M. de la Fuente[2], M. Juan[3], A. Tubau[3], B. Sierra[4], A. Schmidt[1], M. Oliver[1], J. Rosell[4], D. Heine-Suñer[4];*
[1]Investigació-Hospital Universitari Son Espases, Palma de Mallorca, Spain, [2]Cardiologia Pediatrica-Hospital Universitari Son Espases, Palma de Mallorca, Spain, [3]Obstetricia- Hospital Son Llatzer, Palma de Mallorca, Spain, [4]Genetica-Hospital Universitari Son Espases, Palma de Mallorca, Spain.

Cardiac development is controlled by complex genetic and/or environmental interactions. In an effort to identify new genetic factors associated with congenital heart defects (CHD) we selected a subset of 118 patients on which we typed 660.000 SNPs for intensity and genotype using the Illumina 660W beadchip. 38 were syndromic (had at least another major malformation and/or developmental delay) and 80 had an isolated CHD. Typed CHD included Tetralogy of Fallot (TOF n=27), Ventricular and auricular septal defects (ASD and VSD; n=17; n=27), transposition of great vessels (TGV; n=19) and other (n=21). Of all the found imbalances we only considered those larger than 75 kb, include at least a known or predicted gene, and that do not overlap any imbalance found in the Database of Genomic Variants (DGV). Previously, we had screened for the 1.5-3 Mb 22q11.2 deletion and for frequent aneuploidies (13, 18, 21, X and Y chromosomes), and excluded patients that were positive from this study. 24% of patients with an isolated CHD and 34 % of those syndromic, were found to carry a putatively causative imbalance (12 deletions and 22 duplications). Among previously known recurrent syndromes we identified 3 patients with an 11q24 deletion (Jacobsen syndrome); 3 patients with atypical 22q11.2 imbalances; 1 patient with 17q21.31 deletion syndrome and 1 with a 17q12 duplication. Some of the novel, previously not described imbalances were found to include suggestive candidate genes. Although further studies are needed, our study underpins the important role that submicroscopic deletions and duplications play in CHD.

P03.046
Telomere shortening in COPD: potential protective effects of coffee consumption

J. M. J. de Vos-Houben[1], *A. Schuijlenburch*[1], *M. A. Spruit*[2], *E. F. Wouters*[1], *F. J. van Schooten*[1], *G. J. Hageman*[1];
[1]*Maastricht University Medical Centre, Maastricht, Netherlands,* [2]*Program Development Centre, Ciro, a centre of expertise for chronic organ failure, Horn, Netherlands.*

Introduction: Chronic obstructive pulmonary disease (COPD) is characterized by incompletely reversible airflow obstruction, and chronic systemic oxidative stresss and inflammation play a major role in the pathophysiology of COPD. Telomere length has been observed to be inversely associated with increased oxidative stress and inflammation. Since chronic oxidative stress plays a major role in COPD, telomere length is hypothesized to reduce at a faster rate in COPD. The first aim of this study was to investigate telomere length in COPD patients in relation to oxidative stress and inflammation. The second aim of this study was to investigate the effects of caffeine, coffee, tea and alcohol intake on telomere length in COPD patients and healthy controls.

Methods: We measured telomere length in PBMC's of 89 COPD patients and compared these with 93 healthy, (ex-)smoking controls. In addition, the cytokines IL-8, IL-6 and TNF-α were determined, as well as CRP, SOD and plasma homocysteine.

Results and conclusions: We found that telomere length was shorter in COPD patients compared to controls. Cytokine plasma levels as well as CRP and homocysteine plamsa levels were inreased in COPD patients and SOD activity was decreased, indicating elevated oxidative stress in COPD patients. In addition, this study provides a first indication of the possible beneficial effects of coffee consumption and negative effects of alcohol consumption on telomere length. Future studies should focus on interventions with dietary antioxidants or anti-inflammatory compounds, such as those found in coffee, and their possible beneficial health effects in patients with chronic inflammatory diseases.

P03.047
Contiguous interstitial deletion encompassing both PTEN and BMPR1A associated with Cowden Syndrome

M. Hiljadnikova Bajro[1], *E. Sukarova-Angelovska*[2], *M. Chaffanet*[3], *A. J. Dimovski*[1];
[1]*Faculty of Pharmacy, University St. Cyril and Methodius, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Pediatric Clinic, Faculty of Medicine, University St. Cyril and Methodius, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Centre de Recherche en Cancerologie de Marseille, Institut Paoli Calmettes Department d'Oncologie Moleculare, Marseille, France.*

We report on a patient with contiguous interstitial germline deletion of chromosome 10q23 encompassing BMPR1A and PTEN, with clinical manifestations of Juvenile polyposis and Cowden syndrome. The patient presented dysmorphic features including macrocephaly, wide fontanel with partly opened structures, wide forehead with prominent frontal protuberances, coarse features of the face with wide carp-shaped mouth, hypoplastic midface, small nose, retrognathia, prominent furrowed tongue, long philtrum, small low set ears, short neck, bilateral cryptorchidism, broad fingers with deep creases over small joints, short dorsally placed hallux and developmental delay at the age of 5 months. Multiple colonic polyps were diagnosed at the age of 3 years, following an episode of severe abdominal pain and intestinal bleeding. Comparative genomic hybridization revealed a deletion of 6.12MB in the chromosome arm 10q23. Genotyping using 5 microsatellite markers confirmed a *de novo* deletion on the allele originating from the father encompassing both PTEN and BMPR1A genes. The karyotype analysis additionally identified a balanced translocation involving chromosomes 5q and 7q, and inversion at chromosome 2: 46,XY,t(5q;7q)(q13.3-q36), inv(2)(p25q34). The mother was exposed to X-irradiation within the first 2 weeks of pregnancy which could explain the multiple genetic and phenotypic defects as well as the presence of chromosomal rearrangement in all analyzed cells. Current clinical findings and deletion of BMPR1A point to Juvenile Polyposis, but the dysmorphic features and the PTEN loss, strongly suggest a diagnosis of Cowden Syndrome which should be confirmed later in life with development of late onset phenotypic features.

P03.048
Cytogenetic investigation among patients with primary amenorrhea

C. Azimi[1], *M. Khaleghian*[1], *Z. Safari*[2];
[1]*Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Young Researchers Club, Varamin-Pishva Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

One of the sex chromosome aberrations in women is Turner's syndrome, which is much less common than other sex chromosome aneuploidies. The frequency of the Turner's syndrome is about 1 in 5000 live female births. The most frequent chromosome constitution in Turner's syndrome is 45,X. However, about 50 percent of cases have other karyorypes. About 25 percent of cases reveal mosaic karyotypes, in which only a proportion of cells show 45.X. The chromosome constitution is clinically significant, and different cases show rather different manifestations according to their karyotypes.

The typical abnormalities in Turner's syndrome include short stature, webbing of the neck, characteristic unusual face, a broad chest with widely spaced nipples, gonadal dysgenesis, low posterior hairline, and sometimes with renal and cadiovascular malformations or hearing loss.

A total of 267 cases were referred to our Department with primary amenorrhea. Cytogenetic studies were performed on peripheral blood cultured for 72 hours in the presence of PHA. For routine chromosome analysis, 20-30 Giemsa-banded cells were analyzed , with two cells karyotyped.

219 (82%) patients showed normal karyotypes. 48 (18%) patients showed X chromosome abnormalities.

21 (43.7%) cases revealed 45,X. 11 (23%) cases were either 45,X/46,XX or 45,X/46,XY mosaics.

9 (18.7%) cases showed either 46,X,i(Xq) or 45,X/46,X,i(Xq) mosaics.

The rest of 7 (14.6%)cases include: 46,X,t(X;19)(q22;q13) [two cases]; 46,X,delX(q13) [two cases]; 47,X,-X+derXp,derXq; 47,XXX; and 45,X/47,XXX mosaics.

P03.049
A familial translocation t(14;21) in four generations affected by Trisomy 21

R. M. Lago Leston, *R. Rodriguez Lopez, J. M. Carbonell Perez, J. Saenz Hurtado, M. E. Sanchez Gutierrez, T. Herrera Moreno, M. Garcia de Caceres, M. Gonzalez-Carpio Serrano;*
Hospital Infanta Cristina, Badajoz, Spain.

INTRODUCTION: Only 4% of Down Syndrome (DS) occurs whit a homologous or heterologous translocation (13q, 14q, 15q or 22q) of chromosome 21, of which 1% of all DS are familiar. This type of aneuploidies is caused by the incorrect distribution of homologous chromosomes during meiosis.

PATIENTS AND METHODS: In 149 from 600 pregnancies between 2007-2009 was requested molecular testing for early aneuploidy screening. 6 postnatal and 6 prenatal cytogenetic studies were carried out in individuals of three generations belonging to a family carrying a heterologous translocation. The DNA obtained from 3 related prenatal and 2 postnatal samples were amplified for 7 hypervariable genetic markers in chromosome 21 using QF-PCR techniques.

RESULTS: We identified one family carrying the t(14;21) translocation with 5 affected by DS, 9 non-affected carriers and 5 abortions. The definition of associated markers to translocated chromosome 21 in an affected individual, revealed identical genetic makeup except for the more distally located. The third chromosome 21 (paternal) differed in all markers with the two previous.

The pedigree identified a set of individuals at possible risk of fathering children with DS.

CONCLUSIONS: The origin of trisomy 21 was maternal, but double-recombination in meiosis I generated an exchange of genetic material translocated, except the most telomeric region, before the incorrect distribution of homologous chromosomes 21 in meiosis II.

Our results identified an unusual mechanism of double-recombination of the extra chromosome and expose the diversity of causal etiology.

P03.050
Mosaic interstitial duplication 17q

***K. B. M. Hansson**, C. A. L. Ruivenkamp, K. Szuhai, M. E. Hoogenboom, C. Knepfle, T. Segboer, S. Kant, N. S. den Hollander;*
Leiden University Medical Center, Leiden, Netherlands.

Interstitial duplications in the long arm of chromosome 17 are rarely encountered. We report a female patient who was born with multiple congenital anomalies. She had loose skin in the neck, narrow forehead, depressed nasal bridge, long philtrum, split uvula, a sacral dimple, rhizomelic shortening of all extremities, postaxial polydactyly of hands and feet, bilateral pes equinovarus and extreme hypermobility of the large joints.

Conventional karyotyping demonstrated a mosaic (87%) interstitial duplication in the long arm of chromosome 17 between q21 and q25. The duplication was also present in fibroblasts from skin (83%) and cartilage (97%). SNP array analysis was performed to characterize the duplication in more detail. Additional FISH analysis revealed that the duplication was direct. Both parents had a normal karyotype. Detailed molecular characterizations and reports of chromosomal imbalances in combination with clinical phenotypes are important for accurate genotype-phenotype correlations in genetic counseling.

P03.051
The Dyke Davidoff Masson Syndrome as the indicative feature in a child with a 22q11.2 deletion

***S. Dimassi**[1], S. Mougou[1], R. Bousoffara[2], H. Hannechi[1], N. Moulazem[2], A. Saad[1];*
[1]Department of Cytogenetics and Reproductive Biology, Farhat Hached University Teaching Hospital, Sousse, Tunisia, [2]Department of Pediatrics, Tahar Sfar University Teaching Hospital, Mahdia, Tunisia.

Cerebral hemiatrophy with homolateral hypertrophy of the skull and sinuses (resulting in facial asymmetry) and elevation of the sphenoid wing and petrous ridge, associated with contralateral hemiplegia, seizures, mental retardation, difficulty and impairment of speech development are features of the radiological syndrome: Dyke Davidoff Masson Syndrome (DDMS).

We report here, the case of 4 years old boy, with facial asymmetry, hemiparesis, mental retardation and epilepsy. The cerebral MRI showed a cerebral hemiatrophy and a fronto-parietal polymicrogyria (PMG). A cytogenetic study was performed on R-banded chromosomes showed a 46,XY formula. A fluorescence in-situ hybridizing (FISH) using specific *Tuple1* probe showed a 22q11.2 deletion, well characterized by array comparative genomic hybridization (CGH array) revealing a 3Mb 22q deletion, extended from 16,597 to 19,712Mb including *TBX1* gene.

The 22q11.2 deletion syndrome or velocardiofacial (VCF) syndrome is a microdeletion syndrome associating conotruncalcardiac malformation, palatal dysfunction or cleft, facial dysmorphism, immuno-deficiency, developmental delay and vascular anomalies. Several brain malformations as PMG have been described in association with VCF. These anomalies seem to result from abnormal cortical organisation caused by ischemia occurring during a critical period of cortical development. The *TBX1* gene on 22q11.2 encodes T-box1 protein, necessary for the normal development of large arteries, could be a good candidate for DDMS. The deletion of this gene in our case could then explain the PMG observed in the frontal and parietal lobes. This data, improves also the check of the 22q11.2 deletion in DDMS or PMG cases even in the absence of other VCF syndrome features.

P03.052
Rapid Prenatal Diagnosis of Trisomy 18 and 21 by Fluorescence in Situ Hybridization (FISH) on Uncultured Amniotic Fluid Cells

***N. Song**[1], M. Woo[1], J. Choi[1], H. Ko[1], K. Kwon[1], S. Oh[1], C. Park[2], K. Park[3], J. Park[2], J. Jun[2], Y. Choi[2,1], S. Moon[2,1];*
[1]IRMP, SNU, Seoul, Korea, Republic of, [2]2) Department of Obstetrics and Gynecology, College of Medicine, SNU, Seoul, Korea, Republic of, [3]3) Seoul National University Bundang Hospital, Bundang, Korea, Republic of.

Fluorescence in situ hybridization (FISH) in uncultured amniotic fluid samples is a useful tool for rapid prenatal diagnosis in pregnancy with high risk for chromosomal abnormality. FISH using specific probes for chromosome 18 and 21 was performed in 175 amniotic fluid samples referred to the Institute of Reproductive Medicine and Population, Seoul National University. All of the FISH results were compared with the karyotypes from conventional cytogenetic analysis. Amniotic fluid samples were obtained between the 16th and 28th weeks of gestation. The most frequent indication performed FISH analysis was the ultrasonographic (US) findings of fetal anomalies (54.6%). Aneuploidy was identified in 6 out of 175 uncultured amniotic fluid samples by FISH. Three cases of trisomy 18 and three cases of trisomy 21 were detected. 4 out of 6 cases with aneuploidy were with structural abnormalities at US. Conventional cytogenetic results revealed 4 chromosomal abnormalities not detectable by FISH such as 47,XXY, 45,X/46,XX mosaicism, balanced reciprocal translocation, and marker chromosome. These results suggest that FISH in uncultured amniotic fluid samples indicated the abnormal US findings in fetus is a reliable method for the rapid prenatal diagnosis of trisomy 18 and trisomy 21. FISH analysis should generally be used as an adjunct to the conventional cytogenetic analysis and not be used alone. Genetic counseling for prenatal diagnosis is important for patient's understanding about the limitations of FISH for detection of aneuploidy in uncultured amniotic fluid cells.

P03.053
‚Inherited complex mosaicism associated with fragile site at 16q22'

***B. Burnytė**[1,2], A. Matulevičienė[1,2], V. Dirsė[1,2], V. Kučinskas[1,2];*
[1]Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Centre for Medical Genetics at Vilnius University Hospital Santariškių Clinics, Vilnius, Lithuania.

The fragile site of 16q22 is found in 1%-5% of individuals. We report a case of familial chromosomal mosaic fragile site 16q22 in a 17-year-old caucasian adolescent girl with secondary amenorrhea. Pedigree data showed a few cases with menstrual disorders from father's side. Hirsuitism in spine, upper and lower limbs and linea alba region was observed during physical examination of proband. Pelvic and thyroid ultrasonography did not show any abnormalities. Serum hormones levels were in reference ranges.

Conventional G-banded karyotype analysis from GTG banded metaphase chromosomes revealed chromosomal rearrangements in the girl and her father such as: mos 46,XX,del(16)(q22)[8]/ 46,XX,fra(16)(q22)[11]/ 46,XX[31] and mos 46,XY,del(16)(q22)[5]/ 47,XY,del(16)(q22),+ace(16)(q22qter)[3]/ 46,XY,fra(16)(q22)[12]/46,XY[30], respectively. Chromosomal analyses of the proband's mother showed normal karyotype. We used subtelomeric FISH for the chromosome 16 to confirm and determine ratio of these cell clones. FISH analysis showed no del(16)(q22) since we observed both signals of chromosome 16q. One signal of a long arm was detected on the acentric fragment of chromosome 16. FISH analysis of patient's parents indicated fragile chromosome 16 was inherited from patient's father. QT-PCR testing for sex chromosomes aneuploidies was performed. Normal result was obtained, sex chromosomes XX.

P03.054
Whole-genome array-CGH screening in autosomal dominant sensorineural hearing loss patients detects two chromosomal alterations at 5q32 and 7q31.1

***É. L. Freitas**[1], D. T. Uehara[1], R. C. Mingroni-Netto[1], A. C. Krepischi[2], C. Rosenberg[1];*
[1]Department of Genetics and Evolutionary Biology, IB, University of São Paulo, São Paulo, Brazil, [2]Hospital A.C. Camargo, São Paulo, Brazil.

Hereditary hearing loss is a clinically and genetically heterogeneous sensory disorder. In 20% of cases is inherited in an autosomal dominant pattern with no additional clinical signs (ADNSHL). To date, 59 loci for ADNSHL have been mapped to chromosomal regions. Due to tremendous genetic heterogeneity, the identification of genes that affect the process of hearing has been challenging, so in order to verify whether genomic alterations contributed to the hearing loss etiology and to discover novel DFNA locus, we investigated 40 patients with ADNSHL by oligonucleotide array-CGH. Copy number alterations were detected in two ADNSHL patients (5%), both alterations inherited from their affected fathers. The first one, a 56 Kb deletion on 5q32 region, encompasses only one gene, the POU4F3. Mutations in this gene had already been associated with hearing loss in other four cases; the total deletion of the POU4F3 had not been reported. POU4F3 protein has an important role in the maturation, differentiation and survival of cochlear hair cells, defects in these cells may therefore

explain sensorineural hearing loss. The second alteration was a 438 Kb duplication located on 7q31.1 region affecting two genes: IMMP2L and DOCK4. In this case the DOCK4 is a strong candidate gene for causing the ADNSHL since previous studies indicate that a DOCK4 harmonin-activated signaling pathway regulates actin cytoskeleton organization in stereocilia. We report for the first time a case of ADNSHL caused by deletion of the entire POU4F3 gene, and point DOCK4 as a deafness gene in representing a novel DFNA locus.

P03.055
Possible association of heterochromatin variants in human karyotype with reproduction failure

*A. Sipek jr., **A. Panczak**, R. Mihalova, M. Janashia, L. Celbova, M. Kohoutova; Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic.*

Heterochromatin abnormalities of chromosomes are believed to be clinically insignificant variants of the human karyotype. Chromosomes with areas of constitutive heterochromatin (chromosomes 1, 9, 16 and Y) are commonly involved. However, several authors have studied the possible association of heterochromatin variants with selected clinical diagnoses, especially with reproduction failure (sterility and/or repeated abortions).

We have compared the incidence of heterochromatin variants in the group of patients with reproduction failure to the incidence in the control group. The study group was composed of 761 patients (93 individuals and 334 couples) with reproduction failure diagnosis karyotyped between 2007 and 2009 in our cytogenetic laboratory. The control group was composed of 885 fetuses who were karyotyped only because of the advanced age (35 years or more) of their mothers between 2003 and 2009 in our laboratory; cases with unequivocally pathologic findings were not included.

Heterochromatin variants have been found in 106 patients (13.9%) in the study group and only in 74 individuals (8.7%) among controls. The difference was statistically significant ($p < 0.001$). The most common variants were those of chromosome 9 (including pericentric inversions); they were detected in 51 (6.7%) patients with reproduction failure but only in 32 (3.7%) fetuses. This difference was statically significant ($p < 0.01$), too. There was no significant difference in the incidence of heterochromatin variants in men and women karyotyped for reproduction failure.

Our results in Czech population correspond to findings of other authors. However, the causal mechanism for these observations remains unknown for now.

P03.056
Karyotype instability in morphologically abnormal culture of mesenchymal stem cells and PHA-stimulated lymphocytes of the patient

***I. A. Galembo**[1], A. V. Voskresenskaya[2], O. A. Efimova[2], A. A. Pendina[2], A. V. Tikhonov[1], J. G. Lezhnina[1], P. V. Kruglyakov[3], A. V. Krylov[3], T. V. Kuznetzova[2], V. S. Baranov[2];*

[1]Saint-Petersburg State University, Saint-Petersburg, Russian Federation, [2]D.O.Ott's Research Institute of Obstetrics and Gynecology, laboratory for Prenatal Diagnosis of Human Inborn and Inherited Diseases, Saint-Petersburg, Russian Federation, [3]Trans-Technologies, Ltd, Saint-Petersburg, Russian Federation.

The results of cytogenetic study of one bone-marrow derived mesenchymal stem cell (MSC) culture, distinguished from other 200 cultures from donors in stem cell bank by its abnormal morphology are reported. This culture demonstrated spontaneous disturbances in morphology and proliferation at the early passages - cells grew in size, lost adhesion properties, detached from the flask surface, and persistently divided in the suspension. They also showed up-regulated expression of CD106. The donor of this culture had no clinical or laboratory features of bone marrow pathology

We analyzed 58 metaphases of the abnormal MSC culture and revealed various genomic and chromosomal mutations, including tetraploidy, additional marker chromosomes, monosomy 2,8,13,14,15,16,17,21, insertions of chromosome7; derivatives of chromosomes 3,7,9,17, deletions of chromosomes 2,14. Cells with abnormal karyotypes accounted for 22% of all cells studied. No repeatability of karyotype aberrations was observed, which could be attributed to their single cell origin.

The cytogenetic analysis of PHA-stimulated lymphocytes of the same patient showed that 14,4% of cells (23 from 160) featured abnormal karyotype. The cells with polyploidy, tetrasomy 21, double trisomy(+10,+20), trisomy21, double monosomy(-2,-10,), monosomy 18,21,22,Y; derivatives of chromosomes 4,14, isochromosome 9, translocation between chromosomes 8 and 10, homogeneously stained regions in chromosomes 1and4 were registered. Monosomy Y was detected in 5cells and trisomy 21 in 2 cells. Thus, concordance in karyotype aberrations in MSC and lymphocytes was showed for chromosomes 2,14and21.

In conclusion, karyotype aberrations, revealed both in MSC and lymphocytes substantiate genome instability in this particular patient.

Supported by RFBR and Administration of Saint-Petersburg.

P03.057
Co-localization of acetylated histone H3 and methylated DNA demonstrates band and stage-specificity in distribution in human metaphase chromosomes

***J. G. Lezhnina**[1], A. A. Pendina[2], O. A. Efimova[2], A. V. Tikhonov[1], I. A. Galembo[1], O. G. Chiryaeva[2], L. I. Petrova[2], V. S. Dudkina[2], N. A. Sadik[2], T. V. Kuznetzova[2], V. S. Baranov[2];*

[1]Saint-Peterburg State Universuty, Saint-Petersburg, Russian Federation, [2]D.O.Ott's Research Institute of Obstetrics and Gynecology, laboratory for Prenatal Diagnosis of Human Inborn and Inherited Diseases, Saint-Petersburg, Russian Federation.

Distribution of acetylated histone H3 (AcH3K9) in human metaphase chromosomes from lymphocytes of adults was studied. 60 DAPI-stained metaphases (~400 bands per haploid genome) from 5 individuals were analyzed with antibodies against AcH3K9 (Abcam, USA). AcH3K9-rich regions (the brightest AcH3K9-fluorescence) corresponded to 32 R-bands. Medium to weak fluorescent AcH3K9-signals were detected in 86 R-bands. All G-bands demonstrated weak AcH3K9-fluorescence. AcH3K9 was absent in heterochromatic blocks of chromosomes 1, 9, 16, Y.

This H3K9 acetylation profile was compared to the relevant DNA methylation patterns after 5-methylcytosine antibodies staining. Non-acetylated heterochromatic regions were hypermethylated. Among R-bands with medium to weak acetylation 6 demonstrated weak, 48 - medium and 32 - high DNA methylation level. 32 AcH3K9-rich R-bands showed variable DNA methylation levels: 17 - high, 12 - medium and 3 (1p13, 2q31, 2q33) - low. Low level of DNA methylation in highly acetylated bands favors their specific function in lymphocytes.

Both H3K9 acetylation and DNA methylation were also studied in lymphocyte chromosomes from fetal cord blood. Two highly methylated regions 2q31 and 2q33 and one hypoacetylated one - 2q31 - distinguished fetal chromosomes from their counterparts in adult.

The co-location of acetylated and methylated chromosome patterns suggests feasible distribution of active and inactivated chromatin regions which looks to be band and stage specific.

P03.058
Case report: A male with two idic(Y) chromosomes

*D. Begovic, **D. Begovic**, L. Letica, I. Tonkovic Djurisevic, K. Crkvenac Gornik, R. Lasan Trcic, M. salamon, M. Salamon, I. Tonkovic Djurisevic;*

Medical School University of Zagreb, Department of pediatrics, 10000 Zagreb, Croatia.

Idic(Y) cause several sex-linked phenotypes ranging from typical Turner syndrome, to phenotypic males, and to those with ambiguous genitalia. We report a 17-year-old boy with male development, hypogenitalism, small stature, slight obesity and normal inteligence. Cytogenetic analysis and GTG-banding were performed on metaphases from cultured peripheral blood lymphocytes. As a result, the lymphocyte culture revealed a karyotype 45,X with a pericentric inversion of chromosome 9 of maternal origin. Chromosome analysis was also performed on fibroblasts from the skin. Two cell lines were observed: 45,X,inv(9)mat[18] and 47,X, inv(9)mat,+marx2[17] Fluorescent in situ hybridization (FISH) analysis was performed on fibroblasts using the probe for the chromosome X centromere (DXZ1) and the DYZ3 probe for chromosome Y centromere according to the manufacturer's instructions. The presence of four Y-centromeric signals and an X-centromeric signal was observed in 40% of cells while in the remaining 60% of the metaphase cells only one signal for the X chromosome

centromere was present. Dual color FISH with an SRY (Yp11.3) DYZ3 (YCEN) and DYZ1 (Yq12) probes demonstrated the presence of two centromeres and two SRY regions per one marker. The probe for the Y heterochromatic region DYZ1 didn't show any signal. Thus, the patient karyotype was mos 45,X,inv(9)mat[18]/47,X,+idic(Y)(q11) x2dn. ish idic(Y)(q11)(SRY++,DYZ3++,DYZ1-)x2[10]. Only several patients with a cell line containing two isodicentric Y-chromosomes with a break in Yq resulting in tetrasomy of Yp have been described. Correlation between phenotype and karyotype is not yet well defined, this clinical report will be helpful in defining the phenotypic range of this chromosomal abnormality.

P03.059
Tetrasomy 15q in a girl with epilepsy and hypomelanosis

A. Gómez[1], *M. Quintanilla*[1], *P. Martín-Tamayo*[2], *G. M. Varo*[1], *L. Navarro*[1];
[1]*Unidad de Genética Clínica. Servicio de Análisis Clínicos. Complejo Hospitalario Universitario de Albacete., Albacete, Spain,* [2]*Neurología Pediátrica. Complejo Hospitalario Universitario de Albacete, Albacete, Spain.*

The inv dup (15) or idic (15) is the most common of the heterogeneous group of the extra structurally abnormal chromosomes (ESAC). Two cytogenetics types have been identified. One is a metacentric or submetacentric and heterochromatic chromosome, not containing the Prader-Willi Syndrome/ Angelman Syndrome Critical Region (PWS/ASCR) [dic(15)(q11).dic(15)(q11)], can be familial or *de novo* and most children show a normal phenotype. The second type has 15q euchromatin including PWS/ASCR [dic(15)(q12 or q13)], that frequently derives from the two homologous maternal chromosomes at meiosis. This condition is associated with an abnormal phenotype, which constitutes the idic(15) syndrome, and is nearly always sporadic. The inv dup (15) displays distinctive clinical findings represented by early central hypotonia and intellectual disability, epilepsy and autistic behaviour. Expressive language is absent or very poor and often echolalic. Epilepsy with a wide variety of seizures, as a typical Lennox-Gastaut Syndrome (LGS), can occur in these individuals. Areas of increased and reduced skin pigmentation can be occasionally observed.

We report on a 6 years old girl, patient of Neuropediatrics, with language delay, LGS and hypopigmented streaks on the trunk. Cytogenetic studies and FISH analysis showed that she had a de novo 46,XX,+idic(15)(q13) karyotype. Cytogenetic analysis confirm the diagnosis of idic(15) syndrome in our patient.

P03.060
A *de novo* 9Mb deletion into an inherited 2q paracentric inversion gives rise to severe developmental delay and eyelids malformation

A. BRIAND-SULEAU[1], *C. Metay*[1], *M. Portnoi*[2], *J. Bouligand*[3], *B. Tou*[3], *W. Verbecq-Morlot*[1], *A. Guiochon-Mantel*[3], *M. Goossens*[1], *L. Van Maldergem*[4];
[1]*HOPITAL HENRI MONDOR, CRETEIL, France,* [2]*Hopital Trousseau, Paris, France,* [3]*Hopital Bicetre, Le Kremlin-Bicetre, France,* [4]*Centre Hospitalier InterCommunal, CRETEIL, France.*

Our patient, a girl, presented at 14 months- with developmental delay and hypotonia. Her clinical examination also displayed ptosis, blepharophimosis, and a toe malformation. Her karyotype indicated, an apparently balanced 2q paracentric inversion (46, XX, inv(2)(q21q37)) inherited from her normal father, and confirmed by FISH. In addition, Agilent 105k array-CGH proved positive for a 9Mb deletion (2q31.1q31.3) within the inverted region in the index patient. By contrast, array-CGH was normal in her normal father also harboring the 2q31 paracentric inversion. Its *de novo* character was confirmed by FISH and qPCR.

An interstitial (an not terminal) secondary rearrangement occurring within an inverted segment is a rare event that is not readily explained by non allelic homologous recombination (NAHR). The advent of array-CGH as an additional mandatory investigation in case of abnormal phenotype and an apparently balanced translocation has shown in a number of cases an additional loss of chromosomal material in the close vicinity of the breakpoints (neighboring regions). However, in the present case, the deletion occurred at distance of the breakpoints, suggesting an unusual mechanism. The phenotype of our patient deserves consideration, since an eyelid malformation has been also reported in the three patients with similar microdeletions retrieved from literature. More than 50 genes are included in the deleted interval and one can speculate on the involvement of one of them in eyelid differentiation. Our report confirms that developmental delay and malformed eyelids is suggestive of a 2q31 microdeletion syndrome, in addition to the well-known 3q23 BPES microdeletion syndrome.

P03.061
Familial segregation of an interchromosomal insertion (9;15)(q33;q21.1-q22.31) with three individuals carrying an unbalanced karyotype characterized by high resolution array

I. C. Sgardioli, *T. P. Vieira, M. Simioni, N. L. V. Campos, J. R. M. Prota, F. P. Monteiro, V. L. Gil-da-Silva-Lopes;*
Department of Medical Genetics, University of Campinas (UNICAMP), Campinas, Brazil.

Chromosome insertions are complex rearrangements occurring in about 1/5.000 live births. Originally balanced chromosome insertions, after meiotic segregation, can cause unbalanced structural rearrangements with deletions or duplications of the translocated segment, which explains the high risk (50%) of producing an abnormal offspring. Here, we report an interchromosomal insertion in three generations of a family. The proband presented neurological disorders, mitral stenosis, velopharyngeal insufficiency and facial dysmorphisms. The G-banded karyotype showed an insertion in the long arm of chromosome 9 in q33 region. His mother is carried of a balanced insertion [ins(9;15)(q33;q21.1-q22.31)]. The cytogenetic analysis of other family members identified six individuals carrying an apparently balanced rearrangement and two other members carrying the same unbalanced rearrangement [der(9)ins(9;15)(q33;q21.1-q22.31)]. Despite the clinical heterogeneity these individuals present some similar characteristics such as RDNPM, short stature and dysmorphic features. The high resolution array analyses (Genome-Wide Human Array 6.0,Affymetrix®) of three individuals with unbalanced karyotype revealed a duplication of 19.3Mb on chromosome 15 ranging from q21.1 to q22.31 [44275184-63567267 - hg18]. The array analyses of an apparently balanced carrier presenting mental retardation and speech delay showed normal results and is still in investigation. Despite some rare reports of overlapping duplications in 15q21.2-q22.31, this family herein described seems to be the first one with duplication of this specific region. The combined approach of karyotype and array analysis allowed the correct characterization of the rearrangement in most of the family members. **Financial support:** Fapesp and CNPq

Prominent transformation of karyotype of human mesenchymal stem cells 4BL6 in long-term culture

H. Akopyan[1], *N. Huleyuk*[1], *V. Kushniruk*[2], *D. Mykytenko*[3], *A. Iatsyshyna*[2], *I. Kovaliv*[1], *V. Zukin*[3], *L. Lukash*[2];
[1]*Institute of Hereditary Pathology of National Academy of Medical Sciences, Lviv, Ukraine,* [2]*Institute of Molecular Biology & Genetics of National Academy of Sciences, Kyiv, Ukraine,* [3]*Clinic of reproductive medicine "Nadiya", Kyiv, Ukraine.*

4BL6 cells were obtained from donors peripheral blood and were grown in standard monolayer culture. During the observation period (219 passages) the cells maintained fibroblast-like morphology, sensitivity to colchicine and proliferative potential. At 205-th passage 4BL6 cell population contained 36% of polyploid cells and 62.5% of neardiploid cells. Among polyploid cells, 81% were tetraploid and 12.5% were triploid. The number of chromosomes in neardiploid cells varied from 30 to 49. 80.8% of these cells contained 39-44 and 60% - 41-43 chromosomes (possible modal clone). The number of chromosomes in diploid and polyploid cells (42-43 and 84-85 respectively) and their ratio in culture (1.7 : 1) allows to assume that upon reaching 205-th passage, the reproduction of 4BL6 cell line occurs by symmetrical division of polyploid cells. To define the nature of chromosomal anomalies, GTG, QFH/AcD, Cytocell OctoChrom stainings and array CGH were used. X monosomy, t(1;11)(q12;p15) and t(2;?)(q11;?) were defined as most common aberrations and observed in 80%, 65% and 46% of metaphases respectively. 23% of cells contained t(5;15)(p10;q10) and 10% - t(5;15)(p10;q10), that were never registered together. Chromosomes 3, 6, 7, 8, 9, 14, 18, 20, 21 and 22 showed normal number and constitution, whereas chromosomes 1, 2, 4, 10, 12, 13, 16, 17, 19 demonstrated unbalanced structural rearrangements (deletions/duplications) from 0.6 to 10 and more Mb. In our opinion, long-term transformation of the 4BL6 cell line

occured due to formation of typical chromosomal rearrangements that changed the dose of genes-suppressors of cancer growth and genes-inducers of proliferation.

P03.063
Congenital stationary night blindness, high myopia and severe mental retardation: search for a homozygous microdeletion 15q13.3 !

K. Aliferis[1], *S. Gimelli*[1], *F. Borruat*[2], *S. E. Antonarakis*[1,3], *F. Béna*[1], *A. Bottani*[1];
[1]*Service of Genetic Medicine, University Hospitals of Geneva, CMU, Geneva, Switzerland,* [2]*Neuro-ophthalmology Unit, Jules-Gonin Ophthalmic Hospital, Lausanne, Switzerland,* [3]*Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland.*

Heterozygous microdeletions 15q13.3 are not rare and have been associated, among other findings, with intellectual disability, autism, and schizophrenia. It has also been found in controls and healthy relatives of affected individuals. The reason for this wide phenotypical variability is poorly understood. On the contrary, homozygous deletions of this same area have so far been reported in only 4 patients and seem to be linked with a specific clinical presentation, namely severe mental retardation, seizures and visual impairment.

The 12-year-old female patient was born at term with normal growth parameters. Absent visual pursuit was noticed at 2 months and congenital stationary night blindness (CSNB) was diagnosed at 9 months by electroretinography. At 10 months, severe developmental delay was evident and seizures were noticed. High myopia (-10 dioptries) is known since the age of 21 months. Karyotype, methylation of the AS/PWS region and MECP2 analysis were normal. Array CGH (Agilent 244K) revealed a homozygous 1.5 Mb 15q13.3 deletion (28719136-3029809 bp, UCSC Hg19). The deleted interval comprises 6 genes: MTMR15, MTMR10, KLF13, OTUD7A, CHRNA7, TRPM1. A homozygous mutation of TRPM1 has been recently associated with CSNB and myopia (Audo et al., AJHG 2009; 85: 720-729). The asymptomatic parents are both heterozygous carriers.

This report confirms that the clinical picture of homozygous 15q13.3 deletions is very homogeneous and comprises, besides severe mental retardation and seizures, CSNB with myopia as a key feature. It also proves that CSNB due to TRPM1 recessive mutations is caused by a loss of function of the coded protein.

P03.064
Delineation of the Interstitial 6q25 Microdeletion Syndrome: refinement of the critical causative region

M. Michelson[1,2], *C. Vinkler*[1,2], *I. Nezer*[1,2], *M. Yanoov-Sharav*[1,2], *T. Lerman-Sagie*[2,3], *D. Lev*[1,2];
[1]*Institute of Medical Genetics, Holon, Israel,* [2]*Metabolic Neurogenetic Clinic, Holon, Israel,* [3]*Pediatric Neurology Unit, Holon, Israel.*

Cryptic chromosomal aberrations are associated with various syndromes. Microdeletion of the long arm of chromosome 6q is rare but specific clinical entity. Phenotypic presentation includes mental retardation, acquired microcephaly, dysmorphic features, structural brain malformations and other features. The smallest reported region of microdeletion responsible for the phenotype was mapped between 6q24 and 6q27 and spans >3MB with more than 12 coding genes.

A 2 years old boy presented with mental retardation, acquired microcephaly, dysmorphic features and dysgenesis of corpus callosum. He has deep set eyes, prominent forehead, posteriorly rotated ears, short neck, short proximal phalanges, transverse creases, fetal pads and hypoplastic scrotum. Neurological examination revealed mixed axial hypotonia with limbs hypertonia.

He is the fourth child of an unrelated generally healthy couple. The mother is carrier of a Robertsonian translocation (14;15).

Our patient was found to be a carrier of the same translocation and his karyotype is 45 XY,der(14;15)(q10;q10)

Affymetrix Wnole-Genome 2.7M Array Chip revealed deletion of 1191 kbp at 6q25.3. The deleted region contains 2 coding genes:
ARID1B and ZDHHC14.

These genes are highly expressed and evolutionarily conserved. ARID1B encodes a subunit of chromatin-remodeling complex. The encoded protein is expressed in different brain regions during fetal development suggesting its important role in CNS development. ZDHHC14 belongs to a palmitoylating enzyme family proteins. Protein palmitoylation is crucial in CNS development and plays an important role in neurite outgrowth and synaptogenesis.

We found two attractive genes, whose haploinsufficiency caused the distinct phenotype of 6q deletion syndrome with dysgenesis of corpus callosum

P03.065
Detection efficiency of FISH vs MLPA method in microdeletion syndromes patients

R. Mihalova, *K. Hirschfeldova, A. Baxova, V. Kebrdlova, P. Lnenicka, R. Solc, J. Stekrova, K. Vesela;*
Inst of Biology and Medical Genetics, 1st Faculty of Medicine of Charles University, Prague, Czech Republic.

Microdeletion syndromes are complex genetic disorders caused by different changes of contiguous genes located in particular chromosomal regions. These changes are usually cryptic chromosomal aberrations - microdeletions or microduplications. The OMIM database currently contains more than 100 microdeletion/duplication syndromes of various types but due to the extensive phenotypic variation and overlapping phenotypes the correct diagnosis is often difficult to be determined.

We have analysed 64 probands with normal karyotype and specific clinical findings such as mental retardation or developmental delay combined with neonatal hypotonia, congenital anomalies or facial dysmorphism. We used the MLPA method to scan for cryptic rearrangements. Each proband was analysed by the P245 kit to detect 21 most common microdeletion syndromes. Additional microdeletion syndromes were analysed using the P297kit. Moreover, subtelomeric regions were analysed with the P036kit. Overall 10 positives (16%) were detected, 3 duplications and 7 deletions, respectively. The MLPA kit P245 was able to detect 9 of all found rearrangements. One abnormality was detected only by the MLPA kit P036.

We have used the FISH method with locus specific probes to confirm the findings and to compare the efficiency of both methods in cases of MLPA positive probands. Surprisingly, we have found the discrepancy in 2 cases. The deletion of 10p14-15 and 1p36 was detected by MLPA and not confirmed by FISH.

Although the application of FISH method is the matter of choice for the diagnostics of microdeletions, the MLPA method appears as more sensitive and more effective.

Supported by grant IGA MZCR NS10327-3/2009.

P03.066
Contribution of cell cycle control genes epimutations to the origin of chromosomal mosaicism in human miscarriages: a model and experimental evidences

A. A. Kashevarova, *E. N. Tolmacheva, N. N. Sukhanova, I. N. Lebedev;*
Institute of Medical Genetics, Russian Academy of Medical Sciences, Tomsk, Russian Federation.

Chromosomal mosaicism is a hallmark of human miscarriages. Among different factors underlying abnormal chromosome segregation the epimutations of cell cycle genes is of particular interest. Epigenetic reprogramming during early ontogeny may predispose to methylation abnormalities. We aimed to determine the mechanisms and stages of cytogenetic and epigenetic errors origin and suggest a model for identification of epimutations impact on mosaicism formation. Extraembryonic tissues of 69 diploid-aneuploid miscarriages, 20 diploid miscarriages and 22 induced abortions of similar gestational age were examined for epimutations of cell cycle control genes *RB1* and *P14ARF* which were hypermethylated in 42% and 10% of mosaic embryos, respectively. Cytotrophoblast and extraembryonic mesoderm appears a convenient model to determine ontogenetic stages of aneuploidy and epimutations origin because they are derived from different germ layers, isolate after implantation and differ in DNA methylation. Diploid-aneuploid mosaicism originates postzygotically due to trisomy rescue or de novo mitotic error. If mitotic errors occur before germ layers divergence then both tissues will be mosaic. Mosaicism will be confined by one tissue if mitotic mutation occurs after divergence. Epimutations may originate from demethylation and de novo methylation errors during epigenetic reprogramming. Analysis of all possible combinations of cytogenetic and epigenetic abnormalities underlies our model. Interpretation of the methylation role in the origin of mosaicism using the model allowed concluding that *RB1* and *P14ARF* epimutations are primary to diploid-aneuploid mosaicism in

at least 4,7% of mosaic embryos. This study was supported by Federal Program N P806, P1161 and State Contract for National Educational Center 02.740.11.0281.

Popa University of Medicine and Pharmacy - Medical Genetics Department, Iasi, Romania,* [2]*Saint Spiridon Hospital - Immunology and Genetics Laboratory, Iasi, Romania,* [3]*Chidren Hospital - Medical Genetics Department, Iasi, Romania,* [4]*Dept. Genetics UMCG, Groningen , The Netherlands, Groningen, Netherlands.*

Multiplex ligation-dependent probe amplification (MLPA) is a variant of polymerase chain reaction that permits multiple targets to be amplified using a single primerpair. It is a robust, facile, flexible and inexpensive technique that can detect both deletions and duplications for more than 40 loci in one assay. Clinical applications of this modern method are extending quickly.

Due to the advantages mentioned above, we have introduced subtelomeric MLPA as a screening method (before more complex and expensive molecular methods) for patients with complex/ unidentified chromosomal rearrangements. Its' application will be illustrated for 6 cases with mental retardation and multiple congenital anomalies. The karyotype of the patients (G-banding) was abnormal, each one presenting an additional terminal chromosomal fragment (involving chromosome 4,9,15, 8).). Using MLPA we identified in 5 cases terminal duplications and in one case a known polymorphism (chromosome 15). Array comparative genomic hybridization (aCGH) was used in 3 cases to validate our MLPA results. All the abnormalities identified with subtelomeric MLPA have been confirmed, but in one case an extra defecthas been identified. Clinical features, karyotype, MLPA and aCGH results will be will be presented in detail.

In conclusion, we preset 6 cases with mental retardation associated with multiple congenital anomalies and abnormal karyotype in which subtelomeric MLPA contributed to the precise description of the chromosome abnormalities. Confirmation by array CGH provides evidence that MLPA is a very useful tool for the characterization of unbalanced karyotypes.

P03.068
Clinical and Molecular cytogenetic characterization of two cases of mosaic ring chromosome 13

G. Pierquin, *A. Uwineza, A. C. Hellin, M. Jamar, J. H. Caberg, V. Bours;
Center for Human Genetics, CHU Sart-Tilman, University of Liège, Liège, Belgium.*

The mosaic ring chromosome 13 syndrome is a rare chromosomal abnormality. The mechanism of ring chromosome formation is usually associated with loss of genetic material.

We report 2 cases of mosaic ring chromosome 13. For the first patient, a male with a karyotype: 46, XY,r(13)[40]/45,XY, -13 [10]. He presented a delayed psychomotor development, mental retardation, dysmorphic features and bleeding disorders. The second is a case of prenatal diagnosis; completed with the postmortem autopsy of a foetus of 33 week of gestations. The genetic amniocentesis analysis showed a mosaic karyotype : 46, XY, r (13) [8]/45,XY,-13[5] ; which was different of that of the cordocentesis analysis: 46,XY, r(13)(q32q34)[18]/46,XY,dic r(13) (q32q34)[2]. Sonography showed intrauterine growth retardation, holoprosencephaly that have been confirmed by the autopsy report; which revealed additional anomalies such as the partial agenesis of the pancreas. The chromosomal terminal regions exploration by MLPA and FISH techniques revealed a 13qter deletion, for both cases. For the first patient, the array CGH (Affymetrix Cytogenetics Whole-Genome 2,7 M Array) identified two terminal deletions of the ring chromosome 13, one of 350 kb and another of 3740 kb in the 13q34 region.

We reported 2 cases of mosaic ring chromosomal 13 associated with deletion of the terminal region of the chromosome 13. This report describe how molecular cytogenetic and array GCH technologies can give more knowledge about the correlation of genotype-phenotype in the mosaic ring chromosome 13 syndrome; and allow to identify the candidate gene responsible for the clinical features of this syndrome.

P03.069
Mosaicism with a normal cell line and a cryptic unbalanced autosomal reciprocal translocation: three new cases

A. C. J. Gijsbers, *J. Dauwerse, C. A. J. Bosch, E. M. J. Boon, W. van den Ende, S. G. Kant, K. M. B. Hansson, M. H. Breuning, E. Bakker, C. A. L. Ruivenkamp;
Center for Human and Clinical Genetics; Leiden University Medical Center (LUMC), The Netherlands, Leiden, Netherlands.*

Mosaicism involving a normal cell line and an unbalanced autosomal translocation are rare. In this study we present three new cases with such a mosaicism, which were detected by Single Nucleotide Polymorphism (SNP) array analysis in our routine diagnostic setting. These cases were further characterized using Fluorescence in situ Hybridisation (FISH) analysis and conventional karyotyping.

The first case is a mentally retarded male who carries an unbalanced translocation in 87% of his cells. The phenotypically normal mother carries the balanced form of the translocation in all her cells. The second case is a phenotypically normal female who has an unbalanced translocation in 52% of her cells. The inheritance could not be determined. The third case is a female referred for Rubinstein-Taybi syndrome who carries an unbalanced translocation in 60% of her cells. Both parents of this case showed a normal karyotype.

The mechanisms that might be responsible for these mosaic karyotypes are discussed. Furthermore, we demonstrate that high-resolution whole-genome SNP array is a powerful tool to reveal cryptic unbalanced translocations and mosaicisms, including the more rare cases.

P03.070
Simultaneous detection of genomic rearrangements in Myelodysplastic Syndromes (MDS) using the Multiplex Ligation-Dependent Probe Amplification (MLPA) assay

O. Scarciolla[1], *A. Fragasso*[2], *C. Mannarella*[2], *A. Ciancio*[2], *R. Cifarelli*[3], *M. Gentile*[4], *C. Dininno*[3], *C. Mazzone*[4], *A. G. Recchia*[4], *P. Servillo*[4], *E. Vigna*[4], *P. Casieri*[5], *L. Anelli*[5], *F. Morabito*[4], *G. Specchia*[5];
[1]*Internal Medicine, Medical Genetics - Hospital, Matera, Italy,* [2]*Internal Medicine, Hematology Unit Hospital, Matera, Italy,* [3]*Centro ricerca e diagnosi X-Life, Hospital, Matera, Italy,* [4]*U.O.C. di Ematologia, Azienda Ospedaliera di Cosenza, Cosenza, Italy,* [5]*Univeristy of Bari, Hematology, University of Bari Medical School, Bari, Italy.*

Cytogenetic analysis of the bone marrow is indicated in MDS not only for diagnostic purposes, but also to assess individual prognosis and to plan tailored therapy. Conventional cytogenetic (CC) analysis is performed in clinical practice to detect chromosomal abnormalities. A new method has recently been described for the measurement of the gene/chromosome copy number using genomic DNA: Multiplex Ligation-dependent Probe Amplification (MLPA). The purpose of this study was to compare the results of the MLPA assay with the CC data obtained in a series of 38 MDS patients (M: 28, F:10, median age 70 years, range 44-87). Our study showed a good correlation between the MLPA and CC results (Table I), discrepancies were found in 7 samples (18.5%). MLPA analysis did not detect the presence of a chromosomal (chr.) translocation (sample n°4); a chr. deletion and a chr. translocation (sample n°11); a chr. deletion (sample n°15); several chr. translocations and deletions (sample n°20); a chr. gain (sample n°27). On the other hand, CC analysis did not show a small deletion in 2 samples: a deletion of the MLL gene in 11q23 (sample n°23) and deletion of 7q22 (sample n°37). With CC we also observed a karyotype failure (no metaphases) in 4 samples, while the MLPA assay showed 3 chr. deletions (sample n°14), but no anomalies in the other 3 samples (25, 29, 32). MLPA and CC resulted complementary techniques, MLPA being particularly useful in MDS cases with karyotype failure and for identifying small rearrangements.

Table I

Sample	MLPA	Karyotype

The First Report: The Genotoxic Effect of Nicotine on Chromosomes of Human Embryonic Cells in Culture: the Effect of Cigarette Smoking on the Embryo

O. Demirhan[1], *E. Tunç*[1], *N. Inandiklioglu*[1], *C. Demir*[1], *E. Sutcu*[2], *N. Sadikoglu*[3], *B. Ozcan*[3], *M. Izmirli*[4];

[1]*Cukurova University, Adana, Turkey,* [2]*Local Health Authority, Konya, Turkey,* [3]*Science School, Adana, Turkey,* [4]*Bezmialem University, Istanbul, Turkey.*

Nicotine can affect embryonic development, leading to the formation of multinucleated blastomeres and polyploidy in blastocysts. Many studies have shown that nicotine interferes with oocyte meiosis and chromosome disjunction. In this regard, in this study we tried to understand the frequency of embryonal chromosome aberrations (CAs) in pregnancies of active or passive smoking mothers. In order to do so, we examined the effect of nicotine sulphate on amniocytes by designing an experimental setting consisting amniocytes grown in nicotine containing medium, study group, and amniocytes grown in a medium which did not contain nicotine (nicotine sulphate), in control group. Here, we provide the evidence that nicotine exposure in vitro (25 ng/ml) (in fetal serum, range 0.5-25ng/ml), has detrimental effects on fetal cells. According our findings, there is a significant difference in terms of CAs between nicotine containing medium and control medium, determined by the $\chi 2$ test (P <0.001). Nicotine containing medium grown cells, totally 577 cells, revealed mainly numerical aberrations (112 cells, %90.3 of all aberrations). Numerical aberrations observed, usually consisted of polyploidy and aneuploidies. We found, most frequently, numerical abnormalities of chromosomes 21, 22, 8, 15 and 20. In conclusion, results of this study confirm an association between prenatal exposure to cigarette smoke and in utero aneuploidies. The nicotine leads to significant direct genotoxic effects in human fetal cells in vitro. Further studies are needed to clarify the modulation of the genotoxicity of smoke causing various genetic polymorphisms.

P03.072
Detection of copy number variants in patients with Noonan syndrome or cardiofaciocutaneous syndrome

E. Seo[1], *J. Lee*[2], *B. Lee*[1], *I. Park*[1], *H. Yoo*[1];

[1]*University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic of,* [2]*Genome Research Center, Asan Medical Center, Seoul, Korea, Republic of.*

Noonan syndrome (NS) and cardiofaciocutaneous syndrome (CFC) are autosomal dominant congenital anomaly disorders associated with gain-of-function mutations of genes in the RAS/MAPK signaling pathway. Diagnosis is based mainly on clinical grounds characterized by a distinctive craniofacial appearance, heart defects, musculoskeletal and cutaneous abnormalities, and mental retardation. Although molecular genetic testing is available for all known genes, PTPN11, KRAS, SOS1 and RAF1 in NS, and BRAF, MAP2K1, MAP2K2 and KRAS in CFC, overall mutation detection rates are 60% to 70% in both syndromes. To detect pathogenic copy number variants (CNV) for NS and CFC patients who did not have any mutations in sequence analyses of all causative genes, we performed high-resolution CGH-based microarray in 13 NS and 5 CFC patients. Three CFC patients were found to have probably pathogenic CNVs; 3.7 Mb loss in 12q12q13.11, 1.3 Mb gain in 22q11.23, and simultaneous 2 Mb loss in 1p36.33 and 13.0 Mb gain in 17q24.3q25.3. This 22q11.23 duplication has been reported as a recurrent microduplication syndrome. Five CNV regions of unknown clinical significance were observed in 4 NS patients, including gains of GOLGA4, NDUFA4, THSD7A, TPD52L1, EIF3H and FBXO7. In present study, pathogenic CNVs are significantly frequent in CFC than NS patients. This result suggests that patients with CFC-like features can be likely to have large CNVs and need a chromosomal microarray test. And also gene copy changes of unknown significance should be evaluated to validate the clinical relevance.

P03.073
Know how to recognize and appropriately follow-up a recombinant pericentric inversion detected by array CGH

T. Dijkhuizen, *L. K. Leegte, B. Sikkema-Raddatz, R. F. Suijkerbuijk, J. B. G. M. Verheij, R. J. Sinke, C. M. A. van Ravenswaaij-Arts;*

Department of Clinical Genetics, Groningen, Netherlands.

Nowadays, array-based analysis is the first diagnostic tool to examine patients with mental retardation and congenital anomalies. If a genetic imbalance is observed and confirmed by karyotyping and/or FISH, parents are usually analysed with FISH using probes localized in the unbalanced regions to exclude a balanced rearrangement. This is needed to assess the risk for further children with an unbalanced chromosome complement and to provide prenatal diagnostic options. We present a 20-year old male patient with severe developmental delay and autism. Array CGH analysis revealed a terminal gain of 1.07 Mb of 18p11.32 and a terminal loss of 16.8 Mb of 18q21.33q23. The terminal deletion 18q, also known as DeGrouchy syndrome, explained the phenotype in our patient. At this point, parental chromosome studies were offered but denied. Recently, we received amniotic fluid of the sister-in-law of our proband, because of ultrasound abnormalities.

Chromosome analysis showed an abnormal chromosome 18, suggesting an unbalanced 18;18 translocation with extra 18q-material on terminal 18p. After karyotyping, the prospective father and paternal grandfather proved to be carriers of an inv(18)(p11.32q21.33). Consequently, the fetus and the proband exhibited each a different recombinant chromosome 18. The paternal pericentric inversion would remain unrecognized when FISH with probes from the abnormal regions was performed.
In conclusion, the concomitant gain and loss of the terminal long and short arm of the same chromosome at array diagnostics should alert to a recombinant pericentric inversion. Further karyotyping studies in proband and parents are highly recommended, if necessary combined with metaphase FISH.

P03.074
A new variant of Potocky- Lupsky syndrome in two unrelated patients affected by severe epileptic encephalopathy, detected by Genome Array-CGH

A. Nucaro[1], *C. Montaldo*[2], *S. Zorco*[2], *N. Santini*[2], *T. Dettori*[3], *P. Caria*[3], *A. Milia*[4], *C. Cianchetti*[5], *D. Pruna*[5];
[1]*Istituto di Neurogenetica e Neurofarmacologia, Monserrato(Cagliari), Italy,* [2]*Dipartimento di Scienze Chirurgiche, Laboratorio OBL , Università di Cagliari, Italy., Cagliari, Italy,* [3]*Dipartimento di Scienze e Tecnologie Biomediche, sez. Biologia e Genetica, Università di Cagliari, Italy., Monserrato(Cagliari), Italy,* [4]*Dipartimento di Biologia Sperimentale, Università di Cagliari, Italy., Monserrato(Cagliari), Italy,* [5]*Neuropsichiatria Infantile, Azienda Ospedaliero-Universitaria, Cagliari, Italy., Cagliari, Italy.*

The duplication 17p11.2 syndrome, associated with dup(17)(p11.2p11.2), is a recently recognized syndrome of multiple congenital anomalies and mental retardation. It is the first predicted reciprocal microduplication syndrome described_the homologous recombination reciprocal of the Smith-Magenis syndrome (SMS) microdeletion (del(17)(p11.2p11.2)(Potocky et al, 2007).
Herein, we report a novel pathologic variant of this syndrome detected by Genome Array-CGH in two non consanguineous subjects with dup(17)(p11.2p11.2),
Array analysis was performed using the BAC Cyto-chips Blue-Gnome platform, at 0.5 Mb median resolution, and revealed the presence of the same BAC duplication in both patients.
The duplicated BAC (RP11-78O7), of about 140 Kb, maps in 17p11.2 and contains an interesting gene, presumably involved in the pathology. The parents did not show the duplication, suggesting that it was a de novo rearrangement.
Cytogenetic and clinical features of subjects with partial trisomy of proximal 17p have been described, mostly in isolated case reports or literature reviews, and non specific and non characterizing findings include developmental delay, mental retardation, and dysmorphic features.
Our patients present a peculiar form of epileptic encephalopathy associated with severe mental retardation and autistic behaviour. Molecular and genetic studies are in progress to define and characterize the rearrangement and for better genotype/phenotype correlation.

P03.075
Subtelomeric fluorescence *in situ* hybridization in clinical cytogenetics: results of analysis of Lithuanian patients

V. Šliužas[1,2], *V. Dirsė*[1,2], *Ž. Čiuladaitė*[1,2], *B. Aleksiūnienė*[1,2], *V. Kučinskas*[1,2];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius, Lithuania,* [2]*Centre for Medical Genetics at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.*

Background: Subtelomeric fluorescence *in situ* hybridization (FISH) is very multifunctional method in clinical cytogenetics. Usually, subtelomeric FISH is used for detection of subtelomeric rearrangements in patients with intellectual disability (ID). In parallel with detection of subtelomeric deletions/duplications, we have also applied subtelomeric FISH in search or confirmation of other types of chromosome rearrangements: ring chromosomes, translocations, recombinat chromosomes, isochromosomes, mosaics. **Methods:** Analysis has been performed using the set of ToTelVysion™ subtelomeric FISH probes, Nikon Eclipse 80i epifluorescence microscope and LUCIA v1 software. Thirty-eight Lithuanian patients with various clinical features were selected for subtelomeric FISH analysis. **Results:** For detection of subtelomeric deletions/duplications 33 unrelated patients with ID/developmental delay (DD), dysmorphic features and/or multiple congenital anomalies were analysed using subtelomeric FISH. Two subtelomeric aberrations - monosomy of chromosome 1q and monosomy of chromosome 5q were detected. We have chosen subtelomeric FISH as rapid, precise method for confirming balanced translocations in cases where G-banded chromosome analysis results were ambiguous - unclear translocated fragment size or origin. Combining different subtelomeric FISH probe mixtures, we validated two translocations - t(2,12) and t(4,18). Breakpoints of ring chromosomes may be specified by subtelomeric FISH too. We revealed p15 and q35 breakpoints of ring chromosome 5. In one case FISH analysis indicated derivative chromosome 6 which probably has been formed due to pericentric inversion in germline of one of the parents. We confirmed isochromosome X and specified the ratio of the cell clones of mosaicism in patient with Turner syndrome.

Genetics Study of Premature Ovarian Failure in Tunisian Population

N. BOUALI, *B. LAKHAL, R. BERGUIGA, I. BEN ABDALLAH, S. MOUGOU, H. ELGHEZAL, A. SAAD;*
Cytogenetics and Reproductive Biology Department CHU Farhat Hached, Tunisia, Tunisia.

Premature ovarian failure (POF) is a common cause of infertility in women and it affects 3 % of females. It is characterized by amenorrhea, hypo-oestrogenism and elevated gonadotrophin levels in women under the age of 40. Known causes include iatrogenic agents that cause permanent damage to the ovaries, such as chemotherapy, radiation therapy and surgery, autoimmune conditions, X-chromosome abnormalities and autosomal genetic conditions. However, few genes have been identified that can explain a substantial proportion of cases of POF.
The present study is interested in the evaluation of the implication of genetic disorders in etiology of POF. Genetic explorations were used and consist to a chromosomal analysis using karyotyping to detect chromosomal abnormalities, interphasic Fluorescent InSitu Hybridization (FISH) to detect 45,X mosaicism, molecular analysis to detect mutation in FMR1 and comparative Genomic Hybridization (CGH) to detect X chromosome microdeletions. 6 chromosomal aberrations were found among the 39 analyzed Karyotypes (15%). Among patients with normal karyotype, interphasic FISH allows us to detect 45,X mosaicism in 12% of cases. FMR1 gene premutation was detected in 16 cases. One microdeletion was detected among 4 patients explored using array CGH (44K Agilent): a 425 kb microdeletion was found on the chromosome 5 of one patient: arr 5p14.1 [28981864-29407781] × 1. The pathological character of this abnormality remains to confirm.
Further genetic studies of POF are needed to identify a genotype-phenotype correlation.

Design of diagnostic tests for carrier testing in families with rare microdeletions using molecular genetic methods

M. Vlckova[1], *M. Hancarova*[1], *J. Drabova*[1], *Z. Zmitkova*[1], *A. Krepelova*[1], *A. Janda*[2,3], *E. Mejstrikova*[3], *O. Hrusak*[3], *I. Hrachovinova*[4], *T. Freiberger*[5], *V. Curtisova*[6], *S. Vejvalkova*[1], *M. Koudova*[1,7], *Z. Sedlacek*[1];
[1]*Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [2]*Centre of Chronic Immunodeficiency (CCI), University Medical Centre Freiburg and University of Freiburg, Feriburg, Germany,* [3]*Department of Paediatric Haematology and Oncology, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [4]*Coagulation Laboratory, Institute of Haematology and Blood Transfusion, Prague, Czech Republic,* [5]*Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic,* [6]*Department of Medical Genetics and Foetal Medicine, University Hospital Olomouc, Olomouc, Czech Republic,* [7]*Present address: GHC, Prague, Czech Republic, Prague, Czech Republic.*

The assessment and carrier testing for rare microdeletions was difficult in the past. Nowadays, using MLPA, FISH and array CGH (aCGH), this task is much easier. We present 4 families with different unique microdeletions. The proband from Family A suffered from developmental delay, obesity and suspected haemophilia B. Molecular genetic testing revealed a deletion of all exons of the *F9* gene. The

phenotype of the boy suggested a larger deletion, and aCGH indeed showed that the deletion affected 5 additional protein-coding genes. A boy from Family B was tested because of familial malignant histiocytosis. A deletion affecting all *SH2D1A* exons was identified using PCR, and aCGH revealed that the deletion also included a part of the *ODZ1* gene. Family C had a history of non-syndromic aniridia. MLPA confirmed a *PAX6* gene deletion in the proband, and aCGH indicated that the deletion also encompassed 3 additional genes. A boy from Family D died of Norrie disease in infancy. PCR identified a deletion of the whole *NDP* gene, and aCGH showed that the deletion included also the *MAOA* and *MAOB* genes. The aCGH results allowed us to select locus-specific FISH probes and to test a total of 14 patients from these 4 families. Eight of them were females at risk in reproductive age, and 3 were shown to be carriers of the microdeletions. FISH is a very reliable method not only for carrier testing, but also for prenatal or preimplantation diagnostics in these families. Supported by CHERISH (EC FP7 223692) and MZOFNM2005.

P03.078
Patients with ring chromosome 11: molecular characterization and review of the literature

S. G. Kant[1], *F. A. de Snoo*[1], *C. A. Ruivenkamp*[2], *W. Oostdijk*[3], *K. B. Hansson*[2];
[1]*CHCG-Dept. of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*CHCG-Laboratory for Diagnostic Genome Analysis, Leiden University Medical Center, Leiden, Netherlands,* [3]*Dept. of Pediatrics, Leiden University Medical Center, Leiden, Netherlands.*

Ring chromosomes are uncommon cytogenetic findings. Most patients carrying a ring chromosome are phenotypically abnormal due to deletions at one or both arms of the chromosome.

Patients with a ring chromosome 11 usually have growth retardation and developmental delay to some degree, while only some of them have clear facial dysmorphic features. Café au lait spots have been described in almost half of the patients.

We present five new patients carrying a ring chromosome 11, with three of the patients belonging to the same family. All patients do have growth problems and café au lait spots. Four of them have microcephaly, while one has a head circumference just within normal limits. Developmental problems are severe in one patient, but do not exist in two other patients.

In four patients a terminal deletion of the short arm of chromosome 11 was demonstrated. In one of them an additional terminal deletion of chromosome 11q was detected, which does not contain any coding genes. The terminal 11p deletion in the familial ring chromosome contains six more genes than in the other patient. For the extra deleted genes no relationship has been reported with growth retardation or microcephaly. In contrast to the other patients, the fifth patient showed a considerable terminal deletion of 14 Mb on 11q, which fits with a diagnosis of Jacobsen syndrome.

The differences in clinical characteristics are most likely due to the differences in size of the deletions these patients have, and the genes involved in these deletions.

P03.079***
BTRC upregulation alone is insufficient to cause SHFM3 - evidence from 4 new cases.

A. B. R. Bergbaum[1], *M. Irving*[2], *S. Mansour*[3], *T. Homfray*[3], *B. Dimitrov*[2], *F. Flinter*[2], *C. Mackie Ogilvie*[2];
[1]*GSTS Pathology (Guy's Hospital), London, United Kingdom,* [2]*Guy's and St Thomas' Foundation Hospital Trust, London, United Kingdom,* [3]*St George's Healthcare NHS Trust, London, United Kingdom.*

Split hand-foot malformation (SHFM) is a limb reduction defect, resulting most commonly in absence of the central rays. Severity is variable, often with asymmetric expression, and penetrance may be reduced. It is either isolated or it may be part of a wider, syndromic condition. The aetiology of isolated SHFM is complex and remains to be fully elucidated; it has so far been mapped to five loci: 7q21, Xq26, 10q24, 3q27 and 2q31; however, the critical genes for all except one of these loci have not been identified.

SHFM3 has been mapped to 10q24 and previous studies have shown it to be associated with a duplication of a minimum region of ~325kb, thereby implicating several candidate genes including FBX4, LBX1, and BTRC. FISH and expression studies have previously narrowed the minimal region of involvement to two genes, BTRC and POLL, and have also demonstrated up-regulation of BTRC.

We present 4 new cases with overlapping, different sized duplications of 10q24, detected by array CGH: two cases with SHFM had duplication of FBX4, LBX1, BTRC and POLL, one case without SHFM had duplication of BTRC, POLL and FBX4, and a further case without SHFM had duplication of BTRC and POLL only. Our results therefore indicate that duplication of BTRC is not in itself sufficient to cause SHFM and therefore do not support the hypothesis that over-expression of BTRC alone can lead to split hand foot malformation.

P03.080
SNP-array analysis in prenatal and postnatal molecular karyotyping.

M. Trková[1], *V. Bečvářová*[1], *I. Soldátová*[1], *J. Horáček*[1], *L. Dvořáková*[1], *M. Putzová*[1], *V. Krutílková*[1], *D. Rašková*[1], *M. Hejtmánková*[1], *E. Hlavová*[1], *A. Baxová*[2], *G. Křečková*[3], *D. Smetanová*[1], *E. Kulovaný*[1], *M. Hynek*[1], *M. Matoušková*[1], *D. Stejskal*[1];
[1]*Gennet, Prague, Czech Republic,* [2]*UK 1.LF a VFN, Prague, Czech Republic,* [3]*Gennet, Liberec, Czech Republic.*

SNP array represents the unique technique for the identification of cytogenetically undetectable submicroscopic alterations (microdeletions, microduplications) and copy number neutral events (LOH, UPD). During one year (02/10 - 02/11) the whole genome genotyping of 298,649 SNPs in previously (or simultaneously) karyotyped patients was performed using the Illumina HumanCytoSNP-12v2.1. All data were analysed by the GenomeStudiov2010.2 and some of the postnatal samples by the QuantiSNPv2.0. A total number of 251 samples were analysed.

In prenatal diagnosis the array analysis was performed in 99 karyotypically normal foetuses with prenatally identified serious ultrasound anomalies. In 9 cases, healthy parents (n=15) were examined for the assessment of the clinical relevancy of discovered copy number variations. In additional 9 foetuses cytogenetic findings (marker chromosome, de novo translocation, derivative chromosome) were clarified.

In postnatal diagnosis, 82 patients with PMR and normal karyotype and 31 healthy parents were examined. Precise identification of cytogenetically detected chromosomal "balanced" and unbalanced aberrations was performed in additional 15 patients.

In total, 15% (16/108) of foetuses with abnormal ultrasound findings were found to carry clinically relevant CNVs (microdeletions or microduplications). In 12% (10/82) of patients with PMR and normal karyotype clinically relevant CNVs were detected and in additional 17% (14/82) of the CNVs parental samples have not been analysed yet. Chromosomal imbalances were detected in nearly all (13/15) patients with abnormal karyotype. Our data suggest that SNP analysis is clinically significant complementary technique in both prenatal and postnatal diagnosis. In PMR cases SNP analysis should be used as first-choice approach.

P03.081
Somatic mosaicism for chromosome X and Y aneuploidies in monozygotic twins heterozygous for sickle cell disease mutation

H. R. Razzaghian*[1], *M. H. Shahi**[1], *L. A. Forsberg**[1], *T. Diaz de Ståhl*[1], *D. Absher*[2], *N. Dahl*[1], *M. P. Westerman*[3], *J. P. Dumanski*[1], **authors have equally contributed to this paper;*
[1]*Rudbeck laboratory, Department of Immunology, Genetics and Pathology, Uppsala, Sweden,* [2]*HudsonAlpha Institute for Biotechnology, Huntsville, AL, United States,* [3]*Hematology Research, Mount Sinai Hospital Medical Center, Chicago, IL, United States.*

Somatic genetic variation in health and disease is poorly explored. Monozygotic (MZ) twins are a suitable model for studies of somatic mosaicism since genetic differences in twins derived from the same zygote represent an irrefutable example of somatic variation. We report the analysis of a pair of generally healthy female MZ twins, discordant for somatic mosaicism for aneuploidy of chromosomes X and Y. Both twins are heterozygous carriers of sickle cell disease mutation. Genotyping of blood DNA from both twins using Illumina Human 610 SNP array revealed a copy number imbalance for chromosome X in a proportion of cells in one twin. Fluorescent in situ hybridization (FISH) analysis confirmed monosomy X (45,X) in 7% of proband nucleated blood cells. Unexpectedly, FISH analysis of cells from the other twin revealed 45,X and 46,XY lineages, both present in 1% of cells. The

mechanism behind formation of these aneuploidies suggests several aberrant chromosome segregation events in meiosis and mitoses following conception. Our report contributes to the delineation of the frequency of somatic structural genomic variation in normal MZ twins. These results also illustrate the plasticity of the human genome for tolerating large copy number changes in healthy subjects and show the sensitivity of the Illumina platform for detection of aberrations that are present in a minority of the studied cells.

P03.082*

Unrelated hESCs and hIPSCs share a common genomic aberration, detected by molecular cytogenetic techniques.

M. Dekel[1,2], *A. Aviram-Goldring*[2,1], *T. Litmanovitch*[2], *J. Shamash*[1,2], *I. Laevsky*[3], *M. Amit*[3], *J. Itskovitz-Eldor*[3], *E. Schiff*[4], *S. Rienstein*[2];

[1]*Tel Aviv University, Tel Aviv, Israel,* [2]*The Danek Gertner Institute of Human Genetics, Sheba Medical Center, Ramat Gan, Israel,* [3]*Stem Cell Center, Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel,* [4]*Department of Obstetrics and Gynecology & Institute of Endocrinology, Tel Hashomer, Ramat Gan., Israel.*

Multipotency and proliferative capacity of human embryonic stem cells (hESCs) make them a promising source for basic and applied research as well as in therapeutic medicine. The introduction of human induced pluripotent cells (hiPSCs) holds great promise for patient-tailored regenerative medicine therapies. However, in order to use hESCs and hiPSCs for therapeutic purposes, they must maintain long term genomic stability in culture.

Until recently, G-banding was considered to be the gold standard for chromosomal abnormalities' detection in stem cells. Our goal in this study was to apply high resolution techniques (FISH and CGH), that will enable us to examine stem cells genome with an ever finer resolution.

Analysis of three hESC lines and two hiPSC lines over long term culture revealed a recurrent genomic instability, involving the gain of chromosome 1q. This finding was detected in two unrelated cell lines of different origin and implies that gains of chromosome 1q may endow a clonal advantage in culture.

In addition, aneuploidy rate was evaluated at different passages, using FISH probes (12,13,16,17,18,21,X,Y). Genomic integrity was shown to be maintained at early passages of hESCs and hiPSCs. However, at late passages, we observed higher rates of aneuploidy in hESCs, implying a direct correlation between number of passages and increased aneuploidy rate.

These findings, which couldn't be detected by conventional cytogentic, emphasize the importance of using molecular cytogenetic methods for tracking genomic instability in stem cells. It also demonstrates the phenomenon of genomic instability of hESC lines, which bear a resemblance to tumorogenic processes.

P03.083

Small supernumerary marker chromosome derived from chromosome 3 in patient with severe psychomotor developmental delay and dysmorphism

Ž. Čiuladaitė[1,2], *A. Matulevičienė*[1,2], *J. Kasnauskienė*[1,2], *B. Aleksiūnienė*[1,2], *V. Kučinskas*[1,2];

[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Centre for Medical Genetics at Vilnius University Hospital Santariškių Clinics, Vilnius, Lithuania.*

We report on 7 years old girl with severe psychomotor developmental delay and dysmorphic features with a de novo mosaic partial trisomy of chromosome 3, involving euchromatic material from 3p and 3q. Dysmorphic features characterised by high triangular forehead with expressed sagital suture, hypertrichosis, wide spaced eyes, ptosis, down-slanting palpebral fissures, strabismus, broad nasal root, very short nose with anteverted nares, short grooved philtrum, triangular mouth, high narrow palate, micrognathia, malformed ears with preauricular sinus on one of sides and skin lesions typical for chromosomal mosaicism: streaked, whorled and mottled areas of hypopigmentation on trunk and limbs. CT scan showed corpus callosum agenesis and hydrocephaly, X-ray: abnormal feet position.

Conventional cytogenetic analysis revealed female karyotype with presence of supernumerary marker chromosome in 85% of analyzed cells (47,XX,+mar [17]/ 46,XX [3]). The origin of supernumerary marker chromosome was identified by FISH using whole chromosome painting probe for chromosome 3. It demonstrated that marker chromosome derived from chromosome 3 resulting in partial duplication of proximal 3p and q chromosomal regions. The supernumerary chromosome involves more then 30 genes, including EPHA3, POU1F1, ROBO1, ARL13B, which play role in developmental processes. Overdosage of these genes could affect normal development because most embryonic developmental processes depend on strictly balanced levels of proteins. We hypothesize that supernumerary chromosome resulting in extra gene copies lead to severe psychomotor developmental delay and facial dysmorphism.

The research is funded by the Research Council of Lithuania National Scientific Programme Chronic Noninfection Diseases (PROGENET project, No. LIG-1007).

P03.084

Refined molecular cytogenetic characterization of the breakpoints of small supernumerary marker chromosomes derived from chromosome 15

J. B. Melo[1], *A. Jardim*[1], *N. Lavoura*[1], *M. Pires*[1], *E. Matoso*[1], *J. R. Vermeesch*[2], *N. Kosyakova*[3], *T. Liehr*[3], *I. M. Carreira*[1];

[1]*Cytogenetics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*Center for Human Genetics, Katholieke Universiteit Leuven, University Hospital Leuven, Leuven, Belgium,* [3]*Jena University Hospital, Institute of Human Genetics and Anthropology, Jena, Germany.*

Many rearrangements may occur in the imprinted chromosome region 15q11->q14, which is known for its instability due to the presence of repeated DNA elements. This region harbours six common sites that mediate chromosomal rearrangements (BP1 to BP6). Supernumerary marker chromosomes (SMC) originating from chromosome 15 are the most common SMCs. Genotype/phenotype studies have not been able, to date, to show any correlation between type and size of clinically relevant SMC(15)s and the degree of severity of the clinical spectrum.

We report 6 new cases of patients with a SMC(15) that were characterized by molecular cytogenetics (Multicolour FISH) and array CGH techniques, followed by microdissection, for the evaluation of the exact genetic content, correlating clinical features with SMC(15) sizes. One case is a small SMC(15)s and without clinical features and/or development delay. The other 5 cases are large SMC(15)s with the Prader-Willi/Angelman syndrome critical region, all having clinical features associated. Of these large SMC(15)s described, two cases are from group B, having symmetrical pattern corresponding to BP3 (BP3:BP3). The other 3 cases have large SMC(15)s from group A, showing an asymmetrical pattern with distal margins at the known breakpoint BP4.

A full characterization of SMC(15) by array CGH techniques is essential to establish with more precision breakpoints position and size of duplicated segments. Array CGH analysis, after microdissection of the marker, showed to be a powerful approach to detect the duplication and its extent.

P03.085

Genomic microdeletions in patients with syndromic mental retardation diagnosed by molecular cytogenetic and CGH-array analysis.

I. Ben Abdallah[1], *H. Ben Khelifa*[1], *S. Mougou*[2], *N. Soyah*[3], *H. Hannachi*[1], *I. Malek*[1], *B. Lakhal*[1], *S. Brahem*[1], *S. Bouraoui*[1], *R. Berguiga*[1], *H. Elghezal*[1], *A. Saad*[1], *G. Tunisian Network on Mental Retardation.*[4];

Non allelic homologous recombination is supposed to generate cryptic microdeletions as well as microduplications, in the field of mental retardation numerous well-known microdeletion syndromes have been described. We explore twenty five patients with mental retardation and known to be the target of microdeletion (Table 1). The patient's chromosomes were characterized by fluorescence in situ hybridization (FISH) with probe which contains two or three locus region-specific probes. Hybridizations were performed following manufacturer's instructions (**Vysis®).** In this series, we found a 7q11.23 deletion removing the *ELN* gene in four patients with congenital cardiopathy,

profound MR and, retrospectively, craniofacial feature of Williams-Beuren syndrome, a 17q13.3 deletion in a patient with a lissencephaly revealed by magnetic resonance imaging, a 15q11-q13 deletion in a boy with craniofacial feature of Prader-Willi syndrome and a *UBE3A* deletion caused an Angelman Syndrome in a boy with microcephaly, severe epilepsy, language delay and ataxia. For the eighteen normal patients, we explore the DNA with The 44000 Agilent® oligonucleotides. Array-CGH analysis of the 18 patients showed a deletion of 200 Kb in 2q23.1 in a patient presenting similar pseudo-Angelman phenotype, this deletion will be verified with BAC clone RP11-659J19.
The systematic screening of patients with syndromic MR, using FISH and CGH-array diagnoses, should facilitate the estimation of microdeletions frequency in MR population and the characterisation of novol syndrome

Table 1. Diagnosed patients with fluorescence in situ hybridization

P03.086
Molecular analysis of telomere length in subjects with intellectual disability

C. Cieza-Borrella[1,2], *L. Barrio-Real*[1,2], *J. Mirón-Canelo*[3], *R. González-Sarmiento*[1,2];
[1]*Molecular Medicine Unit, Department of Medicine, University of Salamanca., Salamanca, Spain,* [2]*IBMCC. Centro de Investigación del Cáncer (USAL/CSIC), Salamanca, Spain,* [3]*Department of Preventive Medicine and Public Health, University of Salamanca., Salamanca, Spain.*

Telomeres are non-coding regions of DNA that maintain genomic stability. Telomere length decreases with cell divisions despite telomerase which consists of two subunits: TERT (the catalytic unit) and TERC (the RNA component). This process is related directly with cellular and individual aging. The aim of this study was to analyze differences between telomere length in people with Down Syndrome (DS), people with cerebral palsy (CP) and people without intellectual disability. We collected saliva samples from 122 subjects with DS (with a mean age of 34,61) 59 with CP (mean age: 30,85) and 115 without intellectual disability (mean age: 47,65). Genomic DNA was extracted from buccal cells and telomere length was measured by qPCR relative comparative. In addition, we analyzed two polymorphisms associated with lower activity of telomerase: TERT-1327C>T (rs:2735940) and TERC-63G>A (rs:2293607). The relative telomere length and the polymorphisms analysis are shown in table. The analysis of the telomere length in subjects over and under 40 years old, shows significant results in DS and CP (p=0,021 and p=0,050 respectively) but not in controls (p=0,202).

	Telomere length	**TERT (-1327C>T)**	**TERC (-63G>A)**
Probands Vs Controls	P<0,001	P=0,152	P=0,055
DS Vs Controls	P<0,001	P=0,316	P=0,102
CP Vs Controls	P<0,001	P=0,145	P=0,181
DS Vs CP	P=0,952	P=0,711	P=0,898

Our data demonstrate premature biological aging in people with DS and show, for the first time, that people with CP has chromosomal telomeres smaller than people without intellectual disability. The lack of correlation between TERT-1327C>T and TERC-63G>A polymorphisms and telomere shortening suggests the existence of other biological factors involved in the process.

P03.087
Constitutional tetrasomy 18p in a female child - a new case report

V. N. PLAIASU[1], *D. Ochiana*[1], *G. Motei*[1], *E. Neagu*[2], *B. Iancu*[2], *D. Iancu*[2];
[1]*IOMC Prof.dr.Alfred Rusescu, Bucharest, Romania,* [2]*National Institute of Legal Medicine "Mina Minovici", Bucharest, Romania.*

Tetrasomy 18p is a very rare chromosomal disorder and is the result of a spontaneous mutation early in embrionic development in most of the cases. It has a prevalence of 1/140000 live births and affects both genders equally.
In this paper we reported a de novo tetrasomy 18p in a 3 months old female dysmorphic child. The clinical features were distinctive, with a particular facies, strabismus, neonatal hypotonia and microcephaly. A small metacentric marker chromosome has been identified after standard cytogenetic analysis, without recognized parental origin of the supplementary genetic material. The child's parents were also tested and their karyotype results were normal.
The characterization of the marker chromosome using only conventional cytogenetic methods was difficult. Consequently, the marker was evaluated by molecular cytogenetic techniques. Fluorescence in Situ Hybridization (FISH) analysis was the first step of diagnosis. Two types of DNA FISH probes were used in our study to describe the structure of the marker: a probe for the centromeric region of chromosome 18 and probes for the subtelomeric regions of chromosome 18. A more detailed description of the identified isochromosome 18p was performed using MLPA technique.
Our patient was compared with other published cases with tetrasomy 18p.

Balanced translocations and inversions in the genome of Finns

T. M. Luukkonen[1,2], *M. Pöyhönen*[3], *K. O. J. Simola*[4], *K. Aittomäki*[3], *R. Salonen-Cajander*[6], *J. Ignatius*[6], *L. Peltonen*[7,1,2], *A. Palotie*[7,1], *J. Terwilliger*[8,1], *T. Varilo*[9];
[1]*Institute for Molecular Medicine Finland FIMM, Helsinki, Finland,* [2]*National Institute for Health and Welfare, Helsinki, Finland,* [3]*Dept. of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland,* [4]*Dept. of Pediatrics, Tampere University Hospital, Tampere, Finland,* [5]*The Department of Medical Genetics, Väestöliitto, Helsinki, Helsinki, Finland,* [6]*Dept. of Clinical Genetics, Turku University Central Hospital, Turku, Finland,* [7]*Welcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [8]*Dept. of Genetics and Development, Columbia University, New York, NY, United States,* [9]*Dept. of Medical Genetics, University of Helsinki, Helsinki, Finland.*

Finland is acknowledged of its high standard of clinical medicine and in the disease gene hunt of its founder populations. What is perhaps not so well recognized is that Finland has probably the most comprehensive health registers and records: hospitalizations, surgeries, chronic diseases, cancers and prescriptions etc. have been filed for decades.
Relying on this infrastructure we have gathered clinical information from all distinct hospitals and laboratories on all reciprocal balanced translocations and inversions identified in Finland, and are currently constructing a national database (www.fintransloc.org). By analyses of the medical records and by searches of additional national registers, we are obtaining novel information of not only monogenic traits with unidentified mutations, but also of multifactorial traits associated with any given chromosomal abnormality. Moreover, we believe that such a database will greatly assist genetic counseling efforts and scientific collaborations.
To date, we have surveyed 2575 hospital or laboratory contacts involving translocations or inversions consisting of 572 families plus singletons. Some 25 families associating with interesting abnormal phenotypes are selected to investigate the breakpoints' potential effect on the phenotypes. A nationwide systematic sample collection of DNA, RNA and cells with so far over 80% coverage of participants was launched in Aug 2010, and we are breakpoint mapping three pilot families providing presumed shortcut in the identification of their predisposing disease genes.

P03.089
Two rare modes of paternal malsegregation of a translocation t(11;13)(q25;q14) in his two sons

C. METAY[1], *L. Lecerf*[1], *A. Briand-Suleau*[1], *V. Delattre*[1], *S. Serero*[2], *P. Kleinfinger*[3], *M. Goossens*[1], *D. Amram*[4];
[1]*HOPITAL HENRI MONDOR, CRETEIL, France,* [2]*Centre de Biologie et de Cytogenetique Medicales, Evreux, France,* [3]*Laboratoire Cerba, Cergy Pontoise, France,* [4]*Centre Hospitalier InterCommunal, Creteil, France.*

We report a rare case of malsegregation of paternal balanced chromosomal reciprocal translocation t(11;13) in his two sons. The family was seen in genetic counseling for moderate psychomotor delay associated with dysmorphy and immunity deficiency for one son (son 1) and strong psychomotor delay associated with dysmorphy and cardiopathy for the other son (son 2).

Conventional cytogenetic studies show a paternal karyotype with balanced reciprocal translocation t(11;13)(q25;q14) and a maternal normal karyotype. For the son 1, karyotype followed by 105K-Agilent aCGH study revealed partial trisomy of 11q (780Kb) associated with partial trisomy of 13q (28Mb). The son 2 carried a partial monosomy of 11q and partial trisomy of 13q.

This is an unusual occurrence of paternally inherited unbalanced of (1) double partial trisomies (11q;13q) resulting from 3:1 segregation, and (2) partial trisomy 13q and monosomy 11q from adjacent-2 segregation, both in paternal meiosis. Indeed these two modes of malsegregation, rather described in female meiosis, are uncommon in male meiosis and implicate the acrocentric 13 chromosome. Differences in severity of clinical features of both sons are observed. The son 2 developed a more serious phenotype resulting particularly from the monosomy 11qter described associated with Jacobsen syndrome. Clinical features of the son 1 will be discussed in relation with the types of anomalies, the genes localized in the duplications or at their breakpoints with genotype/phenotype correlation and will be compared with previous reports. This report emphasizes the added importance of array-CGH to analysis of offspring born to chromosomal reciprocal translocation carrier parents.

P03.090
Unbalanced transmitted translocation t(3;20) associating epilepsy, behavioral disorders, and severe mental retardation: case report

S. F. Chirieac[1], *M. Budisteanu*[2,1], *A. Tutulan-Cunita*[1], *D. Barca*[2], *I. Borcan*[1], *M. Cristea*[1], *A. Arghir*[1];
[1]*"Victor Babes" National Institute of Pathology, Bucharest, Romania,* [2]*"Alex. Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania.*

We prezent a two year-old boy referred for genetic investigations due to epilepsy and behavioral disorders with heteroagresivity. In addition, he exhibited dysmorphic features (large ears, bilateral preauricular pit, long eyelashes, hairy eyebrows, depressed nasal bridge, bulbous nose, thick lips, ogival palate), severe mental retardation. Congenital heart and renal defects, left umbilical and inguinal hernia were detected.

Classical and molecular cytogenetic investigations were performed on peripheral blood cultures by GTG-banding and FISH standard protocols.

Cytogenetic analysis showed trisomy for the region 3q26.2-qter and monosomy for 20q13.3-qter as a result of an unbalanced translocation. The rearragement was inherited from his clinically healthy mother, who presented a balanced translocation: t(3;20)(q26.2;q13.3). The results were confirmed with BAC-probes FISH.

Both anomalies, duplication of distal 3q and deletion of distal 20q, were previously reported and some of the associated clinical features are also present in our patient. Moreover, trisomy 3q2 is known as a rare syndrome with variable phenotype, depending on the size of the duplicated fragment and the involvement of other chromosomal regions.

The regions involved in our patient chromosomal rearrangement include several genes known to act in nervous system development, such as: NLGN1 on 3q region and ARFGAP1, CHRNA4, KCNQ2 on 20q region.

By our knowledge, this is the first reported unbalanced translocation involving 3q and 20q regions, further contributing to a better understanding the role of these two chromosomal abnormalities in producing of a such complex phenotype.

P03.091
Double partial trisomy 14q and 22q due to maternal translocation t(14;22)(q23.2;q13.32) with unusual clinical findings

K. T. Abe[1], *M. D. V. Oliveira*[1], *B. L. S. Dias*[2], *F. M. Lima*[2], *L. M. Formigli*[1], *M. Schneider*[1], *A. L. V. Coelho*[1], *C. E. Speck-Martins*[1];
[1]*SARAH Network of Rehabilitation Hospitals, Brasilia, Brazil,* [2]*SARAH Network of Rehabilitation Hospitals, Rio de Janeiro, Brazil.*

Trisomies of two autosomes in the same karyotype, even parcially, are very rare in livebirths. We report on 18-month-old male presenting partial proximal trisomy 14q and partial distal trisomy 22q resulting from a maternal translocation. At 13th day of life, he started feeding difficulties, failure to thrive and oliguria. A ventricular septal defect and West syndrome had been diagnosed. At 13 month-old was observed neuropsychomotor delay, hypotonia, microphthalmia, hypertelorism, broad nasal bridge, low-set ears, short neck and phimosis. A cerebral MRI disclosed callosum corpus dysgenesis and ultrasonography showed abnormal rotated kidneys. Neurophysiologic studies were suggestive of auditory dysfunction. Radiographic studies showed toes anomalies. Cervical and lumbar CT studies demonstrated C1, C2, C3, L5 and sacral dysraphism besides T4 and T5 lateral processes fusion. EEG disclosed hemi hypsarrhythmia. He is under anticonvulsivant and gastroesophageal reflux therapy. Cytogenetics analysis showed karyotype 47,XY,t(14;22)(q23.2;q13.32)mat,+der(14)t(14;22). The FISH performed on metaphases with commercially available N25/SHANK3 probes confirmed the karyotype.

To our knowledge, the patient is a first case with partial proximal trisomy 14q and partial distal trisomy 22q. The patient is resultant of alternate 2:2 meiotic segregation containing t(14;22)(q23.2;q13.32) in his chromosome complement. A second event occurred probably in meiosis II with no-disjunction leading to extra der(14)t(14;22). The phenotype includes characteristics of trisomy 14 mosaicism, partial trisomy of proximal 14q, and trisomy of 22q13.3-qter. Moreover, some aditional features are presented on this patient: low-set rotated kidney, skeletal abnormalities with vertebral anomalies, and West syndrome.

True trisomy 2 mosaicism is a very rare event. Few cases with variable phenotypic outcome are reported in the literature. We report a new case of prenatally diagnosed mosaic trisomy 2.

Transabdominal chorionic villus sampling was performed at 15 weeks' gestation (WG) on a 37-year-old woman because of an increased risk of aneuploidy (1/40). Fetal ultrasound revealed hyperechogenic bowel, oligoamnios, hypotrophy and moderate ventriculomegaly. Among the 21 cells observed from the direct preparation, 19 showed 47,XX,+2 karyotype. Trisomy 2 was also present in almost all cells observed from cultures as well as with conventional cytogenetics and with in situ hybridization. At 17 WG, ultrasound revealed only hypotrophy. Follow up amniocentesis was performed at 18 WG and showed on in situ preparations, a mosaic karyotype mos 47,XX,+2[14]/46,XX[86]. At 21 WG, ultrasound displayed hyperechogenic bowel, retrognatism and hypotrophy. Parents opted for termination of pregnancy. No trisomic cells were observed at cordocentesis. At post mortem examination, there was moderate intrauterine growth retardation, no dysmorphy and no malformations. Nevertheless, examination of the brain showed pachygyria, micro-polygyria and focal neuronal heterotopia.

This case is compared with other reported cases of the literature and the follow-up of prenatally diagnosed mosaic trisomy 2 is discussed.

P03.093
Combine application of different cytogenetic techniques for characterization of dicentric X mosaicism in case with Turner syndrome

S. Midyan[1], *A. Hovhannisyan*[1], *H. Mkrtchyan*[1], *C. Halgren*[2], *L. Nazaryan*[2], *N. Tommerup*[2];
[1]*Center of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [2]*Wilhelm Johannsen Centre for Functional Genome Research, Institute of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark.*

Phenotype of Turner syndrome includes short stature, ovarian failure and other somatic stigmata. It is associated not only with X chromosome complete monosomy, but also with its mosaic and partial monosomy forms. Here we describe a case with Turner-like phenotype in 19-year-old female. Initial chromosome analysis of cultured leukocytes revealed female karyotype with derivative X chromosome in all metaphases, where existence of extra chromosomal material was predicted.

However, Afymetrix SNP 6.0 array data of peripheric blood DNA shown only a 48Mb terminal deletion of Xq22.3-qter region (chrX:106762523-127573136; chrX:127574179-154887041) and no gain of X nor other chromosomal material, which contradicted the karyotype picture. We assumed that der(X) is a dicentric chromosome derived from two Xpter-q22.3 chromosomal materials represented in mosaic form in peripheral blood cells.

Further FISH application on cultured leukocytes using centromere probe SE X (Kreatech) confirmed that derivative X chromosome has two X centromere material and thus is dicentric - 46,X,dic X(pter-q22.3). Despite the fact that der(X) was presented in all metaphases in addition to normal X chromosome, in 30% of interphase cells we detected only two signals. In buccal mucosa cells mosaicism was detected with following ratios: 70%, 17% and 13% of cells with one, two and three signals, respectively.

Thus, neither conventional karyotype study nor SNP array didn't find cells with 45,X. Only interphase FISH on buccal mucosa cells discovered monosomy X which could explain our patient phenotype. Our results demonstrate the importance of different tissues study by conventional and molecular cytogenetic techniques to reveal true mosaicism.

P03.094
A de novo interstitial deletion del(2)(q36.1) including PAX3 gene in a girl with hearing loss and subtle dysmorphic features.

M. Drożniewska[1], *A. Chacińska*[2], *O. Zuffardi*[3], *O. Haus*[1,4];
[1]*Department of Clinical Genetics, Collegium Medicum UMK, Bydgoszcz, Poland,* [2]*Genetic Counseling Centre, University Hospital, Wrocław, Poland,* [3]*Biologia Generale e Genetica Medica, Universita di Pavia, Pavia, Italy,* [4]*Department of Hematology, Medical University, Wrocław, Poland.*

Waardenburg syndrome (WS) is an autosomal dominant syndrome which is reported to be the most common form of inherited congenital deafness, with a prevalence of 1:42.000. It is strongly heterogenous with wide spectrum of phenotypes, which resulted in identification of 4 forms of this syndrome. The most characteristic dysmorphic features are pigmentary abnormalities of the hair, iris heterochromy and congenital sensorineural hearing loss. Types 1 and 3 of WS are mainly caused by mutations in the PAX3 gene. Deletions of this gene are less frequently reported.

A 16 years old girl was referred for genetic counseling due to hirsutism, hearing loss, hypertelorism and minor phenotypic features. She was a second child of healthy, unrelated parents.

The dysmorphy included wide set eyes with brilliant blue irides, synophrys, shortened eyelids, hypoplastic alae nasi, low set ears, large hands and feet and profound hearing loss. Her intellectual development was normal.

Routine cytogenetic analysis revealed normal karyotype (46,XX). Molecular screening of GJB2 gene excluded its most common mutation (del35G).

Array CGH analysis with Agilent SurePrint 3G Human CGH Kit (4x180K platform) showed an interstitial deletion of long arm of chromosome 2 [del(2)(q36.1)] of 860 kb, including the PAX3 gene. Subsequent analysis performed in parents revealed no rearrangements in the same region, which led to the conclusion that deletion present in the child was de novo.

To confirm these results, FISH analysis with PAX3 breakapart probe was performed.

Results of our study indicate, that WS can also be caused by chromosomal microdeletions involving PAX3 region.

P03.095
Report of a patient with distal Williams-Beuren deletion.

B. Grisart, *S. Vidrequin, K. Rack, C. Verellen-Dumoulin, A. Destrée;*
Centre de Génétique Humaine, Institut de Pathologie et de Génétique, Charleroi (Gosselies), Belgium.

A 7-years-old boy was referred to the genetic consultation given psychomotor delay, learning difficulties and dysmorphism. He presents behavioral disorders as depression, impulsivity, hyperactivity and relationships difficulties with other children. EEG shows epilepsy. He uses short sentences but with pronunciations difficulties. Developmental quotient was evaluated at 63 (Terman-Merrill). Minor dysmorphic features were observed with upslanting palpebral fissures, strabismus, mild retrognathia and protruding upper lip with long philtrum. Growth parameters at 7-years are in the normal range.

CGH analysis showed a 2.015 Mb deletion distal to the Williams-Beuren deletion. The deletion is maternally inherited. The family belongs to underprivileged socio-cultural environment with relatives presenting learning difficulties and intellectual disabilities. Given this blurring familial situation, this deletion was initially considered as being of unknown clinical significance. Furthermore polymorphic CNV were reported in this region.

Two publications (Edelmann *et al.*, 2007 ; J Med Genet **44**:136-143 and Ramocki *et al.*, 2010 ; Am J Hum Genet **87**:857-865) reported deletions or duplications distal to the Williams-Beuren deletion. These patients exhibit variable expression of epilepsy, learning difficulties, intellectual disabilities (mild to severe developmental delay or intellectual disability with autistic features in some patients) and/or neurobehavioral abnormalities (inattention, hyperactivity, impulsivity and aggression including self-abusive behavior and depression). The majority of the patients have a deletion inherited from a normal or less affected parent. HIP1 and YWHAG genes are also deleted in our patient. However the inheritance from normal relatives, strongly suggests an incomplete penetrance of this deletion which preclude a unambiguous genetic counseling.

P03.096
Williams-Beuren syndrome (WBS) atypical phenotype due to rare familial inversion inv(7)(p10q11.23) in mother and her child: fluorescence in situ hybridization (FISH) analysis of rearrangement breakpoints

A. Polityko[1], *S. Batt*[2], *O. Khurs*[1], *A. Kulpanovich*[1], *L. Isakovich*[1], *N. Yakutina*[3], *A. Frolova*[3], *N. Kvasnikova*[3], *I. Naumchik*[1], *T. Liehr*[2];
[1]*National Medical Center "Mother and Child", Minsk, Belarus,* [2]*Institute of Human Genetics and Anthropology, Jena, Germany,* [3]*Regional Genetic Center, Gomel, Belarus.*

WBS is a neurodevelopmental disorder characterized by distinct facial features, supravalvular aortic/peripheral pulmonary stenosis, mental retardation and typical behavioural features, growth deficiency, infantile hypercalcemia. Typical WBS is characterised cytogenetically by hemizygous 1,55-1,83 Mb deletions including 26-28 genes at chromosomal segment 7q11.23. Diagnostic test for the standard microdeletions detection for classical and atypical WBS is FISH analysis using DNA probes bearing elastin gene locus ELN.

We present a rare family case with atypical WBS phenotype in mother and her 1,2-years old daughter who both had a cytogenetically visible (GTG about 550-600 bands) apparently pericentric inversion. Molecular cytogenetic analysis of chromosome 7 breakpoints using DNA probes for WBS critical region 7q11.23, specific centromeric 7alpha-satellit probe and set of BAC-probes RP4-771P4, RP11-467H10, RP11-343J14 revealed the inv(7)(p10q11.23) in mother and in her child. FISH showed that one breakpoint of inversion is localised within the centromere 7p10 dividing it into two alphoid segments and making abnormal chromosome 7 as pseudodicentric. The second breakpoint was mapped in segment 7q11.23 more distal regarding to centromere of WBS single copy region and distal to the low copy repeats (LCR) sequences B mid, A mid, B tel, A tel and C tel blocks. ELN gene was not disrupted or deleted, therefore supravalvular aortic/peripheral pulmonary defects were absent in the mother and

child, though both of patients had distinctive WBS facial features. We present the clinical data of cases and hypothesize that balanced intrachromosomal rearrangement induces position effect in WBS critical region neighbouring with centromeric sequences.

P03.097
A balanced translocation t(5 ;7)(q32 ; q11.22) disrupting the WBSCR17 gene in a patient with incomplete Williams-Beuren syndrome

F. Abdelhedi[1], *M. Chaabouni*[2], *A. Lebbar*[1], *A. Coussement*[1], *D. Letessier*[1], *H. Chaabouni*[2], *J. M. Dupont*[1];
[1]*Cytogenetic Laboratory, Cochin Hospital, Paris, France,* [2]*Human Genetic Laboratory, Medical School, Tunis, Tunisia.*

The molecular characterization of balanced chromosomal rearrangements associated with an abnormal phenotype (6% of balanced chromosomal rearrangements), has been a successful approach for the identification of disease-causing genes.
Here we describe the breakpoint mapping of a de novo balanced translocation t(5;7)(q 32;q 11.22) in a male patient presenting with a psychomotor delay and moderate mental retardation, associated with facial anomalies observed in Williams-Beuren syndrome (WBS). He has neither cardiovascular malformations nor abdomino-renal anomalies.
Breakpoint mapping on chromosome 7 with FISH, using BACs clones showed that WBSCR17 gene (Williams-Beuren syndrome critical region 17) was disrupted. However, breakpoint characterization on chromosome 5 was not achieved yet. For this we will perform a new technology called array painting, which could map the position of translocation breakpoints more precisely either on chromosome 7 and 5 in a single experiment.
Array-CGH (Whole genome Tiling NimbleGen :Hg18,72K) confirmed that the translocation was balanced, and showed the absence of other unbalanced rearrangements which could explain the phenotype.
These results strengthened the hypothesis that WBSCR17 is responsible for the neuropsychological findings in our patient, in line with its known implication in brain development. However, its implication in facial anomalies is less likely. For this the fine mapping of breakpoints on the two translocated chromosomes by array painting will help us to better understand the genotype / phenotype correlation in our patient.

P03.098
Rare case of 46,X,idic(X)(p11.2)/46,XX mosaicism in an autistic child with developmental delay: a karyotypic marker of X chromosome isodisomy and an X-linked mutation

A. D. Kolotii[1], *S. G. Vorsanova*[1,2,3], *V. Y. Voinova*[1,3], *O. S. Kurinnaia*[1,3], *I. A. Demidova*[1,3], *A. K. Beresheva*[1,2], *V. S. Kravets*[1,3], *I. V. Soloviev*[2], *Y. B. Yurov*[2,1,3], *I. Y. Iourov*[2,1];
[1]*Institute of Pediatrics and Children Surgery, Minzdravsotsrazvitia, Moscow, Russian Federation,* [2]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

Isodicentric chromosomes X are frequent in females with Turner syndrome demonstrating 45,X mosaicism. In contrast, the case reported herein represents mosacism manifesting as 46,X,idic(X)(p11.2)/46,XX without Turner syndrome phenotype and without a cell with 45,X karyotype. In average, 46,X,idic(X)(p11.2) was detected in 10% of cells. The latter was found using multiprobe FISH on 350 metaphase plates and 1000 interphase nuclei. The structure of idic(X) was determined by FISH, as well. BrdU replication banding showed consistent inactivation of idic(X) in all affected cells. Phenotypic features referred to autistic and aggressive behavior (including self-mutilation), severe developmental delay, lack of speech, mild microcephaly, abnormal pigmentation and mild facial dysmorphisms. Taking into account the severity of the phenotype and the amount of abnormal cells, we came to a conclusion that the index case is likely to be associated with an X-linked mutation and X chromosome isodisomy. To support this hypothesis, we have analyzed length of (CGG)n and (CAG)n repeat expansions of *FMR1* and *AR* genes, respectively, using methyl-sensitive restriction and QPCR, which showed the same parental origin of chromosomes X. Therefore, X chromosome isodisomy and an X-linked mutation are most likely to explain phenotypic manifestations in the index case. Looking through the available literature, we concluded that this is the first reported case of mosaicism involving idic(X)(p11.2) without 45,X cell line. Finally, this case shows that such mosaicism is a karyotypic marker of X chromosome isodisomy and X-linked mutations as well as supports association of autism with mosaic X chromosome aneuploidy.

P03.099
A case of the de novo large duplication of 3pter-p13 and deletion of Xpter-p11.3 in a patient with clinical features of Turner syndrome

I. N. Lebedev, *O. Y. Koryagina, N. N. Sukhanova, A. D. Cheremnykh, E. N. Tolmacheva, L. P. Nazarenko;*
Insitute of Medical Genetics, Tomsk, Russian Federation.

Phenotypic manifestations of unbalanced X;autosome translocations in female carriers are usually modulated by X-inactivation. Spreading of inactivation on the autosome fragment can provide gene silencing. But there are controversial data about continuous or discontinuous mode of this process. We report a case of the de novo unbalanced translocation between chromosome X and 3 in a girl with major clinical features of Turner syndrome, gonadal dysgenesis and normal intellectual development. Patient is a 16-year-old girl from first pregnancy. She had a short stature (142 cm), short webbed neck, low frontal and nuchal hair level, slight epicanthus, synophrys, alae nasi hypoplasia, rotated auricles with adherent earlaps, macrostomia, high arched palate, flat chest, pectus excavatum, hypertelorism of nipples, forearm valgus, hypoplasia of little fingers, camptodactily of 3, 4, and 5 fingers, short big toes, sandal fissurae, hirsutism, hypertrichosis, uterus and ovarian aplasia. The patient had a pronounced myotonic syndrome. The karyotype was 46,X,der(X)t(X;3)(p11.3;p13). Both parents had normal karyotype. The presence of the almost entire additional short arm of chromosome 3 had no visible effects because of suspected X inactivation. Analysis of allele polymorphism in the *AR* gene by *Hpa*II digestion has confirmed a 100% skewed X-inactivation. However, the spreading of gene silencing was probably discontinuous because of the presence of camptodactily, which was reported previously in patients with partial trisomies 3pter-p23. Short neck and pectus excavatum were also observed in cases of dup(3)(pter-p25). To our knowledge this is a first report of large duplication without major clinical malformations of trisomy 3p syndrome.

P03.100
A 17q24.2-q24.3duplication in a patient with hypertrichosis and gingival hypertrophy

E. Vallespin[1], *C. Gomez-Fernandez*[2], *M. Palomares*[1], *K. Kutsche*[3], *R. Lucas-Laguna*[2], *M. Feito-Rodriguez*[2], *R. Martin-Arenas*[1], *C. Crespo*[1], *S. Garcia-Miñaur*[1], *F. Santos*[1], *M. Mori*[1], *A. Delicado*[1], *M. Torres*[1], *L. Fernandez*[1], *E. Mansilla*[1], *F. Garcia-Santiago*[1], *P. Lapunzina*[1], *J. Nevado*[1];
[1]*INGEMM-IDIPAZ-HULP, Madrid, Spain,* [2]*Department of Dermatology-HULP, Madrid, Spain,* [3]*Institut für Humangenetik-Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

A 6-year-old boy was referred for evaluation of generalized hypertrichosis that was marked at birth. Furthermore he presented gingival overgrowth that began during early childhood causing hoarseness and difficulty in speaking and in chewing.
Array experiments were performed with a custom made array based on Agilent Technologies, called KaryoArray®. The array comprised specific probes covering all microdeletion and duplication syndromes, telomeres and peri-centromeric regions and also probes of backbone. The average density of the probe coverage is 43 kb. This focused oligonucleotide chip covers more than 350 clinically relevant regions of genomic imbalance.
KaryoArray® identified a copy-number gain of 30 oligo probes spanning 1.579 Mb at 17q24.2-q24.3 (chr17:64150313-65728881-NCBI_Build36). Also array CGH analysis was performed on both parents and neither parent was found to carry a duplication. The duplication identified in our case encompasses 8 genes: ABCA8, ABCA9, ABCA6, ABCA10, ABCA5, MAP2K6, KCNJ16 and KCNJ2.
In one previous reported patient with duplication in chr17:64306843-65736803 the authors points MAP2K6 as a candidate for hypertrichosis and gingival hypertrophy because activating mutations in components of the RAS-MAPK pathway can result in a group of phenotypically overlapping genetic syndromes with several dysmorphic features common to the patients reported in their paper. Altered expression

of the dosage-sensitive genes caused by copy-number mutations has traditionally been viewed as the general pathogenic mechanism for genomic disorders. and Congenital hypertrichosis has been documented in several cases with chromosome 17q trisomy, suggesting that hair overgrowth can result from increased function of the gene(s) on chromosome 17q.

A normal man with uncommon t(15;16)

***A. Faraj Pour**, C. Azimi, B. Ferizadeh;*
Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Reciprocal translocations are usually an exchange of material between nonhomologous chromosomes. Estimates of incidence range from about 1 in 500 to 1 in 625 human newborns. whole-arm translocations result from centric fusion of two chromosomes. Such translocations are usually harmless and may be found through prenatal diagnosis. However, carriers of balanced reciprocal translocations have increased risks of creating gametes with unbalanced chromosome translocations leading to miscarriages or children with abnormalities.Most balanced translocation carriers are healthy and do not have any symptoms. But about 6% of them have a range of symptoms which may include autism, intellectual disability, congenital anomalies, or subfertility. In contrast, patients with unbalanceed whole-arm translocations have abnormal phenotypes.

We report a normal couples which referred by the gynecologist for genetic counseling just because the wife had irregular menstrual cycles. They had a normal son as well.This couples were interested to participate in one of our research project as a normal control. Cytogenetic studies were performed on lymphocyte cultures using G-banding techniques. It was interesting that all the mitoses of the wife showed a reciprocal whole-arm translocation between chromosomes 15 and 16, which according to literatures is very uncommon.

The karotype of wife was: 46,XX,t(15;16)(p10;p10).

Chromosomal investigation on her parents, her husband and her son revealed normal karyotypes.

J03.02
Chromosomal evaluation in couples with reproductive disorders - retrospective study of a selected group of 266 couples

***L. I. Butnariu**[1], M. Covic[2], M. Onofriescu[2], M. Gramescu[2], C. Bujoran[3], L. Caba[2], V. Gorduza[2];*
[1]University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania, [2]University of Medicine and Pharmacy, Iasi, Romania, [3]Saint Mary Childrens Hospital, Iasi, Romania.

Chromosomal evaluation in couples with reproductive disorders - retrospective study of a selected group of 266 couples (Abstract): Reproductive Disorders (RD), manifested by the biological inability to conceive (primary sterility) or inability to carry a pregnancy to full term (infertility), affect 10-15% of reproductive-aged couples. The genetic etiology of RD is represented, in the majority of cases, by the chromosomal abnormalities. Aim: To retrospectively analyze the karyotype results in a selected group of couples with RD. Material and methods: The present study was performed in 266 couples with RD: 80 (30,07%) with primary sterility (ST), 149 (56,01%) with Recurrent Spontaneous Abortions (RSA) and 37 (13,90%) with Stillborn Children (SC). A GTG-banded karyotype was performed on both parteners of each couple. Results: We identified a chromosomal abnormality in 43 individuals (16,16%): 20 cases (7,51%) with ST, 13 cases (4,88%) with RSA and 10 cases (3,75%) with SC. The affected partner was female in 23 cases (8,64%) and male in 20 cases (7,51%). A X chromosome (numerical or structural) abnormality was detected in 18 cases (6,76%), most frequent X chromosome monosomy mosaicism in female and trisomy XXY in male; a balanced structural chromosomal abnormality (BSC) was detected in 23 couples (8,64%); in other two males with ST, the karyotype result was 46,XX. Conclusions: The results of our study are similar to other reported studies and underline the major etiologic role of chromosomal abnormalities in RD and the importance of chromosomal analysis for the etiologic diagnosis and genetic counselling of these patients.

J03.03
Familial Pericentric Inversion of Chromosome 12

*S. Gunes[1], **H. Ozyurek**[2], G. Okten[1], S. Tural[1];*
[1]Ondokuz Mayis University Faculty of Medicine, Department of Medical Biology, Samsun, Turkey, [2]Ondokuz Mayis University Faculty of Medicine, Department of Child Neurology, Samsun, Turkey.

Chromosomal inversion is a balanced rearrangement defined as two breaks with reinsertion of the chromosome after the segment rotates 180^0. The frequency of chromosome inversions is estimated approximately 0.13 in 1,000 in the general population. Most of the individuals carrying inversion are phenotipically normal. Although rarely seen, pericentric inversions are among the most common constitutional chromosome rearrangements and typically involve chromosomes 1, 3, and 7. Pericentric inv (12) is extremely rare, with only 25 reported families in the literature. The common constitutional inversions are the pericentric p11q13 and p13q13. The inv (12) is difficult to detect and may be misinterpreted as a partial deletion by routine cytogenetics. Pericentric inversion of chromosome 12 can be associated with epilepsy, mental retardation and hematological malignancies. Here, we report on a familial inv (12) (pter→p11::q13→p11::q13→qter) in father and two siblings who did not have any clinical manifestations. The mother's chromosomes were normal in blood lymphocytes. Karyotyping was routinely performed by G-banding by using trypsin-Giemsa staining technique. In the light of the findings of our family, we will discuss the literature about pericentric inv (12).

J03.04
Numeric Chromosomal Changes in Acute Leukemia

***C. A. Popa**[1,2], H. Ionita[1,3], M. Serban[1,2], N. Andreescu[1], A. Belengeanu[1];*
[1]University of Medicine and Pharmacy„Victor Babes", Timisoara, Romania, [2]Emergency Children Hospital "Louis Turcanu", Timisoara, Romania, [3]City Universitary and Emergency Hospital, Timisoara, Romania.

Acute myelocytic leukemia (AML) and Acute lymphoblastic leukemia (ALL) is characterized by a variety of numerical and structural chromosome aberrations. Gains and losses of whole chromosomes occur frequently in AML and ALL, both as solitary changes, usually found at diagnosis, and as additional aberrations in later disease stages. 120 cytogenetic analyses of patients with leukemia with ages between 6 month -73 years have been performed in the Cytogenetic laboratory of the University of Medicine and Pharmacy Victor Babes Timisoara during 2004-2010. The cytogenetics diagnosis is a prognostic factor with the capacity to predict the remission rate, the length of the remission and the survivorship period, regardless of the haematological, immunological and clinics parameters. For the confirmation of previous data, CGH may provide useful information regarding the nature of genomic aberrations that take place in cases with complex karyotypes.

J03.05
Report of five de novo translocation Down's syndrome

***M. Moutabi Alavi**, C. Azimi, F. Farzanfar, M. Khaleghian;*
Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

The frequency of Down's syndrome in the most populations is around one in 700-800 live births and shows different karyotypes. Trisomy 21 is the main cause of approximately 95% of observed Down's syndrome, with 88% coming from nondisjunction in the matenal gamete and 7% coming from nondisjunction in the paternal gamete. Robertsonian translocation and isochromosome of the long arm of chromosome 21 are the cause of 2-3% of observed cases of Down's syndrome. It does not show the maternal age effect, and is just as likely to have come from fatherts as mothers. The remaining 1-2% are mosaicism.In about three-fourths of translocation Down's syndrome, neither parent is a carrier, and a mutation in the germ cells of one parent has caused the translocation. The causes of these mutations are unknown.

We report five infants (three boys and two girls) from the five different families, all revealed typical clinical features of the Down's syndrome. The parental age of the five cases were between 20-30 years old. Cytogenetic study were carried out, using the standard banding techniques, for the cases and their parents. The karyotypes of the three cases were: 46,XY,der(21;21)(q10;q10),+21 and the other two cases showed: 46,XX,der(14;21)(q10;q10),+21. Chromosomal analysis of the parents of the five infants were normal.

J03.06
Cytogenetics studies im mild Mental Retardation

J. M. Pina-Neto, *L. S. Abreu, L. F. Mazzucatto, C. M. Lourenço, L. M. Batista;*
School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil.

This study was developed to review the clinical criteria for karyotyping studies in mild mental retardation (MR) patients.

We created 2 patients groups: a) in the first we had 107 patients with mild MR and we do karyotype analysis in 34 selected using the classical clinical criteria (2 ou more malformations and /or dysmorphic features associated) and only in 3 patients (2.8%) we detected chromosomal anomalies (all sexual chromosomal aberrations: 46, XX/45,X; 47, XYY; 48, XXYY). B) in the second group we had 187 patients and we did karyotype analysis in 172 of them independently of the patient had malformations and / or dismorphic features and we detected 10 patients (5.8%) with chromosomal aberrations [6 of them with sexual chromosomal aberrations: 47, XXX (2); 47, XYY; 48, XXXY; 46, XX/45, X; and 4 with autosomal aberrations).

Our work suggested, similar to others authors, that in mild MR the karyotype may be indicate in all patients, independently of the presence of malformations and / or dysmorphic features.

J03.07
Peculiarities of replication of 1qh, 9qh, 16qh and Yqh regions of human chromosome from chorionic villi and embryonic tissues.

I. Trofimova[1,2], *M. Lyapunova*[1], *E. Evdokimenko*[1], *T. Kuznetzova*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,*
[2]*Ott's Institute of obstetrics & gynecology RAMS, Saint-Petersburg, Russian Federation.*

The aim of study was analysis of replication of 1qh, 9qh, 16qh and Yqh regions of human chromosome on semi-direct preparations from chorionic villi samples (CVS) and embryonic tissues (ET). CVS were incubated with BrdU during 12, 24, 36, 48, 72 hours, and ET - 12, 24 hours.

Bright red fluorescence of 1qh, 9qh, 16qh and Yqh regions on chromosomes with and without sister chromatid exchanges using acridine orange staining was registered, thus indicating BrdU incorporation in these regions of both CVS and ET.

Indeed, ET BrdU-antibody signals was observed in these heterochromatin regions as well as along chromosome arms. However in CVS BrdU-antibody signals were detected along of chromosome arms in both chromatids and asymmetric in Yqh region, which indicated that cells passed one cell cycle, but no any signals was detected in 1qh, 9qh and 16qh regions.

The reasons of this unusual cytogenetic phenomenon are discussed, such as technique artifact, cell cycle specificity or underreplication DNA constitutive heterochromatin of CVS.

This work was supported by Carl Zeiss Company grant.

J03.08
A case of monosomy 9q: Clinical data and molecular cytogenetic characterization of a patient

P. Botelho, *M. Souto, O. Moutinho, M. Martins, R. Pinto Leite;*
Centro Hospitalar de Tras-os-Montes e Alto Douro, Vila Real, Portugal.

High resolution cytogenetics analysis techniques are becoming an indispensable tool in the investigation of idiophatic mental retardation and dysmorphic syndromes, allowing previously unrecognized chromosomal rearrangements to be identified.

In recent years many new syndromes have been established, including the clinically recognizable 9q subtelomeric deletion syndrome, in patients with severe mental retardation, hypotonia, brachycephaly, flat face with hypertelorism, synophrys, anteverted nares, cupid bow or tented upper lip, everted lower lip, prognathism, macroglossia, conotruncal heart defects and behavioral problems. The minimal critical region responsible for this 9q subtelomeric deletion (9q34) syndrome has been estimated to be 1 Mb and comprises the euchromatin histone methyl transferase 1 gene (EHMT1).

We describe a child with a *de novo* 9q microdeletion detected by subtelomeric FISH probe. This case contributes to the better characterization of the genotype/phenotype relationship of chromosome 9 rearrangements and emphasizes the role of molecular cytogenetics in the characterization of rare chromosomal disorders.

J03.09
Untargeted cytogenetic effects in human 25 years following Chernobyl accident

M. A. Pilinskaya, *S. S. Dibskiy, O. V. Shemetun, Y. B. Dibskaya;*
Research Centre for Radiation Medicine, Kijiv, Ukraine.

25 years following Chernobyl accident one of the most actual problems of human radiation cytogenetics is evaluation of late untargeted cytogenetic effects, especially, different types of chromosome instability and bystander effect. Such effects in some critical groups of Chernobyl accident victims had been investigated using the following models: long-termed cultures of human blood lymphocytes; G_2-bleomycin sensitivity assay; mixed human lymphocytes culture consisted of cells differed by cytogenetic sex markers. In children born to irradiated parents increased frequency of chromatid breaks in long-term cultures confirmed expression of delayed chromosome instability in consequent mitosis; appearance of stable aberrations may testify about

transmissible chromosome instability. Among unexposed donors, liquidators and shelter's personnel no more than 33% persons hypersensitive to testing bleomycin exposure had been identified that can be considered as genetically caused phenomenon. Among patients recovered from acute radiation sickness ~58% persons expressed hidden chromosome instability that confirmed possibility of modification of inherited chromosome susceptibility to mutagens by high doses of ionizing radiation. Under joint incubation of targeted lymphocytes from Chernobyl male-liquidators with intact female lymphocytes the frequency of chromosome aberrations in bystander cells was significantly higher than their background level. The difference between spectrum of aberrations in exposed and intact cells had been established - in targeted cells cytogenetic markers of irradiation dominated just as in bystander cells chromatid breaks mainly induced. The data received confirmed reality of untargeted cytogenetic effects in delayed terms following Chernobyl accident that can be risk factor for realization of late medical consequences of human radiation exposure.

J03.10
Three cases of de novo isodicentric X chromosome

S. Ahmadpour, *C. Azimi, M. Khaleghian, F. Farzanfar;*
Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Isodicentric X chromosomes, which formed by fusion of two X chromosomes, are rare. The phenotypic effects of this X chromosome aberration are variable and depend on the amount of material deleted and whether the chromosomes are fused by the short or the long arms. Despite the variable presence of a 45,X cell line, they form two distinct groups. Those joined by the short arms reveal shorter than average stature, while those attached by the long arms exhibit normal stature, both with gonadal dysgenesis. Other Turner's syndrome features can occasionally be present in both groups, but are more frequently associated with short arm fusions.

We report three cases which were referred to our Department due to primary amenorrhea. First case was 21-year-old, 159 cm height, 55 kg weight and with intermediate IQ. She presented with the features of Turner. Sonography report showed lack of ovaries and hypoplasia of uterus. Her FSH and LH were high. Karyotyping was performed on peripheral blood lymphocytes using banding techniques according to standard Methods: Her karyotype was: 46,X,idic(X)(q24).

Second case was 20-year-old, 156 cm, 63 kg and subnormal intelligence. She showed some Turner features. Her sonography revealed hypoplastic uterus and absence of gonads.She had elevated FSH and LH.

Her karyotype was: 45,X [80%] / 46,X,idic(X)(q22) [20%].

Third case was 23-year-old, 170 cm, 51 kg, with gonadal dysgenesis. She showed raised FSH and LH.

Her karyotype was: 45,X [8%] / 46,X,idic(X)(p22.3) [72%].

Chromosomal studies of the parents of all three cases and all their sibs revealed normal.

J03.11
Trisomy 21 in a boy whose mother is a carrier of a marker chromosome

M. Rahnama[1], *F. Razazian*[1], *F. Nasiri*[1], *F. Manoochehri*[1], *F. Mortezapour*[1], *F. Mahjoubi*[2], *R. Torabi*[2];
[1]*Iranian Blood Transfusion Organization Reasearch center, Tehran, Islamic Republic of Iran,* [2]*Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.*

A marker chromosome (mar) is a structurally abnormal chromosome in which no part can be identified. The significance of a marker is very variable as it depends on what material is contained within the marker. It is essentially a partial trisomy.

Here we report a 8-month -old boy with history of open heart surgery because of his heart located in right side. He had developmental delay. His father had also same heart problem. Her mother was deaf and mute. She had irregular menstrual cycle and received treatment.

His parents were first cousin. Karyotyping after lymphocyte culture revealed 47,XY,+21, del (21)(q22.3) karyotype. The mother had 47,XX,+mar karyotrype. C-banding revealed that the marker had heterochromatin origin.

Here we discuss the risk of carrying a marker chromosome with no major clinical symptoms and trisomy of small chromosome in the next progeny

J03.12
Subtelomeric chromosomal rearrangements in idiopathic mental retardation by fluorescent in situ hybridization

H. Akin, *E. Karaca, O. Cogulu, B. Durmaz, A. Durmaz, C. Ozkinay;*
Ege University Medical Faculty, İzmir, Turkey.

Mental retardation (MR) affects about 3% of the populations. Final diagnosis could be reached in approximately one third of all cases, and no diagnosis is available in the rest of the patients. Chromosomal abnormalities comprise 30-40% of moderate to severe mental retardation; and nearly 30% of mild mental retardation. Standard cytogenetic analysis is capable of detecting DNA rearrangements of larger than 3-5 Mb. Cryptic *subtelomeric* rearrangements are *responsible* in idiopathic *mental retardation* etiology for 5% to 10% of cases. *The aim of the* study is to evaluate the incidence of subtelomeric cryptic rearrangements in cases with idiopathic mental retardation. Eighty-six moderate to severe mentally retarded patients who were referred to the Department of Medical Genetics between 2008-2010 years. Definite perinatal brain injury, abnormal karyotype, positive FMR1 gene mutation, inherited metabolic or specific neurodegenerative disorders were excluded from the study. Fluorescent in situ hybridization analysis with
subtelomeric specific probes was used to detect cryptic rearrangement. Six cases were identified with subtelomeric rearrangements (7%). One had de novo deletion whereas five had unbalanced translocations due to balanced translocations of
the parents. There was no consanguinity between the parents in any of the cases and all had both mental retardation and multiple congenital anomalies.This study showed ones more that the subtelomeric rearrangements are one of the most significant cause of idiopathic MR with dysmorphic features.

J03.13
Report of a Down syndrome baby girl with double chromosome abnormalities of trisomy 21 and an isochromosome X

N. Mohammadkhani[1], *F. Hadipour*[1], *Z. Hadipour*[1], *Y. Shafaghati*[1], *P. Sarkheyl*[1], *M. Asami*[1], *I. bagherizadeh*[1], *F. Behjati*[1,2];
[1]*Sarem Cell Research Center & Hospital, Medical Genetic Department, Tehran, Islamic Republic of Iran,* [2]*2- Genetics Research Center, University of Social Welfare Rehabilitation Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Down syndrome features was referred to the medical genetics department of Sarem Hospital. Her parents had non consanguineous marriage with no family history of abnormal child. Mother was 21 years old at the time of the pregnancy and had no complication except oligohydramnios. Baby girl showed typical clinical features of Down syndrome including: hypotonia, hypothyroidism, sandel gap, short nose, clinodactyly, up ward slanted palpebral fissure, deep nasal bridge, short neck, small ear, high narrow palate and bilateral simian crease. She also had heart complication and jaundice from the birth time. Chromosomal analysis was carried out using standard high resolution GTG banding technique. The karyotype was abnormal with a double chromosome abnormalities containing a pure trisomy 21 and an isochromosome X described as 47,X,idic(X)(P11.2),+21. Parent's karyotypes were normal. The clinical profile of the Patient in relation to the double chromosome abnormalities will be presented.

J03.14
Cytogenetic studies among 50 Iranian patients with ambiguous genitalia

Z. Safari[1], *S. Morovvati*[2], *F. Farzanfar*[3];
[1]*Young Researchers Club, Varamin-Pishva Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Research Center for Human Genetics, Baqiyatallah University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Human sexual differentiation is a highly complex process that is under the control of multiple genes and hormones. Abnormalities in normal sexual differentiation are relatively common and occur one in 4500 live births, hence it needs immediate and rational management and assignment of sex for rearing should be guided by the etiology of the genital malformation. Using cytogenetic analysis may help determining suspicious cases, since ambiguity can result from chromosome abnormalities.

Diagnosis and sex determination were made using a combination of clinical, radiological and laboratory investigations.

Chromosomal studies were performed on peripheral blood samples using conventional GTG banding techniques in more than 100 metaphases for each sample.

50 patients with ambiguous genitalia were referred for confirmation of sex by karyotyping. They were aged between one month to 24 years.

Our results showed that 29 patients (58%) had normal karyotype.

The karyotypes of the rest of the cases were as follows:

14 patients (28%) were congenital adrenal hyperplasia (CAH), twelve of whom showed 46,XX and two cases were 46,XY karyotype (both 3B-hydroxylase deficiency).

4 patients (8%) were 21-OH deficiency.

1 patient (1%) was phenotypically male but 46,XX karyotype (XX male).

2 cases (2%) have 46, XX/46,XY karyotype. There is a great discrepancy between phenotype-karyotype in individuals having a chromosomal mosaicism.

J03.15
Cryptic imbalances detected by array CGH in cases with identified cytogenetic alterations

I. M. Carreira[1], *S. I. Ferreira*[1], *J. Ferrão*[1], *A. Mascarenhas*[1], *M. Pinto*[1], *E. Matoso*[1], *J. Saraiva*[2], *J. B. Melo*[1];
[1]*Cytogenetics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*Serviço de Genética, Hospital Pediátrico de Coimbra, Centro Hospitalar de Coimbra, Coimbra, Portugal.*

Array-CGH has been assuming a major role in the diagnosis of patients with mental retardation, developmental delay and multiple congenital abnormalities and in the further characterization of cytogenetically detected alterations. Among the available platforms, BAC and oligonucleotides, the last ones allow the detection of smaller imbalances, offering a higher diagnostic yield. Meanwhile, a drawback of this higher resolution is that the generation of more data makes the interpretation increasingly challenging. This is particularly important when talking about copy number variants (CNVs), due to the progressive discovery of CNVs of unclear significance.

We performed array-CGH using Agilent 180K, an oligonucleotide microarray with 180 000 sixty-mer probes and 17 Kb average probe spacing. The patient's samples were hybridized in a loop strategy, where the three samples are labeled in the two colour dyes, Cy3 and Cy5, and then each patient sample is hybridized against the two other samples.

In a small cohort we have identified a cytogenetically detected chromosome 21 duplication that turned out to be an insertion from chromosome 4, a 6q21 deletion in a patient with a t(13;15) and a cryptic 20p12 deletion in Alagille syndrome region in a del2p patient.

Our experimental group shows that more than one structural chromosomal alteration in the same patient might occur and that its frequency is probably underestimated. Array-CGH will allow the

identification of cryptic imbalances that otherwise would be missed.

J03.16
Couples with two or more spontaneous abortions during the years 2000-2010 - performed in Center for medical genetics and immunology- Montenegro

***S. Teofilova**, M. Bulatović, O. Miljanović, T. Ostojić;*
Clinical Center of Montenegro, Podgorica, Montenegro.

Research has shown that couples with balanced translocations are more likely to have miscarriages and increase risk for aberration offspring than couples without balanced translocations. The reported incidence of balanced chromosomal translocations in couples with multiple spontaneous abortions (SABs), for years 2000- 2010 performed in Centre for Medical Genetics and Immunology KCCG - Montenegro. After genetic counselling, family pedigree was drawn by genetic counselor. Some couples had more spontaneous abortions plus a malformed child or stillbirth. Cytogenetic analysis on blood specimens was needed for 325 couples (650 cases) and karyotyping was conducted by analysis of G-band.Chromosomal status was analysed using CytoVision,4.02 Applied Imaging. Balanced translocations were found in 25 cases with an incidence of 3,85%, indeed 7,69% couples. Of the 25 persons with balanced translocations 4 persons had Robertsonian translocation, another had translocation among different autosomes chromosomes.

J03.17
A mosaic Turner girl with ring chromosome X

***F. Manoochehri**[1], F. Mortezapour[1], M. Rahnama[1], F. Nasiri[1], F. Mahjoubi[2], R. Torabi[2];*
[1]Iranian Blood Transfusion Organization Reasearch center, Tehran, Islamic Republic of Iran, [2]Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.

Women with the ring X chromosome are more likely to have psychological sequelae but are less likely to have structural congenital abnormalities, and spontaneous menses occur in about a third.
A 12-year-old girl was referred to our laboratory for chromosome study because of short stature (about 1 meter). Her IQ was within normal range. Other than being short she was physically and mentally normal. Her mother had to consume drug during the pregnancy since she had kidney disease. The karyotype of the patients was found to be 45,X[50]/46,X,r(X)(p?q?)[4].
The clinical manifestation of this patients will be discussed and compared with the similar reported cases.

J03.18
Screening of mitochondrial DNA mutations in the tRNAGlu gene and in tRNA Leu in buccal mucosa and in leucocytes in a Tunisian family with mitochondrial diabetes

***n. mezghani**;*
genetic laboratory, sfax, Tunisia.

Diabetes mellitus (DM) is a heterogeneous disorder characterized by the presence of chronic hyperglycemia. Genetic factors play an important role in the development of this disorder, and several studies reported mutations in nuclear genes implicated in the insulin function. Besides, DM can be maternally transmitted in some families, possibly due to the maternal mitochondrial inheritance.
In this report, we screened a Tunisian family with mitochondrial diabetes for the m.3243A>G and the m.14709T>C mutations, respectively, in the tRNALeu(UUR) and the tRNAGlu genes.
The polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and the sequencing analysis in the leucocytes and the buccal mucosa in the members of this family showed the absence of the m.3243A>G mutation and the presence of the heteroplasmic m.14709T>C mutation in the tRNAGlu gene in the two tested tissues.
We conclude that the m.14709T>C mutation in the tRNAGlu gene could be a cause of mitochondrial diabetes in Tunisian affected family. In addition, the heteroplasmic loads of the m.14709T>C mutation in the leucocytes and buccal mucosa didn't correlate with the severity and the onset of mitochondrial diabetes in the tested Tunisian family suggesting the presence of environmental factors or nuclear modifier genes. Moreover, our results showed that the clinical manifestations of mitochondrial diabetes in this tunisian family appear only in females. These results suggested the presence of a nuclear modifier factor specific to females which enhances the apparition of diabetes.

J03.19
The role of Streptococcus pyogenes and some metabolites in formation of genomic instability by tonsillitis of patient.

***I. E. Kravchenko**, V. V. Semenov, E. S. Koshpaeva;*
Kazan State Medical Universiy, Kazan, Russian Federation.

We investigated content of two metabolites: malonic dialdehid (characterized the intensity of lipid peroxidation in cell membrane) and intercellular DNA (showed the motion of DNA from the cell).
We used extract of Streptococcus pyogenes as primary initiator increasing the intensity of endomutagenesis. It was inspect ed 48 patients with tonsillitis - 38 patients with genomic instabilities and 8 patients with low level of genomic damaging. The concentration of metabolites in blood plasma was determined on third day after beginning of disease.
Mutagenic activities of Streptococcus pyogenes extract was carried out by abdominal injection to white mice and processing of seeds of Crepis capillaries.
It was established that content of malonic dialdehid and intercellular DNA in blood plasma of patients with genomic instabilities exceeded the normal concentrations of ones in 3 times and more. In patients without genomic instabilities the content of above-mentioned metabolites was approximately normal. We worked up the method for determination of free iDNA and iDNA binding with cell membrane. It gives possibility to determine the intensity of apoptosis and necrosis of cells in patients with tonsillitis.
It was also established that the number of micronuclei in erythrocytes of peripheral blood of mice was increased after injection of Streptococcus pyogenes extract in comparison with the mice without injection.
Number of chromosomal aberration in seeds of Crepis capillaries after exposition with extract of Streptococcus pyogenes was significantly riser in comparison with control samples. Mutagenicity of extract depends from the bacterium concentration and rises with increasing of concentration.

J03.20
Cytogenetic investigation among women with multiple recurrent abotiotions

***M. Pilechian Langeroudi**, C. Azimi, F. Farzanfar;*
Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Some of the cases with multiple recurrent abortions are caused by chromosomal aberration in one of the parents. Many investigations have been carried out in various countries to determine the role of chromosomal aberrations in couples with repeated fetal loss. Approximately 15 to 20 % of pregnancies in which the fetuses are affected with chromosomal abnormalities end to spontaneous abortion. A proportion of spontaneous abortions is caused by a balanced chromosomal aberration in one of the parents, which is of importance in genetic counseling. Several studies have been done among couples with multiple recurrent abortions.
This study was carried out among Iranian couples with the same problem. A total of 944 cases (472 couples) with a history of multiple recurrent abortions were examined, and chromosomal analysis was done using the G-banding technique.
26 females (5.5%) and 21 males (4.4%) were found to have abnormal karyotypes. These abnormalities included: one case with a mosaic karyotype 46,XX/46,XX,t(21/21),+21, 8 balanced reciprocal translocations, 14 Robertsonian translocations, 13 inversions, 4 marker chromosomes, 2 cases with fra(16)(q21), and four cases of X chromosome mosaics.

P04.01
Preventive examination of patients with balanced translocation

R. Gaillyová[1,2], *K. Kašíková*[1,3], *M. Vozdová*[4], *E. Oráčová*[4], *P. Kuglík*[1,5], *M. Vilémová*[1], *J. Rubeš*[4];
[1]*Dept. of Medical Genetics, University Hospital, Brno, Czech Republic,* [2]*Biological Institute, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [3]*Dept. of Preventive Medicine, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [4]*Dept. of. Genetics and Reproduction, Veterinary Research Institute, Brno, Czech Republic,* [5]*Dept. of Genetics and Molecular Biology, Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic.*

Karyotypes of 5416 patients were examined at Dept. of Medical Genetics between January 2007 and December 2010. 25 men and 38 women had balanced translocation in their karyotype. Families of these patients were offered genetic consultancy with cytogenetic examination, its purpose was to find out whether translocation is inherited or arisen de novo. In cases when couples planed a child, prenatal genetic diagnostic eventually preimplantation genetic diagnosis was offered too. Free of charge analysis of frequencies of chromosomally unbalanced sperms in ejaculate was offered to adult men (17) but only 4 (23 %) accepted this offer. The frequencies of unbalanced sperm ranged from 5.8 to 23.5 % in Robertsonian and from 40.1 to 70.3 % in reciprocal translocation carriers. It is noteworthy that if a translocation (balanced or unbalanced) was found in children patient then in 80 % cases parents and other relatives underwent cytogenetic examination. When translocation was found in adult (usually examined because of infertility), in only 20 % cases their relatives underwent the examination.

P04.02
Functional analysis of CCDC54, a protein likely involved in spermatogenesis.

A. Massart[1,2], *K. Breckpot*[3], *H. Tournaye*[4,2], *W. Lissens*[1,2], *K. Stouffs*[1,2];
[1]*Center for Medical Genetics, UZ Brussel, Brussels, Belgium,* [2]*Department of Embryology and Genetics, Vrije Universiteit Brussel, Brussels, Belgium,* [3]*Laboratory of Molecular and Cellular Therapy, Department of Physiology-Immunology, Vrije Universiteit Brussel, Brussels, Belgium,* [4]*Center for Reproductive Medicine, UZ Brussel, Brussels, Belgium.*

In search for proteins involved in the complex process of spermatogenesis, coiled-coil domain containing 54 protein (CCDC54), a human testis-expressed protein with unknown function, was studied. Expression of this gene is predomintantly in testis and in silico analysis of the CCDC54 gene suggested it is a conserved gene. A yeast two hybrid screening was performed, which identified Testis specific Zinc Finger Protein (TZFP), a transcriptional repressor, as a binding partner of CCDC54. To further investigate the effect of the binding of CCDC54 on the activity of TZFP, a luciferase reporter assay was performed. This suggested that CCDC54 is a negative co-regulator of TZFP. Immunohistochemical staining of human testis tissue shows an overall expression of the CCDC54 protein in the seminiferous tubules.
At the DNA level, conservation of the CCDC54 gene was verified and mutation analysis was performed. To detect the reported c.316G>T or p.Glu106X polymorphism, a restriction digestion with BccI was performed on a control group of 150 European normozoospermic men, but the polymorphism was not found. The CCDC54 gene of 16 European men with a maturation arrest of spermatogenesis and 32 European men with Sertoli cell-only syndrome (SCOS) was sequenced and only one missense mutation was found in 2 SCOS patients.
These preliminary results suggest that CCDC54 could be an important protein for spermatogenesis.

P04.03
Early embryonic developmental arrest and chromosomal aneuploidies

M. Maurer[1], *T. Ebner*[2], *H. Duba*[1];
[1]*Landes- Frauen- und Kinderklinik Linz, Humangenetische Untersuchungs- und Beratungsstelle, Linz, Austria,* [2]*Landes- Frauen- und Kinderklinik Linz, Kinderwunschzentrum, Linz, Austria.*

OBJECTIVE: Despite strongly improved culture conditions approximately 10 - 20 % of IVF embryos show a permanent cell cycle arrest state. Of special interest for this study is an increased rate of numerical chromosomal abnormalities found in embryos with early developmental arrest.
MATERIALS/METHODS: The study was approved by the local ethical review board and can be accomplished in accordance with the strict Austrian legal regulations. Arrested embryos used in this study were donated by patients undergoing IVF treatment for infertility, and written patient consent was obtained in each case. Embryos were considered to be arrested when no cleavage had occurred during 48 h. Blastomeres of embryos with developmental arrest were analysed using Fluorescence *in situ* hybridisation (FISH). Arrested embryos were classified into different categories: normal diploid (euploid), homogeneously abnormal (aneuploid), abnormal mosaics, chaotic (complex), polyploid and haploid.
RESULTS: The most frequent finding in the study was the chaotic pattern with various numerical chromosome abnormalities, which can be different from cell to cell. Polyploidy comes a close second and represent a special case, since here probably not the polyploidy is the reason for embryonic arrest, but the arrest is the cause for the polyploidy.
CONCLUSION: Almost 70% of the analysed arrested embryos displayed chromosomal abnormalities, suggesting that the elevated levels of chromosomal abnormalities represent a not negligible factor for developmental arrest.

P04.04
Genomic alterations in Endometriosis

M. Saare[1], *K. Vaidla*[2], *D. Sõritsa*[3], *L. Järva*[3], *P. Palta*[4], *K. Madissoo*[5], *M. Laan*[6], *H. Karro*[7], *A. Sõritsa*[8], *A. Salumets*[9], *M. Peters*[1];

The origin and genetic background of endometriosis are still unknown. Several studies have reported presence or absence of genomic alterations and copy neutral loss of heterozygosity (LOH) in eutopic and ectopic endometrium of women with endometriosis. In this study, we used high-density SNP-arrays to determine inherited DNA copy number variations (CNVs), *de novo* somatic copy number aberrations (CNAs) and LOH pattern in DNA samples extracted from endometriosis lesions and compared to the original situation in blood cells and eutopic endometrium to reveal the genetic component of endometriosis development. Peripheral blood samples, endometrial biopsy and laser microdissected ectopic endometriotic tissues were collected from 11 women with endometriosis. The data was analysed using QuantiSNP and PennCNV programs. We examined the genomic changes in microdissected endometriotic foci matching with endometrium and blood samples. An average of 9 CNVs was detected per investigated genome with a size range from 700 bp to 350 kb. We found that CNVs and LOH pattern are largely invariable in different compartments (blood, endometrium and ectopic tissue) of each individual patient. Likewise, no endometriosis-specific CNVs or LOH regions were found when different endometriosis patients were compared. Majority of detected CNVs were common CNVs. Also, ectopic endometrial tissue showed no large chromosomal aberrations in our study group. Therefore, we conclude that there is no convincing evidence that endometriosis originates from genomic alteration in eutopic endometrium and the disease is not accompanied by extensive genomic rearrangements.

P04.05
Search for genes associated with number of pregnancies

T. Laisk[1,2], *T. Esko*[3,4,5], *A. Salumets*[1,2], *A. Metspalu*[3,4,5];
[1]*Department of Obstetrics and Gynecology, University of Tartu, Tartu, Estonia,* [2]*Competence Centre on Reproductive Medicine and Biology, Tartu, Estonia,*

[3]Estonian Genome Center, University of Tartu, Tartu, Estonia, [4]Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [5]Genotyping Core Facility, Estonian Biocenter, Tartu, Estonia.

While data about the genetic background of different infertility-related conditions in women is growing rapidly, the genetic component of general fertility and fertility potential is still largely unknown. Research in this field is hindered by the fact that in modern societies the number of pregnancies is mostly determined by socioeconomic, psychological and environmental factors, and the availability and awareness of contraception, whereas the original genetic determinants fade into the background. In Estonia modern contraceptives became available in the beginning of the nineties, illustrated by the fact that in 1994 only 234 out of every 1000 fertile women were using effective means of contraception and the abortion rate was 54 per 1000 women of reproductive age.

We analyzed data from 944 women aged 40-101 (average age 65.2 years) with an average of 3.5 pregnancies (range 1-14); furthermore, 43% of the studied women had had at least 4 pregnancies. Preliminary analysis of data obtained from genome-wide association study revealed possible association between the number of pregnancies and regions in or near genes previously associated with menarche, pathophysiology of placental diseases, steroid hormone receptor modification, maintenance of normal pregnancy, VEGF signalling and adiponectin levels.

In conclusion, although research regarding the genetic component of fertility potential is complicated due to numerous confounding factors, our results suggest genetic determinants can still be found. Analysis of data obtained from further studies might reveal additional associations and confirm current findings.

Chromosomes aneuploidies detected in decondensed sperm nuclei using FISH

A. Belengeanu[1], *M. Stoian*[2], *N. Andreescu*[2], *V. Belengeanu*[2], *D. Stoicanescu*[2], *S. Farcas*[2];

[1]*University of Medicine and Pharmacy, Department of Cellular and Molecular Biology, Timisoara, Romania,* [2]*University of Medicine and Pharmacy, Department of Medical Genetics, Timisoara, Romania.*

The aim of this study was to evaluate the hypothesis that infertile men, having oligoasthenozoospermia present a higher grade of chromosomal aneuploidies than men with normal fertility. FISH technique allows the study of a significant number of spermatozoa in a relatively short period. This is very important for the correct evaluation of the patients with oligoasthenozoospermia, knowing that the frequency of chromosomal anomalies in spermatozoa of infertile men is 10 times bigger than in men with normal fertility. In this study we included 15 men with oligoasthenozoospermia and a control lot of donors for whom at least 1000 spermatozoa were evaluated. Sperm count revealed a number varing betwen $3x10^3$ and $3x10^6$ and 50-80% of the spermatozoa were imobile. All the patients inluded in this study had normal constitutional karyotype. We performed FISH technique using Abbott Vysis 13, 18, 21, X and Y chromosomes probes following the standard protocol provided by the manufacturer with slight modifications. We assessed the chromosomes that have most frecquently major clinically signifiance in children with aneuploidies. The aneuploidies rate of the studied chromosomes in our oligoasthenozoospermic patients spermatozoa was 13.61%, the higher incidence was recorded for gonosomes followed by disomy of chromosomes 13, 21, 18. Our results show an increase frequency of sperm chromosome abnormalities in infertile patients compared with control donors. Patients with normal karyotype, low sperm concentration and reduced spermatozoa motility have an increased risk of producing spermatozoa with chromosomal number aberrations, particularly for the sex chromosomes.

P04.07

Intermediate and normal sized CGG repeat on the FMR1 (fragile X) gene does not affect ovarian response

J. A. Ortiz[1], *J. Guerrero*[2], *B. Lledo*[1], *R. Morales*[1], *J. Ten*[2], *J. Giménez*[2], *J. Llacer*[2], *R. Bernabeu*[2];

[1]*IB Biotech, Alicante, Spain,* [2]*Instituto Bernabeu, Alicante, Spain.*

INTRODUCTION: Fragile X syndrome is not just the most common cause of inherited mental retardation, but of of low ovarian response and premature ovarian failure (POF) as well. Gleicher et al reported a direct statistical association between the number of CGG repeats (at 35 to 55) an ovarian reserve.

The goal of this study is investigated whether CGG repeats on the FMR1 gene have predictive value for ovarian response to stimulation with gonadotropins and cycle outcome during an oocyte donors programme.

MATERIALS AND METHODS: We performed fragile X genetic screening routinely to all our oocyte donors from 2008. We include the results of X fragile genetic screening from 204 (141 control and 63 study groups) oocyte donors. The study population was divided into three groups: women with 35-39 repeats (n=34), 40-45 (n=12) and >45 (n=17).

RESULTS: No significance differences in cycle outcome was observed between groups, neither between different subgroups. According to ovarian stimulation, no differences were observed in donor age and number of oocyte yield between control and population groups and subgroups. Gonadotropin dosages and days of stimulation correlated with respect to the number of CGG repeats. These results disagreed with previously work performed on infertility patients.

DISCUSSION: For the first time we present data showing the relation between normal and intermediated sized CGG repeats on FMR1 gene and ovarian stimulation using a non-confusion model as oocyte donor. Our data suggest that ovarian stimulation does not be affected by CGG repeats on normal and intermediated range.

The utility of methylation sensitive high resolution melting assay at imprinted genes in the diagnosis of complete and partial hydatidiform mole

H. Landolsi[1,2], *L. Philibert*[3], *C. Rittore*[3], *S. Brahem*[2], *M. Gribaa*[2], *A. Saad*[2], *S. Hmissa*[1], *M. Yacoubi*[1], *I. Touitou*[3];

[1]*Laboratoire d'anatomie et de cytologie pathologiques, CHU. Farhat Hached, Sousse, Tunisia,* [2]*Laboratoire de Cytogénétique, de Génétique Moléculaire et de Biologie de la Reproduction, CHU Farhat Hached, Sousse, Tunisia,* [3]*Unité Médicale des Maladies Auto-Inflammatoires, Laboratoire de Génétique, Hôpital Arnaud de Villeneuve, Montpellier, France.*

Background: Hydatidiform mole (HM), represents a disorder of genomic imprinting, a phenomenon whereby genes are monoallelically expressed from the maternally or paternally-derived copy of the gene. HM are classified as partial (PHM) or complete (CHM). The aim of this study was to analyze and to compare the methylation patterns of imprinted genes in CHM and PHM.

Material and Methods: We used methylation-sensitive high-resolution melting technique (MS-HRM) for the methylation analysis of three paternally expressed genes, *SNRPN*, *KCNQ1OT1* and *GNAS-XLaS*, that are normally only methylated on the maternal allele, and a maternally expressed gene, *H19*, which is normally only methylated on the paternal allele. DNA samples including 25 CHM and 20 PHM were scored as hypermethylated, normal, or hypomethylated.

Results: We found loss of cytosine methylation in 19 CHM and 1 PHM at *SNRPN* DMRs, 20 CHM and 1 PHM at *KCNQ1OT1* DMRs, and in 24 CHM and 3 PHM at *GNAS-XlaS* DMRs. Hypermethylation at *H19* DMRs was showed in 21 CHM and 1 PHM. Abnormal DNA methylation patterns at all imprinted genes were highly correlated to CHM than PHM ($p<0.05$).

Conclusion: Our data confirm that abnormal methylation status of imprinted genes is significantly associated to androgenic CHM characterized by diffuse trophoblastic hyperplasia and the lack of foetal development. So, we confirm the correlation between phenotypic variability of different forms of HM and various degrees of disorder of imprinting. MS-HRM analysis is a rapid, specific and sensitive method, which can be applied for the accurate differentiation between CHM and PHM.

Prenatal diagnosis for Huntington disease in the Netherlands (1998-2008)

P. A. M. de Koning Gans[1], *M. C. van Rij*[2], *C. M. Aalfs*[3], *M. Elting*[4], *P. F. Ippel*[5], *J. A. Maat-Kievit*[6], *C. C. Verschuuren-Bemelmans*[7], *M. van Belzen*[1], *R. Belfroid*[1], *M. Losekoot*[1], *A. Tibben*[1], *E. K. Bijlsma*[1];

[1]*Centre for Human and Clinical Genetics, Leiden, Netherlands,* [2]*Dept of Clinical Genetics MUMC, Maastricht, Netherlands,* [3]*Dept of Clinical Genetics*

AMC, Amsterdam, Netherlands, [4]Dept of Clinical Genetics VUmc, Amsterdam, Netherlands, [5]Dept of Clinical Genetics UMCU, Utrecht, Netherlands, [6]Dept of Clinical Genetics ErasmusMC, Rotterdam, Netherlands, [7]Dept of Clinical Genetics UMCG, Groningen, Netherlands.

Prenatal diagnosis for Huntington's disease (HD) is possible using linkage analysis since 1987 and using direct mutation analysis since 1993, when the HTT-gene was identified.

In a previous study in the Netherlands (Maat-Kievit et al. 1999), prenatal diagnosis for HD was categorized for the period 1987-1997. In this study we categorized the next decade: 1998-2008.

We studied the medical records from all couples that had prenatal diagnosis between 1 Jan 1998 and 31 Dec 2008, to collect data regarding reproductive history, DNA results (predictive and prenatal) and decisions made in pregnancies.

In the study period 126 couples had 218 prenatal tests, 187 (86%) direct mutation analyses and 31 (14%) exclusion tests. In the previous decade, figures/data were respectively 41 and 31.

Of the couples that had their first prenatal test in this period, 13% opted for an exclusion test.

We identified a new category of at risk parents opting for prenatal testing: carriers of a CAG repeat in the low penetrance or intermediate range. In 92 prenatal tests the result indicated an affected fetus. Of those, 11 pregnancies were continued (12%).

Though the proportion of direct tests has increased, linkage analysis is still the first choice for a minority. We found that quite some pregnancies with an unfavorable result were continued. The circumstances that led to this decision will be specified.In a separate survey we will investigate how many couples switched to preimplantation genetic diagnosis at some point in their reproductive choice.

P04.10

Idiopathic Hypogonadotropic Hypogonadism in Finland

J. Tommiska[1,2], *K. Vaaralahti*[1,2], *E. Eklund*[1], *R. Koivu*[1], *E. Laitinen*[1,2], *T. Raivio*[1,2];

[1]*University of Helsinki, Institute of Biomedicine, Helsinki, Finland,* [2]*Children's Hospital, Helsinki University Central Hospital, Helsinki, Finland.*

Idiopathic hypogonadotropic hypogonadism (IHH) is a clinically and genetically heterogeneous disorder characterized by absent or incomplete puberty with anosmia (Kallmann Syndrome; KS), or with a normal sense of smell (normosmic IHH; nIHH). The molecular genetic cause can only be identified in ~30% of patients. We investigated epidemiological, clinical, and genetic features of IHH in Finland. The minimal incidence estimate of KS was 1:48 000, with a clear difference between males (1:30 000) and females (1:125 000) (p=0.02). The phenotypes of 30 KS probands (25 men; 5 women) ranged from severe IHH to partial puberty. Mutation analysis of *KAL1*, *FGFR1*, *FGF8*, *PROK2*, *PROKR2*, *NELF*, *CHD7*, and *WDR11* genes revealed mutations in *KAL1* (3 men) and *FGFR1* (all 5 women vs. 4/25 men), but not in other genes. In addition, 15 patients with nIHH were phenotyped, and screened for mutations in *FGFR1*, *FGF8*, *PROK2*, *PROKR2*, *NELF*, *CHD7*, *WDR11*, *GNRHR*, *GNRH1*, *KISS1R*, *KISS1*, *TAC3*, *TACR3*, *FSHB* (6 females), and *LHB* (9 males). Three patients were compound heterozygotes for *GNRHR* mutations, but no mutations were found in other genes. The lack of mutations in *PROK2*, *PROKR2*, *TAC3*, and *TACR3*, implicated in recessive IHH, may reflect the special genetic features of the Finnish population. No evidence of oligogenic inheritance, suggested to contribute to IHH, was observed. Altogether 30 patients (67%) remained without identified mutations in any of the known IHH genes, and we expect to identify mutations in previously undescribed genes underlying IHH among the Finnish patients.

P04.11

Sperm and lymphocyte low level aneuploidy in patients with olygozoospermia

N. V. Zotova, *E. V. Markova, O. A. Serebrennikova, A. V. Svetlakov;*

Krasnoyarsk Center for Reproductive Medicine, Krasnoyarsk, Russian Federation.

Karyotype abnormalities contribute to male infertility. But normal male karyotyte does not exclude low level aneuploidy in somatic cells and sperm aneuploidy. Abnormal semen parameters in chromosomally normal men could be a risk factor of sperm aneuploidy. Numerous data are available regarding sperm aneuploidy in patients with oligozoospermia (OS) but they are very disconnected, and there are no acceptable normative parameters.

We investigated germ and somatic cells of 20 men with normal male karyotype: 10 patients with oligozoospermia and 10 fertile normozoospermic men. The karyotyping was performed by GTG-banding technique. Aneuploidy level for chromosomes 13, 18, 21, X, and Y was investigated in cultivated lymphocytes and fixed decondensed sperms by FISH. Limits and confidence intervals were scored for control group. Semen analysis was performed according to the standard WHO criteria.

A total of 20000 sperm and 20000 lymphocytes were scored for five chromosomes. We found significant differences in aneuploidy level for five chromosomes between OS patients and control group both in lymphocytes: 2.04±0.21% and 1.04±0.07% (increase of limit) and in sperm: 2.17±0.28% and 1.17±0.14% (P=0.001). Inverse correlation was found between sperm aneuploidy level and sperm concentration in ejaculate (r=0.644). There was a mild association between aneuploidy level in blood and germ cells for chromosomes 13 and 18 (r=0.426 and r=0.392).

In our investigation we determined limits of sperm and lymphocyte aneuploidy in the control group. These data can be useful for cases of mosaicism (especially low level) and sperm aneuploidy analysis. OS patients had elevated aneuploidy level.

P04.12

Hemochromatosis gene mutations (HFE) in infertility

T. Adyan, *O. Schagina;*

Medical Genetics Research Center, Moscow, Russian Federation.

Hemochromatosis - an autosomal recessive disorder, the most common causes of it are two mutations of HFE gene: C282Y and H63D. The HFE gene mutations lead to increased iron absorption in the gastrointestinal tract. Detailed clinical symptoms occur in 4-5 decade of life. Before that, the iron is gradually accumulates in the body tissues. So violations of the male reproductive function as impotence, testicular atrophy, azoospermia, and so female reproductive function as amenorrhea may occur long before the major symptoms of hemochromatosis. Based on these data and high-frequency carrier of fhe disease in different populations, the search of C282Y and H63D mutations of HFE gene was carried in a group of 132 men with infertility diagnose. As a control, we studied a sample of 204 not clinically surveyed residents of the Russian Federation.

C282Y mutation in the heterozygous state was detected in 12 patients from the infertile group and in 13 ones from the group of population controls, H63D in 47 and 35 ones, respectively. H63D mutation in the homozygous state was detected in 2 patients from the infertile group and in 7 persons of the control group, 1 patient and 2 persons from the comparison group were compounds for investigated mutations. Neither statistically significant differences of C282Y and H63D mutations allele frequencies for studied groups no differences between the incidence of two mutations carriers were found.

Thus, it was found that the HFE gene mutations do not contribute to the development of infertility among residents of the Russian Federation.

P04.13

Study of GT-repeat expansion in Heme oxygenase-1 gene promoter as genetic cause of male infertility

S. Aleyasin[1], *F. Jahanshad*[2], *E. Siasi*[3], *H. Saheb Kashaf*[2];

[1]*National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [2]*Navid Insistute of Infertility, Tehran, Islamic Republic of Iran,* [3]*Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

A reduction in the level of HO-1 protein has been observed in the seminal plasma and reported to be associated with oligospermia and azoospermia in men with infertility. The length of GT-repeats polymorphic region in the promoter of human Heme oxygenase-1 gene (HO-1) alters the level of its transcriptional activity in response to oxidative stress. This is the first study to investigate the association between GT-repeat expansion in the promoter of HO-1 and male infertility in Iranian population. The GT-repeats alleles were determined in 100 cases and 100 normal controls by molecular analysis method such as PCR-PAGE, ABI fragment analysis genotyping and sequencing. Two classes of S allele with 27 GT-repeats were specified as 4 to 6 alleles. The L allele frequency was significantly higher (54.5%) among case group than that in the normal controls (37.5%). Statistical analysis provide significant relationship between L alleles and male infertility

(P<0.001). This study shows for the first time that GT repeat expansion in promoter of the HO-1 gene is associated with oligospermia and azoospermia in male infertility among Iranian infertile cases.

P04.14
Cytogenetic investigations in Assisted Reproductive Technology (ART) - experiences of Center of Reproductive Medicine (Belarus)

***S. Zhukovskaya**, L. Savenko, N. Rumiantsava, H. Abramchik, L. Shamgina;*
Center of Reproductive Medicine, Minsk, Belarus.

Cytogenetic investigations of sterile patients, couples with reproductive failures, fetuses suspected for chromosomal disorders play an important role in diagnostics of etiology of infertility, fetal loss, handicapped offspring. We present a scheme of genetic service, cytogenetic results, selective fetal reduction data. Genetic service of CRM provides counseling of infertile couples, pregnant women after ART with fetal loss or abnormalities; cytogenetic and molecular analyses, prenatal combined (US + serum markers) screening, genetic risk calculation. Among 3865 examined patients (lymphocytes, GTG) aberrations were detected in 1.2%. Balanced rearrangements (71%) presented Robertsonian and reciprocal translocations, inversions of chromosomes 2;5;6;7;9;10;X;Y. Unbalanced aberrations (29%) included numerical gonosome abnormalities, markers (47,XYY; 47,XYY/46,XY; 47,XY,+mar; 47,XY,+mar/46,XY; 45,X/46,XY,gh+; 47,ÕÕÕ; 47,XXX/46,XX; 45,X/46,XX; 45,X/48,XXXX/46,XX), X and Y deletions. 1312 pregnant women underwent screening in the 1st trimester. Couples with increased risk - advanced maternal age (27.7%), calculated risk for combined screening ≤1:360 (9.7%), parental balanced rearrangements - were selected for prenatal karyotyping (CVS, GTG). 14 reductions of fetuses with aneuploidy were performed in the 1st trimester using Berkowitz's method (one test-positive couple refused which resulted in the birth of a child with Down's syndrome). 13/14 terminated cases presented twin pregnancy after IVF (4) or IVF+ICSI (9) with one affected fetus (trisomy 21, 18, 13, monosomy X; inherited structural autosomal unbalance). Pregnancies resulted in deliveries of healthy newborns. Conclusion: Prenatal testing for fetal abnormalities is a necessary preventive measure - in cases of elevated risk of severe consequences for an offspring's health, reduction of the affected fetus is preferred.

P04.15
Diagnostic testing for Male Factor Infertility using APEX microarrays

***E. Oitmaa**[1,2], A. Tammiste[1,3], S. Suvi[2], M. Punab[4], M. Remm[1], A. Metspalu[1,5], A. Salumets[3,6];*
[1]Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [2]Asper Biotech Ltd, Tartu, Estonia, [3]Competence Centre on Reproductive Medicine and Biology, Tartu, Estonia, [4]Andrology Centre, Tartu University Hospital, Tartu, Estonia, [5]The Estonian Genome Center of University of Tartu, Tartu, Estonia, [6]Department of Obstetrics and Gynecology, University of Tartu, Tartu, Estonia.

Objective: Male factor infertility (MFI) issues are causative in approximately 15-20% of infertile couples. The unfavourable genetic background is thought to cause for 15-30% of male factor infertility cases. Therefore, the correct determination of genetic basis of infertility is very important for further treatment of patients. Here, we demonstrate a single-step Arrayed Primer Extension (APEX) based microarray assay for the MFI diagnosis.

Design & Method: The MFI-APEX assay enables analysis of numerous genetic factors simultaneously, like AZF-microdeletions; Klinefelter syndrome; mutations in cystic fibrosis transmembrane conductance regulator (CFTR) gene; genes involved in folate metabolism; cryptorchidism, hypogonadism, spermatogenic failure linked genes; and polymorphisms in androgen receptor gene. For validation of the MFI-APEX assay we used blood samples obtained from 22 infertile men and 10 fertile men as controls.

Results: We developed MFI-APEX microarray assay for the detection of genetic factor of the male infertility. Analysis of the APEX results revealed that 14 out of 22 patients had Klinefelter syndrome; 2 patients had Klinefelter syndrome and mutations in CFTR gene; 2 patients had AZFbc microdeletion; 5 patients had AZFc microdeletion; and 1 patient had AZFc deletion and mutation in CFTR gene. No alterations were found in fertile men with MFI-APEX assay.

Conclusions: Our experiments demonstrated that MFI-APEX assay is suitable for the rapid single-step, robust, reliable and cost-effective detection of possible genetic cause for male infertility problem. Furthermore, MFI-APEX testing is recommended before the couple undergoes assisted reproduction in order to prevent the possible inheritance of the genetic lesion to the next generation.

P04.16
Array-CGH analysis in patients with maturation arrest of spermatogenesis

***K. Stouffs**[1,2], D. Vandermaelen[1,2], A. Massart[1,2], B. Menten[3], H. Tournaye[4], W. Lissens[1,2];*
[1]Reproduction and Genetics, Vrije Universiteit Brussel, Brussels, Belgium, [2]Center for Medical Genetics, UZ Brussel, Brussels, Belgium, [3]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [4]Center for Reproductive Medicine, UZ Brussel, Brussels, Belgium.

Introduction. The past decades, many studies have been performed aiming to identify genetic causes of maturation arrest of spermatogenesis (MA). However, these studies were rather disappointing. In the present study, we looked for the presence of copy number variations (CNVs) in patients with MA and controls with normal sperm parameters

Material and methods. CNVs were identified using 244K arrays in 9 patients. For regions of possible interest, more patients and especially larger groups of control men were investigated by qPCR.

Results. In the patient and control groups, on average 25±4 and 24±7 CNVs were detected, respectively. After elimination of regions that are not containing any known genes and regions that were also detected as CNVs in controls, 32 regions remained. A further reduction to nine regions was done by eliminating deletions that are completely intronic (fi in PRKG), regions that were recently amplified in evolution (f.i. BAGE and PNMA genes) and regions with a well-known function not involved in spermatogenesis. The remaining nine regions are being investigated by qPCR in order to investigate large numbers of controls (>100) and to conclude whether the observed CNVs are common or related to the fertility problems. Preliminary results show that at least some of the regions are exclusively detected in the patients.

Conclusions. In this study, a small group of patients with MA have been thoroughly investigated using array-CGH. No common region was detected in the patient group that was absent in control samples. Six promising regions will be further investigated.

P04.17
Association of polymorphisms in eight genes (FASLG, JMJD1A, LOC203413, TEX15, BRDT, OR2W3, INSR and TAS2R38) with male infertility

***D. Plaseska-Karanfilska**[1], P. Noveski[1], T. Plaseski[2], G. D. Efremov[1];*
[1]Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Faculty of Medicine, Clinic of Endocrinology and Metabolic Disorders, Skopje, Macedonia, The Former Yugoslav Republic of.

The analysis of polymorphisms in genes involved in spermatogenesis represents an exciting area of research in genetics of male infertility. Polymorphisms in these genes are considered potential risk factors which may contribute to the severity of spermatogenic failure. Here we have investigated the possible association of nine single nucleotide polymorphisms (SNPs) in eight different genes (FASLG, JMJD1A, LOC203413, TEX15, BRDT, OR2W3, INSR and TAS2R38) with male infertility. The SNPs were selected because they were found to be associated with azoospermia and /or oligozoospermia in a recent study (Aston KI et al, Hum Reprod, 25:1383-97, 2010).

We have analysed a total of 136 men with idiopathic infertility (60 azoospermic and 76 oligozospermic) and 161 fertile controls. Ninety three of the infertile men were Macedonians, 32 were Albanians and 11 men were of other ethnic origin. The control group was composed of 125 Macedonian and 36 Albanian men. The methodology included multiplex PCR/SNaPshot method, followed by capillary electrophoresis on ABI3130 Genetic Analyzer.

Of the nine SNPs evaluated, we have found significant association ($p<0.05$) for three. The most significant association was found for rs5911500, an intergenic SNP located on the X chromosome. This SNP as well as rs3088232 in BRDT gene showed association with azoospermia both among Macedonians and Albanians, while

rs11204546 in OR2W3 gene was also associated with azoospermia, but only among Macedonian men. Another SNP (rs34605051 in JMJD1A gene) was present with higher frequency among all groups of infertile men in comparison to fertile controls, but the differences were not significant.

P04.18
Analysis of *DLK1* gene and microRNA expression in male infertility due to idiopathic testicular dysfunction

*S. Bonache[1], R. A. de la Fuente[1], F. Algaba[2], L. Bassas[2], **S. Larriba**[1];*
[1]IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain, [2]Fundació Puigvert, Barcelona, Spain.

Cellular interactions between germ-line and somatic components of the testicular seminiferous tubule form a complex network, and are essential for efficient germ-cell development. Gene expression of Leydig cells is crucial to maintain male fertility.

We have assessed the expression profile of *DLK1* gene (preferentially expressed by Leydig cells) and its regulation by miRNAs (involved in posttranscriptional gene silencing) in impaired spermatogenesis.

We have analysed *DLK1* and three *DLK1*-target miRNAs *(miR-33a, miR-514* and *miR-377)* expression levels in testicular biopsies of 33 non-obstructive infertile men (patients), who showed total absence of germ cells (SCO; n=14), complete meiotic arrest (MA; n=7) and hypospermatogenesis (HS; n=12), and 16 men with obstructive azoospermia and conserved spermatogenesis (controls). The current method was the real time RT-PCR (7300 Real Time PCR System and TaqMan Assays) and the 2-ΔΔCt strategy. *PGK1* gene was selected as normalizer for *DLK1* data and *RNU6B* for miRNA data. The Mann-Whitney U test was used to analyse expression differences between groups.

Preliminary results show significant *DLK1* over-expression in the three patient subphenotypes compared to controls. The expression levels of the three miRNAs were found significantly increased in the SCO subphenotype.

These results suggest that changes in the expression of *DLK1* in Leydig cells might be associated to spermatogenic impairment. These differences in expression are not associated to *miR-33a, miR-514* and *miR-377* miRNA regulation. These data would contribute to a better understanding of the molecular mechanisms underlying male infertility.

Supported by FIS (PI09/01727) and Generalitat de Catalunya (CES09/020)

P04.19
Role of genetic factors and oxidative stress in male infertility

***J. Thilagavathi**, S. Venkatesh, M. B. Shamsi, R. Dada;*
All India Institute of Medical Sciences, New Delhi, India.

Introduction: Infertility affects 15% of couples in their reproductive age group where 30 to 40% of males are the sole contributor and majority of these are idiopathic. Methods: The study included 200 men with idiopathic infertility and 100 fertile controls. The work involved cytogenetic and Y chromosome micro-deletion analysis, evaluation of seminal reactive oxygen species levels by chemiluminescence assay and sperm DNA damage by sperm chromatin structure assay (SCSA). Results and Discussion: Out of 200 infertile men screened, 13% harbored cytogenetic abnormalities. Azoospermia factor (AZF) microdeletions were detected in 9.5% infertile men, where AZFc deletion were predominant followed by AZFb and AZFa deletions. This frequency is similar to that reported in French & Danish population. Level of ROS in both washed and neat semen was found to be significantly (P<0.0001) higher in infertile men compared to controls. The average mean DNA fragmentation index (DFI) in infertile men was found to be 40.85% which was significantly higher (p<0.0001) compared to average mean DFI (25.62%) in controls. Conclusion: Cytogenetic abnormalities and Yq microdeletions are present in about 22% of men with idiopathic infertility. Analysis of sperm DFI and the cut off level of 30.42% is useful to predict outcome of ART as conventional semen analysis is a moderate predictor of fertility potential. Early detection of OS and suitable antioxidants therapy may prevent further deterioration of semen quality and improves chances of fertilization as it improves membrane integrity. Thus genetic analysis, assessment of ROS levels & DFI has both diagnostic and prognostic capabilities.

P04.20
Study of T886C SNP in TAS2R38 gene association with azoospermia and oligospermia in idiopathic infertile men.

***e. siasi**[1], A. Aleyasin[2];*
[1]Tarbiat modares university, Tehran, Islamic Republic of Iran, [2]National institute of genetic and biotrchnology, Tehran, Islamic Republic of Iran.

Back ground- Genome wide SNP association study (GWAS) by microarray method could identified several SNPs that had potential relevance to oligospermia and azoospermia have occurred due to idiopathic infertile men. One such study by Aston et al in 2010 has reported significant SNPs in European population. The most significant association found for an intergenic SNP (T886C) in TAS2R38 gene with male infertility. This SNP results in a conservative amino acide change of Isolucine to Valin.

Objective- This is the first study to evaluated association between T886C SNP in TAS2R38 gene with oligospermia or azoospermia in idiopathic infertile men in Iranian population.

Methods- This relationship has been studied in 96 idiopathic infertile men with azoospermia and oligospermia and 100 normal control men. Primer pairs were designed to amplify 192bp fragment contained T886C polymorphism. Analysis of SNP was performed by PCR-RFLP and High Resolution Melt (real time PCR-HRM corbett). Amplified fragment was sequenced to determine the PCR product and allelic identify.

Results- Genotype frequencies of the TT, TC and CC were as 20.8%, 34.4% and 44.8%, in the case group and 21%, 34% and 45% in the control group respectively. The prevalence of tested SNP was approximately similar in both infertile patients and fertile control groups. Statistical analysis showed no significant relationship P=0.9 for this SNP (T886C) in TAS2R38 gene.

Conclusion- This result is indicated that (T886C) in TAS2R38 gene was not associated with oligospermia and azoospermia that could caused idiopatic male infertility in Iranian population.

P04.21
Gene expression alteration of the YBX2 and DAZ genes is associated with male factor infertility

***F. Raicu**, R. Cocoş, L. Bohîlţea;*
University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Y chromosome microdeletions are the major molecular determinants for male infertility by removing key-genes for male germ cell development and maintenance. Despite the large number of studies about the molecular basis of male infertility the molecular mechanism leading to spermatogenesis disruption is still largely unknown. Several forms of male infertility can be determined by a common pathogenic mechanism related to alterations in testicular mRNA storage. DAZ and YBX2 are the main genes involved in the regulation of the stability and storage of male germ cell mRNAs. We previously analyzed using quantitative real-time SYBR Green PCR assays the YBX2 and its direct interacting genes: PRM2, ODF1, TP1, ACTL7B and found large reductions in mRNA levels in all patients with spermatogenic defects except patients with idiopathic oligozoospermia. Patients with idiopathic azoospermia had similar levels of gene expression as those carrying Y chromosome microdeletions independently from their SCOS or HS phenotype, suggesting a possible link of the selected genes to a common pathway leading to infertility and that variability of the histopathology is related to other genetic and environmental factors. Further investigations revealed that DAZ gene was not expressed in six patients without the AZFc deletion in the peripheral blood as expected. Testis biopsy was obtained from patients with obstructive azoospermia (10 normospermic controls) and infertile male (10 with Y microdeletions and 10 with idiopathic infertility) with the histopathology ranged from SCOS to severe hypospermatogenesis

P04.22
Association of b2/b3 deletion with spermatogenic failure

***P. Noveski**[1], T. Plaseski[2], G. D. Efremov[1], D. Plaseska-Karanfilska[1];*
[1]Macedonian Academy of Sciences and Arts; Research Centre for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Faculty of Medicine, Clinic of Endocrinology and Metabolic Disorders, Skopje, Macedonia, The Former Yugoslav Republic of.

The b2/b3 deletion removes 1.8Mb of the AZFc region on the Y chromosome, including 12 members of 8 testis-specific gene families.

It was suggested that geographical and ethnic differences might affect the Y chromosomal background and phenotypic expression of this deletion. The association of the b2/b3 deletion with male infertility has been reported in Chinese men, whereas no predisposition was detected in several other populations. The b2/b3 deletion is found fixed in the Y haplogroup N which is widely distributed among men in the Northern Europe. It is present with low frequencies among other European populations. We studied the occurrence of partial AZFc deletions among 77 men with azoospermia, 93 with oligozoospermia, 44 normozoospermic individuals with unexplained couple infertility and 233 fertile controls (proven fathers). The methodology included analysis of AZFc specific STS markers, DAZ and CDY gene dosage and single nucleotide variants. The Y chromosome haplogroups were determined by 28 Y-chromosome SNP markers, which were typed by multiplex PCR/SNaPshot reactions. We found 6 men with b2/b3 deletion, one azoospermic men, 4 oligozoospermic and one fertile control. The b2/b3 deletion was significantly more frequent among men with impaired spermatogenesis (5 out of 170 men or 2,9%) than among fertile controls (1 out of 233 or 0,4%; p=0,04). The highest frequency was present in oligozoospermic men (4,3%; p=0,01). There was a difference in the distribution of the Y haplogroups among males with b2/b3 deletion; all five infertile men belonged to haplogroup E3b1, while the only fertile men belonged to haplogroup N3.

P04.23
High prevalence of two Y chromosomal haplogroups N1c1-M178 and N(xM178) in Russian infertile men with b2/b3 deletion

V. B. Chernykh, *T. M. Sorokina, L. V. Shileiko, L. F. Kurilo, O. P. Balanovsky, M. A. Kuznetsova, A. V. Shanko, E. V. Balanovskaya, O. P. Ryzhkova, A. V. Polyakov;*

Research Center for Medical Genetics, Moscow, Russian Federation.

An association between Y chromosome deletion b2/b3 and haplogroup N is well defined. The aim of our study was to evaluate a frequency of partial AZFc deletions and to analyze of Y haplogroups in Russian infertile men with b2/b3 deletion.

Materials and Methods: We screened 2933 infertile Russian men for Y microdeletions. Complete AZF deletions were detected according to Laboratory guidelines EAA/EMQN (1999). Partial AZFc deletions were tested by mPCR for STSs: sY142, sY1197, sY1192, sY1291, sY1206, sY1054, sY1125. Y haplogroups were analyzed in randomly selected 158 individuals with b2/b3 deletions. DNA samples have been genotyped by the set of Y chromosomal SNPs to identify the association with Y haplogroups. SNP typing was performed by the custom TaqMan assays on the real-time PCR instrument 7900 (Applied Biosystems).

Results: Partial AZFc deletions were found in 12.1% infertile men. The b2/b3 deletion was detected in 8.6% individuals. The patients with b2/b3 deletions presented with a wide range of spermatogenetic failure, at that severe oligozoospermia to azoospermia were prevalent. About 80% of samples fall into haplogroup N1c1-M178, 10% fall into the related haplogroup N-LLY22 (xM178), and only the rest 10% fall into other haplogroups, including R1a-M198. Note, that 90% of the studied individuals were ethnic Russians, and the obtained frequencies of Y haplogroups drastically differ from the frequencies in the general Russian population.

Conclusion: The b2/b3 deletion is commonest Y chromosome microdeletion in Russian infertile men. We conclude that this deletion exhibit strong association with two related Y chromosomal haplogroups: N1c1-M178 and N-LLY22(xM178).

P04.24
The study of Y chromosome microdeletions and mutations in the androgen receptor gene in Iranian patients with idiopathic non-obstructive azoospermia

R. Mirfakhraie[1], *M. Montazeri*[1], *S. M. Kalantar*[2], *N. Salsabili*[3];

[1]*National Institute of Genetic Engineering and Biotecnology, Tehran, Islamic Republic of Iran,* [2]*Genetics Department, Research & Clinical Centre for Infertility, Yazd, Islamic Republic of Iran,* [3]*IVF Department, Mirza Kouchak Khan Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Genetic factors, including Y chromosome microdeletions and androgen receptor (*AR*) gene mutations are responsible for male infertility. The aim of this study was to determine the incidence of AZF deletions and the prevalence of *AR* gene mutations among Iranian infertile men with idiopathic non-obstructive azoospermia.

Materials and Methods: A total of 100 Iranian azoospermic infertile men was selected for the molecular study of Y chromosome microdeletions and mutations in the AR gene. The presence of eight sequence tagged site (STS) markers from AZF region was investigated using multiplex PCR. Screening for *AR* gene mutation was performed using PCR-SSCP (Single-strand conformational polymorphism) and sequencing.

Results: 12% of the patients showed Y chromosome microdeletions and among these patients, deletion in AZFb region was the most frequent (66.67%). PCR-SSCP and sequencing analysis revealed a novel 1510C→A transversion in the exon 1 of the *AR* gene resulted in p.Pro504Thr substitution. Analysis of CAG repeats in the exon 1 of the *AR* gene showed a significant statistical difference between the CAG length in the patients and fertile controls (P=0.014).

Conclusion: According to the relatively high incidence of Y chromosome microdeletions among Iranian azoospermic patients molecular screening should be advised to infertile men before using assisted reproductive treatments. Furthermore, the present study indicates that molecular analyses of *AR* gene play an important role in diagnosing the cause of infertility in patients with azoospermia and therefore, may be useful for genetic counseling of candidates for assisted reproductive techniques.

P04.25
Mutation analyses of the TSPYL1 gene in infertile patients with azoospermia, cryptozoospermia or oligozoospermia

P. Javaher-Haghighi[1], *M. Stuhrmann*[1], *C. Wilke*[1], *E. Frenzel*[1], *G. Manukjan*[1], *F. Dechend*[2], *E. Schwaab*[3], *C. Hübner*[1], *J. Schmidtke*[1], *S. Schubert*[1];

[1]*Institute of Human Genetics, Hannover Medical School, Hannover, Germany,* [2]*Laboratory of Cytogenetic and Molecular Genetics, Hildesheim, Germany,* [3]*Human Genetic Practice, Wiesbaden, Germany.*

Background: Recently, mutations in the *TSPYL1* gene have been reported to be associated with an autosomal recessive sudden infant death with dysgenesis of the testes syndrome (SIDDT) and with 46,XY disorder of sex development (DSD) and male idiopathic infertility, respectively. However, the exact function of TSPYL1 in testicular development and spermatogenesis is currently uncertain.

Methods: Mutation analysis was performed for *TSPYL1* in a cohort of 106 infertile men with idiopathic non-obstructive azoospermia, cryptozoospermia and oligozoospermia, and in a control group of up to 105 men with proven paternity.

Results: 8 known SNPs were detected in the *TSPYL1* gene of which none was significantly associated with male infertility. One azoospermic man was heterozygous for the yet undescribed missense mutation c.419C>G (p.Ser140Cys). This sequence variation was not observed in 102 fertile men with proven paternity. Additionally, one out of 101 fertile men was shown to be heterozygous for the missense change c.487G>A (p.Val163Ile). The p.Val163Ile variant was not identified in 106 infertile men. We analyzed both missense mutations with the online-softwares “Mutation Taster” (www.mutationtaster.org), “PolyPhen2” (http://genetics.bwh.harvard.edu/pph2/) and “PMut” (http://mmb.pcb.ub.es/PMut/), and none of these programs predicted a disease causing effect for c.419C>G (p.Ser140Cys) and c.487G>A (p.Val163Ile), respectively. These assessments await confirmation by functional studies.

Conclusions: Mutations in the *TSPYL1* gene do not seem to play a major role in the pathogenesis of idiopathic male infertility. Mutation screening of the *TSPYL1* gene can currently not be recommended in diagnostics of idiopathic male infertility.

P04.26
MTHFR C677T and A1298C mutations in couples with infertility problems

S. Stangler Herodez[1], *B. Zagradisnik*[1], *K. Zerjavic*[2], *A. Erjavec Skerget*[1], *V. Vlaisavljević*[3], ***N. Kokalj Vokac***[1,4];

[1]*Laboratory of Medical Genetics, University Clinical Centre Maribor, SI-2000 Maribor, Slovenia,* [2]*Laboratory of Medical Genetics, University Clinical Centre Maribor, Maribor, Slovenia,* [3]*Department of Reproductive Medicine and Gynecologic Endocrinology, University Clinical Centre Maribor, SI-2000 Maribor, Slovenia,* [4]*Medical Faculty, University of Maribor, SI-2000 Maribor, Slovenia.*

INTRODUCTION. Infertility is a worldwide reproductive health problem that affects approximately 15% of married couples.

Methylenetetrahydrofolate reductase (MTHFR) C677T and A1298C mutations are associated with recurrent spontaneous abortions and may be overrepresented in couples who have fertility problems or have experienced recurrent miscarriages. In this study we have analyzed the MTHFR C677T and A1298C genotype distributions in couples with unexplained fertility problems and healthy controls.
METHODS. DNA was extracted from peripheral blood samples and allele specific PCR was performed for the detection of each mutation. The MTHFR C677T and A1298C mutation frequencies between patient groups and the control groups were analyzed using the Chi-square test. P-values of <0.05 were taken as statistically significant.
RESULTS. Comparison of combined MTHFR C677T/A1298C genotype distributions between probands and controls is presented in table.

Genotype MTHFR C677T/A1298C	Infertility probands (n = 200)	Controls (n = 222)	Female probands (n = 100)	Female controls (n = 111)	Male probands (n = 100)	Male controls (n = 111)
CC/AA	17	21	8	10	9	11
CC/AC	35	49	20	22	15	27
CC/CC	26	24	11	15	15	9
CT/AA	36	45)	17	22	19	23
CT/AC	49	47	25	24	24	23
CT/CC	6	8	3	4	3	4
TT/AA	20	25	11	11	9	14
TT/AC	8	1	3	1	5	0
TT/CC	3	2	2	2	1	0
chi square (all samples vs. controls) 9.25, p = 0.03 (df = 8)						
chi square (female infertility vs. femal controls) 1.33, p = 0.72 (df = 8)						
chi square (male samples vs. male controls) 13.23, p < 0.001 (df = 8)						

CONCLUSIONS. The present finding indicates that significant difference in the prevalence of MTHFR C677T/A1298C mutations can be found in probands with fertility problems when compared with controls without an infertility history. However, only male probands contributed to the association indicating that MTHFR mutation may be a gender specific factor which affects fertility of grown adults. The presence of combined MTHFR C677T/A1298C genotypes highly increased the risk of men infertility. Our presented data highlight the importance of MTHFR mutation screening in couples with unexplained infertility, especially by male adults.

P04.27
Disruption of the gene for zona pellucida binding protein detected by array CGH in male infertility

***V. Damyanova**, I. Dimova, A. Savov, D. Nesheva, S. Hadjidekova, B. Rukova, R. Jivkova, V. Nikolova, I. Vatev, D. Toncheva;*
Medical faculty, Sofia, Bulgaria.

The infertility affects 10-15% of all couples. In about 40% of the cases the male factor is reported to be the main reason for unsuccessful fertilization. Although in 70% of male factor infertility the etiology is recognizable, in the remaining 30% the reason is unknown and the male infertility is named idiopathic. In the current study, we selected 14 patients with idiopathic infertility, affected by azoospermia and oligoasthenoteratozoospermia. All patients were subjected to DNA analysis for deletions of Y chromosome and cytogenetic analysis for chromosomal aberrations. After these analyses, the patients without such kind of abnormalities were further analyzed by array CGH.
Cytogenetic analysis revealed two patients with chromosomal mutations - inv(9)(p11;q13) and t(Y;9)(q12.3;q21.1). Other two patients were detected to have deletions of AZFc region of Y-chromosome. Thus, we applied array CGH analysis for the ten patients without chromosomal or Y-chromosome aberrations. Despite of the presence of known polymorphisms, we established copy number alteration in 17q12-17q21.2 - a region, containing the gene for zona pellucida binding protein ZPBP2. This protein plays a crucial role for the proper spermatogenesis. Our results prompted for investigation of this gene and protein as a potential candidate for spermatogenic failure.

P04.28
High incidence of Y-chromosome AZF microdeletions and AZFc region partial deletions among azoospermic/oligospermic males from Western Ukraine

***H. Makukh**[1], M. Tyrkus[1], D. Zastavna[1], O. Hnateyko[1], S. Gavrylyshyn[2];*
[1]State institution ï¿½Institute of Hereditary Pathology of Academy of Medical Science of Ukraineï¿½, Lviv, Ukraine, [2]Prycarpatian Center of Human Reproductions,, Ivano-Frankivsk, Ukraine.

Genes of AZF regions of Y chromosome play an essential role in spermatogenesis. The objective of the study was to establish frequency and spectrum of Y-chromosome microdeletions and AZFc region partial deletions among idiopathic azoospermic/oligospermic males from Western Ukraine.
Two hundred idiopathic infertile men (100 with azoospermia and 100 severe oligospermia) and one hundred random fertile men, all with karyotype 46, XY from western region of Ukraine were included in the study. DNA of the above samples was isolated using the salting out method and microdeletions of AZF region and AZFc partial deletions were analyzed by multiplex PCR.
AZF microdeletions were detected among 13.0% males with azoospermia (p=0.0001) and 8.0% (p=0.004) males with severe oligospermia: AZFa subregion was deleted in one patient (4.8%), AZFb - 3 (14.3%), AZFb+c - 7 (33.3%), AZFc - 10 (47.6%) As AZFc subregion was the most frequently altered the study of AZFc partial deletions was done. 8.0% azoospermic/oligospermic men without AZF microdeletions were detected to have AZFc partial deletions. The analysis of AZFc partial deletions has shown the presence of AZFc gr/gr deletion among 2.5% persons (mainly with oligospermia), b2/b3 deletions - 4.5% (three with aspermia and six with oligoastenoteratospermia) and absence of sY1291 locus in 1.0% of patients.
No carriers of AZF microdeletions or partial AZFc deletions were identified among control group of fertile men. The differences in Y-chromosomal partial AZFc deletions frequencies between infertile men (azoospermic/oligospermic) versus group of fertile men are significant (p=0.004) and substantiated AZFc partial deletion testing for practical purposes.

P04.29
Detection of DNA fragmentation in human spermatozoa of patients with asthenozoospermia

***S. Brahem**, M. Mehdi, H. Landolsi, H. Ghédir, A. Bennour, R. Berguiga, I. Ben Abdallah, S. Bouraoui, N. Bou Ali, H. Ben Khélifa, H. Elghezal, A. Saad;*
Laboratoire de Cytogénétique, Biologie Moléculaire et Biologie de la Reproduction Humaines, sousse, Tunisia.

Objective: The aim of the present study was to evaluate levels of sperm nuclear DNA fragmentation in a population of infertile men with asthenozoospermia (low motility) and to compare the results from that of fertile population.
Materials and Methods: Semen samples were collected from 30 asthenozoospermic infertile men selected from couples attending the infertility clinic with a history of infertility ≥ 1 year and 30 healthy fertile men with normal semen parameters served as the control group.
After routine sperm analysis according Word Health Organisation (WHO) guidelines, DNA fragmentation was determined using the terminal desoxynucleotidyl transferase-mediated deoxyuridine triphosphate biotin nick-end labeling (TUNEL) assay. Approximately 500 cells were counted, and the percentage of spermatozoa with fragmented DNA (DFI) was calculated.
Results: There are no significant differences in the mean of participant's age, sperm concentration, normal sperm morphology in two groups but the mean of sperm motility of fertile males was significantly higher than that of asthenozoospermic males.
The difference was not significant between the percentage of DNA fragmentation in patients with asthenozoospermia and the normozoospermics men (9.46 ± 8.68 and 8.19 ± 6.84). In addition, no significant correlation was found between the degree of asthenozoospermia and the DFI value in the asthenozoospermic group, when this group was subdivided into moderate, severe, and extreme asthenozoospermia.
Conclusion: Asthenozoospermia was not associated with an increase of DNA fragmentation. So impairment of sperm motility is not a critical parameter for analysis of sperm DNA damage.

P04.30
Evaluation of *SHOX* duplications in Finnish patients with Müllerian aplasia

M. Sandbacka[1,2], *M. Puhakka*[2], *M. Halttunen*[3], *V. Jokimaa*[4], *H. Laivuori*[2,5], *K. Aittomäki*[1,6];
[1]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [2]*Haartman Institute, Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [3]*Department of Obstetrics and Gynecology, Helsinki University Central Hospital, Helsinki, Finland,* [4]*Departments of Obstetrics and Gynecology, University of Turku, Turku, Finland,* [5]*Women's Health Research Program, University of Helsinki, Helsinki, Finland,* [6]*Department of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland.*

Duplications of the short stature homeobox (*SHOX*) gene have been reported in some patients with Müllerian aplasia (MA), a reproductive disorder presenting as congenital absence of uterus and upper two third of the vagina. We have performed MLPA (Multiplex Ligation-dependent Probe Amplification) studies in a cohort of 98 Finnish patients with MA (sporadic, N=96 and familial, N=2) and 118 healthy women in order to identify *SHOX* duplications. A commercial kit (SALSA MLPA kit PO18-E1 SHOX, MRC Holland) including probes for each exon of *SHOX* as well as probes for regulatory areas of the gene were used in the analysis. All patients and controls showed normal amplification of *SHOX*. Aberrant amplifications for regions downstream of *SHOX* were detected in a few patients and in some of the healthy controls. However, these observed copy number changes were reported in the Database of Genomic Variants (http://projects.tcag.ca/variation), indicating that these were harmless polymorphisms. Our MLPA results from a large cohort of patients with MA suggest that duplications of *SHOX* are not a frequent cause of the disorder. Further genetic studies are needed to find out the underlying cause(es) for MA.

P04.31
The Association between LH, FSH, Testosterone hormones' serum levels and prevalence of gr/gr, b1/b2, b2/b3 polymorphisms in Iranian oligozoospermia males

M. Ataei[1], *N. Salsabili*[2], *P. Yaghmaei*[1], *N. Hayati*[1], *R. Mirfakhraei*[3], *M. Montazeri*[3], *M. Ataei Talebi*[1];
[1]*Science and Research branch of Islamic Azad University, tehran, Islamic Republic of Iran,* [2]*Tehran Medical University, Tehran, Islamic Republic of Iran,* [3]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.*

Introduction: Infertility is a main healthy problem. About 10-15% of couples suffer this problem and in the 50 %, the male factor affects. The human Y chromosome contains essential genes for spermatogenesis specially those which are located on four major intervals defined as AZFa, AZFb, AZFc and AZFd. Partial deletions of the AZFc region is reported as a significant risk factor for oligo-/azoospermia. The main purpose of this study is to investigate the association between Testosterone, FSH, LH serum levels and the prevalence of partial deletions in the AZFc region (gr/gr, b1/b2, b2/b3) in Iranian oligozoospermia males.

Material and methods: Multiplex PCR technique and agarose gel electrophoresis were used to assess complete and partial deletions in 30 oligozoospermia infertile and 50 fertile men, and Levels of hormones were measured by Imunoenzymatic kit (EIA) in all samples.

Results: 3.3% of the patients showed AZFb deletion but no microdeletion was detected in the control samples. In AZFc region, 17% patients showed deletions, in which 13.7% had gr/gr and 3.4% had b2/b3 deletions. 12% of the healthy individuals showed partial deletions, including gr/gr (10%) and b2/b3(2%). No significant correlation was detected between the presence of gr/gr microdeletion and the testosterone serum level (p=0.856). However, the serum levels for FSH and LH were significantly higher in patients with gr/gr microdeletion (p=0.0001, p=0.0001 respectively).

Conclusion: The present study suggests that applying molecular investigation in oligozoospermia patients with increased serum levels for FSH and LH may be informative before using assisted reproductive treatments.

Pleiotropic effects of human Growth Hormone/Chorionic Somatomammotropin (hGH/CSH) genes on the fetal growth and maternal metabolism

J. Männik[1], *P. Vaas*[1,2,3], *K. Rull*[1,2,3], *P. Teesalu*[3], *M. Laan*[1];
[1]*Department of Biotechnology, University of Tartu, Tartu, Estonia,* [2]*Department of Obstetrics and Gynecology, University of Tartu, Tartu, Estonia,* [3]*Tartu University Hospital Womens's Clinic, Tartu, Estonia.*

The hGH/CSH locus at 17q22-24, consisting of a pituitary-expressed GH1 and four placenta-expressed genes GH2, CSH1, CSH2, and CSHL1, is implicated in regulation of postnatal and intrauterine growth, and in the maternal metabolic adaptation to pregnancy.

We hypothesized that the mRNA expression profiles, including alternative splice-products of placental hGH/CSH genes contribute to the determination of the birthweight and normal course of pregnancy. To address this question we developed a sensitive, fluorescently labeled semi-quantitative RT-PCR assay coupled with gene-specific restriction resolved on an ABI capillary electrophoresis. The detailed profile of alternative transcripts of GH2, CSH1, CSH2, and CSHL1 genes in placental samples of REPROMETA collection from uncomplicated term pregnancies was determined in association with the birthweight of newborns, grouped as appropriate-for-gestational-age (AGA; n=23), small-for-gestational-age (SGA; n=15), and large-for-gestational-age (LGA; n=34), and by maternal pregnancy-related conditions of pre-eclampsia (PE; n=17) and gestational diabetes mellitus (GD; n=11).

The majority of pregnancies with SGA newborn show down-regulation of the entire hGH/CSH cluster in placenta, while in case of LGA the expression of CSH1-1, CSH2-1 and CSHL1-4 mRNA transcripts in placenta is significantly increased compared to AGA newborns (P<0.0001, P=0.009, P=0.002, respectively) (Männik et al., 2010, J Clin Endocrinol Metab. 95:2433-42). Similarly, the entire hGH/CSH cluster shows reduced expression in placentas of PE compared to uncomplicated pregnancies. In case of GD, the individual genes in hGH/CSH cluster demonstrate differential expression pattern compared to uncomplicated pregnancies.

Our results show that the expression level of placental hGH/CSH genes correlates with fetal growth and may influence maternal metabolism.

P04.33
Clinical relevance of SF-1 (NR5A1) gene mutation screening in primary ovarian insufficiency

L. M. de With[1], *F. Janse*[1], *B. C. J. M. Fauser*[1], *C. B. Lambalk*[2], *J. S. E. Laven*[3], *A. J. Goverde*[1], *J. C. Giltay*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*VU MC, Amsterdam, Netherlands,* [3]*Erasmus MC, Rotterdam, Netherlands.*

Introduction: Steroidogenic Factor-1 (SF-1), encoded by the *NR5A1* gene, regulates the transcription of multiple genes associated with steroidogenesis, sexual development and reproduction. Recently *NR5A1* mutations were found to be associated with sporadic and familial primary ovarian insufficiency (POI). The high mutation rate in the previously published paper prompted us to further establish the significance of *NR5A1* mutations in a large cohort of women with POI.

Materials & Methods: In 2005 a nationwide phenotype and genotype study on POI was initiated in the Netherlands; all study cases were included for the current study. The entire coding region (exon 2-7) and splice sites of the *NR5A1* gene were PCR-amplified and sequenced. The pathogenicity of identified mutations was determined with splice site involvement, Align-GVGD class and Grantham scores.

Results: 383 Women with POI were included, 77 of them had a family history for POI. Adrenal dysfunction was excluded in all women. Five non conservative missense mutations (mutation rate 1.3%) in 3 sporadic and 2 familial cases of POI were found. Grantham variations were 29, 64, 98, 99, and 113. Splice sites were not involved. Align-GVGD classes ranged from C0 to C25, indicating low to intermediate pathogenicity.

Conclusions: The prevalence of *NR5A1* mutations in a large cohort of women with POI (1.3%) is lower than published previously. Furthermore, low to intermediate pathogenicity was predicted for these mutations. There seems to be limited value for the inclusion of SF-1 gene mutation screening in the diagnostic work-up for women with POI.

P04.34
The frequency of DNA- repair and cell cycle control polymorphisms and pregnancy

V. Lotnik, *E. Mashkina, T. Shkurat;*
Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian Federation.

Recently increasing attention is paid to the study of allelic polymorphism of genes related to gene regulatory network of pregnancy pathology. The aim of this work was to study the frequency of polymorphic genes of DNA-repair APEX 1 (APE 1) (Asp148Glu), XPD (Lys751Gln), XPG (Asp1104His), XRCC 1 (Arg194Trp), hOGG 1 (Ser326Cys) and cell cycle control CHEK 2 (1100delC) in women with physiological (control group) and pathological (miscarriage) pregnancy. The investigated material included samples of the endometrium (E), chorion (Ch) obtained after medical or spontaneous abortion, as well as blood (B), taken from the cubital vein.

In reviewing the study groups for the presence of a combination of several unfavorable genetic factors revealed that in women with recurrent miscarriages 3.1% (Ch), 3.7% (E) were simultaneously heterozygotes for five genes, which were not observed in the control group. Moreover, in the group with pathological pregnancy the number of heterozygotes for the four genes simultaneously increased: 18,7% (Ch), 18.5% (E) 5,9% (B) (5.9% (Ch), 16,7% (E) 0% (K) in the control group, respectively). It is important to note that in the group with the pathology of pregnancy 6.3% (Ch), 3.7% (E) were homozygous for polymorphic alleles of two genes simultaneously - APEX 1 and XPD, 13,6% (B) - homozygotes for polymorphic alleles of three genes simultaneously - APEX 1, XPD, hOGG 1.

Analyzing the data, it was found that the combination of certain genotypes in polymorphic loci of DNA-repair and cell cycle control genes may influence on susceptibility to reproductive pathology.

P04.35
Risk assessment of ART and its related factors in the development of Prader - Willi syndrome

K. Matsubara[1,2], *N. Murakami*[2], *S. Sakazume*[2], *Y. Ooto*[2], *T. Ogata*[1], *T. Nagai*[2];
[1]*National Research Institute for Child Health and Development, Tokyo, Japan,*
[2]*Dokkyo Medical University Koshigaya Hospital, Saitama, Japan.*

To examine whether assisted reproductive technology (ART) and its related factors can be a risk factor for the development of Prader-Willi syndrome (PWS), we studied 74 Japanese PWS patients who were born during the years 1997-2008 when statistical data on ART are available in Japan.

Of the 74 patients, seven were born after ART (six after ICSI and one after IVF). Molecular studies revealed underlying genetic causes in all patients, including the seven patients born after ART of whom two had deletion of the paternally derived 15q imprinted region and five had trisomy rescue type upd(15)mat (TR-upd(15)mat). The maternal ages at birth were increased in PWS patients conceived after ART (36-45 years), especially in those with TR-upd(15)mat (38-45 years), consistent with the notion that the advanced maternal age is a risk factor for the development of TR-upd(15)mat.

The frequency of births after ART was significantly higher in PWS patients than in the general population ($P=2.2\times10^{-9}$), even after adjusting maternal ages (≥35 years) ($P=5.4\times10^{-6}$). Among PWS patients, however, although the relative frequency of TR-upd(15) mat was significantly higher in patients conceived after ART than in those conceived naturally (P =0.008), it became non-significant after adjusting maternal ages (≥35 years) between the two groups (P=0.22). The results imply that ART and/or ART-related parental and environmental factors can be a risk factor for PWS in general. In addition, the relative predominance of TR-upd(15)mat in patients born after ART is primarily ascribed to an ART-related maternal age factor rather than ART itself.

P04.36
Laeverin expression and its role in invasion and migration of human trophoblast cells: Possible implications in the pathogenesis of preeclampsia

M. Nystad[1,2], *V. Sitras*[3], *M. Larsen*[4], *G. Acharya*[5,6];
[1]*Division of Child and Adolescent Health, Department of Medical Genetics, University Hospital of North Norway, Tromsø, Norway, TROMSOE, Norway,*
[2]*Women's Health and Perinatology Research Group, Department of Clinical Medicine, Faculty of Health Sciences, University of Tromsø, Norway, Tromsø, Norway,* [3]*Department of Obstetrics and Gynaecology, Akershus University Hospital, Lørenskog, Norway, Oslo, Norway,* [4]*Occupational and Environmental Medicine, University Hospital of North Norway, Tromsø, Norway, TROMSOE, Norway,* [5]*Women's Health and Perinatology Research Group, Department of Clinical Medicine, Faculty of Health Sciences, University of Tromsø, Norway, TROMSOE, Norway,* [6]*Department of Obstetrics and Gynaecology, University Hospital of North Norway, Tromsø, Norway, Tromsø, Norway.*

We reported previously that mRNA levels of laeverin, a membrane-bound aminopeptidase, are 10-fold up-regulated in placentas from severely preeclamptic women compared to their healthy controls. In the present study, using immunofluorescence of tissue sections and tissue arrays, we demonstrate a shift in laeverin protein expression from the cell membrane in healthy trophoblast to cytosol in preeclampsia. Electronmicroscopy indicated that laeverin is retained in the Golgi apparatus in preeclamptic placentas. Additionally, we tested the hypothesis that *laeverin* gene-silencing reduces the invasiveness of the cell line HTR-8/SVneo trophoblasts through a basement membrane-like matrix (Matrigel). Trophoblast invasion was reduced by 58% in *laeverin* knock-out cells compared to controls. Wound healing assay demonstrated reduced migration of trophoblast cell line transfected with siRNA against *laeverin*. We further performed gene expression profiling using RT2 Profiler TM PCR Array in order to find the molecular pathways that might be affected by *laeverin*-silencing. Among the 84 genes present on the array, three genes were significantly (>4-fold) down-regulated: *integrin alpha-2* (39-fold), *matrix metalloproteinase 1* (36-fold) and *integrin beta-3* (5-fold). In conclusion, laeverin is up-regulated in the preeclamptic placenta both at transcriptional and protein level. It appears to regulate trophoblast invasion by affecting cell adhesion molecules and degradation of the extracellular matrix and thus might have a role in the pathogenesis of preeclampsia.

P04.37
A simple approach for detecting novel short-tandem repeat (STR) markers for preimplantation genetic diagnosis

M. Malcov, *T. Frumkin, V. Gold, S. Peleg, D. Ben Yosef, N. Mey Raz, B. Almog, A. Amit, Y. Yaron;*
Racine IVF Unit, Department of Ob/Gyn, Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Tel Aviv, Israel.

Introduction: Misdiagnosis in PGD occurs mainly due to allele drop-out (ADO), but can be prevented by the use of flanking polymorphic markers (most commonly CA-repeats). The reliability of diagnosis depends on the number, heterozygosity and informativity of such markers. When database search yields insufficient results, it is essential to discover novel markers.

Aim: To describe a simple approach for detecting novel locus-specific polymorphic markers.

Material and Methods: To detect CA-repeats, we copy the sequence of interest spanning 1 Mb upstream and downstream from the mutation site into a MS Word file. Then we search this sequence using the Ctrl-F function for (CA)n or (TG)n, (where n>10). Such STRs will often be polymorphic. Primers are then designed for each site. A marker is considered informative when the CA repeat size is different among the various alleles in family members.

Results: Over the last 8 years we performed PGD for 65 different disease genes, using 545 flanking polymorphic markers. Of these, 344 (63.1%) were obtained using published data. However, for more than 20 disease genes, with insufficient informative markers, we were able to detect an additional 201 (36.9%) novel CA-repeats using this approach. More than 90% of these sites indeed proved to be polymorphic. This allowed the use of at least 4 informative markers for each case of PGD.

Conclusion **:** We demonstrated a simple approach for search of novel informative CA-repeats that allows maximizing accuracy in PGD and prevention of ADO. This approach is now routinely used in our PGD lab.

P04.38
Deduction of meiotic segregation patterns by pachytene shape analysis in PGD for translocation carriers

T. Frumkin, *M. Malcov, D. Ben Yosef, T. Schwartz, A. Carmon, F. Azem, B. Almog, A. Amit, Y. Yaron;*
Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

Introduction**:** In translocation carriers, meiosis produces different segregation variants. Most studies of segregation variant frequencies were obtained from observations of viable probands. PGD provides a unique insight into this phenomenon.
Aim**:** Deduction of meiotic segregation patterns as assessed in embryos of translocation carriers undergoing PGD.
M&M: Ninety PGD cycles were performed for 35 translocation carriers. Two blastomeres were aspirated from each embryo for FISH analysis. The resulting segregation variants were deduced. Observed frequencies of different segregants were compared to predicted frequencies, based on pachytene shape analysis, taking into account the length of the centric versus the translocated fragments**.**
Results: Overall 583 embryos were analyzed: 441 from reciprocal translocation carriers and 142 from Robertsonian translocations. In reciprocal translocations, alternate segregation (balanced) was seen in 23.1% of embryos, whereas most were unbalanced (adjacent-1 in 29.4%; adjacent-2 in 5.9%; 3:1 segregation in 25.6%; and 16% had other anomalies).The overall incidence of unbalanced embryos was 71.4%, but was significantly higher in reciprocal translocations. In most translocations, adjacent-2 segregation was rare, but when present, the rate of balanced gametes was lower. There was no significant difference in the rate of unbalanced embryos between female and male carriers. Finally, the distribution of segregation modes was predicted correctly in 82%.
Conclusions: Translocation carriers have a significantly high frequency of unbalanced embryos, more so among reciprocal translocation carriers. In PGD, the frequencies of the different segregation patterns can be predicted by pachytene shape analysis. Some translocations predispose to a higher rate of unbalanced gametes, as compared to others.

P04.39
Preimplantation genetic diagnosis for spinal muscular atrophy at the blastocyst stage

C. Hung[1,2], *S. Chen*[3], *S. Lin*[3,4], *C. Lee*[4], *Y. Su*[1,2,3];
[1]*Graduate Institute of Clinical Genomics, National Taiwan University College of Medicine, Taipei, Taiwan,* [2]*Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan,* [3]*Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan,* [4]*Department of Obstetrics and Gynecology, National Taiwan University Hospital, Taipei, Taiwan.*

Background: Approximately 94% of spinal muscular atrophy (SMA) cases are caused by common homozygous absence of the *SMN1* gene. Although preimplantation genetic diagnosis (PGD) is an alternative option for couples at risk of having a child with single gene disorder, blastomere biopsy has been employed in most *in vitro* fertilization procedures.
Methods: In the present study, we validated and applied protocol clinically for PGD through the use of blastocyst biopsy, whole genome amplification, mini-sequencing genotype coupling with genetic linkage of *SMN* gene involving three informative microsatellite markers, and thawed embryo transfer. We report data to identify the *SMN1* gene deletion on eighteen clinical embryos obtained from one participating couple, where both partners are heterozygous SMA carriers with 1-*SMN1*/3-*SMN2* genotypes.
Results: Approximately 78% (14/18) of blastocysts were successfully amplified in a single PGD cycle. Among these embryos, ten (72%, 10/14) were diagnosed as unaffected, two (14%, 2/14) as affected, and two embryos (14%, 2/14) had no conclusive diagnosis due to allele drop-out (ADO). Two unaffected embryos were thawed and transferred in the next cycle resulting in a singleton pregnancy, and the birth of a healthy girl who carries the 1-*SMN1*/3-*SMN2* genotype.
Conclusions: The strategy of PGD using blastocyst biopsy and thawed embryo transfer increased the reliability of the results and permitted more time for the execution of molecular diagnosis. The improved protocol for PGD could be adopted for other monogenic diseases in the future.

P04.40
Preimplantation genetic aneuploidy screening by fluorescent in situ hybridization

E. Karaca[1], *E. Tavmergen Göker*[2], *B. Durmaz*[1], *A. Akdogan*[2], *C. Gunduz*[3], *M. Bilgin*[2], *E. Tavmergen*[2], *F. Ozkinay*[1];
[1]*Ege University Faculty of Medicine,Department of Medical Genetics, izmir, Turkey,* [2]*Ege University Faculty of Medicine, Assisted Reproductive Techniques Unit of Department of Obstetrics and Gynecology, izmir, Turkey,* [3]*Ege University Faculty of Medicine,Department of Medical Biology, izmir, Turkey.*

Preimplantation genetic diagnosis (PGD) is a method used to identify genetic defects in embryos created through intracytoplasmic sperm injection (ICSI) or in vitro fertilization (IVF). Single gene defects, hereditary chromosomal disorders (especially couples with translocations carriers) and aneuploidy screening are the most frequent indications for PGD. The aim of the study is to evaluate the incidence of embryo aneuploidy and pregnancy outcome rates. Thirty-three ICSI/IVF patients with various indications who referred to Assisted Reproductive Techniques Unit of Department of Obstetrics and Gynecology were included in the study between 2008-2010 years. Biopsies are performed in their 3rd day embryos with 6-8 blastomers and aneuploidy screening was performed by fluorescent in situ hybridization (FISH) method on the same day. Aneuploidy screening for chromosomes 13, 16, 18, 21 and 22 were analyzed except low grade Turner mosaicism cases. In these cases X and Y chromosomes were analyzed instead of chromosomes 16 and 22. Blastomere biopsy was performed on 165 embryos, which had grade I or II quality. The indications for PGD were as follows; history of a recurrent implantation failure (no: 17, 51.5%), low grade Turner mosaicism (no: 10, 30%), recurrent abortion (no:5, 15%) and Klinefelter syndrome (no: 1, 3.5%). Embryo transfer was performed in 23 patients after PGD, chemical and clinical pregnancy rates were 3 (13%) and 8 (34%), respectively. In conclusion PGD seems to be an effective method in ICSI/IVF patients with chromosomal anomalies.

P04.41
Health of babies born after Preimplantation Genetic Diagnosis; results of a multi-centre retrospective study piloting a parental questionnaire

A. Lashwood[1], *T. Solomonides*[2], *M. Olive*[2], *G. Harton*[3], *C. Patch*[4], *F. Flinter*[1];
[1]*Centre for Preimplantation Genetic Diagnosis, Guy's Hospital, London, United Kingdom,* [2]*University West of England, Bristol, United Kingdom,* [3]*Reprogenetics, Livingston, NJ, United States,* [4]*Clinical Genetics, Guy's Hospital, London, United Kingdom.*

Follow up of babies born after preimplantation genetic diagnosis and screening (PGD/PGS) is recommended and international collaboration is required as the number of PGD babies born is low. A pilot parental postal questionnaire was developed to retrospectively collect information about treatment cycles, pregnancy, birth, longer term child health and development. An open source relational database was constructed using MySQL.
Six European PGD centres provided data on 401 deliveries; 112 PGD, 288 PGS cycles and one for both. Between December 1999 and October 2007 493 babies were born: 307(62.3%) singletons, 180 (36.5%) twins & 6(1.2%) triplets (2 not known). Mean birth weights were 3.17, 2.55 and 1.67kgs respectively. Eighty one percent of babies were born at ≥36 wks, 14.5% between 30-36 wks and 3.2% ≤ 30 wks gestation. Neonatal problems occurred in 129 babies (26%), 113 babies (22.9%) requiring special care. Nine abnormalities were recorded in 7 babies (1.42%) included tongue tie, cardiac anomalies, hip dysplasia, talipes, hypospadias & undescended testes. Since birth 378 (76.7%) babies were recorded as having no health problems.
The study allowed the development of standardised nomenclature for data capture which used in a web based format, could provide easy access to a wide demographic population for prospective data collection. The birth abnormality rate in this cohort is low at 1.42%. However 22.9% of PGD infants required special care and the incidence of health problems since birth was 23.3%. Further analysis of these health problems is required to determine major & minor rates.

P04.42
Ten years experience of prenatal diagnosis and preimplantation genetic diagnosis for Huntington disease in the Netherlands

M. C. Van Rij[1], *P. de Koning Gans*[2], *M. van Belzen*[3], *C. E. M. de Die*[1], *E. K. Bijlsma*[2], *J. P. M. Geraedts*[1];
[1]*Dept. Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands,* [2]*Dept. Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands,* [3]*Laboratory for Diagnostic Genome Analyses, Leiden University Medical Centre, Leiden, Netherlands.*

INTRODUCTION: In the Netherlands prenatal diagnosis (PND) for Huntington disease (HD) is available since 1987. Preimplantation genetic diagnosis (PGD) was first applied in 1999. For this study we surveyed all couples referred for PND and/or PGD for HD between 1996 and 2008.
METHODS: Information on couples' reproductive history, pregnancies with/without PND, PGD cycles, and follow up of all subsequent pregnancies was included until December 2010.
RESULTS: 184 couples were surveyed. For the first pregnancy 59% opted for PND, 14% started PGD, 13% had their first child untested, 11% refrained from PGD after intake and had no PND in subsequent pregnancies, 3% had a miscarriage. In 79.9% of couples one partner was a known carrier (61 males/86 females). In 20.1% one of the partners was at risk (26 males/11 females).
In subsequent pregnancies, 29 couples started PGD (24 after a history of PND and/or miscarriage). 22 couples secondarily underwent PND (19 after untested pregnancies, 3 after ≥1 PGD cycles). 68 couples applied for PND in ≥ 2 subsequent pregnancies.
In total 132 couples performed PND in 266 pregnancies (86% direct testing, 14% exclusion testing): more details will be provided.
PGD was performed in 51 couples (1 exclusion PGD): 123 cycles resulted in 25 deliveries (23 couples).
CONCLUSIONS: According to the alternating use of PND and PGD we conclude that couples reconsider their choices in every subsequent pregnancy based on their previous experience, personal beliefs, and probably time pressure.

P04.43
Preimplantation genetic diagnosis for chromosomal rearrangements: results of 2000 embryos

C. Beyazyurek, *C. Cinar Yapan, G. C. Ekmekci, H. Yelke, H. Karagozoglu, S. Kahraman;*
Reproductive Endocrinology and Genetics Laboratory, Istanbul, Turkey.

Preimplantation genetic diagnosis is a technique used to identify genetic defects in embryos created through in vitro fertilization (IVF) before transferring them to the uterus. Carriers of chromosomal rearrangements are one of the major group of patients who get benefit from this technique. Here we present our results for PGD performed for translocation and inversion carriers. From 2001 to 2011, 213 patients underwent PGD following 304 assited reproductive treatment (ART) cycles. 136 patients were carrying reciprocal translocation (RecT), 63 patients were carrying robertsonian translocation (RobT), 1 patient was carrying both reciprocal and robertsonian translocation, 1 patient was carrying a complex translocation and 12 patients were carrying inversions. Blastomeres or trophectoderm tissues were fixed with hypotonic solution/3:1 fixative method.Commercially supplied telomeric,locus specific and centromeric FISH probes were used. For cases done in years between 2007 and 2011, aneuploidy panel (13,16,18,21,22) was also included in the PGD study. From a total of 2000 biopsied embryos, 90% were diagnosed. For RecT carriers 197 cycles, for RobT carriers 90 cycles and for inversion carriers 14 cycles were performed. The clinical pregnancy rates were 36.8%, and 31.1% respectively. For RecT carriers 20.3% and for RobT carriers 34.7% of embryos were found to be normal or balanced. It was found that; the gender of the translocation carrier, maternal age and the type of the translocation affected the percentage of normal or balanced embryos. To date, 59 healthy babies have been born for translocation and inversion carriers.

P04.44
Preimplantation diagnosis of monogenic diseases in GENNET

M. Putzová, *I. Eliášová, I. Soldátová, V. Krutílková, A. Langerová, J. Míka, R. Křen, D. Stejskal;*
GENNET, s.r.o., Praha 7, Czech Republic.

In 2007 we completed the first in vitro fertilization cycle (IVF) followed by preimplantation genetic diagnostics (PGD) of cystic fibrosis. Since than, we have performed over 120 cycles with scheduled PGD for 43 different monogenic diseases. The list of diagnosis where we can offer PGD is being continually extended.
In our center we use genetic haplotyping technique by multiplex PCR technique on products of MDA (multiple displacement amplification) from 1 blastomere biopsied from the cleavage-stage embryo.
In rare cases of unambiguous results from the blastomere, analysis can be repeated from trofoectoderm and embryo is still managed to be transfer on the day 5. We have been working on expanding of PGD cases resolvable in our center. This year we successfully completed first cycle of male partner de-novo mutation case based on sperm-haplotyping analysis supplemented by proof of mutation by sequencing analysis.
Up to now, we have accomplished 120 IVF cycles with PGH. In average 7-8 embryos were biopsied in one IVF cycle, as preferably mild stimulation protocols were applied.
We completed accreditation of the method by ISO regulation 15189:2007 in 2009. We annually participate in EQA organized by UK NEQAS.
PGD represents an alternative within prenatal diagnosis services and so offers a chance for many couples in risk of genetic disease to have a healthy baby and to avoid the risk termination of the pregnancy from genetic reasons or birth of affected child. Currently available PGD technology can help eliminate some genetic diseases in the future.

P04.45
PRM1 and PRM2 gene polymorphisms in Czech men with idiopathic oligozoospermia, normozoospermic men and men with proven fertility

P. Křenková[1], *F. Tüttelmann*[2], *P. Paulasová*[1], *J. Diblík*[1], *M. Macek jr.*[1], ***M. Macek sr.***[1];
[1]*Department of Biology and Medical Genetics, University Hospital Motol, Prague, Czech Republic,* [2]*Institute of Human Genetics, University of Münster, Münster, Germany.*

The most frequent ACC haplotype formed by PRM1 230A>C and PRM2 298G>C/373C>A variants was associated with increased sperm counts in German males [1]. The aim of our study was to verify this impact on spermatogenesis in Czech males with idiopathic oligozoospermia.
PRM1 and PRM2 sequencing was performed on 3130xl Genetic Analyzer in 52 men with idiopathic oligozoospermia, in 52 normozoospermic and in 75 males with proven fertility.
In PRM1 we detected one common variant (230A>C) with an overall minor allele frequency (MAF) of 28.5% and three rare variants (c.54G>A, c.102G>T and c.166C>T) with overall frequencies of 0.56%, 0.28% and 0.28%, respectively. In PRM2 we detected two common polymorphisms (298G>C and 373C>A) with overall MAFs of 49.1% and 29.3%, respectively, and two rare variants (c.201C>T, c.377C>T), both with overall frequencies of 0.28%.
The prevalence of all detected variants and the ACC haplotype between men with idiopathic oligozoospermia and controls was not significantly different. The rare protamine gene variants are also not directly related to disorders of spermiogenesis in Czech males as previously described in German males [1]. In contrast, we have not confirmed any relationship of the ACC haplotype with sperm concentration. Our results indicate that the impact of PRM1 and PRM2 gene variants on increased sperm counts is dependent on population genetic background and/or epigenetic impacts of different environment and lifestyle factors.
Supported by MZ0FNM2005.

Preimplantation Genetic Diagnosis in female and male carriers of Reciprocal Translocations: clinical outcome of 312 cycles.

K. Keymolen[1], *C. Staessen*[1], *W. Verpoest*[2], *M. Bonduelle*[1], *I. Liebaers*[1];
[1]*Centre for Medical Genetics, UZ Brussel, Brussels, Belgium,* [2]*Centre for Reproductive Medicine, Brussels, Belgium.*

Introduction: Carriers of Reciprocal Translocations (RecT) are at risk for reproductive problems. For some carrier couples Preimplantation Genetic Diagnosis (PGD) could be an option to fulfil their child wish.
In this study we retrospectively analyse the results of PGD for RecT at our centre.
Materials and methods: An observational study was performed of all cycles for PGD for RecT at a tertiary referral centre between January 1997 and December 2007.
Data on patient characteristics and cycle outcomes were registered.
Results: During a period of 11 years 312 PGD cycles were performed for 69 male and 73 female carriers of RecT. The mean female age was 32.8years, the mean male age 35.8 years. Most carriers were diagnosed with a translocation because of fertility problems or recurrent miscarriages and most of them opted for PGD to avoid these problems.
In 150 of the 312 cycles, embryo transfer was feasible and 40 women delivered a healthy singleton or twin. This gives a live birth delivery rate of 12.8% per started cycle and of 26.7% per cycle with embryo transfer.
Conclusion: Due to the large number of abnormal embryos, PGD cycles for RecT often lead to cancellation of embryo transfer, explaining the low success rate when expressed per cycle with oocyte pick-up.
Once embryo transfer was feasible, the live birth delivery rate was similar to that of PGD in general at our centre.
PGD is therefore an established option for specific RecT carriers and its availability should be discussed during reproductive counseling.

P04.47
Multiple epimutations of imprinting genes in early pregnancy loss

E. A. Sazhenova, *I. N. Lebedev;*
Institute of Medical Genetics, Tomsk, Russian Federation.

Genomic imprinting plays a critical role in regulation of fetal development. Previously we have reported a tissue-specific loss of methylation in KCNQ1OT1 and PLAGL1 in 9.5% and 10.3% spontaneous abortions, respectively. The aim of the present research was identify DNA methylation levels of 115 differentially methylated sites of 52 imprinting genes in samples of first-trimester spontaneous abortions using GoldenGate Methylation Cancer Panel I (Illumina, USA). We have analyzed cytotrophoblast (CT) and extraembryonic mesoderm (EM) from 13 first-trimester spontaneous abortions (8.3±1.8 weeks) with normal karyotype and 4 induced abortions (7.8±0.7 weeks) as a control group. Fourteen (27%) imprinting genes have revealed abnormal methylation in most miscarriages. Eight of these genes (PEG10, GRB10, CPA4, PHLDA2, WT1, ZNF215, HTR2A, GABRB3) were hypomethylated, whereas 6 genes (DCN, TRPM5, H19, INS, GABRA5, PWCR1) were hypermethylated. Significantly, epimutations were found in both tissues (22%) or confined by EM (65%) or CT (13%). Presence of hypomethylation in both tissues indicates reprogramming errors in the primordial germ cells during gametogenesis or at early stages of preimplantation development. The hypermethylation of imprinted genes in both tissues can be a result of reprogramming errors during gametogenesis. Whereas, tissue-specific epimutations allows suggesting independent sporadic epigenetic errors in imprinting maintenance in derivates of various embryonic germ layers after its divergence. Our results provide first evidence for the multiple germinative and somatic epimutations of CpGs within imprinting genes, which can be responsible for the dysfunction of imprinted loci during early embryo development. This study was supported by Federal Program (contracts P303 and P806).

P04.48
Locus copy number variation (CNV) may contribute to recurrent miscarriage

L. Kasak, *L. Nagirnaja, P. Palta, K. Rull, M. Remm, M. Laan;*
Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, Tartu, Estonia.

Recurrent miscarriage (RM; ≥3 miscarriages) is a heterogeneous condition occurring in 1-2% of fertile couples. Despite a wide spectrum of known causes and mechanisms leading to RM (disruptions of thrombophilic, immunologic or endocrine pathways), 50% of the cases are defined as idiopathic. The aims of the current study were (1) to explore whether gene copy number variations (CNV) may contribute to inheritable predisposition to RM, and (2) to identify novel loci involved in establishing a successful pregnancy and to provide new insights into the mechanism of RM.
In total, 73 Estonian samples (43 RM patients and 30 fertile) were analyzed on Illumina Infinum genome-wide genotyping platform. In order to predict the presence of a CNV, two algorithms (PennCNV and QuantiSNP) were used in parallel to analyze the genome-wide data. For twelve genomic loci number of gene copies in each discovery individual (n=73) was experimentally validated by TaqMan qPCR. Six validated CNV regions were selected for the replication experiment in an independent sample (Estonians; n=119 RM patients and n=128 controls).
In the Estonian discovery and replication samples, three tested rare CNVs (MAF <10%, 25-52 kb) showed concordant allele frequency differences between cases and controls. Two of these CNVs cover loci, which have been previously shown to function in the establishment of a successful pregnancy - regulation of trophoblast invasiveness or immunological response. In order to confirm the impact of the identified CNVs in susceptibility to recurrent pregnancy loss, experiments for the replication of these initial findings in other populations are ongoing.

P04.49
Diagnostic value of a-CGH method for recurrent miscarriage and implantation failures

R. Akkoyunlu, *B. Enguzel, N. Cine, D. Sunnetci, N. Uzulmez, S. Eren, E. Gumuslu, Z. Ilkay, D. Yavuz, H. Savli;*
Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.

INTRODUCTION: Endometrial and tubular problems, defective embryo, genetic factors and environmental impacts are among the reasons for recurrent miscarriages and implantation failures. A-CGH is a new method to investigate these impacts.A-CGH can detect chromosomal abnormalities in a reliable way and this technology compares the copy number of segments in two different genomes.
MATERIAL AND METHOD: Whole genome scan was performed on 50 patients admitted to Kocaeli University Medical Genetics Laboratory with the prediagnosis of recurrent miscarriage and implantation failure. DNA of the patient was hybridized on 4x44K microchips as per the protocol. Microarray scanner (Agilent Microarray Scanner; Agilent Technologies, Palo Alto, CA) was used for scanning. The data was pooled in Agilent Feature Extraction software and normalized using CytoSure Analysis Software v.2.0.8.
RESULTS: In our study, various genetic aberrations were observed in 4 patients out of 50 who underwent whole genome scan with a-CGH method. Array-CGH results are as follows: in Xp22.31 region deletion of 1.5 Mb; and the following duplications were detected: in 17q12 region 1.383 Mb, in 20p12.3 region 1.37 Mb, between the bands 4q12 570 Kb.
CONCLUSION: Conventional cytogenetic methods help by 5-8% and a-CGH method helps by 10% in the diagnosis of recurrent miscarriage and implantation failures. A-CGH technology could be a new diagnostic opportunity to screen recurrent miscarriage and implantation failures.

P04.50
Recurrent Pregnancy Loss and Its Relation to Combined Parental Thrombophilic Gene Mutations

O. Ozdemir[1], *G. I. Yenicesu*[2], *F. Sılan*[1], *M. Cetin*[2], *B. Koksal*[2], *S. Atik*[1], *F. Ozen*[2], *M. Gol*[1], *A. Cetin*[2];
[1]*Faculty of Medicine, Canakkale, Turkey,* [2]*Faculty of Medicine, Sivas, Turkey.*

Background and Aim: Recurrent pregnancy loss (RPL) is a heterogeneous disorder that has been associated with antiphospholipid

syndrome and other prothombotic parameters. The contribution of specific thrombophilic genes to the pathophysiology of RPL has remained controversial. We aimed to investigate the prevalences of 12 thrombophilic gene mutations in RPL couples in the current results. ***Method*** :In the current prospective case-control study, in a total of 543 Turkish women with RPL and 327 of their male partners (870 individuals with RPL) , and a control group of 106 fertile couples (control) were analyzed for FV Leiden, factor V H1299R, factor II prothrombin G20210A, F XIII V34L, β-fibrinogen −455G>A, plasminogen activator inhibitor-1, GPIIIa L33P (HPA-1 a/b L33P), MTHFR C677T, MTHFR A1298C, ACE I/D, Apo B R3500Q, and Apo E genes.***Results:*** The overall, heterozygous and/or homozygous point mutations in FV Leiden - FVR2, ApoE2, PAI-1, MTHFR C677T - A1298C and ACE genes were associated with RPL. There was no meaningful association between RPL and other studied genes. ***Conclusion:*** In contrast to the other point mutations and polymorphisms, the homozygosity of 4G in PAI-1 and MTHFR C677T genes in women with recurrent pregnancy loss, and heterozygosity of FV Leiden, FVR2, ACE, ApoE2 genes in both parents play crucial role in RPL and should be considered as a risk factor in RPL. Current results showed that RPL is related to combined parental (not only maternal) thrombophilic gene mutations.

P04.51
Polymorphisms in the annexin A5 gene promoter in Japanese women with recurrent pregnancy loss

H. Kurahashi[1], *H. Miyamura*[1], *H. Nishizawa*[2], *S. Ota*[1], *M. Suzuki*[1], *A. Inagaki*[1], *H. Egusa*[1], *S. Nishiyama*[1], *T. Kato*[1], *K. Pryor-Koishi*[2], *I. Nakanishi*[3], *T. Fujita*[3], *Y. Imayoshi*[3], *R. Negi*[4], *A. Markoff*[5], *I. Yanagihara*[3], *Y. Udagawa*[2];
[1]*ICMS, Fujita Health University, Toyoake, Aichi, Japan,* [2]*Fujita Health University School of Medicine, Toyoake, Aichi, Japan,* [3]*Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Osaka, Japan,* [4]*National Cerebral and Cardiovascular Center, Suita, Osaka, Japan,* [5]*Institute of Medical Biochemistry, Center for Molecular Biology of Inflammation, University of Muenster, Muenster, Germany.*

Recent findings have raised the possibility that polymorphisms within the annexin A5 gene (*ANXA5*) promoter contribute to the etiology of recurrent pregnancy loss (RPL). In our present study, 243 Japanese women who had suffered more than three fetal losses and a group of 119 fertile controls were genotyped for four *ANXA5* gene promoter SNPs (SNP1-4: g.-467G>A, g.-448A>C, g.-422T>C, g.-373G>A) previously reported to be associated with this disorder. Additional two SNPs located within the 5'-untranslated region of the *ANXA5* (SNP5 and 6: g-302T>G, g.-1C>T) were also evaluated. Our case-control study revealed that the minor allele was significantly frequent in the RPL group for all six of these SNPs, among which SNP5 showed the highest significance (*P*=0.002). As with the M2 haplotype for SNP1-4 (A-C-C-A) suggested for a western population in previous reports, a haplotype comprising all of the minor alleles for SNP1-6 (A-C-C-A-G-T), the third major haplotype in the Japanese population, showed a significant frequency in our current RPL subjects (*P*=0.025). In addition, the second major haplotype (G-A-T-G-G-C) was also found to confer a significant risk of RPL (*P*=0.036), implicating SNP5 as a major risk determinant for this disease. Our present findings support the hypothesis that genomic variations within the *ANXA5* gene upstream region impact upon the disease susceptibility to RPL. Our data also indicate that SNP5 is a novel risk factor for this disease in the Japanese population.

P04.52
Cytogenetic, Y chromosome microdeletion, and sperm DNA integrity analysis in male partners of couples experiencing recurrent spontaneous abortions

S. Venkatesh[1], *K. Kumar*[1], *J. Thilagavathi*[1], *D. Deka*[2], *P. Talwar*[3], *R. Dada*[1];
[1]*Lab for Mol. Reprod and Genetics, Department of Anatomy, All India Institute of Medical Sciences, New Delhi, India,* [2]*Department of Obsetrics and Gynecology, All India Institute of Medical Sciences, New Delhi, India,* [3]*ART Centre, R & R Hospital, New Delhi, India.*

Couples experiencing recurrent spontaneous abortions (RSA) undergo severe physical and emotional stress, where the aetiology in majority of (60%) cases is still unknown. The aim of the study was to find the role of cytogenetic, Y chromosome microdeletion, and sperm DNA fragmentation in male partners of couples experiencing RSA. Forty eight couples with history of RSA and 20 fertile controls were included in the study. The study subjects were divided into male partners of RSA couples with abnormal sperm parameters (SA) (N= 16), male partners of RSA couples with normal sperm parameters (NS) (N=32) and age matched fertile controls with normal sperm parameters (FC) (N=20). Semen analysis, Karyotyping and Y chromosome microdeletion analysis were carried out as per standard protocol. Sperm DNA damage was measured by flow cytometry and expressed as DNA fragmentation index (DFI). One of 48 RSA men (2%) showed 46, XY (1qh-) chromosomal complement. None of the subject showed Yq deletions. Sperm count was found be significantly lower in SA cases compared to group NS cases ($p<0.0001$) and FC ($p<0.005$). Male partners of RSA couples with abnormal and normal sperm parameters had higher sperm DNA damage ($P<0.0001$). Other than chromosomal anomalies, sperm DNA fragmentation may be the underlying pathology in RSA, thus screening for DNA fragmentation has diagnostic capabilities. However, Yq microdeletion screening in male partners of RSA couples has no diagnostic or prognostic value.

P04.53
Paternal factors: sperm oxidative stress and DNA damage in idiopathic recurrent spontaneous abortions

K. Kishlay, *S. Venkatesh, M. B. Shamsi, D. Deka, R. Dada;*
All India Institute of Medical Sciences, New Delhi, India.

Aim: The most common problem in couples attempting pregnancy is recurrent spontaneous abortions (RSA). In majority of the couples experiencing RSA, the causes are unknown. This study was planned to analyze seminal oxidative stress (OS) as well as the level of DNA damage of sperm in couples with history of idiopathic RSA.
Materials and Methods: Twenty two (22) couples experienced RSA and 30 fertile controls were included in the study. OS were evaluated by assessing ROS levels in the semen by chemiluminescence assay and were expressed as RLU/min/20 million sperm. For analysis of the DNA fragmentation, SCSA (Sperm chromatin structure assay) was used as it delivers a highly accurate measure of fertility potential.
Results: RSA and control groups did not show any significant differences in the sperm parameters. However, the mean seminal reactive oxygen species levels were found to be significantly higher in RSA group as compared to controls (12629.23 ± 3245.12 Vs 2535.55 ± 135.24). Fourty percent (40%) of RSA group had higher ROS levels (>2535.55) as compared to controls. Sperm DFI in patients was 32.88±7.41% as compared to 22.50±2.8% in controls.
Conclusion: Thus seminal oxidative stress and sperm DNA fragmentation may be one of the causes for unexplained RSA. Thus DFI (DNA fragmentation index) and OS could be a good clinical prognostic marker and helps to predict outcomes of both assisted and spontaneous conceptions. Treatment with antioxidant can reduce ROS levels and after 3-6 months result in significant decline in sperm DNA damage.

P04.54
Habitual abortion and *de novo* 2q37 deletion

A. K. Eek[1], *K. O. Clausen*[1], *K. E. Klovning*[2], *G. J. Braathen*[1,3];
[1]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Department of Gynecology, Telemark Hospital, Skien, Norway,* [3]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway.*

Background. Habitual abortion or recurrent miscarriage is the occurrence of three or more pregnancies ending in miscarriage, usually before 20 weeks of gestation. Miscarriages frequently occur in the population.
Methods. We describe a couple with recurrent miscarriages and the genetic analyses of placental material from their last spontaneous abortion in first trimester.
Results. Array Comparative Genomic Hybridization (aCGH) identified a *de novo* 2q37 deletion.
Conclusions. The identified mutation and the deleted genes may broaden the clinical spectrum around abortions. ACGH may be the investigation of choice rather than ordinary chromosomal investigations since it is difficult to culture cells from aborted material.

P04.55
Recombination hotspots and preimplantation genetic haplotyping for sickle cell anaemia

***H. Patel**, C. Ogilvie, Y. Khalaf, P. Renwick;*
Guy's Hospital, London, United Kingdom.

Preimplantation genetic haplotyping (PGH) involves amplification of the whole genome from a single blastomere followed by haplotyping. PGH requires sufficient fully-informative STR markers in close proximity to the gene of interest for any given couple.
Sickle cell anaemia (SCA) is caused by specific mutations in the HBB gene (mainly HbS or HbC). Our experience with PGH for SCA using STR markers indicates that recombination hot spots close to the gene reduce the number of transferable embryos available, due to recombinant haplotypes, which may or may not carry the mutation. The distance between the recombination hotspot and the common mutation is ~30kb; informative markers within this region are therefore necessary in order to diagnose mutation status in all recombinant embryos. Alternatively, identification of a common haplotype harbouring the mutation could be informative for diagnosis.
Novel STRs and SNPs were identified across the region; however, none were found within the 30kb region of interest. Following testing of DNA from 36 members of SCA families and 28 MDA products of single cells from embryos using these SNPs and STRs, a common mutation-carrying HbS haplotype was observed in 9/10 cases. The single exception found means that this approach is unsuitable for definitive PGH diagnosis. An ARMS test was therefore designed for unique identification of HbA, HbS and HbC alleles; this test is now used when a recombination event is observed, for direct determination of the mutation status of the embryo.

P04.56
Spontaneous abortions: "Split's protocol" for successful next pregnancy

***V. Culic**[1], J. Pavelic[2], S. Miskovic[1];*
[1]Pediatric Clinic, Departement for Medical Genetics, 21 000 Split, Croatia, [2]Institute Rudjer Boskovic, Zagreb, 10 000 Zagreb, Croatia.

During the last 17 years 534 couples attended Genetic Counseling Unit, Split, Croatia asking for genetic counseling due to the repeated spontaneous abortions (RSA). The couples expect the information about the risk for having a live-born child with potentially serious anomalies, as well as the risk for future miscarriage. Therefore, the objectives of this retrospective case-control study were to find the possible reason(s) for RSA in chromosomally normal parents. Our hypothesis is that the RSA is caused by two hits. The first one is familiar predisposition, while the second is chronic infections. To validate this hypothesis we analyzed the data obtained from couple's medical history and pedigree analysis such as a) personal life-style and habits, b) existence of former urinary and/or genital infections in both partners and their relatives in a first, second and third generation; c) earlier spontaneous abortions (SA), stillborns, other illnesses of both parents and their family members d) SA among the siblings of second generation, e) serological results for EBV, CMV, HSV1/2 and for other viral or protozoa infections, as well as reactivation of latent EBV infection, as well as f) pathohystological status of aborted material, g) former or present urinary and/or genital infection in both partners, h) iron and feritine values. The data confirmed the proposed "two hits" theory for RSA. Based on this "Split protocol" for successful next pregnancy is suggested.

P04.57
Thrombophilic mutations among woman with spontaneous abortions

***S. Madjunkova**, G. D. Efremov, D. Plaseska-Karanfilska;*
Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of.

Inherited thrombophilia as a genetic risk factor for thrombosis has been implicated in etiology of spontaneous abortions and may contribute to adverse pregnancy outcomes. Maternal thrombophilia augment thrombotic tendency of pregnancy leading to impaired implantation and placentation of the embryo. To determine the association of specific inherited thrombophilias and spontaneous abortions, 10 gene mutations (Factor V Leiden G1691A, Factor V A1299G, Factor II G20210A, Factor XIII G34C, PAI-I -675 4G/5G, FG-ß -455G/A, MTHFR C677T, MTHFR A1298C, MTR A2756G and MTRR A66G) were investigated using multiplex SNaPshot analysis and separation of the fragments by capillary electrophoresis. The prevalence of these thrombophilic markers was studied in 95 women with history of fetal loss (40 of Macedonian and 55 of Albanian ethnicity) and 72 matched fertile controls (37 of Macedonian and 35 of Albanian ethnicity) . Genotype and allele frequencies of the studied mutations were not statistically different between patients and controls and between the two ethnic groups. However, we found higher percentage of thrombophilic mutations in patients than in controls although statistically not significant (≥3 mutations: 92.6% vs. 84.7%, ≥4 mutations: 74.7% vs 69.4%, ≥5 mutations: 52.6% vs 43.1%, ≥6 mutations: 25.3% vs 18.1%, ≥7 mutations: 13.7 vs 8.3%, respectively). These results indicate that thrombophilia might contribute to etiology of spontaneous abortions.

P04.58
Chromosome 21 Copy Number Analysis in Sperm

***E. Iwarsson**[1,2], U. Kvist[3], M. A. Hultén[1,4];*
[1]Dept of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Dept of Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden, [3]Centre for Andrology and Sexual Medicine, Karolinska University Hospital, Stockholm, Sweden, [4]Warwick Medical School, University of Warwick, Coventry, Sweden.

The mechanism(s) underlying the low paternal origin of trisomy 21 Down syndrome (less than 10%) is/are still unknown. We have previously suggested that the common maternal origin of trisomy 21 Down syndrome is due to foetal ovarian mosaicism (Hultén et al 2008). In contrast, foetal testicular mosaicism does not seem a likely reason for the rare cases of paternal origin (Hultén et al 2010a; review in Hultén et al 2010b). In order to get to grips with the paternal origin we have now initiated FISH studies to record the copy number of chromosome 21 at various stages of spermatogenesis. We here present the initial data on the chromosome 21 copy number by FISH analysis of spermatozoa from a sample of 5 men with normal spermiograms. It is well known that both false positive and false negative results may be common, when applying a single chromosome-specific probe. We have therefore in this study (as in the previous) applied two 21q probes (Vysis 21q22 and Cytocell 21qtel) and a control chromosome 18 probe for the identification of the copy number of chromosome 21. The disomy frequency was found to be on average 0, 11%, with a range of variation at 0,00 - 0,25% by analysis of 2000 spermatozoa per case. To our knowledge this is the first FISH study using two rather than a single probe for the estimation of the copy number of chromosome 21 in spermatozoa from a control population of men with normal spermatogenesis.

P04.59
The choice of spouse and social homogamy in the Region of Sidi El Kamel (West of Morocco)

***M. Latifi**, L. Sbii, H. Hami, R. Hmimou, A. Soulaymani, A. Mokhtari;*
Laboratoire de Génétique et Biométrie, Kenitra, Morocco.

Genes circulate throughout society according to the dynamics established by the types of encounters and associations between individuals who carry these genes.The choice of spouse influences the genetic structure of the family and guides the evolution of the gene pool of the population.
The objective of this work is to study two modes of assortative mating: educational homogamy and homogamy social and professional.
Our study is a prospective study, between January and June 2008, included 490 families in the region of Sidi El Kamel.
The results of this study show quite marked homogamous behavior.
The frequency of consanguineous marriages decreased over the generations, but the decline in the practice marriage is still very low.

J04.01
Chromosomal abnormalities in couples with recurrent abortions and stillborn malformed child

***A. Mitroi**[1], I. Dimofte[2], M. Aschie[2];*
[1]Clinical Emergency County Hospital, Constanta, Romania, [2]Ovidius University, Constanta, Romania.

Cytogenetics studies have an important role in the evaluation of couples with history of recurrent abortions and stillborn malformed child. In order to estimate the frequency of chromosomal abnormalities

in the couples with this kind of reproductive failure we performed a study on 81 couples (162 patients) whose kariotype was established on GTG-banding metaphases from peripheral blood lymphocytes cultures using standard methods.
The frequency of chromosomal abnormalities on our studied patients was 4.32%. The affected partner was female in 4.93% of cases and male in 2.47% of cases. All of the chromosomal abnormalities observed were translocations: four were reciprocal translocations and three were Robertsonian translocations. In addition 6 patients presented structural variants referred as heteromorphic.
Chromosomal analyses are necessary for establishing the etiology and an appropriate recurrence risk in the couples with recurrent abortions and stillborn malformed child.

Carrier woman with a duplication of MECP2 gene - case report

F. M. NEDELEA[1], *D. Iancu*[2], *B. C. Iancu*[2], *E. Neagu*[2], *V. Plaiasu*[3], *L. Turculet*[1], *G. Tona*[1], *M. Bari*[1], *A. Stana*[1], *L. Barbarii*[2], *G. Peltecu*[1];
[1]*Clinical Hospital Filantropia, Bucharest, Romania,* [2]*INML Mina Minovici, Bucharest, Romania,* [3]*IOMC Alfred Rusescu, Bucharest, Romania.*

Mutations in the MECP2 (Methyl-CpG-binding protein 2) gene are responsible for neurodevelopmental disorders like Rett syndrome, mental retardation or severe neonatal encephalopathy. Whole gene duplication along with several other neighbour genes can cause Lubs X-linked mental retardation syndrome (MIM ID #300260) in males. Carrier females may be asymptomatic due to a skewd X inactivation or may have related clinical findings.
We report a case of a woman with mild dysmorphic features as short stature and brachicephaly and negative family history who delivered a Down syndrome afected child, who died few hours after birth. The karyotype performed in order to exclude a chromosomal translocation in the mother, was normal. MLPA testing for the presence of a microdeletion syndrome showed duplication of the MECP2 gene.
Further tests are currently performed in order to better characterize the limits of the genetic defect and to check for its presence in other family members. Prenatal diagnosis is recomanded in a future pregnancy.

J04.03
Evaluation of Abnormal Recombinant Frequency between Chromosomes X and Y in Sperm Nuclei of Patients with Structural Chromosome Aberrations

H. Acar[1], *Z. B. Bulut*[1], *M. Kılınç*[2];
[1]*Department of Medical Genetics, Selcuk University, Selçuklu Medical Faculty,, Konya, Turkey,* [2]*Department of Urology, Selcuk University, Meram Medical Faculty,, Konya, Turkey.*

Meiosis reduces the chromosome complement by half to generate haploid gametes to allow for genome doubling at fertilization in sexually reproducing organisms. During meiosis, homologous chromosomes undergo pairing, synapsis, recombination, and faithful segregation. In male, sex chromosome recombination behaviors are fundamentally different from female meiosis. Recombination between chromosomes X and Y is normally restricted to the pseudoautosomal regions located at both ends of the sex chromosomes. An obligate crossover in the pseudoautosomal region (PAR1) during male meiosis seems to be necessary for male fertility. Defects in meiosis are a leading cause of both infertility and birth defects (trisomy and monosomy) in humans. In the present study, abnormal recombination frequency between chromosome X and chromosome Y was estimated in sperm nuclei of patients with structural chromosome aberrations such as reciprocal, Robertsonian translocations and other structural changes by using FISH technique. We report herein our results on the incidence of abnormal recombinant products in sperm nuclei as related to structural chromosome aberrations.
This study was supported by Selcuk University Research Fund (No:09102001).

Polymorphism of genes and pregnancy loss

E. Mashkina[1], *K. Kovalenko*[1], *N. Fomina*[1], *A. Rimashevsky*[2], *T. Shkurat*[1];
[1]*Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian Federation,* [2]*Medical University, Rostov-on-Don, Russian Federation.*

The genetic factors are leading to pregnancy loss, especially in the early stages. It is established that the syndrome of fetal loss is caused not only by chromosomal mutations, but also polymorphism of some genes. These genes can be divided into several functional groups. The purpose of this study was to investigate the polymorphism frequency of some genes (coagulation factors genes and folate cycle protein genes) in women of two groups: a control group and women with the pregnancy loss (8 - 12 week of pregnancy). Placentas were obtained from women with informed consent. The frequencies of gene polymorphisms (C807T ITGA2, -675 5G/4G PAI1, Ala222Val MTHFR, Ile22Met MTRR, Asp919Gly MTR) in control group and among women with pregnancy loss are identical. The combined analysis of genotypes also did not show difference among two groups of women.

J04.05
Polymorphic variants on chromosomes in infertile couples.

V. Radoi;
Life Memorial Hospital, Bucharest, Romania.

Cytogenetic heteromorphisms are described as heritable variations at specific chromosomal regions without a proven impact on phenotype.Reproductive failure represent a problem for many couples.We have studied the heterochromatic region polymorphism and pericentric inversions in infertile couple (recurrent abortions or primary infertility).
Cytogenetic heteromorphisms are described as heritable variations at specific chromosomal regions without a proven impact on phenotype.Reproductive failure represent a problem for many couples.We have studied the heterochromatic region polymorphism and pericentric inversions in infertile couple (recurrent abortions or primary infertility).
Heteromorphisms of chromosome 9 are among the most common variations in the human karyotype(1-3%). The pericentromeric polymorphisms of chromosome 9 include variations in the size of q-arm heterochromatin, pericentric inversions, and rarely, additional C-band-negative, G-band-positive material. Heteromorphism of heterochromatic regions of chromosome 1,9,16 is also frequent polymorphic variant.
In this study we compared the presence of chromosome heteromorphisms in the karyotypes of two patient groups. The first group of patients consisted of 248 individuals of 124 infertile couples attending an our IVF department with primary infertility or recurrent miscariages. The second group, consisted of 530 amniocentesis samples (for abnormal serum screening). This group was considered to be a sample of the fertile population (spontaneous pregnancy).
Results: 21 individuals (8,46%) and 11 fetuses (2.07%) were found to have chromosome heteromorphisms.
Conclusions: It is suggested that variants should not be ignored by cytogeneticists. Screening prospective gamete donors for chromosome variants may help enhance the success of IVF.

Y chromosome evaluation in spontaneous abortion cases

G. Koc[1], *K. Ulucan*[1], *D. Kirac*[2], *D. Ergec*[3], *T. Tarcan*[4], *A. I. Guney*[1];
[1]*Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey,* [2]*Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [3]*Yeni Yuzyil University, Faculty of Art and Science, Department of Molecular Biology and Genetics, Istanbul, Turkey,* [4]*Marmara University, Faculty of Medicine, Department of Urology, Istanbul, Turkey.*

Introduction: In gestation before the 22nd week of duration, spontaneous abortion (SAB) is the expulsion of an embryo or fetus due to accidental trauma or natural causes. It is one of the most common adverse pregnancy outcomes, affecting up to 15% clinically recognized pregnancies. Etiology of SAB has been tried to be explained by lots of studies however the results are still controversial. In these researches, chromosomal anomalies and Y-micro deletions are considered to be the main reason of SAB, except the advanced maternal age and teratogenic factors. Primarily, cytogenetic evaluation was performed from peripheral blood samples of the couples in spontaneous abortion cases. Additionally, the frequency of Y-micro deletions of these patients and the same control group was examined.
Material-Methods: 30 women who had at least two spontaneous abortions and their husbands were karyotyped to detect the chromosome anomalies. Conventional karyotyping from peripheral blood samples with Giemsa staining was applied. Deletion Detection Kit (Promega- USA) was used for Y-microdeletion analyses.
Results: All the women were 46, XX and the men were 46, XY. No Y-microdeletion was detected in AZFa, AZFb and AZFc regions.
Conclusion: Environmental and genetic factors seem to play combinational roles in the etiology of SAB. In our study we couldn't

detect any causative results in patients. More studies including the teratogenic and genetic factors with high sample number need to be carried out to have an informative knowledge in the etiology of SAB.

Genetics staffs role at maternity ward

Y. GOTO[1,2], A. KONDO[1,2], Y. ONUKI[2], H. MORIYA[2], K. TSUJI[2], H. YOKOYAMA[2], T. MATSUMOTO[1,2], M. MIZOGUCHI[2], S. IZUMI[1,2];
[1]Dept. of Obstetrics and Gynecology, Tokai University Hospital, Kanagawa, Japan, [2]Dept. of Genetics, Tokai University Hospital, Kanagawa, Japan.

[Introduction]
As for prenatal service, genetic counseling is basically offered before and after genetic test in Japan. It sometimes makes difficult us to follow up patients continuously. However, at our hospital, genetic staffs have opportunities to see patients at maternity visits and also at the delivery. In this report, we reconfirm our role for the patients and for midwives at maternity ward.
[Case 1] 39 y/o. Para 0 Gravida 0. At 29 weeks, congenital heart defect and single umbilical cord were detected at the growth scan. At 31 weeks, the fetus was diagnosed as 18 trisomy by amniocentesis.
[Case 2] 33 y/o. Para 0 Gravida 0. At 12 weeks, she was referred to our hospital because of NT thickness. After genetic counseling, she declined any prenatal test and had been followed by former clinic. At 27 weeks, she was referred to our hospital again because of polyhydramnios. She decided to have chromosome test at that stage and diagnosed as 18 trisomy.
[Case 3] 36 y/o. Para 1 Gravida 1. At 31 weeks, she was referred to our hospital because of intrauterine growth retardation, omphalocele and congenital heart defect. She declined further prenatal test after genetic counseling. At 35 weeks, we had to remove amniotic fluid because of polyhydramnios, and then she desired to have chromosome test and diagnosed as 18 trisomy.
[Conclusions]
The diagnosis of chromosomal anomaly could be physical and mental stress for patients. We consider that the continuous support both genetics staffs and maternity ward is very important.

Allgrove syndrome or Triple A syndrome is an autosomal recessive disease including a clinical triad; Alacrima, Achalasia, and Addisonism. Progressive neurological impairment could be associated.
The defective gene AAAS, located in 12q13, encodes a WD-repeat protein, ALADIN. Tullio pellet suggested that this disease in Maghreb is associated to an ancestral founder mutation, the same in six Algerian and three Tunisian families).
The classical triad was not required to enclose patients in our study. Alacrima associated to achalasia and/or adrenocortical insufficiency was sufficient criteria. In our study, we include twenty two patients belonging to fourteen Maghrebin families, twelve from Tunisia and two from Libya. The molecular analysis targets the major mutation in AAAS gene. In our study, we used the (PCR-RFLP) assay with sequencing method to valid the mutation IVS14 + 1G → A.
Clinical analysis showed variable expressivity but constant alacrima and also consanguinity in all families. The molecular analysis showed that all patients were homozygote and all parents were heterozygote for the same mutation (IVS14 + 1G → A).
The (PCR-RFLP) assay is an easy technique to detect and descry healthy heterozygote, healthy homozygote and affected homozygote. The sequencing method is used to check and valid the mutation in each family.
As the mutation in maghrebin Allgrove's patients seems to be unique and the PCR-restriction fragment length polymorphism assay allows a rapid molecular diagnosis, the genetic counselling became easier. Neonatal molecular diagnosis allows an early optimized follow-up, while prenatal diagnosis raises ethical queries'.

P05.03
A case of mosaic karyotype 45, XO/46, XY - [75%]/ [25%] detected by QF-PCR and confirmed with cytogenetic analysis

R. Raynova[1], *I. Bradinova[2], R. Vazharova[2], Z. Emilova[3], A. Savov[2], I. Kremensky[2];*
[1]National Genetic Laboratory,University Hospital of Obstetrics and Gynecology,, Sofia, Bulgaria, [2]National Genetic Laboratory, Sofia, Bulgaria, [3]Neonatology Clinic, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.

Rapid diagnosis by Quantitative Fluorescent PCR analysis (QF-PCR) has proved its cost-efficiency, speed and efficacy for detection of the most common autosome aneuploidies - trisomy 21, trisomy 18, trisomy 13 and some of sex chromosomes aneuploidies. Besides of its wide application in prenatal diagnosis, QF-PCR is very useful for rapid sex determination of neonates when needed.
We report a case of mosaic karyotype 45, XO/46, XY - [75%]/ [25%] detected by QF-PCR and confirmed with cytogenetic analysis. A neonate, born of second normal pregnancy of young healthy parents was referred to the National Genetic Laboratory for genetic counseling and sex determination. The baby had ambiguous genitalia (severe hypospadic micropenis and bilateral crytorchism) and mild facial dismorphism.
QF-PCR and cytogenetic analysis were performed on peripheral blood. DNA was amplified with commercial QF-PCR kit Aneufast (Molgentix SL, Barcelona, Spain) and analyzed on ABI 3110 XL. Cytogenetic analysis was performed on G-banded metaphases from cultured lymphocytes at resolution 400 bands.
QF-PCR showed results consistent with an aneuploidy, SRY was present. Pseudoautosomal marker AMEL (Xp22.31-22.32/ Yp11) showed a ratio 4:1. Markers on chromosome X - HPRT, DXS6803, SMBA, DXS6809, DXS8377 were in hemizygous pattern. A week later cytogenetic analysis revealed 45, XO/46, XY - [75%]/ [25%] karyotype. Our 10-years experience shows that DNA analysis is informative in cases of mosaics but cytogenetic analysis should be held for a complete diagnosis.

P05.04
Detection of hard palate abnormalities using 3D ultrasound

D. V. Deva[1], C. C. Albu[2], D. F. Albu[2], E. Severin[3], ***M. C. Dumitrescu***[4];
[1]Alco San Clinic, Bucharest, Romania, [2]University of Medicine and Pharmacy Carol Davila; Alco San Clinic, Bucharest, Romania, [3]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania, [4]Marius Nasta Hospital; Alco San Clinic, Bucharest, Romania.

Objective: The aim of this study was to asess the three-dimensional ultrasound technique in prenatal detection of hard palate abnormalities.
Methods: 82 cases of suspected cleft palate, diagnosed by routine 2D ultrasound scan, were referred to us for a detailed assesment of the lips and palate, using 3D ultrasound. A G.E.Voluson 730 Expert was used by two experienced operators,one of them scaned using 3D reverse-face view technique,and the other scaned using angled insonation and anterior axial techniques,all of which seek to maximize visualizationof the palate without shadowing.
Results: Of 82 pacients, in 8, 3D views were not obtained, leaving 74 cases for asessment. The sensitivity for the diagnosis was 86,3%, false positive rate was 12% and false negative rate was 9%.
Conclusion: The data reported suggest that 3D ultrasound is a very usefull method of prenatal evaluation of the fetus, and can give parents a more detalied asessment of the nature and extent of facial and hard palate clefts; the most important advantage of 3D volume scanning is the ease and rapidity with which the different planes can be accessed.

P05.05
Clinical use of array comparative genomic hybridization (aCGH) for prenatal diagnosis in 1000 cases

F. FIORENTINO, *S. Napolitano, F. Caiazzo, L. Spizzichino, S. Bono, M. Sessa, A. Nuccitelli, A. Biricik, M. Baldi;*
"GENOMA"- Molecular Genetics Laboratory, ROME, Italy.

Array-based comparative genomic hybridization (aCGH) allows for fast and accurate detection of chromosomal aneuploidies, submicroscopic deletions or duplications and other unbalanced chromosomal abnormalities. While experience with diagnostic aCGH in the genetic evaluation of pediatric patients is extensive, experience with its use for clinical prenatal diagnosis is still limited.

To assess the feasibility of offering CGH microarray for prenatal diagnosis as a first-line test, a blind study was conducted comparing the results obtained from array CGH with those obtained from a standard karyotype.

Women undergoing amniocentesis or chorionic villus sampling (CVS) for karyotype were offered aCGH analysis using whole-genome BAC arrays with an average resolution of 0.5-1 Mb. A total of 1000 prenatal samples were processed in parallel using both aCGH, performed on DNA isolated from uncultured AF (83%) or CVS (17%), and G-banded for standard karyotyping.

Chromosomal abnormalities were identified in 34 (3.4%) samples; in 10 of which (29.4%) aCGH detected pathogenic copy number variations (CNVs) that would not have been found if only a standard karyotype had been performed.This study demonstrates that aCGH represents an improved diagnostic tool for prenatal detection of chromosomal abnormalities. Although larger studies are needed, the above results provide a further evidence on the feasibility of using aCGH as first-line diagnostic test to detect chromosomal abnormalities in prenatal samples.

P05.06
Preimplantation Genetic Diagnosis (PGD) for Cartilage Hair Hypoplasia combined with Human Leukocyte Antigen (HLA) matching

M. De Rycke[1], *D. Van Boxstael*[1], *W. Verpoest*[2], *P. Verdyck*[1], *P. De Becker*[1], *H. Van de Velde*[2], *I. Liebaers*[1], *M. Bonduelle*[1];
[1]*Centre for Medical Genetics UZ Brussel, Brussels, Belgium,* [2]*Centre for Reproductive Medecine UZ Brussel, Brussels, Belgium.*

Cartilage-hair hypoplasia (CHH) is a rare autosomal recessive disorder, characterised by dwarfism, hypoplastic hair and immunodeficiency. Allogeneic hematopoietic stem cell transplantation (HSCT) has been shown to be an effective treatment for CHH patients. We present a couple, both carriers of different ribonuclease mitochondrial RNA-processing (RMRP) mutations underlying CHH, which relied on In Vitro Fertilisation (IVF) and PGD to select unaffected embryos that were HLA compatible with an affected compound heterozygous sibling.

Preclinical workup involved confirmation of the maternal g.126C>T and paternal g.40G>A mutations in genomic DNA of the couple and affected child, together with informativity and segregation testing of RMRP polymorphic markers (STR16GT at 248 kb 5' and STR16AAT at 34 kb 3') and markers in the HLA locus of 4 Mb (MOG3, D6S2700, D6S2670, D6S2443, D6S1560 and D6S1618). (Half)-informative HLA and RMRP markers were selected and combined with the amplicon of the mutations in a single-cell multiplex PCR protocol. The mutations were detected using post-PCR minisequencing reactions. The RMRP markers ensured an accurate diagnosis of the mutations whereas the HLA markers provided indirect preimplantation HLA haplotyping.

The couple achieved an ongoing singleton pregnancy in their third IVF/PGD cycle and the PGD results were confirmed in prenatal testing. At birth, hematopoietic stem cells will be collected from the cord blood and used to transplant the affected sibling.

This report shows that PGD with HLA matching is an alternative therapeutic option for couples of reproductive age with children affected by CHH requiring a non-urgent HSCT and lacking suitable donors.

P05.07
Multicenter validation of reverse-hybridization teststrips for the detection of common CYP21A2 mutations in dried blood spots.

S. Nemeth[1], *G. Kriegshäuser*[1], *S. Baumgartner-Parzer*[2], *P. Concolino*[3], *V. Neocleous*[4], *L. A. Phylactou*[4], *M. Borucka-Mankiewicz*[5], *H. Onay*[6], *A. Tukun*[7], *S. Riedl*[8], ***C. Oberkanins***[1];
[1]*ViennaLab Diagnostics GmbH, Vienna, Austria,* [2]*Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Vienna, Austria,* [3]*Laboratory of Molecular Biology, Institute of Biochemistry and Clinical Biochemistry, Catholic University, Rome, Italy,* [4]*Department of Molecular Genetics, Function & Therapy, The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,* [5]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [6]*Department of Medical Genetics, Ege University Faculty of Medicine, Izmir, Turkey,* [7]*Department of Medical Genetics, Ankara University Faculty of Medicine, Ankara, Turkey,* [8]*Department of Pediatrics, Medical University of Vienna, Vienna, Austria.*

Congenital adrenal hyperplasia (CAH) comprises a group of inborn errors in the synthesis of adrenal corticoid hormones. More than 90% of cases arise from mutations in the CYP21A2 gene encoding steroid 21-hydroxylase. The average incidence of classical CAH is about 1 in 15,000 births worldwide. Newborn screening programs based on 17-hydroxyprogesterone (17-OHP) levels have been introduced in various countries, but due to the considerable false positive recall rate a concurrent genetic testing would be desireable.

We have developed a reverse-hybridization teststrip-based assay for the rapid and simultaneous analysis of the following 11 common CYP21A2 mutations from dried blood spots: P30L, I2 splice (655A/C>G), Del 8bp E3, I172N, I236N/V237E/M239K (Cluster E6), V281L, L307Frameshift, Q318Stop, R356W, P453S and R483P. Automated instrumentation and use of a scanner-based software tool for recording and interpreting results can make the StripAssay a useful tool in CAH newborn screening programs.

The new CAH StripAssay was validated in a series of 243 DNA samples of known CYP21A2 genotype. By using the StripAssay in combination with a real-time quantitative PCR approach (Parajes et al., 2007), all 11 mutations covered plus CYP21A2 copy number variations and chimeric genes were unambiguously identified. Our results have been confirmed by DNA sequencing and MLPA. In 19 (7.8%) probands of our heterogeneous European cohort we found at least one rare CYP21A2 mutation that was not represented on the teststrip; however, as several of these represented members of the same family the prevalence of rare mutations is expected to be lower. (oberkanins@viennalab.co.at)

P05.08
Array-CGH in fetuses with ultrasound anomalies and normal karyotype

M. Mori[1,2,3], *E. Vallespin*[1,2,3], *R. Rodriguez*[4], *J. Nevado*[1,2,3], *F. Garcia*[1,2,3], *E. Mansilla*[1,2,3], *M. de Torres*[1,2,3], *P. Lapunzina*[1,2,3];
[1]*INGEMM-HULP, Madrid, Spain,* [2]*Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER), Madrid, Spain,* [3]*IdiPAZ, Madrid, Spain,* [4]*Fetal Medicine Unit-HULP, Madrid, Spain.*

Background: congenital malformations are the main cause of infant morbidity and mortality during the first year of life. Approximately 18-30% of fetuses with congenital malformations have chromosomal imbalances. However the causes of defects remain unknown in almost 50% of cases.

Methods: a retrospective study in 40 fetuses with isolated or multiple malformations , and/ or Intrauterine Growth Restriction detected by ultrasound, were done using a 8x60K Agilent-based custom oligo genome-wide array(**KaryoArray®**). The average density of the probe coverage is 43 kb, comprising specific probes covering microdeletion and microduplication syndromes, telomeres and peri-centromeric regions, including more than 350 clinically relevant regions.

Samples were from CVS, AF, fetal blood and tissues (fibroblasts and others). Parents' studies by array-CGH were done when genomic imbalances were found.

Results: 6/40 genomic imbalances with pathological significant were identified: one Complex Chromosomal Rearrangement (CCR), one 8p terminal deletion resulting from malsegregation of a criptic maternal balance translocation, two cases of mosaicism (1q duplication and a trisomy 8, both detected in tissues), one 9q interstitial deletion, and one 17q12

microdeletion syndrome (RCAD: renal cyst and diabetes). Additionally several polymorphic variants were detected, some of them inherited.
Conclusions: array-CGH improved overall detection rates of clinically significant chromosomal abnormalities in fetuses with sonographic anomalies and normal karyotype. The use of this technology will have an important impact on genetic counseling in pregnancies with fetal anomalies. The possibility of having an accurate genetic diagnosis will decrease the anxiety of couples facing a future pregnant.
This study was granted by FIS-08/1207

P05.09
DFNB1 markers associated with nonsyndromic hearing loss in Romanian children

C. Dragomir[1], *A. M. Stan*[1], *D. T. Stefanescu*[1], *L. Savu*[1], *E. Severin*[2];
[1]*Genetic Lab, Bucharest, Romania,* [2]*Carol Davila Univ Med Pharm, Bucharest, Romania.*

Background: The DFNB1 locus has been linked to a nonsyndromic “invisible handicap” called congenital sensorineural hearing loss (HL) and deafness. Mutations of the GJB2 and GJB6 genes are both associated with deafness at the DFNB1 locus. The diagnosis of DFNB1 is made with molecular genetic testing.
Here we report the first study of D13S1830 and D13S1854 markers performed in Romania.
Objective: Our goal was to use molecular testing of children at risk for identifying the contribution of the DFNB1 markers to prelingual HL; these markers are known to be of high prevalence in other European populations.
Patients and Methods: This study was carried out on 253 children with prelingual HL, originating from various regions of Romania. Blood samples were obtained and DNA was isolated by standard protocols. The 35delG GJB2 mutation was detected by ARMS-PCR. We included beta-actin sequence detection as internal control. Analysis of del(GJB6-D13S1830) and del(GJB6-D13S1854) was performed by multiplex-PCR.
Results: GJB2 mutations were detected in 33% of patients, all of them having 35delG homozygous mutation. Only 3% of children presented 35delG mutation in a heterozygous form. None of them was found to have the GJB6 mutations. Physical examination revealed no other abnormal findings.
Conclusions: The identification of the most frequent causal mutation of prelingual HL in Romanian population will contribute to develop both prenatal and postnatal molecular diagnosis protocols well suited for our population.

P05.10
Residual risk of other chromosome abnormalities following NIPD for Down Syndrome

M. Susman[1,2], ***J. L. Halliday***[1,2], *E. Muggli*[1], *D. Amor*[1,3];
[1]*Murdoch Childrens Research Institute, Parkville, Australia,* [2]*University of Melbourne, Dept Paediatrics, Parkville, Australia,* [3]*Genetic Health Services Victoria, Parkville, Australia.*

Background:Non-invasive prenatal diagnosis (NIPD) using next generation sequencing is impending. Reports to date suggest that initially NIPD will test for Down Syndrome (DS) only. One essential piece of information that needs to be considered will be women’s residual risk for the chromosome abnormalities that NIPD won’t detect.
Aim: To calculate the residual risk of fetal chromosome abnormalities in women at increased risk of DS if they had NIPD for (1) DS only (2) DS, plus Trisomy 18 and Trisomy 13 (3) DS, plus Trisomy 18, Trisomy 13, and sex chromosome aneuploidies.
Method: A population based data set of all prenatal diagnostic tests in Victoria, Australia, for 2008 (70,000 births) was used. Frequencies of abnormal fetal karyotypes amongst women referred for an increased risk of DS were extracted.
Results: There were 2954 amniocenteses or CVS for increased risk of DS, and 287 chromosome abnormalities detected (1 in 10). Of these, 129 were DS i.e. 1 in 23 overall.
This means that 1 in 19 pregnancies had some other chromosome abnormality (residual risk). Inclusion of T18 and T13 in the detection panel reduces residual risk to 1 in 30, and if sex aneuploidies are added, to 1 in 42.
Conclusion: In a population of women at increased risk of DS, the risk of non-DS chromosome abnormalities is higher than the risk of DS. Women need to be informed about the spectrum of chromosome disorders currently detected by karyotyping that will no longer be detected by NIPD for DS.

P05.11
The effectiveness of prenatal cytogenetic diagnosis of Down syndrome in the Republic of Moldova.

N. I. Barbova, *M. Sprincean, E. A. Halabudenco, M. S. Stratila, T. Samoilenco, A. N. Mishina, V. P. Secrieru, V. Nour;*
State Center of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of.

Prevention of chromosomal pathology and, in particular, Down syndrome (DS) is the main task of the medical genetic services. The average frequency of trisomy 21 or SD in the EUROCAT is 9,5 / 10 000 births.
The aim of the study was to evaluate the effectiveness of prenatal cytogenetic diagnosis of DS in Moldova.
To obtain the epidemiological characteristics of Down syndrome were used monitoring data DS for the period from 2005 to 2009; the total number of births during this period was 193076. DS was diagnosed in 209 children. DS in fetus were carried out in 16-18 weeks of pregnancy by amniocentesis and cytogenetic diagnosis in 232 women, 23 pregnancies were terminated.
The indications for karyotyping were: age 35 and older, the presence of ultrasound markers of fetal chromosomal pathology, family history, balanced chromosomal translocations in relatives, the deviations of maternal serum markers and the combination of these factors.
The average frequency of DS in Moldova in 2005-2009 was 12.02 / 10 000 (1:924). In 21% of DS cases the age of mothers was 35 years and older, as well as age younger than 18 years. The frequency of DS in 2005-2009 in the population of the Republic of Moldova was 1 for 924 births. Excluding the data of prenatal cytogenetic diagnosis of DS in the frequency of Moldova would be 1:832 newborns. The effectiveness of prenatal cytogenetic diagnosis of DS during II trimester of pregnancy for the analyzed period was 10%.

P05.12
Application of multiplex real-time PCR assay using TaqMan MGB probes on CVS and amniocyte samples for prenatal diagnosis of trisomy 21

M. Hashemi[1], *M. Behroozaghdam*[2], *R. Mahdian*[3], *A. kamyab*[4];
[1]*Scientific Society of Cellular and Molecular, Centeral Commission of Scientific, Literary and Artistic .Science and Research branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Science and Research branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [3]*Biotechnology Research Center, Molecular Medicine Department, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [4]*Islamic Azad University,Sceince and Reseach Branch, Tehran, Islamic Republic of Iran.*

DOWN syndrome (DS), the most common fetal aneuploidy, is caused by an extra copy of chromosome 21 (trisomy 21) affecting 1 in 700-1000 live births Therefore diagnosis and prevention of live-born affected fetus is a health care priority.
We have successfully used a novel MGB TaqMan probe-based real time PCR assay for rapid diagnosis of trisomy 21.
Chorionic Villus Samples (CVS) and **amniocyte samples** was obtained from 59 pregnant women who had the high risk criteria of having fetus with trisomy 21. Quality and quantity of DNA was measured by the optical absorbance. DYRK1A and DSCAM genes (target genes) and PMP22 (reference gene) were selected and specific primers and probs for these genes and were designed. After determining of standard curve and PCR efficiencies for each gene, the target/reference genes ratio was calculated using comparative cycle threshold method .
The results of gene dosage analysis showed the target/reference genes ratio of 1.56±0.09 and 1.02±0.11 in trisomy 21 and normal samples for Chorionic Villus Samples and 1.61 ± 0.09 and 1.03 ± 0.05 for **amniocyte samples** respectively that showed statistically significant difference between two groups.
The conventional cytogenetic analysis needs live cultured cells and is too time-consuming for clinical application. In contrast, molecular methods such as FISH, QF-PCR, MLPA and quantitative Real-time PCR are rapid assays with results in 24h.Therefore, Real-Time PCR technique can be used as an accurate, rapid and sensitive method for prenatal diagnosis of trisomy 21.

P05.13
A novel digital PCR platform accurately detects and quantifies fetal DNA in maternal plasma

B. Hindson[1], *S. Saxonov*[1], *C. Hindson*[1], *S. Hodges*[1], *G. Karlin-Neumann*[1], *H. White*[2];
[1]*QuantaLife, Inc, Pleasanton, CA, United States,* [2]*National Genetics Reference Laboratory (Wessex), Salisbury, United Kingdom.*

Determination of fetal load in maternal plasma is a pre-requisite for a number of non-invasive approaches to detecting fetal abnormalities. Existing techniques are faced with difficulties when trying to quantify the minute amounts of fetal DNA in maternal plasma, particularly for female fetuses. A new droplet digital™ PCR (ddPCR™) system was developed to address these challenges.

The ddPCR system partitions the sample into 20,000 droplets, each one nanoliter in volume, such that some contain the target of interest and some do not. The emulsion is thermocycled to end-point, then every droplet is read with a two-color fluorescence detector. The number of positive and negative droplets is used to compute an absolute concentration of the target with high precision and accuracy. The simple workflow uses standard 96-well plate processing enabling the system to generate data for millions of PCR replicates within a matter of hours.

The assay uses a SRY Y-chromosome marker for male fetuses and methyl-sensitive restriction enzyme digestion of a RASSF1A marker as a gender-independent test. We applied this method to the analysis of more than one hundred maternal plasma samples to obtain a distribution of total DNA and fetal load.

P05.14
Different application of Y-specific sequence detection using cell free fetal DNA from maternal plasma

I. Hudecova[1,2], *M. Hasko*[1], *I. Svecova*[1], *J. Visnovsky*[1], *J. Danko*[1], *Z. Lasabova*[2];
[1]*Department of Obstetrics and Gynecology, Comenius University Bratislava, Jessenius Faculty of Medicine, Martin, Slovakia,* [2]*Department of Molecular Biology, Comenius University Bratislava, Jessenius Faculty of Medicine, Vrutky, Slovakia.*

Noninvasive prenatal identification of fetal gender is currently feasible through analysis of cell free fetal DNA from maternal plasma. Two approaches to fetal sex prediction, testing *DYS14* and *SRY* sequence, were compared with respect to precision, sensitivity, specificity and reproducibility of the test. Quantification of the fetal single-copy *SRY* sequence was evaluated as a precondition for the investigation of quantitative abnormalities in cell free fetal DNA concentration for pregnancy-associated pathologic conditions such as preeclampsia or intrauterine growth retardation.

Thirty-seven plasma samples from pregnant women taken between the 15th and 18th week of gestation were analysed. Real-time PCR analysis employing TaqMan technology was used for amplification of fetal Y-specific sequences *DYS14* and *SRY*. A blind test for final validation used anonymized plasma samples, and the fetal genders of all analyzed samples were confirmed after birth.

The results confirmed that both protocols are reliable methods for fetal gender determination, with sensitivity, specificity and accuracy rates of 100% having been observed for both approaches. Higher reproducibility with a lower coefficient of variation for multi-copy *DYS14* protocol was observed in comparison with *SRY*. A distinct shift of nearly 4 Ct values was detected between both protocols. The detection limit for *SRY* assay reached 3 GE/ml and the mean concentration value for single-copy *SRY* sequence was 15 GE/ml .

Our study confirmed *DYS14* protocol as a precise method for assessment of fetal gender whereas *SRY* assay as an appropriate precondition for monitoring of pathologic states in pregnancy.

P05.15
Amniocentesis after established carrier status of balanced structural chromosome abnormality

C. GUG[1,2], *G. Budau*[1], *N. Hrubaru*[1], *D. Chiriac*[1], *D. Grigoras*[1], *G. Furau*[3], *V. Gorduza*[4];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*Genetics Medical Center, Timişoara, Romania,* [3]*West University "Vasile Goldis", Arad, Romania,* [4]*University of Medicine and Pharmacy, Iasi, Romania.*

About 6% of couples investigated in our laboratory for recurrent miscarriage are carriers of a structural chromosome abnormality. We offered all of them prenatal diagnosis for future pregnancies. We collected data from couples with chromosomal rearrangement investigated for karyotyping after two or more miscarriages. Twentyfour couples were identified with chromosomal inversions and 13 of them had prenatal diagnosis performed, as following: 1 case with inv(7), 1 case with inv(10) and 11 cases with inv(9). In all cases amniocentesis showed fetuses carriers of invesions and pregnancies continued. We encountered 7 couples with Robertsonian translocations: 4 cases with trob(13;22) and 3 cases with trob(13;14). At one case of each category, prenatal diagnosis was performed and pregnancy evolved normaly. One of these fetuses was normal and one was a carrier with balanced translocation trob(13;22), just like the mother. We found 26 couples with a balanced translocations. Seven of these couples performed prenatal diagnosis. Parental karyotype showed the following translocations: 46,XY,t(1;5)(q23;p12), 46,XX,t(3;15)(q12;q13), 46,XX,t(4;10)(q22.2;q22.2-ter), 46,XX,t(7;9)(p14q24), 46,XX,t(7;10)(p22;p12.1), 46,XX,t(17;20)(q12;q11), 46,XY,t(15p;19p). Fetal karyotype showed 3 normal fetuses, 4 carriers of a balanced translocation and one carrier of non-balanced translocation 46,XY,dup(10q22.2-ter), consequently this last pregnancy was terminated. One couple performed twice amniocentesis and fetal karyotype showed in both cases carriers of the balanced translocation t(7;10)(p22;p12.1), as was their mother. Detection of a structural chromosome abnormality in couples with recurrent miscarriage has a striking influence on their decision to undergo prenatal diagnosis. Genetic counseling helps these couples to understand the recurrence risk and consequently to evaluate their options.

P05.16
Improvement of the recovery of fetal nucleated red blood cells (NRBCs) and its application to the prenatal genetic diagnosis.

K. Kwon[1,2], *S. Hwang*[2], *N. Song*[1], *Y. Kim*[3], *H. Chung*[4], *S. Moon*[1], *S. Oh*[1];
[1]*Institute of Reproductive Medicine and Population, Medical Research Center, Seoul National Universit, Seoul, Korea, Republic of,* [2]*GenDix, Inc., Seoul, Korea, Seoul, Korea, Republic of,* [3]*Department of Obstetrics and Gynecology, Ewha Womans University, Seoul, Korea, Seoul, Korea, Republic of,* [4]*School of Public Health and Institute of Health & Environment, Seoul National University, Seoul, Korea, Seoul, Korea, Republic of.*

Fetal nucleated red blood cells (NRBCs) have emerged as the best candidates for noninvasive prenatal diagnosis. But fetal NRBCs are rare in the maternal circulation. To assess the detection efficiency of the isolation of fetal NRBCs using the different density gradients and different osmolality of percoll, we counted number of NRBCs in the blood of pregnant women at different gestational ages.

Fetal NRBCs were isolated from 10ml of maternal in 179 cases using double percoll gradient with optimal osmolality (280 mOs/kg$H_2$0, 1.077 g/ml and 520 mOs/kg$H_2$0, 1.119 g/ml). Magnetic activated cell sorting was used to enrich isolated NRBCs, and morphological differentiation was performed with Kleihauer-Betke stain. Fluorescence in situ hybridization (FISH) analysis was used to detect of chromosomes 13, 18, 21, X and Y.

The mean number of NRBCs were 8.73 (6 to 14 week of gestation), 15.24 (15 to 20 week of gestation), 17.52 (21 to 28 week of gestation) and significantly increased during the period from 6 to 28 weeks of pregnancy (p=0.043, p=0.036). The frequencies of fetal NRBCs were 71.35% (6 to 14 week of gestation), 60.78% (15 to 20 week of gestation), 55.83% (21 to 28 week of gestation). There was a significant increase in the frequency of fetal NRBCs in a first trimester compared to a second and third trimester (p=0.005).

The NRBC enrichment method using optimal osmolality in first trimester can be a more useful prenatal diagnostic tool for fetal aneuploidy than in second trimester.This research was supported by grant SC1150 .

P05.17
Detection of genetic abnormalities by array comparative genomic hybridization for fetal tissues

S. Eren, *N. Cine, D. Sunnetci, N. Uzulmez, E. Gumuslu, B. Enguzel, R. Akkoyunlu, Z. Ilkay, D. Yavuz, B. Dal, H. Savli;*
Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.

Introduction: Array-CGH is a microarray-based technology which can be used to perfoming molecular karyotyping. The use of array CGH in genetic diagnosis has originated a new perspective in methodology of

fetal tissue diagnosis. Whole genome analysis with high resolution can be performed efficiently through this technology. Our aim is to detect genetic aberations in fetal tissues by array CGH method.

Materials And Method: Materials included nine fetal tissues which are from terminated pregnancies that are diagnosed in Gynecology and Pathology departments of Kocaeli Medical Faculty. Whole genome analysis was performed in Medical Genetic Department of Kocaeli Medical Faculty. gDNAs of patients were hybridized with array CGH platforms using syndrome Plus ISCA Microarray 4X44K format (Oxford Gene Technology Oxford, UK). Hybridized microchips were scanned with Agilent Microarray scanner. The data were pooled in Agilent Feature Extraction software and normalized using CytoSure Analysis Software v.2.0.8

Results: We found dup(7)(q31.1-q36.3) and del(18)(p11.23-11.32) in fetal tissues. We confirmed the abnormalities of fetal tissues with parental chromosome analysis. Maternal karyotype was t(8;17)(q31.1)(p11.2). This balanced translocation carrier mother had imbalanced fetus with partial trisomy and partial monosomy.

Conclusion: Our findings indicate that array CGH has been a useful tool in discovering microscobic and submicroscobic genetic changes in fetal tissues.

P05.18
FGFR-3 Related Skeletal Dysplasias Diagnosed Prenatally by Ultrasonography and Molecular Analysis: Presentation of 17 Cases

*A. Hatzaki[1], S. Sifakis[2], D. Apostolopoulou[1,3], **D. Bouzarelou**[1], A. Konstantinidou[4], D. Kappou[2], A. Sideris[5], E. Tzortzis[5], A. Athanassiadis[6], L. Florentin[7], P. Theodoropoulos[8], C. Makatsoris[1], C. Karadimas[1], V. Velissariou[1];*
[1]Department of Genetics & Molecular Biology, "MITERA" General, Maternity & Children's Hospital, Marousi, Attiki, Greece, [2]Department of Obstetrics & Gynaecology, University of Crete, Heraklion, Crete, Greece, [3]Department of Genetics and Biotechnology, Faculty of Biology, School of Physical Sciences, National and Kapodistrian University of Athens, Athens, Greece, [4]1st Department of Pathology, National Kapodistrian University of Athens, Athens, Greece, [5]Fetal Medicine Department, "MITERA" General, Maternity & Children's Hospital, Marousi, Attiki, Greece, [6]2nd Department of Obstetrics & Gynaecology, Aristotle University of Thessaloniki, Thessaloniki, Greece, [7]"Alpha Lab" Molecular Biology and Cytogenetics Center, Athens, Greece, [8]"Embryodiagnosis" Center, Athens, Greece.

Fibroblast Growth Factor Receptor-3 (FGFR-3) related skeletal dysplasias are caused by mutations in the FGFR-3 gene that result in increased activation of the receptors alterations in the process of endochondral ossification in all long bones, and include achondroplasia, hypochondroplasia, thanatophoric dysplasia and severe achondroplasia with developmental delay and acanthosis nigricans (SADDAN). Reports of prenatal diagnosis of FGFR-3 related skeletal dysplasias are not rare, however, the correlation between 2nd trimester ultrasonographic (U/S) findings and underlying molecular defect in these cases is relatively poor. There is a need for specific U/S predictors than can distinguish lethal from non-lethal cases and aid an earlier prenatal diagnosis. Here we present sixteen (16) sporadic and one (1) familial cases with FGFR-3 related skeletal dysplasia and a normal karyotype. We evaluate biometric parameters and U/S findings consistent with the molecular diagnosis of skeletal dysplasia. U/S scan performed even at the 18th week of gestation can indicate a decreased rate of development of the femora (femur length<5th centile), while the mean gestational age at diagnosis is still around the 26th week. The utility of other biometric parameters and ratios is discussed (foot length, BPD, HC, FL/foot and FL/AC). In two cases of discontinued pregnancy, fetal autopsy led to a phenotypic diagnosis and confirmed the prenatal prediction of lethality. We conclude that the combination of U/S and molecular genetic approach is helpful for establishing an accurate diagnosis of FGFR-3 related skeletal dysplasias *in utero* and subsequently for appropriate genetic counselling and perinatal management.

P05.19
Facilitating the Fragile X post- and prenatal genetic diagnostic testing workflow by use of the Abbott FMR1 TP-PCR and FMR1 sizing PCR products.

***S. J. Van Dooren**, S. Seneca, K. Endels, K. Keymolen, M. De Rademaeker, K. Van Berkel, W. Lissens, M. Bonduelle;*
Centre for Medical Genetics, UZ Brussel and VUB, Brussels, Belgium.

Molecular testing of FMR1 (CGG)n expanded repeats remains hard to tackle given the limitations of sizing PCR in detecting large and uninformative alleles, resulting in a significant number of samples that require confirmation through laborious southern blot analysis. Abbott Molecular recently developed a TP-PCR to be used in combination with their sizing PCR to facilitate the Fragile X diagnostic testing workflow.

This study aimed at comparing Abbott Molecular FMR1 Sizing PCR and TP-PCR versus in-house sizing PCR and southern blot in order to evaluate the sizing accuracy and detection sensitivity of normal, intermediate, premutation and full mutation alleles. Over 100 samples of different sources (approximately 50% whole blood, 40% chorion villi and 10% amniocytes) and a panel of artificially mimicked mosaic samples were evaluated.

Signal intensity and sizing accuracy met expectations in the normal to small premutation range. The sizing 'long run' greatly improved the detection capacity and sizing accuracy of longer range (large premutation to full mutation) fragments, although inspection of raw data is recommended. TP-PCR allowed discrimination between normal/intermediate and premutation/full mutation alleles. However, premutation and full mutation TP-PCR signal patterns were very similar, therefore requiring the Abbott FMR1 Sizing PCR to distinguish them.

Mosaic detection in Sizing- or TP-PCR ranged from 20% down to 10%, depending on the repeat range mixture used.

Our results corroborate the workflow proposed by Abbott Molecular of using FMR1 TP-PCR as a first line screening platform in combination with the FMR1 Sizing PCR as second line test.

P05.20
Evaluation of a CGG Repeat Primed PCR system, designed for detection of Fragile X expanded alleles, in clinical prenatal samples.

***S. Seneca**[1,2], S. Van Dooren[1], W. Lissens[1,2], K. Keymolen[1], M. De Rademaeker[1], M. Bonduelle[1,2];*
[1]UZ Brussel, Brussels, Belgium, [2]Vrije Universiteit Brussel, Brussels, Belgium.

Abnormal expansion of the $(CGG)_n$ repeat in the 5'untranslated region (UTR) of the *FMR1* gene is known to generate Fragile X syndrome (FXS), the most common form of cognitive impairment, and several other diseases in patients. The expansion reduces the expression of the *FMR1* by promoting DNA hypermethylation of this region when exceeding ≈ 200 repeats. Molecular diagnosis relies on determination of the number of allele repeats in the DNA template, and assessment of the methylation state of the *FMR1* locus. Current conventional PCR amplification is only successful for normal and small permutation alleles, and is not informative for homozygous repeat alleles. Expanded alleles too large to amplify efficiently and female homozygous samples require additional Southern Blot (SB) analysis for categorization and sizing. Although regarded as gold standard, this technique is laborious, time consuming and involves (not always available) large amounts of DNA. However, accurate and efficient quantification of the number of repeats in the 5' UTR of *FMR1* gene is essential as premutation alleles are common in the general population.

We evaluated a commercially available assay (Asuragen) using a large set of blinded archived prenatal samples that were previously analyzed for FXS with conventional PCR and SB analysis in our Center. The PCR reagentia were able to identify accurately and quickly *FMR1* genotypes, ranging from normal over premutation to full mutation alleles, in patient and control samples. Exact sizing was possible for a spectrum of permutation alleles. The assay is also sensitive to size mosaicism and AGG interruptions.

P05.21
Isolation of fetal free nucleic acids from maternal plasma and detection of fetal gender

N. Kehler, L. Lázár, J. Rigó Jr, ***B. Nagy****;*
1st Dept of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.

The detection of fetal cells and free fetal DNA opened new horizonts in the non-invasive prenatal diagnosis. We aimed to try out two types of isolation kits and to compare the effect of the quantity of the maternal plasma ont he concentration of the obtained DNA.
We collected EDTA blood samples from 40 pregnant women. Samples were centrifuged and the supernatants were stored on -85 ºC until use. We used two kits for DNA isolation from the maternal plasmas, High Pure PCR Template Preparation kit (Roche, Germany) and NucleoSpin Plasma XS kit (Macharey Nagel GmbH, Germany). In the case of the NucleoSpin we increased the quantity of the initial plasma to get correct comparison. DNA concentrations were measured by Qubit Fluorometer (Invitrogen, USA). SRY primers and probes were used by quantitative real-time PCR for determination of fetal gender.
The concentration of the free DNA were almost the same by using equal quantity of the initial plasma (2.96±1.04 ng/ml and 3.09±1.76 ng/ml), while it was significantly lower when we used smaller quantity as recommended with Nucleospin. We were able to detect the fetal sex in all samples correctly.
According to our results it seems that the concentration of the isolated free nucleic acids depends on the initial maternal serum quantity.

P05.22
Relationship of high pregnancy associated plasma protein-A (PAPP-A) levels to demographics and pregnancy outcomes

H. Kaymakçalan*[1,2], J. Härkönen[3];*
[1]Bahçeşehir University, İstanbul, Turkey, [2]Yale University, New Haven, CT, United States, [3]Stockholm University, Stockholm, Sweden.

There are many studies on the adverse effects of low pregnancy associated plasma protein-A (PAPP-A), but very few studies on high PAPP-A levels which creates uncertainty and stress on pregnancy counselling.
We retrospectively analyzed the PAPP-A levels and demographics of 12,428 pregnant women who were seen at Yale University Hospital prenatal unit between November 2002 and November 2008. Among these 12,428 pregnancies we first investigated the PAPP-A above 5 MoM, then the values between 4 and 5 MoM. For both groups we excluded the twin pregnancies and other invalid data.Then we compared the results with the general population. (It is estimated that 2.5% of newborns have a recognizable malformation at birth.)
There were 47 pregnancies (0.38%) with PAPP-A above 5 MoM. After exclusion, 23 pregnancies remained. 4 pregnancies (17.3%) ended with complications which is too few to draw a statistical conclusion.
There were 78 pregnancies (0.64%) with PAPP-A between 4 and 5 MoM.After exclusion, 72 pregnancies remained. 8 pregnancies (11.1%) ended with complications.This is statistically significant. (p< 0.01).However, we need more studies with bigger population numbers to suppose that the outcome of pregnancy will differ with high PAPP-A values. Our study also provides useful data for examining the relationship between certain demographic factors, such as race and diabetes, and PAPP-A levels. Whites have higher PAPP-A (mean=1.19) than blacks (mean=1.49). (p < 0.001) Diabetics have lower PAPP-A(mean=1.04) than non diabetics (1.22). (p= 0.001)

P05.23
When fate hits a family...!

W. Courtens*[1], J. Biard[2], G. Mortier[3], P. Coucke[4];*
[1]Center of Human Genetics, Université Catholique de Louvain, Cliniques Universitaires St-Luc, Brussels, Belgium, [2]Department of Obstetrics, Cliniques Universitaires St-Luc, Brussels, Belgium, [3]Center of Medical Genetics, University Hospital Antwerp, Antwerp, Belgium, [4]Center of Medical Genetics, University Hospital Ghent, Ghent, Belgium.

We report on a family with hypochondroplasia, in whom the pregnant mother was referred for a detailed ultrasound examination at 33 weeks because of the presence of polyhydramnios and shortening of bones.
Prior to this pregnancy, the diagnosis of hypochondroplasia was established in the daughter of the proband. Molecular studies showed a p.N540K (c.1659C>G) mutation in the *FGFR3* gene. Subsequent investigations revealed that the mother also had this mutation, as well as her son.
The detailed fetal ultrasound of the ongoing pregnancy evoked the diagnosis of achondroplasia rather than hypochondroplasia. Initial molecular testing on amniotic cells failed to detect the p.N540K mutation. Because of the suspicion on fetal ultrasounds of achondroplasia further molecular analysis was performed, and revealed the presence of the classic achondroplasia mutation p.G380R (c1138G>C), hereby confirming the diagnosis of achondroplasia in this foetus.
In conclusion: this baby with a prenatal diagnosis of achondroplasia, was born in a family with a mother and 2 sibs affected with hypochondroplasia. The age of the father at conception was 33 years. Since this is an unusual finding, further molecular studies to determine the parental origin of the p.G380R mutation using flanking polymorphisms, are performed and the results will be discussed. If the mutation is located on the maternal chromosome there might be a mechanism that can explain that the *FGFR3* gene in the mother is more prone to mutations. If the achondroplasia mutation is located on the paternal allele, this remarkable situation is just coincidence.

P05.24
Low Apgar scores linked with idiopathic congenital cataract: a long-term follow-up study in a Romanian primary care centre

V. Dumitrascu*[1], A. Matusz[2], D. Vlad[3], A. Cimporescu[3], C. Gug[4];*
[1]Pharmacology Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, [2]General Private Office, Timisoara, Romania, [3]Emergency County Hospital, Timisoara, Romania, [4]Medical Genetics Department, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background: Several studies have shown that low Apgar scores bellow 7 can be linked to different neurologic diseases, but few were related to ophthalmologic disorders. Congenital (or infantile) cataract is a frequent cause of blindness among children.
Methods: In a ten years longitudinal study, between 1 January 1998 and 31 December 2008, we prospectively enrolled and followed up a population-based cohort study of 550 live newborns in a Romanian primary care setting by using medical data obtained after delivery. The Apgar scores at 1 or 5 minutes were recorded following standardized procedures. We obtained information on idiopathic congenital cataract by linking the cohort with the Pediatric Ophthalmology Hospital Register. Cohort members were followed from birth until onset of the ophthalmologic disease or 31 December 2008, whichever came first.
Results: The decreasing Apgar scores were linked with significant increased rate of idiopathic congenital cataract. The incidence rate of idiopathic congenital cataract was 235 per 100,000 person-years for those with 5-minute Apgar scores of 1 to 3 and 75 per 100,000 person-years for those with a score of 10. This incidence remained particularly high in early childhood. Bilateral isolated cataract cases were male dominated (68%), and associated with low birth weight (<2000 g). No significant associations were found with older age (≥40 years) of mothers at delivery or cesarean section.
Conclusions: Neonates with a suboptimal Apgar score have a higher risk of idiopathic congenital cataract that lasts into early childhood.

P05.25
Relatively high frequency of recurrent microdeletion syndromes and subtelomeric deletions/duplications uncovered through non-selective application of a MLPA based extended prenatal panel in routine prenatal diagnosis

C. G. Pangalos*, B. Hagnefelt, S. Sevastidou, S. Karapanou, K. Pispili, A. Markaki, C. Konialis;*
InterGenetics - Diagnostic Genetic Center, Athens, Greece.

Numerous recurrent genomic disorders have been described, involving gain or loss of genetic material at a level not detectable by routine karyotype analysis, and are the underlying cause of various congenital abnormalities with or without mental retardation. Although individually rare, these genetic syndromes may occur collectively in more than 1 in 1,200 live births, while prenatal ultrasound examination and karyotype analysis will typically fail to detect most, if not all, of the above anomalies in the fetus. Since 2006 we have applied a multiplex ligation-dependent probe amplification (MLPA) based screening approach in 1722 typical unselected prenatal cases, with (16.1%) or without (77.7%) ultrasound findings, for the simultaneous

targeted detection of 23 recurrent microdeletion syndromes as well as subtelomeric copy number assessment for all chromosomes. Following amniocentesis or chorionic villus sampling, samples were processed for routine karyotype analysis while DNA was extracted in parallel for MLPA analysis. When necessary, parental samples were analyzed to determine the inheritance of the detected aberrations. We identified nine (9) fetuses with pathological genomic abnormalities (approximately 1 in 191), five of which had as sole indication advanced maternal age (1 in 240). In 2 cases an abnormality was suspected from karyotype analysis, while the remaining 7 cases would have otherwise remained totally undetected. Our data represent the largest published series involving this type of genomic analysis in routine prenatal diagnosis, without indication bias. The panel increases significantly the diagnostic yield of conventional prenatal chromosomal diagnosis and does not pose major interpretation problems. Furthermore, our findings raise some interesting points to consider and perhaps contribute towards a careful reevaluation of traditional risk assessment and our strategy position, in terms of what we aim for in prenatal chromosomal diagnosis.

P05.26
Targeted inhibitory PCR, an attractive laboratory assay for quantitative detection of fetal DNA isolated from maternal plasma.

A. O. H. Nygren[1], *J. Dean*[1], *D. van den Boom*[2], *M. Ehrich*[2];
[1]*Sequenom CMM, San Diego, CA, United States,* [2]*Sequenom, San Diego, CA, United States.*

Several methods have been developed for non-invasive prenatal diagnosis (NIPD) based on circulating cell-free fetal DNA isolated from maternal plasma. In particular massive parallel shotgun sequencing (MPSS) is capable to identify fetal trisomies. The accuracy of this approach is dependent on the number of fetal DNA molecules present and the overall fetal fraction. A control reaction that is able to assess the fetal contribution to the DNA sample is therefore highly beneficial.
We have previously developed a multiplex assay that utilized DNA methylation as a basis for discrimination of fetal derived DNA from maternal DNA. First, methylation-sensitive restriction is used to isolate the methylated fetal DNA markers and amplified using competitive PCR in one multiplex reaction. Finally the amplicons are quantified using MALDI-TOF mass spectrometry. This setup allowed us to obtain both fetal and total copy numbers and the overall fetal fraction.
To minimize the complexity of the MPSS workflow, we have modified this fetal quantifier assay to integrate with standard laboratory equipment already used in the MPSS process. We have developed a novel PCR strategy where the amplification of the abundant total DNA markers is modulated using target specific PCR primer inhibitors. Finally the amplicons are quantified using standard electrophoresis instrumentation. Using this setup we have screened 200 DNA samples obtained from pregnant women and non-pregnant women. Our results show that this rapid and high-throughput assay can reliably detect and quantify the small fraction of fetal DNA isolated in maternal plasma.

P05.27
A validation study for non-invasive fetal sexing and the comparison of different maternal discrimination tests in diagnostics.

J. M. E. van den Oever[1], *S. Balkassmi*[1], *T. Segboer*[1], *P. N. Adama van Scheltema*[2], *D. Oepkes*[2], *E. Bakker*[1], ***E. M. J. Boon***[1];
[1]*Leiden University Medical Center, Department of Clinical Genetics, LDGA, Leiden, Netherlands,* [2]*Leiden University Medical Center, Department of Obstetrics, Leiden, Netherlands.*

While prenatal diagnosis for fetal sex determination mainly relies on invasive procedures which carry a risk of fetal loss, there is a growing need to explore more alternative tests for non-invasive prenatal diagnosis early in gestation.
We have explored the application of free fetal DNA (ffDNA) from maternal plasma for non-invasive fetal sexing and maternal discrimination tests.
In 2008, we started a large validation and implementation study for non-invasive fetal sexing from maternal plasma in diagnostics. In this study 209 pregnant women were included (n=112 male and n=97 female pregnancies).
As described earlier we used a combination of Real-Time PCR and Pyrophosphorolysis-activated Polymerization (PAP) for the detection of the Y chromosome. All fetal gender results were concordant with gender confirmed at birth or after karyotyping in n=194 cases with a sensitivity and specificity of both 100% (CI95% [98.5%-100%]). In n=15 cases results were inconclusive.
To confirm the presence of fetal DNA in plasma in cases with a negative result, we performed maternal discrimination tests. In this study 3 different methods for maternal discrimination testing are compared.
This study shows that fetal gender could be determined from ffDNA in maternal plasma, using a combination of Real-Time PCR and PAP. Although we can detect fetal sex reliably using only these two methods, we do perform a maternal discrimination test for diagnostics in cases with negative results.
This validation study has been completed. As of March 1 2011, fetal sexing is implemented for diagnostics in our department and can be requested.

P05.28
COLD-PCR, a new tool for noninvasive prenatal diagnosis of genetic diseases.

S. Galbiati[1], *A. Brisci*[1], *F. Lalatta*[2], *M. Seia*[3], *M. G. Makrigiorgos*[4], *M. Ferrari*[1,5,6], *L. Cremonesi*[1];

Following the discovery of fetal DNA in maternal plasma different strategies have been reported for noninvasive prenatal diagnosis of genetic diseases. Despite the advances in improving the analytical sensitivity of methods it is still very challenging to distinguish between fetal and maternal sequences and noninvasive prenatal diagnosis of genetic diseases has not yet attained a clinical routine application. Fetal DNA in maternal plasma is in the presence of a large majority of wild-type sequences of maternal origin which hamper the identification of fetal paternally inherited mutated alleles. To make widely accessible noninvasive prenatal diagnosis we developed conditions for the enrichment of fetal alleles based on co-amplification at lower denaturation temperature-PCR (COLD-PCR).
We designed assays for the identification of two beta-thalassemia mutations, based on full COLD-PCR. In this protocol, heteroduplexes generated between mutant and wild-type sequences were selectively denatured at a critical temperature and amplified allowing the enrichment of fetal mutated alleles which could then be simply detected by direct sequencing. Full COLD-PCR enabled correct identification of fetal paternally inherited alleles in 35 couples.
We provide the first evidence that the application of COLD-PCR enables straightforward and reliable identification of inherited mutated alleles without the need of sophisticated procedures or advanced and costly equipment. Full COLD-PCR can be successfully applied to enrich DNA variants irrespective of the kind and position of the mutation thus providing a powerful tool for noninvasive prenatal diagnosis of fetal alleles in a variety of genetic diseases or in general for the identification of muted minority alleles.

P05.29
Microchip for determination of the syndromes tied to increased Nuchal Translucency

K. Joost[1,2,3], *K. Sak*[3], *M. Mällo*[3], *M. Vahter*[3], *C. Alamillo*[4], *M. Fiddler*[4], *E. Pergament*[4];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Department of Biochemistry, University of Tartu, Tartu, Estonia,* [3]*Asper Biotech Ltd, Tartu, Estonia,* [4]*Northwestern Reproductive Genetics, Inc., Chicago, IL, United States.*

Increased foetal nuchal translucency (NT) between 11 and 14 weeks' gestation is a common phenotypic expression of chromosomal abnormalities. In the absence of aneuploidy it is associated with adverse perinatal outcome due to foetal malformations and genetic syndromes, including some monogenic disorders. Arrayed primer extension

(APEX) microarray assay was developed to analyse conditions which are related to increased NT in case aneuploidy is excluded. The test includes 3 monogenic disorders (21-hydroxylase deficiency, Smith-Lemli-Opitz syndrome, spinal muscular atrophy), mutations in 5 genes associated with Noonan syndrome and polymorphisms in 22q11.2 region for detection of del22q11.2 syndrome.
Objective: to evaluate the informativeness of the prenatal diagnostic test in case of increased NT in the foetuses with normal karyotype.
Methods: 267 variations in 16 different genes were tested with APEX array in 220 DNA samples isolated from the foetal chorionic cells or amniocytes.
Results: Genetic changes were detected in 24 DNA. In 9 foetuses mutations in gene related to 21-hydroxylase deficiency was detected. Mutations associated with Noonan syndrome were present in 10 foetuses and with Smith-Lemli-Opitz syndrome in 1 foetus. In one foetus homozygosity of the signals in locus 22q11.2 was observed and deletion in this region was suspected. Detailed genotypes and their phenotypic consequences are discussed.
Conclusion: according to our preliminary data the informativeness of our diagnostic test is 9,1% in cohort of the foetuses with NT> 3mm and normal karyotype. This test provides valuable information for the antenatal genetic management of foetuses with increased NT.

P05.30
Ultrasound and molecular prenatal diagnosis of Ophthalmo-Acromelic Syndrome: bowing of the tibia might be an early recognizable feature

A. Wischmeijer[1,2], *F. Buscherini*[2], *G. Comitini*[3], *L. Brondelli*[4], *E. Della Giustina*[5], *L. Garavelli*[1], *C. Rossi*[2], *M. Seri*[2], *H. van Bokhoven*[6], *A. Superti-Furga*[7], *D. R. Fitzpatrick*[8];

Ophthalmo-Acromelic Syndrome (OAS, MIM 206920) is an autosomal recessive condition mainly characterized by uni- or bilateral microphthalmia or anophthalmia and limb anomalies, especially synostosis of fourth and fifth metacarpals and foot oligodactyly. Recently, loss of function mutations in the SMOC1 gene have been shown to be responsible for the disorder.
We report on a consanguineous couple requesting a prenatal diagnosis of OAS; they have a son (6y) with bilateral anophthalmia, ulnar and fibular reduction defects, bowed tibiae, abnormal Vth fingers, fused IVth and Vth metacarpals, absence of Vth toes and metatarsals, and syndactyly between IInd and IIIrd toes in whom we had diagnosed OAS. Molecular genetic analysis of the SMOC1 gene confirmed the diagnosis identifying the homozygous mutation c.395dupA (p. Tyr132fsX1) of which both parents are carriers.
At 12 weeks and 1 day of amenorrhea (ultrasound corresponding to 11^{+4}) the mother underwent CVS for prenatal diagnosis of OAS and karyotyping. At early morphologic ultrasonography, the lower limbs were bowed and shortened in length, raising the suspicion of distal lower limb defects. Fetal karyotype resulted normal (46, XY), but mutation analysis of fetal DNA revealed the presence of the SMOC1 mutation in homozygosity. Identification of SMOC1 as causative gene will help defining the clinical picture of OAS. This case suggests that a severe lower limb reduction defect with bowing of the tibia can be an early recognizable feature of OAS.

P05.31
Confirmation of genetic outcomes in preimplantation genetic haplotyping (PGH).

E. Ronaldson*, C. Ogilvie, H. Patel, Y. Khalaf, P. Renwick;*
Centre for PGD, Guy's Hospital, London, United Kingdom.

At our PGD centre, 3-day embryos at risk of familial single gene disorders are diagnosed by preimplantation genetic haplotyping (PGH) following whole genome amplification and testing with a panel of STR markers linked to the disease gene. Meiotic microsatellite mutation or PCR "slippage" may compromise diagnosis using such linkage approaches. Confirmation of diagnosis (COD) was therefore carried out on a cohort of embryos following PGH.
Over a one-year period, 49 CODs were carried out using material collected from embryos 1 to 4 days post-biopsy; 9 (18%) were discordant with biopsy diagnosis. One discordance was due to biopsy of a binucleate cell. Of the remaining 8, two were DMD cases with mosaicism for the X chromosome; three CF cases were diagnosed as affected at biopsy, but had a third (low-risk) haplotype at COD; two SMA cases gave aneuploid results with affected haplotypes at biopsy, whilst COD indicated euploid carrier status; one HD case appeared to have monosomy 4 at biopsy, but a normal status at COD. Therefore, these discordances were all likely to be due to mosaicism in the cleavage stage embryos. In only one case (DMD) did COD detect a mutant haplotype not found at biopsy; in this case, the sex chromosome complement was abnormal, and this embryo would therefore not have been considered for transfer. No novel alleles were found in any of these embryos.
These data indicate that neither meiotic mutation nor PCR slippage is likely to compromise PGH diagnosis.

P05.32
New strategy of routine 250K SNP array analysis instead of karyotyping for prenatally diagnosing fetuses with structural ultrasound anomalies

B. H. W. Faas, I. Feenstra, A. J. A. Kooper, R. Pfundt, A. Eggink, ***N. de Leeuw****;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

In October 2010, we implemented a new strategy for routine prenatal diagnosing fetuses with structural ultrasound fetal anomalies (including increased nuchal translucency). We either apply QF-PCR and subsequent 250K SNP array (QF/array), after pre-test counseling and obtaining blood and informed consent from both parents, or QF-PCR and subsequent routine karyotyping (QF/karyo), when parents were not counseled or did not opt for array analysis. Abnormal QF-PCR results were always followed up by karyotyping.
We received 95 fetal samples. In 63/95 (66%), QF/array analysis was requested: 18/63 (29%) were abnormal with QF-PCR, the remaining samples were array analysed. Although this revealed no clinically relevant abnormalities, we detected one paternally inherited gain in 16p13.11 (susceptibility locus), six inherited CNVs and one large contiguous stretch of homozygosity. No incidental, possibly clinically relevant, findings were detected in parental samples. Array analysis was mostly carried out on DNA from uncultured samples and results were often available within 10 days. In 32/95 (34%) fetuses, QF/karyo analysis was performed: 5/32 were abnormal with QF-PCR and 2/32 revealed an abnormal karyotype, not detectable with QF-PCR (but detectable with array analysis).
In conclusion, the QF/array analysis strategy did not reveal additional clinically relevant abnormalities, indicating that, to increase the detection rate, fetuses with more specific fetal ultrasound abnormalities might be selected. Alternatively, as results were mostly available within 10 days and SNP array analysis involves a complete genome analysis with no additional tests needed, one can also opt for implementing the QF/array strategy for all fetuses with structural ultrasound anomalies.

P05.33
Evaluation of specific prenatal ultrasound abnormalities as chromosomal risk factors

E. Jungwirth[1], *K. Orendi*[1], *M. Häusler*[2], *M. Speicher*[1], *W. Emberger*[1];
[1]*Institute of Human Genetics, Graz, Austria,* [2]*Department of Obstetrics & Gynaecology, Graz, Austria.*

Various fetal abnormalities detected by prenatal ultrasound are well established markers for invasive prenatal diagnosis due to their association with fetal chromosomal aberrations. Aim of this study

was to investigate the correlation of pathologic karyotypes with the number of prenatal ultrasound abnormalities (PUA) and/or certain affected organ systems. 469 pregnancies with suspect ultrasound findings which subsequently underwent invasive prenatal diagnosis were karyotyped. We assigned PUAs to 8 organ specific categories and the impact of quantitative and qualitative subgroup involvement was analyzed.
A pathologic karyotype was found in 18.6% of these pregnancies. An almost linear increase of chromosomal abnormalities with the number of PUAs was found with up to 56% chromosomal abnormality rate when 5 or more PUAs were present. Multiple subgroup involvement showed even higher rates (62%). Single detected PUAs within the subgroups were qualitatively analyzed and the highest incidence of pathologic karyotypes was found amongst single detected hygromas or hydrops (39%). Single detected PUAs in all other subgroups were only rarely associated with a chromosomal abnormality (2.4%). The most frequent, single reported PUAs were choroid plexus cysts and ventriculomegaly with less than 1% chromosomal abnormality rate.
Due to the high impact of the number of detected PUAs and the number of affected organ systems on chromosomal abnormality rates any detection of PUAs should lead to an extensive screening for further fetal anomalies. If certain abnormalities such as choroid plexus cysts and ventriculomegaly are found solitarily, the risk for chromosomal abnormalities remains low.

P05.34
Prenatal detection of numerical chromosomal aberrations in Institute for Children and Youth Health Care Institute of Vojvodina in last 12 years

J. Jovanovic Privrodski, *I. I. Kavecan, M. Kolarski, J. Rudez, D. Radovanov, L. Gacina, S. Radnovic, T. Tarasenko;*
Institute for Children and Youth Health Care Vojvodina, Novi Sad, Serbia.

In this paper we present incidence of prenatally detected aneuploidies during last twelve years (1999-2010) in Medical Genetic Centre in Novi Sad, Vojvodina, northern part of Serbia. We used conventional cytogenetic analysis (G banding technique) for detection of chromosomal abnormalities. Samples were obtained from women in risk for chromosomal abnormalities, who underwent amniocentesis between 16th and 19th week of gestation or cordocentesis between 20th and 22nd week of gestation.
We performed retrospective study for aneuploidies on 22847 amniotic fluid and fetal blood samples. We detected 376 cases of numerical aberrations at all. We detected autosomal trisomy in 243 cases; gonosomal aneuploidies in 110 cases; polyploidies in 19 cases and 4 monosomies.
Amniocentesis and cordocentesis was recommended for pregnant women over age 35, women who had an abnormal fetal ultrasound result, women who had an abnormal ,,double screen“ or “triple screen” biochemical screening test during first or second trimester of pregnancy, or women who had (or whose husbands had) a family history of certain diseases, chromosomal abberations or birth defects. Couples had opportunity to choose termination of pregnancy or continue the pregnancy after invasive prenatal diagnosis.

P05.35
Prenatal diagnosis of 48,XXX,+18 double trisomy

I. Ouertani, *M. Chaabouni, F. Maazoul, H. Chaabouni;*
department of congenital and hereditary disorders, tunis, Tunisia.

Double trisomy (DT) is a rare event. Commonly, pregnancy ends in miscarriage. Pregnancies that continue beyond the first trimester are rare and have DT involving one sex chromosome in combination with potentially viable autosomal trisomies such as 21, 18 and 13.
We present a case of DT, 48,XXX,+18, diagnosed because of sonographic findings in the second trimester.
FISH analysis was performed in the first time showing 3 chromosomes 18 and 3 chromosomes X. karyotyping confirmed the DT.
Parents elected to terminate the pregnancy and fetal autopsy confirmed the sonographic findings.
DT is rare event. Only few pregnancies continue. Ultrasounds controls are important to discover fetal malformations and perform karyotype.

P05.36
Dual testing with QF-PCR and karyotype analysis as standard approach of prenatal diagnosis of chromosomal abnormalities. Evaluation of 13,500 cases in Greece.

I. D. Papoulidis[1], *E. Siomou*[1], *E. Manolakos*[2], *G. Efstathiou*[1], *M. Kontodiou*[2], *T. Tsiligianni*[1], *E. Anastasakis*[3], *A. P. Athanasiadis*[4], *M. B. Petersen*[2];
[1]*Eurogenetica S.A., Thessaloniki, Greece,* [2]*Eurogenetica S.A., Athens, Greece,* [3]*Athens Navy Hospital, Athens, Greece,* [4]*School of Medicine, Aristotle University, Thessaloniki, Greece.*

Last years, the need for rapid prenatal diagnosis of the most common fetal aneuploidies and improvement of pregnancy management provoked the development of a reliable and cost-effective method known as Quantitative Fluorescent PCR (QF-PCR), to be used in a dual test with conventional karyotype analysis. In this study, we report our experience of dual prenatal testing with QF-PCR and karyotype analysis in 13,500 cases. The main aim of the study is to examine the detection rate of clinically significant chromosomal abnormalities by QF-PCR compared to karyotype analysis and assess the necessity of dual prenatal testing in all cases, regardless indications of referral. The rates of concordant results between the two methods were evaluated. Abnormal karyotype was found in 325 out of 13,500 cases (2.4%). From these, QF-PCR did not detect the abnormality in 70 cases (21.5%), while 34 (10.5%) had a high or unknown risk of adverse outcome. By selectively applying dual testing only at cases with ultrasound findings and/or genetic history, 20 out of these 34 would have been correctly diagnosed. Selective dual testing would lead to prenatal diagnosis of normal and high risk abnormal karyotypes in 13,483 out of the 13,500 pregnancies (99.87%). Our study strengthens the shift towards selective dual testing in the presence of ultrasound findings and/or genetic history, and QF-PCR as stand alone test for the rest of the cases. However, ethical issues still exist and further evaluation of more studies would be needed for final conclusions.

P05.37
Prenatal diagnosis of chromosome abnormalities by quantitive fluorescent PCR in North-West Russia

T. Ivashchenko, *O. Tarasenko, J. Nasykhova, A. Koroteev, O. Chiryaeva, O. Chiryaeva, L. Petrova, N. Sadik, V. Dudkina, T. Kuznetzova, V. Baranov;*
Ott’s institute of obstetrics and gynecology, St.Petersdurg, Russian Federation.

Prenatal diagnosis for the most common chromosome abnormalities, such as Down’s, Edwards’, Patau’s syndromes and also numerical sex chromosomes abnormalities has been carried out by quantitative fluorescent PCR (QF-PCR). QF-PCR relieves anxiety of most parents within 24 hour from sampling and accelerates therapeutic interventions in the case of an abnormal result. The study summarizes our experience of prenatal diagnosis for chromosome abnormalities by QF-PCR. 17 STR markers (D21S11, D21S1437 D21S1411, D21S226, D13S628, D13S634, D13S742, D18S380, D18S386, D18S391, D18S535, AMXY, DXS981, DXS6854, X22, P39, XHPRT) were used.The heterozygosity value for each chromosome-specific marker was determined. The use of 3 to 4 markers for each chromosome increases heterozygosity and informative value of QF-PCR assay up to 99-100%. From all 763 samples of fetus tissue 32 trisomic cases, including 22 cases of trisomy 21, 8 case of trisomy 18, 2 case of 47 XXY, 2 case of 45X and 1case of 69 XXY were identified. Submicroscopic polymorphic duplications of microsatellites were observed in 7 cases as clear trisomic triallelic or diallelic patterns for one chromosome-specific STRs. Results of molecular study were verified by conventional cytogenetic analysis. QF-PCR can be suggested as a fast, simple and reliable method of prenatal diagnosis of common chromosome diseases.

P05.38
Detection of STR duplications in prenatal diagnosis of chromosome abnormalities by quantitative fluorescent PCR

Y. A. Nasykhova, *T. E. Ivashchenko, O. A. Tarasenko, A. L. Koroteev, V. S. Baranov;*
Ott’s Institute of Obstetrics & Gynecology, St-Petersburg, Russian Federation.

The quantitative fluorescent PCR (QF-PCR) assay, introduced during the last few years, allows prenatal diagnoses of common chromosome aneuploidies within a few hours after sampling. In the past 2 years, we have tested 560 prenatal samples for trisomies 13, 18 and 21 using a quantitative fluorescence-PCR (QF-PCR) approach. Submicroscopic polymorphic duplications of microsatellites were observed in 7 cases

as clear trisomic triallelic or diallelic patterns for one chromosome-specific STRs. Duplications were observed in one sample for one STR on chromosome 21(D21S1437), in five cases for one of the markers on chromosome 13 (3 cases for D13S634 and 2 cases for D13S742) as well as for D18S391 marker of chromosome 18. The maternal origin of the duplication could be demonstrated in 6 cases by QF-PCR analysis of the same marker in both parents; in all samples the polymorphism was found as inherited from the mother. In one sample the duplication was found to be de novo.
The finding of submicroscopic duplications in microsatellites should also be a warning about the risk in reporting an autosomal trisomy detected with a single informative STR. While the same result could also be due to partial trisomies (i.e. unbalanced translocation), the analysis of both parents with the same marker allowed us to distinguish the rare inherited polymorphism in 6 out of 7 cases.

P05.39
" A deletion in 18 chromosome with QF-PCR"

***C. CURCIO**, C. Lodrini, C. Melles, A. Biasi, M. Seia;*
IRCCS FONDAZIONE OSP. MAGGIORE - MILANO, MILANO, Italy.

The diagnosis of β-thalassemia relies on measuring red blood cell indices that reveal microcytic hypochromic anemia, nucleated red blood cells on peripheral blood smear, hemoglobin analysis that reveals decreased amounts of HbA and increased amounts of HbF after age 12 months, and the clinical severity of anemia. Molecular genetic testing of the gene encoding the hemoglobin subunit beta (*HBB*) is available in our laboratory and may be useful for predicting the clinical phenotype in some cases as well as presymptomatic diagnosis of at-risk family members and prenatal diagnosis.
Prenatal diagnosis is possible when both parents are carriers.
Our protocol consists in: Fetal DNA extraction from chorionic villi sampling at 11-12 weeks' gestation; detection of parental mutations with Reverse Dot Blot Analysis (RDB) and/or direct sequencing; the potential presence of maternal cell contamination (MCC) in fetal samples is detected by Quantitative Fluorescent-Polimerase Chain Reaction (QF-PCR).
Here we report a case of prenatal diagnosis in which both parents were carriers of the nonsense mutation Codon39. The fetus resulted heterozygote Codon 39. QF-PCR showed no MCC but revealed a missing paternal correlation for the microsatellite D18S386.
Fetal and parental samples underwent array Comparative Genomic Hybridization (aCGH) to detect a possible microdeletion in that locus. This analysis confirmed a 147 kb deletion at 18q22.3 in the propositus inherited from the father, and so we can exclude any patological meaning.
The QF-PCR test could allow not only identification of MCC in the fetal material but also detection of chromosome rearrangements (13,18, 21 and sexual chromosome).

P05.40
Unexpected findings using QF-PCR as a rapid test for aneuploidy detection in prenatal diagnosis

*K. D. Lichtenbelt[1,2], K. Kusters[1,2], G. C. M. L. Page-Christiaens[1,3], A. C. C. van Oppen[1,3], **G. H. Schuring-Blom**[1,2];*
[1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]Dept. of Biomedical Genetics, Utrecht, Netherlands, [3]Dept. of Obstetrics, Wilhelmina Children's Hospital, Utrecht, Netherlands.

Rapid aneuploidy testing in prenatal diagnosis using MLPA or QF-PCR with markers for the chromosomes 13, 18, 21 and XY is now being widely used. Arguments for using these tests are the short reporting time, high throughput and low costs. Additionally, unexpected findings as seen in full karyotyping and leading to difficult counselling issues, which cause anxiety for the parents, can be avoided. The tests may be used in combination with karyotyping or as a standalone test for specific indications such as advanced maternal age or increased risk for Down syndrome.
In 2010 a total of 397 amniotic fluid samples were analysed in our laboratory with QF-PCR, using Aneufast kit S1/S2 and M13, M18, M21 and MXY (Genomed Ltd, Kent, UK), followed by karyotyping. QF-PCR yielded unexpected findings in two cases: in one case the two most distal markers on the long arm of chromosome 18 were trisomic. Additional karyotyping showed an unbalanced translocation (47,XX,+der(9) t(9;18)). The second case showed a mosaic 46,XX/46,XY, but no peak was seen for the SRY-marker. Karyotyping showed a 45,X cell line and a cell line with an additional small derivative Y-chromosome.
We report two cases of unexpected findings with QF-PCR in prenatal diagnosis. We conclude that, when offering QF-PCR as a standalone test, unexpected findings are not completely excluded and should be discussed with the patient. In a minority of cases, full karyotyping will still be necessary to enable appropriate prenatal counselling on the significance of the QF-PCR results.

P05.41
The development of a rapid assay for prenatal detection of common aneuploidies and microdeletion syndromes

***J. B. Ravnan**, J. Coppinger, S. A. Morton, S. Alliman, J. Burleson, R. Traylor, C. Walker, S. Byerly, R. Schultz, C. D. Kashork, B. S. Torchia, S. Sulpizio, K. Sundin, B. C. Ballif, L. G. Shaffer;*
Signature Genomics, Spokane, WA, United States.

Fluorescence *in situ* hybridization (FISH) testing on uncultured cells has been widely used as a rapid test to identify the common aneuploidies in prenatal samples. We have developed a novel assay utilizing Luminex xMAP® technology for the evaluation of 15 microdeletions in addition to the common aneuploidies for use in low-risk pregnancies. We selected microdeletion syndromes that are not easily detectable by karyotype analysis and that are not usually associated with an abnormal ultrasound. Our validation involved 430 samples including both direct and cultured CVS and amniotic fluid samples, as well as samples diluted with normal control DNA to simulate maternal cell contamination (MCC) and mosaicism. Four investigators reviewed the results and correctly identified all microdeletions and aneuploidies. The only exceptions were a 69,XXX, which cannot be distinguished from a normal female by this assay, and a normal male with ~20% MCC that was incorrectly interpreted as 69,XXY. In experiments simulating MCC, the admixture of normal female cells became apparent at a level of 20%-30% MCC, although abnormalities were still evident up to 45-50% MCC. Simulated mosaicism for trisomy 21 showed detection of the abnormal cell line down to a level of 30-35%. Below this level, the abnormal cell line was not consistently identified. We have developed an alternative to FISH aneuploidy screening and microarray analysis in low-risk pregnancies undergoing invasive testing. This assay is likely to be preferred by women who seek testing beyond routine karyotyping and aneuploidy FISH but are reluctant to consider microarray analysis.

P05.42
Unbalanced reciprocal translocations identified at prenatal diagnosis

***V. Cejnova**, V. Harmas, M. Wilimska, M. Stara, M. Soukupova, J. Lastuvkova;*
Regional Health Corporation, Masaryk Hospital in Usti nad Labem, Department of Medical Genetics, Usti nad Labem, Czech Republic.

Balanced reciprocal translocations, which are typically an exchange of two terminal segments from different chromosomes, occur in approximately one in 500 live births, and are usually associated with a normal phenotype. Reciprocal translocations may be associated with infertility in some carriers, while all carriers have reproductive risks due to abnormal segregation of the translocation chromosomes at meiosis, resulting in sperm or eggs with chromosome imbalance.
We present three types of unbalanced reciprocal translocations detected prenatally using G-banding, fluorescent *in situ* hybridization and spectral karyotyping. The first two cases represent partial monosomy 4q and partial trisomy 4q due to a balanced translocation 4q;21p in the mother. Isolated 4q duplications result in variable clinical features, often including growth and developmental delay and dysmorphic appearance. Patients with 4q terminal deletions share enough similarities to represent an identifiable phenotype. Findings in these patients include craniofacial anomalies, congenital heart and genitourinary defects, moderate to severe mental retardation, poor postnatal growth, and hypotonia. In third case we report an unbalanced segregation of a maternal translocation t(3;8)(p26;p22) causing partial trisomy 3p/partial monosomy 8p. It was the fifth pregnancy of the mother with four miscarriages and fetal ultrasound showed a hypoplastic left heart. There are described in the literature recurrent deletions of a region of 8p23.1 which are associated with congenital heart defects.
Couples carrying reciprocal translocations may request preimplantation genetic diagnosis in order to select embryos with no genetic imbalance and hence increase their chances of a successful pregnancy.

P05.43
Identification of a novel common microdeletion within the *RHD* gene in 56 French patients: implication for prenatal diagnosis

Y. Fichou[1], *D. Jamet*[1], *L. Bryckaert*[1], *C. Guerry*[1], *C. Bénech*[1], *I. Dupont*[1], *J. Chen*[1], *C. Le Maréchal*[1,2,3], *C. Férec*[1,2,3];
[1]*Etablissement Français du Sang - Inserm, U613, Brest, France,* [2]*CHRU Brest, Hôpital Morvan, Brest, France,* [3]*Faculté de Médecine et des Sciences de la Santé, Université de Bretagne Occidentale, Brest, France.*

In the field of blood transfusion, the accurate typing of *RHD* alleles is of major clinical relevance to prevent from alloimmunizing *RHD*- recipients with blood from *RHD*+ donors. In ~1-2% of cases, discrepancy in the phenotypical typing of rare *D* alleles may occur, and a molecular analysis of the *RHD* genotype is therefore required. From January 2003 to July 2010 more than 2,000 blood samples presenting ambiguity for D phenotype by routine serologic analyses were collected in laboratories from the French Blood Centre (Etablissement Français du Sang) in several French regions. Since the amplification of *RHD* exon 10 could not be achieved by a conventional PCR method in 56 blood samples, we designed a protocol to investigate the region that was suspected to be deleted. We report the identification of a 5.4-kb microdeletion in all samples, including the whole sequence of exon 10, which contains the stop codon. Although the transcript that is generated is suspected to be aberrant and thus degraded, a substantial amount of protein appears to be biosynthesized and some antigens may be partly recognized by anti-D specific antibodies, then potentially conferring a weak D phenotype. This finding raises the question of noninvasive method for fetal *RHD* typing by amplification of exon 10, which is supposed to be negative while an aberrant, antigenic protein is nonetheless produced. Subsequent molecular analyses are currently in progress to investigate whether this haplotype derives from a common ancestor, or if the breakpoint is a mutation hotspot.

P05.44
The fetal RHD genotyping from cell-free fetal DNA circulating in maternal blood - The first non-invasive prenatal test in Romania

A. M. Stan[1], *C. Dragomir*[1], *E. Severin*[2], *L. Savu*[1];
[1]*Genetic Lab S.R.L., Bucharest, Romania,* [2]*Carol Davila Univ Med Pharm, Bucharest, Romania.*

Background: Detection of cell-free fetal DNA in maternal circulation, the new non-invasive prenatal diagnosis (NIPD) approach, raised the challenge of finding safer methods for prenatal diagnosis.
We report the first study of non-invasive fetal RHD genotyping performed in Romania.
Objective: The prenatal diagnosis procedures currently employed in Romania are based exclusively on invasive sampling procedures of fetal cells. Our aim was to develop a protocol for non-invasive fetal RHD genotyping in pregnancies at risk: the pregnant woman is RhD negative and her partner is RhD positive.
Methods: We developed a three-step method for fetal RHD genotyping and we tested 56 pregnant RhD negative women with RhD positive partners. The cell-free total DNA extraction was performed from 1ml maternal plasma using the QIAamp® DSP Virus kit with some adjustments to the standard QIAGEN protocol. We performed the fetal RHD genotyping using a commercial 2x multiplex PCR master mix and specific primers for two sequences in the exon 5 and respectively exon 7 of the RHD gene. We also included the beta-globin sequence detection as internal control. The PCR products were automated analyzed by high resolution capillary electrophoresis.
Results: We detected 39 fetuses with RHD positive genotype and 17 fetuses with RHD negative genotype. All 56 cases were analyzed in triplicate and the results were confirmed by the invasive method.
Conclusion: Our results confirm that this non-invasive approach is feasible and accurate and improve the management of mother-fetus RhD incompatibility and isoimmunization by eliminating the invasive procedure for fetal RHD genotyping.

P05.45
Presence of a partial RH1 by fetal genotyping RHD in maternal plasma: Clinical and biological expression at birth. About a case

E. GUINCHARD[1], *C. FEREC*[2], *P. BRICCA*[1];
[1]*EFS Rhône-Alpes site de Lyon-GHE, 69677 BRON Cedex, France,* [2]*EFS Bretagne Site de brest, 29200 BREST, France.*

Introduction: mrs. B. Marie, caucasian, 5th pregnancy, presents a poly-alloimmunization already known during a previous pregnancy: a non evolutive anti-RH1 + an anti-RH2
+ an anti-JK1.
fetal RHD genotyping in maternal plasma performed at 23 weeks and 33 weeks show an amplification of exon 10, but no amplification of exons 4 and 5. Maternal buffy coat showed no amplification. It may be a partial D inherited his African father (RHD gene no analyzed) .
The birth takes place at 37 weeks: at birth, the child has no anemia, moderate hyperbilirubinemia quickly contained by phototherapy, no transfusion was necessary.
Results and hypothesis: the direct antiglobulin test is positive at birth. Elution test finds the presence of anti-RH2, anti-JK1 and anti-RH1 while the newborn is Rh: -1.2 and JK: 1. The sequencing of the RHD gene shows an aspect of partial D associated with a deletion of some exons: how is the expression profile? It may be a nonfunctional gene and anti-RH1 found in the eluate is present in the free state, in the close environment of the erythrocyte (Matuhasi-Ogata phenomenon). Conversely, in case of a gene with partial antigen expression, the result of RH1 phenotype at birth may be due to saturation of antigenic sites by corresponding antibodies.
Conclusion: a new sample a few month after birth would confirm its RH1 phenotype.

P05.46
Fetal RHD genotyping in maternal plasma: Detection of variantsforms

S. MONNIER, *E. GUINCHARD;*
EFS Rhône-Alpes site de Lyon-GHE, 69677 BRON Cedex, France.

Background and aims: the prenatal determination of fetal RH1 represents an important tool to guide the management of pregnancy in severe maternal alloimmunization context or to indicate an immunoprophylaxis during pregnancy of non anti-RH1 allo-immunized women.
Normal and partial RH:1 phenotype can induce or re-activate an anti-RH1 allo-immunization: It's therefore important to detect wild and variant forms of RHD gene, this capacity is determined by the choice of primers and probes.
Methodology: exons 4, 5 and 10 of RHD gene are analysed on free fetal DNA containing maternal plasma after 10 weeks of pregnancy by quantitative real-time PCR using TaqMan technology.
Variant forms are suspected if non homogeneous amplifications of the three exons are observed, like the pseudogene Ψ by Africans. Buffy-coat of one or the two parents are tested following the Ct values obtained by fetal genotyping. Variant RHD gene can be sequenced to study its functionality.
Results: all variant forms of RHD gene found in our laboratory show amplification of at least one but not the three tested exons.
Conclusions and prospects: buffy-coat amplification profile of a few blood donnors in Rhône-Alpes with sequenced variant forms of RHD gene are currently studied to verify the specificity of the method.

P05.47
Seckel syndrome diagnosed prenatally and confirmed postnatal

S. Farcas[1], *G. Olaru*[2], *A. Ratiu*[3], *N. Andreescu*[1], *M. Stoian*[1], *V. Belengeanu*[1];
[1]*University of Medicine and Pharmacy, Department of Medical Genetics, Timisoara, Romania,* [2]*University of Medicine and Pharmacy, Department of Neonatology, Timisoara, Romania,* [3]*University of Medicine and Pharmacy, Department of Obstetrics and Gynecology, Timisoara, Romania.*

Seckel syndrome is a rare form of primordial dwarfism, characterized by severe intrauterine and postnatal dwarfism, severe microcephaly with variable mental retardation, facial anomalies and skeletal abnormalities.
We report a case of Seckel syndrome diagnosed prenatally by ultrasound and confirmed postnatal. Ultrasound examination at 20 weeks of gestation revealed the following parameters on the lower growth curve corresponding to fetus age: biparietal diameter, head

circumference, abdomen circumference, occipitofrontal diameter, femur length, estimated fetal weight. The examination at 26 weeks of gestation showed severe intrauterine growth retardation. The suspicion of Seckel syndrome was raised, corroborating the growth parameter data with the typical facial signs: beak-like protrusion of nose and micrognathia.
A male infant was delivered by caesarian section at 40 weeks of gestation, with weight of 1520 g; length of 39 cm; cranial circumference of 26 cm. On examination we noticed characteristic narrow face, receding forehead, large eyes, prominent beaked nose, micrognathia, low-set ears. Other manifestations were: closed anterior and posterior fontanelles, clinodactyly of fifth finger, supernumerary nipple on the left side and criptorchidism. Thoracic X-ray showed only 11 ribs, while cranial X-ray revealed sinostosys of sagittal and metopic sutures. MRI revealed smaller cerebral hemisphere volume, enlarged lateral ventricles, cerebellar hypoplasia**.** The diagnosis of Seckel syndrome was set based on postnatal typical clinical and imagistic findings. The patient will be followed up to asses the development of mental status for a correct management.
Seckel syndrome should be considered as possible diagnosis when prenatal ultrasound reveals severe microcephaly and intrauterine growth restriction.

P05.48
Fetal presentation of Silver Russell syndrome

*M. Ghanim[1,2], I. Netchine[3], S. Rossignol[4], L. Devisme[5], B. Delobel[2], J. Andrieux[6], V. Debarge[7], J. Plennevaux[8], S. Lucidarme-Rossi[9], S. Manouvrier[1], **C. Vincent-Delorme**[10];*
[1]Centre de Référence Anomalies du Développement et Syndromes Malformatifs Nord de France, CHRU Lille, France, [2]Hôpital Saint Vincent, Lille, France, [3]Laboratoire d'explorations fonctionnelles endocriniennes: Hôpital d'enfants Armand -Trousseau, APHP, UPMC, INSERM U-398, Paris, France, [4]Laboratoire d'explorations fonctionnelles endocriniennes: Hôpital d'enfants Armand-Trousseau, APHP, UPMC, INSERM U-398, Paris, France, [5]Service d'Anatomie Pathologique, CHRU Lille, France, [6]Laboratoire de Génétique Médicale, CHRU Lille, France, [7]Service de Gynécologie-Obstétrique, CHRU Lille, France, [8]Service de Gynécologie-Obstétrique, CH Arras, France, [9]Service de Néonatologie, CH Arras, France, [10]Centre de Référence Anomalies du Développement et Syndromes Malformatifs Nord de France, CH Arras-CHRU Lille, France.

Silver-Russell syndrome (SRS) is characterized by intrauterine (IUGR), postnatal growth restriction, relative macrocephaly and typical dysmorphic features. Two mechanisms account for 70% of SRS cases: hypomethylation of 11p15.5 imprinting center region 1 (ICR1) and maternal uniparental disomy for chromosome 7 (matUPD7). Prenatal diagnosis is possible only for matUPD7.
We report the antenatal and postnatal data of three unrelated cases of SRS. Pregnancy was marked by asymmetric IUGR sparing the head at 22 weeks of gestation (WG) with normal prenatal karyotype. Cesarean section delivery was induced due to cessation of fetal growth at 32 WG (case 1) and at 30 WG (case 2) while case 3 was stillbirth at 27 WG. Postnatal echocardiography detected blocked supracardiac total anomalous pulmonary venous return (TAPVR) in case 1 and hypoplastic aortic arch and cardiac TAPVR in case 2. Both died shortly after birth. Autopsy (refused in case 1) findings were: multivisceral hypoplasia (case 2), genital and extremity anomalies (case 3). Hypomethylation of ICR1 11p15.5 was identified in the three cases and confirmed the clinically suspected diagnosis of SRS.
SRS should be considered in cases with second trimester asymmetric IUGR sparing the head. Notably, the association of SRS and lethal cardiopathies is rarely reported. Either they represent two distinct pathologies or SRS might be underdiagnosed when associated with lethal cardiopathies. Finally, IUGR, cardiopathies and prematurity led to death of cases (1 and 2). Should premature delivery in SRS be avoided to improve prognosis? A reliable prenatal diagnosis for SRS would prove to be useful.

P05.49
Sirenomelia and caudal malformations in two families.

***M. GERARD**[1,2], V. LAYET[3], T. COSTA[4], P. CHENAL[5], A. VERLOES[1,6], B. GERARD[1,7];*
[1]Department of Medical Genetics, Paris, France, [2]Genetic Department, Caen, France, [3]Cytogenetics and medical genetics, Le Havre, France, [4]McGill University, Montréal, QC, Canada, [5]Pathology, Le Havre, France, [6]INSERM U676, Paris, France, [7]Faculté de Médecine, Strasbourg, France.

Sirenomelia is a rare fatal condition characterized by abnormal fusion of the lower extremities. Sirenomelia is usually sporadic, and monozygotic twins are usually discordant (Stocker, 1987). Familial recurrence of sirenomelia is exceptional, with only one family reported, with two sirenomelic sibs, another with renal agenesis and the last with imperforate anus (Rudd and Klimek, 1990). In monozygotic twinning, concordant twins have been described (Roberge, 1963), and semi-concordants (Martinelli et al., 1982; Akbiyik et al., 2000). Sirenomelia with renal and anal anomalies in other siblings has been described once (Selig et al., 1993). We report two additional families. In the first family, the mother was operated of a short form of imperforate anus. Her first pregnancy was terminated because of presence of bilateral renal agenesis with anamnios. Her second pregnancy was interrupted because of sirenomelia. The second family was referred because of the occurrence of caudal malformation in their two children. Parents have normal X-rays of the spine. The first pregnancy gave birth to a girl with imperforate anus. X rays showed absent S3-S5 and coccyx. CT-scan of the pelvis showed abnormal pelvic floor with poor musculature, mostly fibrous fatty content without tendinous attachments. The bladder was very anterior and almost bifid inferiorly. A bifid uterus was present. The second pregnancy gave birth to a baby girl with sirenomelia. No diabetes were present in the pregnancies. Molecular studies are underway to better elucidate the genetic basis of sirenomelia in human.

P05.50
Prenatal diagnosis of tetrasomy 5p by CVS and amniocentesis

***V. Curtisova**[1], I. Dhaifalah[1], P. Čapkova[1], E. Popelinska[2], L. Tuckova[3], M. Holzerova[4];*
[1]Institute of Human Genetics and Fetal Medicine, Teaching hospital Olomouc, Olomouc, Czech Republic, [2]Cytogeneticka laborator Brno, Brno, Czech Republic, [3]Department of pathology, Teaching hospital Olomouc, Olomouc, Czech Republic, [4]Heamoto-oncological clinic, Teaching hospital Olomouc, Olomouc, Czech Republic.

We report the prenatal diagnosis of a fetus with tetrasomy 5p resulting from a supernumerary isochromosome for the short arm of chromosome 5 detected in all cells obtained from chorion villous sampling preformed for a positive combined first trimester screening test with an increased nuchal translucency at a maternal age of 42 years. An amniocentesis revealed the same finding in a mosaic with 7% aberrant cells by a standard karyotyping and 20% by FISH. The pregnancy was terminated. The fetus had some dysmorphic features-hypertelorism, a wide nasal bridge, microgantia, small earlobes, a hypoplastic right upper lung lobe and a bicornate uterus. The examination of fibroblasts revealed the mosaic of isochromosome 5p in 13% of mitosis by karyotyping. Isochromosome 5p seems to be present relatively frequently as a confined placental mosiacism, but when an aberrant ultrasound finding is detected there is a higher risk of true mosaicism, as was in our case. CVS findings need to be verified by amniocentesis. A parental age effect has been reported with the formation of izochromosomes, which is also supported by our findings.

P05.51
A case of co-inheritance of alpha and beta thalassaemia with almost normal haematological indices: an alert for carrier screening

***E. Boutou**, A. Balassopoulou, E. Voskaridou;*
Laiko Hospital, Athens, Greece.

Thalassaemias are a group of monogenic disorders characterized by reduction of one or more globin chain synthesis.
Prevention of haemoglobinopathies, mainly through prenatal diagnosis, is the major strategy against expansion of the disease. Prevention is based upon carrier identification based on red cell indices and HbA2 values. The high incidence of α- and β- thalassemia traits in Greece often results in co-inheritance of both mutant aplotypes. In practically all cases, the haematological phenotype of a double heterozygote for both α- and β-thalassemia is similar to the one of a β-thalassemia carrier except from an increase in MCV values.
We present here a quite interesting rare case of an α- and β-thalassemia carrier whose erythrocyte indices are far from characteristic of the

underlying beta globin gene mutation. An adult pregnant female was screened for thalassaemia and presented the following values: Hb:11,7g/dL; HCT:34,6%; RBC:4,29x10^6/ml; MCV:**80,7**fL; MCH:**27,3**pg and HbA_2:**4,1**%. Subsequent molecular genetic analysis, due to the increased HbA_2, revealed that the individual was a double heterozygote for both α- and β-thalassemia (beta globin gene: IVS-1-6 T->C substitution and alpha globin gene locus: -α3.7 deletion). Occasionally, carriers of IVS-I-6 and IVS-I-110 with only mild reduction in MCV and MCH values have been observed. In such cases, co-inheritance of a-thalassaemia, as in the herein reported case, might further improve erythrocyte indices, near to normal, a fact which increases the risk for misdiagnosis. In conclusion, we propose that in similar cases identification of the underlying mutations is mandatory in order to avoid misdiagnosis.

P05.52
National Thalassemia Prevention Programs in the Middle East Muslim countries with emphasis on Iranian experience

S. Zeinali[1], *A. Samavat*[2], *M. S. Fallah*[3], *H. Bagherian*[3];
[1]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Genetics Office, Ministry of Health and Medical Education, Tehran, Islamic Republic of Iran,* [3]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran.*

Thalassemia is associated with people in Iran, Pakistan, Arab countries around Persian Gulf (Oman, Bahrain, UAE and Saudi Arabia), Egypt, Syria and Turkey. Thalassemia has high burden on health resources and has raised the need to adopt community-based prevention program. This may include public awareness, population screening, genetic counseling, and PND to reduce the incidence of thalassemia. Establishment of a comprehensive screening and prevention program faces many problems when prenatal diagnosis and termination of pregnancy is not permitted or financial resources are limited. In Iran, National Program for the Prevention of Thalassemia was implemented in 1997. This led to a sharp drop on the birth of affected children with thalassemia and sickle cell disease during the past 13 years by providing help to those couples who were both carriers. After this experience, Jordan, Saudi Arabia and Bahrain implemented similar programs for thalassemia and SCD in 2001, 2002 and 2004 respectively. UAE and Oman are taking similar measures. Program in SA and Bahrain lacks prenatal diagnosis component, therefore one does not expect sharp drop in the birth of affected children unless carrier couples are guided to go to other countries for therapeutic abortions. In SA, in 1990, a Fatwa “allows termination of pregnancy in the first 120 days after conception if the fetus is shown beyond doubt to be affected with severe malformation that is not amenable to treatment.” Bahraini government also has stated that they have noticed sharp drop on the birth of SCD after the implementation of the program.

Two prenatal cases of 22q11 duplication detected by SNP array

V. Krutilkova, *E. Hlavova, M. Trkova, V. Becvarova, D. Smetanova, D. Stejskal; Centre for Medical Genetics and Reproductive Medicine GENNET, Praque, Czech Republic.*

The 22q11 region is predisposed to rearrangements. The 22q11.2 microdeletion syndrome is the most common. We report two prenatal cases of 22q11 duplication detected by Illumina SNP array using HumanCytoSNP-12v2.1. Generated data were analysed by Illumina KaryoStudio 1.3 and GenomeStudio V2010.2.

Case 1: In the foetus with ultrasound detection of agenesis of the corpus callosum 22q11.2 duplication was found. The 22q11.2 duplication phenotype is extremely variable. According to our knowledge it is the first report of a case 22q11.2 duplication associated with such type of the abnormality of central nervous system.

Case 2: In the foetus with abnormal ultrasound findings including high probably rectal atresia and agenesis of one umbilical artery marker chromosome was detected. Using SNP array the marker chromosome was identified as 22q11.1 duplication overlapping the critical region for cat-eye syndrome (CES).

The SNP array together with other molecular cytogenetic techniques is very useful in identifying of the small structural abnormalities of foetal chromosomes. This is important to specify prognosis of an affected foetus.

Role of prophylactic therapy in inherited thrombophilia - study on a group of patients in Oncomed medical center

R. Mihaescu[1,2], *E. Sirbu*[2,3], *A. Stoian*[4], *A. Dan*[4], *C. Gug*[1], *A. Caraba*[1];
[1]*University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Municipal Clinical Hospital, Timisoara, Romania,* [3]*West University, Department of Physiotherapy, Timisoara, Romania,* [4]*Oncomed Medical Center, Timisoara, Romania.*

Thrombophilias are hereditary or acquired conditions that determine a hypercoagulable state predisposing to thromboembolic events. The aim of our study was to prove the efficiency of thromboprophylaxis in pregnant women with hereditary thrombophilia.

Methods: A total of 41 women with inherited thrombophilia were followed in the medical center ONCOMED Timisoara. 14 patients had a MTHFR-PAI mutation, 3 women were homozygous for the C677T MTHFR mutation, 3 were homozygous for the A1298C MTHFR mutation and 2 were heterozygous for this mutation. MTHFR heterozygous mutation combined with the factor V Leiden mutation was observed in 6 patients. The prevalence of protein C deficiency has been found in 5 patients, the protein S deficiency in 4 women and the combined deficit for protein C and S**,** in 2 patients. 2 patients presented a heterozygous prothrombin mutation. All women with heterozygous mutations received aspirin 75 mg/day and folic acid 5 mg/day during pregnancy whereas those with homozygous mutation, low molecular weight heparins (dalteparin) 5000IU/day.

Results: We found no significant differences between the groups related to the incidence of congenital malformations or abortions, intrauterine growth restriction or preterm deliveries. 2 women in dalteparin group gave birth to a child with patent ductus arteriosus. 3 women in the same group had heparin induced thrombocytopenia. There were no cases of pregnancy related thrombosis in either group and all women had a live birth.

Conclusion: Thromboprophylaxis in pregnant women with hereditary thrombophilia has an important role in ensuring a normal pregnancy and a live birth for these women.

Fetal Akinesia in Metatropic Dysplasia: Overlap between Chondrodysplasia and Neuropathy?

E. Lausch[1], *F. Stanzial*[2], *G. Gillesen-Kaesbach*[3], *C. Di Stefano*[4], *E. Bertini*[5], *C. Dionisi-Vici*[6], *B. Nilius*[7], *B. Zabel*[1], *A. Superti-Furga*[8], ***S. Unger***[9];
[1]*Centre for Pediatrics and Adolescent Medicine, Freiburg University Hospital, Freiburg, Germany,* [2]*Servizio Multizonale di Consulenza Genetica, Bolsano, Italy,* [3]*Institut für Humangenetik, Lübeck, Germany,* [4]*Ospedale Umberto I Nocera Inferiore, Salerno, Italy,* [5]*Molecular Medicine, Institute from Hospital Care to Science (IRCCS), Rome, Italy,* [6]*Division of Metabolism, Bambino Gesù Children's Hospital, Rome, Italy,* [7]*Department of Molecular Cell Biology, Leuven, Belgium,* [8]*Department of Pediatrics, Lausanne, Switzerland,* [9]*Department of Medical Genetics, Lausanne, Switzerland.*

Heterozygous mutations in the TRPV4 gene have been associated with a family of skeletal dysplasias (metatropic dysplasia, Pseudomorquio type 2, SMD Kozlowski, and brachyolmia) as well as with dominantly inherited neuropathies (hereditary motor and sensory neuropathy 2C, scapuloperoneal spinal muscular atrophy (SMA), and congenital distal SMA). While there is phenotypic overlap between the various members of each group, the two groups were considered to be separate with the former being strictly a structural skeletal condition and the latter group being confined to the nervous system. We report here on fetal akinesia as the presenting feature of severe metatropic dysplasia, suggesting that certain TRPV4 mutations can cause both a skeletal and a neuropathic phenotype.

Case 1 was diagnosed at week 20 with short limbs, absence of limb movements, elbow pterygia, and finger contractures. Cases 2 and 3 (twins) were observed to have short limbs with arthrogryposis and akinesia at week 20. Both pregnancies were interrupted and fetal radiographs suggested metatropic dysplasia. Case 4 presented with joint contractures and absent limb movements at birth; skeletal survey showed typical features of metatropic dysplasia. The baby died of respiratory complications at age 4 months. Sequencing of the TRPV4 gene confirmed the presence of de novo heterozygous mutations predicting G78W (case 1), T740I (cases 2 and 3), and K276E (case 4). Although some degree of restriction of movements is not uncommon in fetuses with skeletal dysplasia, akinesia as leading sign is unusual and may indicate that certain TRPV4 mutations produce a severe “overlap” phenotype.

P05.56
Congenital diaphragmatic hernia associated with a bifid tongue and cleft palate: a case report.

E. Pompilii[1], *A. Elmakky*[1], *E. Contro*[2], *S. Miccoli*[1], *G. Pilù*[2], *M. Seri*[1];
[1]*Medical Genetics Unit, St Orsola Malpighi Hospital, University of Bologna, BOLOGNA, Italy,* [2]*Department of Obstetrics and Gynecology, St Orsola Malpighi Hospital, University of Bologna, BOLOGNA, Italy.*

Objective: We describe a female infant, in whom a left congenital diaphragmatic hernia, a bifid tongue, cleft palate and other congenital anomalies coexisted.

Case report**:** A 39-years-old female, G5P2, had undergone regular prenatal care. She underwent amniocentesis at 16^{+6} weeks of gestation. The result showed normal female karyotype (46, XX). Fetal growth was appropriate throughout the pregnancy. At 20 weeks, ultrasound scan revealed a bifid tongue and a left congenital diaphragmatic hernia; no other abnormalities were evidenced. A genetic consultation was obtained after these findings. At birth, the baby showed respiratory distress and poor respiratory functions, for that she was immediately intubated by the pediatrician and sent to the intensive care unit for further evaluation. After few days, the baby underwent surgical intervention for the diaphragmatic hernia. Clinical evaluation has demonstrated the presence of pedunculated lingual mass, soft mass arising from the palate and cleft palate. Histological examination of the excised tissues from the revealed masses is ongoing. A blood sample was withdrawn from the baby to perform CGH-array in our laboratory. This analysis is still ongoing.

Conclusion: These conditions, independently, may be isolated or associated with other congenital anomalies; however, to our knowledge, their coexistence in the same patient is not described before.

J05.01
Prenatal diagnosis for hemophilia A using Inverse-shifting PCR in an Iranian family

L. Kokabee*, M. kokabee, S. Zeinali, M. Karimipoor;*
Molecular Medicine Dep., Biotechnology Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.

Hemophilia A (HA) is an X -linked coagulation disorder with a world-wide incidence of approximately 1 in every 5000 males. Almost half of the patients with severe HA have large inversions that disrupt either intron 22 (Inv22) or intron 1 (Inv1) of the factor VIII (F8) gene. The identification of carriers and the prenatal diagnosis of Inv22 and Inv1 have greatly improved with new strategies. Recently, inverse shifting-PCR (IS-PCR) has been developed as a new diagnostic test. Here we report the reproducibility of the modified method in prenatal diagnosis of Inv22 in an obligate carrier with a male fetus at 13 weeks of gestation. After determination the carrier status of the mother, genomic DNA of chorionic villus sample (CVS) was dissected and extracted according to standard protocols. Genomic DNA was digested by BclI, followed by self-ligation to create BclI circles. PCR was performed on circular genomic DNA. Our results confirmed Inv 22 is responsible for the disease in the family and fetus was normal. Prenatal diagnosis offers an option, namely to restrict abortions to hemophilic fetuses only, and thus retain the chance of bearing normal sons. It seems IS-PCR technique have proven to be a rapid, robust and reliable technique for genotyping of inv22 in HA patients, carrier detection and prenatal diagnosis.

J05.02
Prenatal screening for triploidy using nuchal translucency and maternal serum pregnancy associated plasma protein A in first trimester of gestation.

D. Mierla[1]*, V. Radoi*[1,2];
[1]*Life Memorial Hospital, Bucharest, Romania,* [2]*UMF Carol Davila, Bucharest, Romania.*

Triploidy has been estimated to occur in 1-2% of all clinically recognized conceptions. It has been assessed that only 1/3 of triploid conceptuses survive post 15 weeks gestation.

There are two types of triploidy. In type I, where the additional chromosome set is of paternal origin, the placenta is partially molar and the fetus is relatively well-grown. Type II, where the extra chromosome set is of maternal origin, is characterized by a small normal looking placenta and severe asymmetrical fetal growth restriction.

We present a case of triploidy discovered by amniocentesis which was carried out at 16 weeks gestation in a 25-year-old woman, following an abnormal maternal serum screening test at the first trimester of gestation and fetal nuchal translucency (NT) thickness was significantly increased (1.97 MoM).The maternal serum markers used were free human chorionic gonadotrophin (freehCG), and pregnancy associated plasma protein A. The fetus was identified as screen-positive for Edward's syndrome (trisomy 18), with very low level PAPP A (MoM = 0,15), and normal hCG levels. Ultrasound findings showed at 16 week of gestation early intrauterine growth retardation and severe oligohydramnios. To identify any possible chromosomal abnormality, cytogenetic investigation was carried out on the amniotic fluid sample. The fetus's karyotype showed triploidy with 69, XXY chromosome complement in all the metaphase spreads obtained from two different cultures, using GTG banding technique.

Triploidy could be identified in the first trimester using NT, maternal serum free beta-hCG and PAPP-A.

J05.03
Prevalence of RFC - 1 A80G polymorphism in romanian mothers having children with Down Syndrome

D. Neagos*, R. Cretu, L. C. Bohiltea;*
Genetic Department, UMF Carol Davila, Bucharest, Romania.

The *RFC1* (reduced folate carrier protein) gene is located on chromosome 21 and likely overexpressed in trisomy 21 individuals. The polymorphisms of the genes involved in folate metabolism may be associated with higher risk of Down syndrome (DS) pregnancy.

Our study included 26 women who gave birth to DS babies and 46 control mothers of healthy children. All women in our study reside in the same geographic area and have a similar social background. The DS mothers were younger than 40 years old and 7 of them had a history of spontaneous miscarriages (26.92%). Genomic DNA was isolated from whole peripheral blood collected on EDTA, using peqGOLD blood DNA mini kit (ATP Biotech). The *RFC1* A80G mutations were investigated by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analysis.The results show that there was no significant difference in heterozygous genotype frequencies between the two groups. Moreover, while AA homozygous genotype frequency was higher among control mothers than among DS mothers (10.87% versus 3.85%), the overall combination of GA heterozygous and AA homozygous *RFC1* variant genotypes did not show significant difference between the case and control groups (OR 0.59 [0.21-1.70] P 0.33). This is the first study that has analyzed the *RFC1* A80G polymorphism as a maternal risk factor for DS, in a cohort of Romanian mothers of DS children, in comparison with control mothers.

J05.04
MTHFR gene polymorphism as a maternal risk factor of Down Syndrome in romanian population

R. Cretu*, D. Neagos, L. C. Bohiltea;*
Genetic Department, UMF, Bucharest, Romania.

Methylenetetrahydrofolate reductase (*MTHFR*) is an important enzyme involved in folate metabolism; it catalyzes the conversion of 5,10-methylenetetrahydrofolate (5,10-MTHF) in 5-methyltetrahydrofolate (5-MeTHF), the latter representing the active form of folate that is involved in remethylation of homocysteine to methyonine.

MTHFR polymorphism involves an adenosyne to cytosine substitution at base pair 1298 (A1298C), causing a glutamate to alanine substitution in the MTHFR protein. The polymorphism is located in exon 7, within the presumptive regulatory domain. The present study includes 72 women (ages 20-42 years old): 26 of them, that gave birth to DS children, citogenetically confirmed as regular trisomy 21, including 7 women with a history of spontaneous miscarriages, and 46 control mothers that gave birth only to healthy children, without any history of miscarriages or abnormal pregnancies. All genotype analyses were performed using PCR-RFLP.CC homozygous genotype frequency at position 1298 was higher in DS mothers than in controls (19.2 % versus 6.5% respectively, with an odds ratio of 4.167 (95% CI 0,80 to 21.68, P value 0.08). AC heterozygous genotype did not show any difference between the two groups. *MTHFR* A1298C polymorphism does not associate with a higher risk, at a statistically significant level.

J05.05
Umbilical cord stem cells a boon to man-kind but karyotyping a necessity

R. S. Patil[1,2], *C. Vaidya*[3], *S. Gaitonde*[3];
[1]*Gebetics, Genectics center, Navi Mumbai, india., mumbai, India,* [2]*D.Y.Patil college of biotechnology and bioinformatics, India, Mumbai, India,* [3]*Gebetics, Genectics center, Navi Mumbai, india., Mumbai, India.*

The isolation of umbilical cord stem cells is of great value for treatment of several disease/disorders. These cells are unique because they can be expanded to therapeutically relevant numbers and cryopreserved for different uses. Cord blood collections from full-term and babies range from 70-130 mL. Umbilical cord blood stem cells have now been used in more than 10,000 transplants as an alternative to hematopoietic stem cells. The parent's blood is tested for infectious diseases. The cord blood unit is delivered to the cord blood bank. Once stored, it is available for a transplant for the child or donated to a patient if he is a match. But many genetic disorders such as balanced translocation are not observed in the beginning or even in the whole life span. This type of umbilical cord stem cells if used in transplant can result in a severe and hazardous effects on the patient. Karyotyping is a test to examine chromosomes in a sample of cells, which can help identify genetic problems. So this type of abnormalities can be prevented from being transferred, by making karyotyping mandatory. Many parents do not consider prenatal karyotyping as it is dangerous for child so at lest it should be made mandatory during blood banking or after birth.

J05.06
Prenatal diagnosis of Klinefelter's syndrome by QF-PCR

O. A. Tarasenko, *L. I. Petrova, O. E. Talantova, A. L. Koroteev, O. G. Chiryaeva, T. E. Ivashchenko;*
Ott's Institute of Obstetrics & Gynecology, St-Petersburg, Russian Federation.

The 26 years old Patient has been directed for prenatal diagnosis of the most frequent chromosome aberrations Indication was the results of biochemical screening in the second trimester. We used QF-PCR to detection the most frequent chromosome aberrations. The analysis of STR markers for autosomes 13, 18, 21 (markers D13S628, D13S634, D13S742, D18S3801, D18S386, D18S391, D18S535, D21S11, D21S1437 D21S1411, D21S226,) revealed the normal parity of peaks for all analyzed loci. The analysis of molecular markers on sex chromosomes demonstrated the parity of peaks for marker AMXY - 2:1 and X22-1:2, while other markers of chromosome X (DXS981, DXS6854, P39, XHPRT) were presented by single peaks. This parity of peaks for the markers localized both on X, and on Y chromosomes (AMXY - 2:1 and X22 - 1:2) testifies for either the non-disjuncted X chromosomes in the second division of meiosis, or for the mosaic karyotype 45, X/46, XY at least in 50 % of cells. After this the Patient was recommended cordocentesis for karyotyping fetal cord blood lymphocytes. The Klinfelter's syndrome in the fetus (47,XXY) has been revealed.

To detect whether the origin of Klinfelter's syndrome in this case was due to X chromosome non-disjunction in the second division of maternal meiosis, we analyzed STR markers of X chromosome in the parental DNA samples. QF-PCR showed that extra X chromosome has maternal origin. Thus, on the basis of this case we developed the algorithm for prenatal detection of numerical sex chromosome aberrations

Investigation of expression level of MRP1 in Iranian colorectal cancer (CRC) patients

S. Samanian[1], *F. Mahjoubi*[1], *B. Mahjoubi*[2], *R. Mirzaee*[2];
[1]*Dept. of Medical Biotechnology, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran,* [2]*Hazrat Rasool hospital,Iran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Background: Drug resistance is still a great obstacle to the success treatment of breast cancer. The Multi Drug Resistance Related Protein1 (MRP1) is a member of the ABC-transporter that located on chromosome 16p13 and transports a wide range of compounds including glutathione conjugates and cyclic nucleotides out of cells
In this study we attempted to investigate the possible correlation between MRP1 and clinical response in patients with colorectal cancer (CRC).
Materials and Methods: Tumor and adjacent normal tissues from 60 Iranian patients with colorectal cancer were assessed for the expression level of MRP1 by Real Time RT-PCR.
Sixty CRC patients were enrolled in this study. The project was approved by the local ethical committee of National Institute for Genetic Engineering and Biotechnology (NIGEB) and written informed consent was obtained from all cases. Tissue specimens (tumor and normal tissue adjacent to tumor) were collected from Hazrat Rasool hospital between 2008and September 2010, Histological diagnosis was confirmed for all samples.
Results: No statistically significant increase in MRP1 expression level was observed when tumor tissues were compared with normal tissues. Furthermore, The MRP1 expression was also independent of the age and sex of the patients, localization and size of the primary tumor, tumor infiltration of the lymph nodes, distant metastases and histological grading.
Conclusion: Our results suggest that MRP1 unlikely have an affect the clinical response to treatment in CRC patients.

P06.002
Association between tumor necrosis factor α -308 gene polymorphism and risk of acute lymphoblastic leukemia in Serbian children

R. Milicevic[1], *B. Popovic*[2], *L. Brankovic*[1], *H. Stamenkovic*[1], *J. Milasin*[2];
[1]*Pediatric Clinic, Nis, Serbia,* [2]*Institute of Human Genetics, School of Dentistry, University of Belgrade, Belgrade, Serbia.*

Tumor necrosis factor TNF plays a major role in growth regulation, cell differentiation, response to viral, bacterial and other infections. TNF can be produced by tumor-infiltrating macrophages and by several types of animal and human cancers (e.g. ovarian and colorectal cancers, melanoma and hematological malignancies). Since TNF are potent controllers of cell functions, it would be of interest to demonstrate that deregulation of TNF-α production in ALL patients in genetically determined and therefore might be a contributing factor in the pathophysiology of lymphoproliferative disease.
A common genetic polymorphism in the TNF gene- G308A is associated with greater susceptibility to various carcinomas. Guanine to adenine transition at the -308 site in the TNF promoter region (TNF A allele) and LTα +250 have both been associated with variable TNFα secretion after different stimulations, with increased levels associated with the allele A, at both sites. We investigated a possible association of TNF polymorphisms G308A, and increased risk for acute lymphoblastic leukemia (ALL). PCR-RFLP analysis of the TNF gene was performed on DNA obtaind from 89 ALL patients and 124 healthy individuals.The following genotype frequencies were found: 56% (GG), 41% (GA) and 3% (AA) in ALL patients. Genotypes in controls were: 71% (GG), 29% (GA) and 0% (AA). A statistically significant difference ($p<0.05$) was found in the genotype frequencies between ALL patients and the control pointing to the association between TNF α -308 polymorphism and ALL risk in the Serbian population.

P06.003
The frequency and association of C609T and C465T polymorphisms of NAD (P) H: quinone oxidoreductase gene in adult acute myeloid leukemia

a. safaei[1], *z. farhad*[2], *m. hashemi*[3], *p. yaghmaei*[1];
[1]*science and reaserch branch Islamic Azad University Tehran Ir, tehran, Islamic Republic of Iran,* [2]*- Department of Hematology Cellular & Molecular Research Center Tehran University of Medical Science, Tehran, Iran, tehran, Islamic Republic of Iran,* [3]*Islamic Azad University,Tehran Medical Branch, tehran, Islamic Republic of Iran.*

Objective: Genetic variations and mutations are the etiological factors of leukemia. NAD (P) H: quinone oxidoreductase (NQO1) plays an important role in detoxification of quinones. C609T and C465T are two common polymorphisms in NQO1 that result in a lower NQO1 activity compared with wild type. We assessed the frequency of C609T (NQO1*2) and C465T (NQO1*3) polymorphisms of NQO1 gene among Iranian population to judge about the association between these

polymorphisms and susceptibility to adult acute myeloid leukemia (AML).
Methods: Frequencies of NQO1 gene polymorphisms were determined in 140 and 124 AML patients for NQO1*2 and NQO1*3, respectively. In addition, 80 age-sex matched controls for NQO1*2 and NQO1*3 were participated in this study. Genotyping was done using PCR-RFLP. We calculated Odd ratio (OR) and confidence interval (CI) of NQO1 genotypes to examine if these polymorphisms are associated with AML.
Results: No significant association was observed between these two polymorphisms of NQO1 and the risk of AML. Odds ratio for C609T and C465T were 0.913 (95%CI= 0.511-1.632) and 2.009 (95%CI= 0.572-7.657), respectively. Men showed a higher incidence of C609T and C465T NQO1 than women. The majority of patients with mutant allele were diagnosed as M3 sub type of FAB classification.
Conclusions: Our findings suggest that the NQO1 C609T and C465T gene variants do not have a major influence on the susceptibility to adult AML. Interestingly, we found a higher incidence of T allele in NQO1*2 than NQO1*3 in both control and patient groups.

P06.004
The effect of arsenic trioxide treatment on mitochondrial apoptotic gene expression in acute promyelocytic leukemia cell line

M. Sharifizadeh[1], *M. Hashemi*[2], *M. Momeny*[3], *K. Alimoghaddam*[3], *A. Ghavamzadeh*[3], *H. Ghaffari*[3];
[1]*Islamic Azad University,Sceince and Reseach Branch, Tehran, Islamic Republic of Iran,* [2]*Islamic Azad University,Tehran medical Branch, Tehran, Islamic Republic of Iran,* [3]*Oncology and Stem Cell Research Center of Shariati Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Background and Objectives: Acute promyelocytic leukemia (APL) is one of the most malignant forms of acute leukemia with a fatal course of only weeks which represents 10-15% of AML in adults. Arsenic trioxide as a single agent factor (without chemotherapy) is the treatment of choice for APL patients; it induces cell death through apoptosis but the mechanism by which arsenic targets apoptosis and dramatically affects gene expression remains poorly understood. Since arsenic is used as first line treatment in Iran, it is worth investigating its effect on expression of genes involved in APL.
Materials and Methods: In this descriptive study, to understand the underlying mechanisms of cell death induction by arsenic, we treated NB4 cell line in a dose and time dependent manner. Extracting RNA and synthesis of cDNA, gene expression of apoptotic genes in mitochondrial pathway including caspase3, Mcl-1 and Bcl-2 was analyzed through Real-Time PCR.
Results: Our findings showed that As_2O_3-induced cell death was paralleled by reduced expression of the antiapoptotic protein Bcl-2 but the expression of Caspase3 and Mcl-1 did not change after arsenic treatment.
Conclusions: These results suggest that changes in Bcl-2 gene expression may be one of the mechanisms of action of arsenic in induction of apoptosis, while Caspase3 and Mcl-1 gene expression are not affected by arsenic at the transcriptional level.

P06.005
Copy number variation analysis in 134 unrelated patients with mutation negative adenomatous polyposis

S. Horpaopan[1], *S. Vogt*[1], *I. Spier*[1], *A. M. Zink*[1], *K. Woellen*[1], *S. Herms*[1], *M. Draaken*[1], *A. Kaufmann*[1], *D. Stienen*[1], *S. Uhlhaas*[1], *E. Holinski-Feder*[2,3], *M. M. Noethen*[1], *P. Hoffmann*[1], *S. Aretz*[1];
[1]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [2]*University Hospital of the Ludwig Maximilians University, Munich, Germany,* [3]*MGZ - Center of Medical Genetics, Munich, Germany.*

Background: In up to 50% of patients with colorectal adenomatous polyposis no germline mutation in the currently known genes - *APC* and *MUTYH* - can be identified. Copy number variants (CNVs) have recently been recognised as important forms of structural variation which also predispose to human disease. It can be hypothesised that in particular heterozygous microdeletions contribute to the underlying cause in yet unidentified genes responsible for adenomatous polyposis syndromes.
Methods: Genomic DNA from 134 unrelated mutation negative polyposis patients was used for genome-wide SNP genotyping with the HumanOmni1-Quad BeadArray (Illumina). Putative CNVs were identified by the QuantiSNP v2.2 algorithm, filtered according to various criteria by use of the CartageniaBench software, by in-silico-analysis, and by comparison with 531 healthy controls, and validated by qPCR.
Results: 35 unique heterozygous deletion CNVs containing 38 genes could be identified in 33 of 134 patients but not in healthy controls. All CNVs are present only once in the whole cohort; all except two patients harbour just one CNV. 25 genes are partly or completely deleted, in 13 more the deletion affects intronic regions only. Candidate adenoma genes include protein kinases, transcription factors, and potential tumour suppressors.
Conclusions: By applying stringent filter criteria we identified a group of rare deletions which might contain predisposing genes for adenoma formation. The further work-up will prioritize genes according to gene function and pathway. Promising candidates will be sequenced in all patients to look for germline point mutations. The study was supported by the German Cancer Aid (Deutsche Krebshilfe).

Background. Polymorphisms for genes encoding alpha 1 antitrypsin (A1AT) and glutathione S-transferase (GSTM1/GSTT1) might contribute to the variability in individual susceptibility to lung cancer.
Objectives. This is a cross-sectional, randomized, case control study for the evaluation of the frequency of A1AT (MS, MZ) and GST (GSTM1/GSTT1 null) alleles among patients with lung cancer.
The study included 56 cases of lung cancer diagnosed patients (histopathological examination), recruted from the Pneumology Hospital Leon Daniello Cluj and 125 healthy unrelated controls, selected among patients observed in the Internal Medicine Department.
Methods. A1AT genotyping was carried out using PCR amplification of relevant gene segment was followed by restriction enzyme digestion Taq1. Detection of A1AT gene S and Z alleles was determined through analysis of resulting restriction fragment length polymorphism (RFLP). For GSTM and GSTT genotyping we used Multiplex PCR, followed by gel electrophoresis analysis.
Results. The molecular analysis identified the MS genotype in 3 (5,4%) patients with lung cancer and 1 (0,8%) of the controls. The heterozigous MZ state was detected neither among cases nor in controls. The prevalence of GSTM null genotype in lung cancer patients was 49,4% compared to 42,8% of controls, also the prevalence of GSTT null genotype in lung cancer patients was 24,5% compared to 18,2% of controls.
Conclusions. The results of our study reached statistical significance, our findings suggest that heritable A1AT and GST status may influence the risk of lung cancer developement.

P06.007
Expression analysis of two testis specific genes OIP5 and TAF7L in peripheral blood of Acute Myeloid Leukemia patients

F. Yazarlou[1], *R. Shirkoohi*[2], *A. H. Emami*[2], *M. H. Modarressi*[1];
[1]*Tehran University of Medical Sciences, Department of Medical Genetics, Tehran, Islamic Republic of Iran,* [2]*Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Acute Myeloid Leukemia (AML) has been known as a highly heterogeneous hematological disorder which arises from a variety of alterations. Expression of testis specific genes (TSG) has been reported in various tumor types and makes a specific group of genes, named Cancer Testis Antigens (CTAs). The present study aimed to determine the expression levels of two TSG's, OIP5 and TAF7L in Peripheral Blood Mononuclear Cells (PBMCs) of AML patients and healthy subjects.
44 AML patients (subtypes: M1, M2, M3, M4, M5, M7) and 33 healthy

subjects were enrolled. Specimens were collected and PBMCs were isolated followed by total RNA extraction and cDNA synthesis. Real-time QPCR was carried out and data was analyzed by LinReg 11 and REST 2009.
Unexpectedly, our results showed dimorphic expression of these genes between affected males and females. In affected females compared to healthy females, OIP5 showed overexpression by a factor 3.079 (p<0.001) in contrast to no significant change in expression in affected males compared to healthy males. TAF7L was lower-expressed by a factor 0.162 (p<0.03) in affected males compared to healthy males versus no significant change in affected females compared to healthy females.
Overexpression of OIP5 in females could have an added advantage of analyzing its expression for MRD (Minimal Residual Disease) monitoring and also applying in immunotherapy. These findings may shed light on the different susceptibility of developing leukemia in a gender specific manner that needs to be investigated and confirmed in future.

P06.008
Androgen Receptor is a target gene for mutations in colorectal tumors with microsatellite instability and the mutated alleles undergo hypermethylation.

*E. Hernández-Illán[1], **A. Martínez-Cantó**[1], E. Irles[1], M. I. Castillejo[1], C. Egoavil[1], V. M. Barberá[1], C. Guarinos[2], L. Pérez-Carbonell[2], C. Alenda[3], A. Payá[3], R. Jover[4], J. L. Soto[1], A. Castillejo[1];*
[1]Cancer Genetics. Hospital Universitario Elche, Elche, Spain, [2]Research Unit. Hospital Universitario Alicante, Alicante, Spain, [3]Pathology Department. Hospital Universitario Alicante, Alicante, Spain, [4]Gastroenterology Department. Hospital Universitario Alicante, Alicante, Spain.

Microsatellite instability (MSI) is a consequence of a functional deficiency of the mismatch repair genes, and is a feature of the majority of Lynch syndrome tumors, and of a minority of sporadic colorectal (CRC), gastric and endometrial cancers. Several genes have been described to be target for mutations of the MSI condition. Androgen Receptor (*AR*) gene has been involved in colorectal carcinogenesis.
We aimed to assess the implication of *AR* gene in the carcinogenic process of CRC with MSI.
We tested 343 sporadic CRC for MSI using five monomorphic mononucleotide markers. Polymorphic CAG repeat at exon 1 of the *AR* gene was analyzed from the normal and tumoral DNA. HpaII methylation-sensitive restriction enzyme, was used to analyze the methylation status of the CAG repeat pattern. Capillary electrophoresis and *GeneScan* analysis was used for all these experiments.
MSI was present in 31 of the 311 CRC analyzed (10%). Insertion-deletion mutations at CAG repeat were detected in 25 out of 31 MSI tumors (80.6%) and in one of the 40 analyzed microsatellite stable tumors (2.5%) indicating that *AR* might be a new target gene for MSI tumors (p<0.001). Interestingly, methylation analysis of MSI tumors with *AR* mutations showed 17 tumors with hypermethylation of the mutated alleles and two tumors without methylation (p=0.023). The remaining six cases were considered as non-informative.
Our results suggests that *AR* gene is specifically mutated in tumors with MSI and those mutated alleles might be silenced by hypermethylation. The consequences of these observations need to be explored.

P06.009
Development of a workflow to detect sequence variants in the APC Gene

***S. Gonzalez**[1], E. Segura[1], C. Goméz[1], C. Garcia[1], R. Petraroli[2], B. Cabot[2], N. Koch[2], C. Davidson[2], G. Munar[1];*
[1]Molecular Diagnostics Unit, Hereditary Cancer Programme, Catalan Institute of Oncology, Barcelona, Spain, [2]Life Technologies Corporation, Foster City, CA, United States.

Germline mutations within the adenomatous polyposis coli (APC) gene are responsible for up to 80% of classical familial adenomatous polyposis (FAP). To date, more than 800 different APC germline mutations have been characterized. The high number and distinct spectrum of variations together with gene length make the automated capillary electrophoresis DNA sequencing the gold standard method to develop an efficient and robust analysis of this gene. We have set up a 3-step workflow to detect mutations in the APC gene in a rapid manner aimed to homogenize and facilitate the experimental work. Step 1: Analysis of 65% of exon 15 in three amplicons (which harbors the majority of mutations); Step 2: Analysis of 12 amplicons with RSA primers in a 96 well plate; Step 3: Analysis of the remaining sequence (8 amplicons). All sequencing reactions were run in a 3730XL Genetic Analyzer. We have studied 32 individuals; 8 with classical and 24 with an attenuated phenotype. Six germline variants were detected in FAP individuals and 8 in the AFAP families. Of these 7 were pathogenic and the remaining 7 were classified as USV. Ten of the 32 cases were reanalyzed on the newest 3500 Genetic Analyzer showing a perfect concordance regarding mutation detection when compared to the 3730XL analyses. Conclusion: Simple workflow adapted to distinct Genetic Analyzer Instruments is a cost-effective approach to analyze large genes such as APC. The 3730XL and 3500 Genetic Analyzer are for research use only, not for use in diagnostic procedures

P06.010
The Effects of Kaempherol and Silymarin on Cell Cycle and Apoptosis Signal Transduction Pathways at Chronic Myelogenous Leukemia Cell Line K562

***Z. O. Dogan Sigva**, S. Yilmaz, C. Biray Avci, M. Yucebas, T. Balci, C. Gunduz;*
Ege University Medical Faculty Department of Medical Biology, İzmir, Turkey.

Silymarin, an active component of *Silybum marianum L.*, has been shown as a powerful antioxidant, anti-inflammatory and anticancer agent.Kaempferol, an active component of *Epilobium parviflorum*, is a flavonoid with anti- oxidant activity and protective against various cancers.
We aimed to evaluate the effects of kaempherol and silymarin in gene expression of apoptosis pathway and the expression changes of cell cycle genes in K562 cell line.
Cytotoxicity analysis was performed for silymarin and kaempherol between 4.69-300.00µM and 10.6-30.25µM doses, respectively, at 24 hours intervals for three days using XTT assay.Total RNA was isolated from the cells exposed to IC_{50} doses of silymarin and kaempherol and the expressions of 45 genes each from apoptotic pathway and cell cycle controls were studied by real time online RT-PCR.Results were compared with silymarin or kaempherol-free cells.
Silymarin, used at IC_{50} dose (29.02µM) significantly increased the expression of genes responsible for cell cycle pathway (CDK2,CDK6, CDK7,CDK8,CDKN1A,CDKN1B,CDKN2C,CDKN3,CDC25A, CDC34, CHEK1 and CHEK2) and the genes which induces apoptosis (APAF1, BCL2, BCLAF1, CASP2, CASP3, CASP4, CASP7 and CASP9).No difference was found in none of the genes following the treatment with IC_{50} doses of kaempherol (9.84µM).
In conclusion, 29.02µM of silymarin induced apoptosis and arrested cell cycle at G2/M transition in K562 cell line.These results lead to the idea that, this extract seemed to be effective in the treatment of leukemia, however further studies are needed to elucidate the molecular mechanism of these genes expressions at protein levels.
*The research was supported by Scientific and Technical Research Council of Turkey.

P06.011
Towards TRAIL to silencing of SMURF and NEDD4: FLIP is flopped

***A. A. Farooqi**, S. Fayyaz, S. Bhatti;*
IMBB, The University of Lahore, Lahore, Pakistan.

Objective: Heterogeneity of the prostate cancer offers stumbling blocks in standardization of therapeutic interventions. TRAIL and cFLIP are two diametrically opposed key mediators that antagonize each others function. In this particular study we hypothesized whether abrogation of negative regulators of TGF signaling potentiates and abolishes the expression of TRAIL and cFLIP respectively or not.
Materials and methods: we have used androgen sensitive prostate cancer cell line (LNCaP) and treated it with TGF. TGF treatment was also given to LNCaP cell line. RNA interference technique was used to unfold the correlation betweeen TGF signaling and TRAIL and cFLIP expression in the LNCaP cell line. The results were analyzed by RT PCR and western blot.
Results: We have treated the TGF treated cell line with siRNA of NEDD4 and SMURF. There was a successful blockade of both genes at transcriptional level as evidenced by RT PCR study. Simultaneously there was remarkable upregulation in the expression of TRAIL. Another interesting observation was that TGF treatment triggered expression

of TRAIL and ablated cFLIP and this activity was pronounced after abrogation of negative regulators of TGF signal transduction.
Conclusion: In this study, we show that TRAIL expression is upregulated and cFLIP is downregulated upon exposure of LNCaP cell lines to TGF-β and etoposide and that TRAIL is a major contributor to apoptosis mediated by TGF-β. it is obvious that NEDD4 and SMURF are the major proteins involved in the deviation of core biological systems and their inhibition might offer exciting avenues in translational oncology

P06.012
Aven blocks DNA damage-indused apoptosis by stabilizing Bcl-Xl

*O. Kutuk[1], **S. G. Temel**[2], S. Tolunay[3], H. Basaga[4];*
[1]Sabanci University, Biological Sciences and Bioengineering Program, Faculty of Natural Sciences and Engineering, Istanbul, Turkey, [2]University of Uludag, Faculty of Medicine, Department of Medical Genetics, Bursa, Turkey, [3]University of Uludag, Faculty of Medicine, Department of Pathology, Bursa, Turkey, [4]1. University of Sabanci, Biological Sciences and Bioengineering Program, Faculty of Natural Sciences and Engineering, Istanbul, Turkey.

Induction of apoptosis by DNA damaging agents involves the activation of mitochondrial apoptotic pathway. Aven has been identified as an antiapoptotic protein and has been shown to activate ATM in response to DNA damage. In this study, we demonstrated that enforced expression of Aven blocks UV-irradiation-, SN-38- or cisplatin-induced apoptosis upstream of mitochondria by stabilizing Bcl-xL protein levels in breast cancer cells. Aven silencing by RNA interference markedly enhanced apoptotic response following treatment with DNA-damaging agents. Aven is complexed with Bcl-xL in untreated breast cancer cells and treatment with DNA damaging agents led to decreased Aven/Bcl-xL interaction. Importantly, Bcl-xL was necessary for the prosurvival activity of Aven and depletion of Bcl-xL abrogated Aven-mediated protection against DNA damage-induced apoptosis. Analysis of breast cancer tissue microarrays revealed decreased Aven nuclear expression in breast
cancer tissues compared with non-neoplastic breast tissues. In particular, we detected reduced nuclear expression of Aven in infiltrating ductal carcinoma and papillary carcinoma breast cancer subtypes compared with non-neoplastic breast tissues and infiltrating lobular breast cancer tissues. Our resultssuggest that Aven is an important mediator in DNA damage-induced apoptotic signaling in breast
cancer cells and its nuclear expression is altered in breast cancer tissues, which may contribute to genomic instability in breast cancer tumors.

P06.013
Association of p53 gene variants, p21 Ser31Arg and P73 exon 2 genetic polymorphisms with the risk of bladder cancer in North Indian cohort

***P. K. Jaiswal**, P. Srivastava, R. Kapoor, A. Mandhani, R. D. Mittal;*
Sanjay Gandhi Postgradute Institute of Medical Sciences Lucknow, India.

Objective: TP53 is the most frequently mutated gene in all forms of human cancers. In addition to mutations, other genetic events, such as single nucleotide polymorphisms (SNPs) in the TP53 gene, have been shown to contribute to the development of various cancers. Hence we hypothesize those polymorphic sites in p53 gene variants at codon 11, Pro47Ser, codon 248 (exon 7), codon 31 of P21 and P73 exon 2 (GC/AT) may modulate risk for Bladder cancer (BC) progression in North Indians.
Materials and Method: Genotyping for these polymorphisms were done in a group of 200 BC and 200 age matched, similar ethnicity unrelated healthy controls using PCR-based methods.
Results: In P53 codon248 polymorphism, heterozygous genotype showed high risk with BC (p<0.001; OR=1.58). Whereas in case of P73 exon2, variant genotype demonstrated significant risk (p=0.014, OR=3.80), the tumorigenic effect of which was observed to be more enhanced in case of smoking exposure. Haplotype Glu-Pro-Trp/Gln was associated with two-fold risk (OR, 1.91; p=0.002). Variant genotype of P73 G4C14>A4T14 was associated with higher risk of recurrence (HR=3.04, P=0.039) in superficial BC patients receiving BCG treatment thus showing least survival (log rank= 0.029).
Conclusion: Our study provided evidence, for the first time, that the P53 codon 248 (exon7) and P73 G4C14>A4T14 polymorphisms were associated with higher risk of BC in North Indians. Also the frequency of homozygous p21 Arg/Arg genotype was too few to be meaningfully evaluated for its association with risk of BC, which warrants larger studies for further validation of our findings.

P06.014
beta2-microglobulin mutations in melanoma

***D. S. Polyakov**[1,2], M. V. Kupriianova[3], M. K. Kozhemyakina[3];*
[1]Institute of Experimental Medicine Nord-West Branch of Russian Academy of Medical Sciences, Saint-Petersburg, Russian Federation, [2]Saint-Petersburg State Pediatric Medical Academy, Saint Petersburg, Russian Federation, [3]Saint-Petersburg State Institute of Technology (Technical University), Saint-Petersburg, Russian Federation.

Cytotoxic CD8+ T lymphocytes can eliminate malignant cells by recognizing peptide epitopes from tumor antigens in the complex with human MHC class I molecules. One mechanism allowing tumors to escape from that control is the downregulation or complete loss of MHC class I molecules. Total loss of MHC I expression can be due to mutations in beta2-microglobulin (b2m) gene located on chromosome 15q21. The b2m protein is noncovalently associated with alpha chain of the MHC I for antigen presentation. When b2m protein is corrupted, or b2m expression is lost, stable antigen-MHC I complexes cannot be formed.
We analyzed tissue specimens of 50 primary melanomas. The tissue microdissection technique was applied to obtain DNA from the tumors. DNA from microdissected tumor tissues was obtained using phenol-chloroform method. The technique of single-strand conformation polymorphism (SSCP) was used to screen 50 melanoma samples, and 172 normal DNA samples for mutations in the b2m. The leader peptide sequence/exon 1 and exon 2 PCR products were analyzed.
Our results exclude any homozygotic/heterozygotic nucleotide change in exons 1 and 2 of b2m in 172 healthy controls. In the context of high frequency of single nucleotide polymorphisms in the human genome, b2m coding sequence is remarkably stable. To date the known exceptions are b2m mutations observed in some types of neoplastic cells. In our work, SSCP of DNA of 50 melanomas showed eight mutations in exon 1 and four mutations in exon 2. Double-stranded direct sequencing of PCR products is required to confirm these results.

P06.015
Homozygote variant genotype of AKR1C3 rs12529 polymorphism confers protection against bladder cancer

***N. Ersoy Tunali**[1], O. Tiryakioglu[1], O. Cakir[2];*
[1]Halic University, Department of Molecular Biology and Genetics, Istanbul, Turkey, [2]T.R. Ministry of Health, Bagcılar Training and Research Hospital, Istanbul, Turkey.

Occupational exposure to carcinogens and cigarette smoking are among the most significant risk factors for bladder cancer. Polymorphisms in genes coding for the xenobiotic metabolizing enzymes may affect the relevant enzyme activity and therefore cause inter-individual metabolic differences. Aldo-keto reductases (AKR) are highly polymorphic phase-I drug metabolizing enzymes, which are involved in tobacco carcinogenesis. AKR 1C family member 3 (AKR1C3) is one of the four known human AKR1C enzymes. The polymorphisms in the AKR1C3 gene may lead to changes in its expression or enzyme activity. When considered together with certain demographic and environmental factors, AKR1C3 genetic polymorphisms possibly define the levels of individual susceptibility to bladder cancer.
In this study, the effect of the rs12529, a non-synonymous polymorphism of the AKR1C3 gene, on the susceptibility to bladder cancer was investigated in conjunction with cigarette smoking and sex. Using genotype data of 101 bladder cancer cases and 101 healthy controls, we demonstrated that men (OR=9,032; %95 CI=4,308-18,938) and cigarette smokers (OR=4,89; %95 CI =2,617-8,963) are under high risk for developing bladder cancer and that rs12529 homozygote variant (GG) has a protective effect (OR=0,255; %95 CI= 0,101-0,644) when compared with the wild type homozygote (CC). The protective effect of the GG genotype becomes more apparent when the odds ratio is adjusted for cigarette smoking and sex (OR=0,243; %95 CI=0,743-0,8). These results indicate a strong relationship between AKR1C3 rs12529 polymorphism and bladder cancer susceptibility.

P06.016
AKR1C3-35 A/G polymorphism in bladder cancer susceptibility

Ö. Kurnaz[1], *N. O. Tiryakioglu*[1], *O. Cakır*[2], *N. Ersoy Tunali*[1];
[1]*Haliç University, Faculty of Arts and Sciences, Department of Molecular Biology and Genetics, İSTANBUL, Turkey,* [2]*T.R. Ministry of Health, Bağcılar Training and Research Hospital, İSTANBUL, Turkey.*

The ten known human aldo-keto reductase (AKR) enzymes play central roles in the metabolisms of drugs, carcinogens and reactive aldehydes, which result in their activation or detoxification. They are especially involved in tobacco-related cancers, since they both activate polycyclic aromatic trans-dihydrodiols and catalyze the detoxication of nicotine-derived nitrosamino ketones. AKR1C3 is one of the four human AKR1C enzymes that are. highly polymorphic, and single nucleotide polymorphisms may confer variations in their metabolizing activities. This implies that inter-individual variations of the xenobiotic metabolism are associated with differential susceptibility for carcinogenesis. In the framework of this study, we investigated the role of the AKR1C3-35 A/G (rs1937920) polymorphism in bladder cancer formation. The genotypes of 145 cases and 81 controls were determined by PCR-RFLP method and analyzed in conjunction with their sex and cigarette smoking status, using logistic regression. A significant increase in the risk of bladder cancer was observed for the AG (OR=1,50; %95CI= 0,995-2,261) and GG (OR=1,773; %95CI=1,225-2,565) genotypes, when compared with the wild type genotype (AA). Upon adjustments for sex and smoking, the risks for both the AG and GG geotypes were further increased (OR=2,750; %95 CI=1,39-5,43 and OR=2.12; %95 CI= 1,125-4.00, respectively). According to these results, AKR1C3-35 A/G variation can be regarded as a risk factor for bladder cancer.

Potential usage of Helix lucorum and Rapana venosa hemocyanins in bladder cancer therapy

O. S. Boyanova[1], *P. Dolashka-Angelova*[2], *L. Yosifova*[3], *S. Zaharieva*[3], *L. Velkova*[2], *B. Rukova*[1], *I. Dimova*[1], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University- Sofia, Bulgaria, Sofia, Bulgaria,* [2]*Institute of Organic Chemistry with Centre of Phitochemistry, BAS, Sofia, Bulgaria,* [3]*Institute of Experimental Pathology and Parasitology - Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Urinary bladder cancer is a socially significant healthcare problem. Risk factors such as: smoking, infections, diet and aging of the world population are responsible for its growing incidence. One therapeutic approach is the usage of a nonspecific immunostimulant Keyhole limpet hemocyanin (KLH). Our laboratory investigates in vitro effect of hemocyanins derived from species Helix lucorum (HlH) and Rapana venosa (RvH), and their potential clinical use in comparison to KLH.

Three structural subunits were isolated from HlH and two from RvH. Each subunit contains 8 functional units with mass ~50 kDa.

The anti-tumor effect was investigated on 647-V bladder tumor cell line and results suggest a direct cytotoxicity mainly from functional units. Gene expression profiling of the two pathways: Human Inflammatory cytokines (PAHS011) and Signal transduction pathway (PAHS014) on the tumor cells before and after hemocyanins treatment was performed.

Results suggest upregulation of genes for IL1A, IL1B, IL8 and C3 in Group1-G1 (cell line treated with Hlh Fu-7). IL1A and IL1B were significantly overexpressed compared to Group G2 (cell line treated with RvH-II-6). Only gene for C3 showed slightly expression in G2 compared to G1.

Ten genes from the PAHS014 were highly upregulated in G1 - CSF2, CDKN1A, IL1A, VEGFA, IL8, GADD45A, ODC1, BCL2L1, FASN, and BAX. Among them: CSF2, CDKN1A, FASN and BAX had more than 10 times higher expression in group G1 versus genes in group G2.

Our result shows which genes behavior differs vastly after treatment with HIH Fu-7. They indicate the potential biological mechanism of its action.

P06.018
The prevalence of BRCA mutations in Czech patients with triple negative breast cancer

M. Mikova, *E. Machackova, J. Hazova, M. Navratilova, L. Foretova, M. Svoboda;*
Masaryk Memorial Cancer Institute, Brno, Czech Republic, Brno, Czech Republic.

Several studies have shown that breast tumours arising in women carrying germline mutations of the BRCA1 tumour-suppressor gene are often triple negative (negative for estrogen-receptor, progesterone-receptor and HER2 expression). In our study, we estimated the proportion of BRCA1 and BRCA2 mutation carriers among women with triple negative breast cancer.

BRCA1 screening of 109 patients who were diagnosed with triple negative breast cancer was performed in our laboratory. These patients were divided into 4 groups:

I. Patients with family history of breast/ovarian cancer or bilateral breast/ovarian cancer patients

II. Early-onset sporadic unilateral breast cancer patients diagnosed before 40 years of age

III. Patients with medullary type of breast cancer diagnosed after 40 years of age

IV. Sporadic breast cancer patients diagnosed after 40 years of age

There were identified 43 mutations (68.3%) in the first group, 6 mutations (23.1%) in the second group, one mutation (25%) in the third group and 5 mutations (15.2%) in the fourth group (overall 50,5%).

In addition there was performed BRCA2 screening of 93 patients out of group I-III with the result: four mutations (6.4%) were identified in the first group, two mutations (7.7%) in the second group and no mutation in the third group.

Our results confirm that women with triple-negative breast cancer are candidates for genetic testing of BRCA1 gene, especially those with family history. BRCA2 mutations were detectable in 6.5% of cases.

Evaluation of 53 sequence variants of unknown significance of the BRCA genes using bioinformatics predictions of RNA splicing and functional splicing assays

J. C. Théry[1], ***S. Krieger***[2], *P. Gaildrat*[1], *F. Révillon*[3], *M. P. Buisine*[4], *A. Killian*[1], *C. Duponchel*[1], *A. Rousselin*[2], *D. Vaur*[2], *J. P. Peyrat*[3], *P. Berthet*[5], *T. Frébourg*[1,6], *A. Martins*[1], *A. Hardouin*[2], *M. Tosi*[1];
[1]*Inserm U614, Faculty of Medicine, Institute for Biomedical Research and Innovation, Rouen, France,* [2]*Molecular Genetics, CRLCC François Baclesse, Caen, France,* [3]*Molecular Genetics, CRLCC Oscar Lambret, Lille, France,* [4]*Molecular Genetics, University Hospital, Lille, France,* [5]*Cancer Genetics, CRLCC François Baclesse, Caen, France,* [6]*Departement of Genetics, University Hospital, Rouen, France.*

A large fraction of sequence variants of unknown significance (VUS) of the breast and ovarian cancer susceptibility genes *BRCA1* and *BRCA2* may induce splicing defects. We analyzed 53 VUS of *BRCA1* or *BRCA2*, detected in consecutive molecular screenings, by using 5 splicing prediction programs and we classified them into two groups according to the strength of the predictions. In parallel, we tested them by using splicing minigene assays. Ten VUS were predicted by two or more programs to induce a significant reduction of splice site strength, or activation of cryptic splice sites, or generation of new splice sites. Minigene-based splicing assays confirmed 4 of these predictions. Five additional VUS, all at internal exon positions, were not predicted to induce alterations of splice sites, but revealed variable levels of exon skipping, most likely induced by the modification of exonic splicing regulatory elements. We provide new data in favor of the pathogenic nature of the variants *BRCA1* c.212+3A>G and *BRCA1* c.5194-12G>A, which induced aberrant out-of-frame mRNA forms. Moreover, the novel variant *BRCA2* c.7977-7C>G induced in frame inclusion of 6 nt from the 3' end of intron 17. The novel variants *BRCA2* c.520C>T and *BRCA2* c7992T>A induced incomplete but strong skipping of exons 7 and 18, respectively. We confirm the sensitivity of current algorithms for detecting VUS that induce changes of splice site strength or generate/activate new splice sites. However, an important fraction of internal exonic variants escape bioinformatics detection, highlighting the need of more accurate bioinformatics predictions for internal exonic variants.

P06.020

Using heteroduplex analysis by mismatch-specific endonuclease for the detection of *BRCA* mutations and SNPs

A. NEGURA[1], *L. NEGURA*[2], *A. CONEAC*[3], *D. PEPTANARIU*[2], *N. UHRHAMMER*[4], *Y. BIGNON*[4];

[1]*Alexandru Ioan Cuza University, IASI, Romania,* [2]*University of Medicine and Pharmacy Gr. T. Popa, IASI, Romania,* [3]*University of Medicine and Pharmacy Iuliu Hatieganu, CLUJ-NAPOCA, Romania,* [4]*Centre Jean Perrin, CLERMONT-FERRAND, France.*

BRCA1 and *BRCA2* are major cancer predisposition genes, responsible for a large percentage of hereditary breast and ovarian cancer (HBOC) families. Screening for mutations in these genes is now standard practice for HBOC cases in Europe, and permits medical follow-up and genetic counselling adapted to the needs of individuals in such families.

Currently, most laboratories performing diagnostic analysis of the *BRCA* genes use PCR of exons and intron-exon boundaries coupled to a pre-screening step to identify anomalous amplicons. The techniques employed for the detection of mutations and polymorphisms have evolved over time and vary in sensitivity, specificity and cost-effectiveness.

Recognising that direct sequencing is too expensive for us to apply systematically to all HBOC families for the foreseeable future, we turned to the recently developed Surveyor™ heteroduplex cleavage method as a sensitive and specific technique to reveal anomalous amplicons of the *BRCA* genes, using only basic laboratory equipment and agarose gel electrophoresis.

We managed to detect by this technique 3 *BRCA* deleterious mutations, as well as 2 unclassified sequence variants (UVs) and 3 common SNPs. All variants were confirmed by forward and reverse dideoxy sequencing. We recommend therefore heteroduplex analysis (HA) by mismatch-specific endonuclease as a sensitive pre-screening method to precede systematic sequencing. Together with other alternative techniques, HA allows us now to save about 30% of *BRCA* sequencing costs, and certainly can do even better.

This study was possible with partial financial support from the Romanian Ministry for Education and Research, by the CNCSIS research grant PN-II-ID-PCE-2008, code 1990/2008.

P06.021

Breast cancer genetics: Her2/neu overexpression may be a negative predictor of BRCA mutations

A. Rahman[1], *C. J. Curry*[1,2], ***C. D. DeLozier***[2,3,1];

[1]*University of California San Francisco-Fresno, Fresno, CA, United States,* [2]*Genetic Medicine Central California, Fresno, CA, United States,* [3]*Saint Agnes Medical Center, Fresno, CA, United States.*

BRCA-1 and BRCA-2 are the genes most frequently implicated in “monogenic” predisposition to breast cancer. Soon after clinical testing for BRCA mutations became available, a flurry of publications compared the histological characteristics and prognostic marker status of breast cancers in patients with BRCA-1 vs. BRCA-2 vs. BRCA-X (negative) patients. Invasive ductal cancer with medullary features and “triple negative” (for ER, PR and Her2/neu expression) prognostic marker status are considered suggestive of BRCA-associated breast cancer. The next wave of publications was epidemiological, whereas the current focus is molecular profiling of breast cancers for somatic mutations. In the interim, histology and prognostic markers have been displaced as major determinates in genetic risk assessment. We recently suggested that lobular histology is rarely, if at all, linked to BRCA mutations (DeLozier et. al., 2010). Our experience also suggests that her2/neu overexpression at initial diagnosis may be an important *negative* predictor of BRCA status.

We have counseled and tested 185 patients with invasive breast cancer at significant risk of carrying a BRCA mutation, for whom histology and prognostic marker information were available/adequate and for whom BRCA results were unequivocal. Of these 185 patients, 35 (19%) had Her2/neu overexpression as diagnosed by immunohistochemistry (IHC) and/or FISH assays. Twenty five patients (13.5%) were BRCA-positive, but none of the Her2/neu-positive patients had BRCA mutations, in spite of an average age at diagnosis of <40. If confirmed in larger studies, Her2/neu positivity might constitute a cost-effective means of screening prior to the offering of BRCA testing.

Development of an easy and robust workflow to Detect Sequence Variants in the BRCA1 and BRCA2 Genes

M. Wenz[1], *J. Theelen*[1], *P. Ma*[1], *H. Ouchene*[2], *M. Nelen*[2], *S. Berosik*[1], *S. Hung*[1], *S. Schneider*[1], *S. Lim*[1], *R. Petraroli*[1];

[1]*Life Technologies Corporation, Foster City, CA, United States,* [2]*Universitair Medisch Centrum St Radboud, Nijmegen, Netherlands.*

One of the major responsibilities of a clinical genetics research laboratory is mutation scanning in one or more genes related to an inherited disease. There are many different techniques for mutation scanning: (1) a prescreen that detects but does not characterize variants, and (2) the industry-standard technique: direct sequence analysis of the DNA by Sanger sequencing. Here we describe the development and verification of a direct resequencing workflow for mutation screening of BRCA1 and BRCA2 genes on the 3500 Genetic Analyzer .This workflow contains all steps, from purified DNA to data analysis covering both genes, PCR cleanup, cycle sequencing, electrophoresis and data analysis. To simplify workflows and decrease time to result, we focused on a robust assay based on a “one individual - one test” approach. Key to the success of this workflow was the 96-well plate design, which contained pre spotted PCR primers covering both genes and also included multiplex non template controls. Finally the use of the new developed BigDye® Direct Cycle Sequencing chemistry eliminates the need for a separate PCR clean-up step. This simplified process without a separate PCR clean-up step reduced the overall workflow time by 40%. This verified workflow permits to accelerated analysis, reduced labor time, and simplified laboratory set up enabling to skip pre screening methods. The 3500 Genetic Analyzer and BigDye® products are for research use only, and not intended for any animal or human therapeutic or diagnostic use

BRCA1 haplotype analysis in patients with familial and non-familial breast cancer from Castilla y León (Spain)

D. Fernández[1], *E. Sánchez*[1], *E. Castro*[1], *T. Martín*[2], *J. Cruz-Hernández*[1,2], *R. Gonzalez-Sarmiento*[1,3];

[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Servicio de Oncología. Hospital Clínico Universitario de Salamanca, Salamanca, Spain,* [3]*Departamento de Medicina. Facultad de Medicina. Universidad de Salamanca, Salamanca, Spain.*

Pathogenic mutations in BRCA1 and BRCA2 are highly penetrating. The carriers of these mutations have a high risk, between 40 and 80%, to develop breast cancer. However, the number of women in the general population with breast cancer attributable to these mutations is very small (<5%), which is raising the possibility that there may be low-penetrance mutations in these genes that could change the susceptibility to breast cancer.

There are several mutations in BRCA1 gene that appear frequently in the population (polymorphisms). We showed more attention to the group of missense mutations in exon 11 (including c.2731 C> T [rs799917], c. 3232 A> G [rs16941] and c. 3667 A> G [rs16942] that cause changes amino acid (p. 871 P> L, p. 1038 E> G and p. 1183 E> G).

In this study, we hypothesized that clustering of mutations in exon 11 of BRCA1 gene may modify the risk of developing breast cancer in our population.

The analysis of the distribution of these polymorphisms in patients diagnosed

with breast cancer, carrying mutations in one of the BRCA genes, showed that the TGG alleles are inherited together as a haplotype.

Statistical analysis of results shows that there is a statistically significant relationship between the group of patients with familial breast cancer carriers of BRCA gene mutations and the presence of the haplotype TGG.

P06.024

Identification of novel intronic *BRCA1* variants of uncertain significance in a Thai hereditary breast cancer family

A. Ratanaphan[1], *P. Panomwan*[1], *B. Canyuk*[1], *T. Maipang*[2];

[1]*Faculty of Pharmaceutical Sciences, Prince of Songkla University, Hat-Yai, Songkhla, Thailand,* [2]*Faculty of Medicine, Prince of Songkla University, Hat-Yai,*

Songkhla, Thailand.
We have screened for mutation in the entire coding sequence of the *BRCA1* gene in 50 Thai breast cancer patients. Screening for mutations was carried out using the polymerase chain reaction-based on single-stranded conformational polymorphism (PCR-SSCP) and direct DNA sequencing. The genetic alterations were not found in patients without a family history of breast cancer. One patient with a family history of five breast cancer cases harbored a germ-line mutation in the *BRCA1* gene, that was a novel intronic *BRCA1* mutation (IVS7+34_47delTTCTTTTCTTTTTT). In addition, two unclassified intronic *BRCA1* variations (IVS7+34_47delAAGAAAAGAAAAAA in the antisense strand and IVS7+50_63delTTCTTTTTTTTTTT in the sense strand) and one unclassified intronic point mutation (IVS7+38T>C) were also identified in the patient's healthy daughter at the age of 25. RNA analysis of variants of unknown significance revealed a normally occurring splicing process. These alterations were not found in family members or unrelated healthy volunteers. Of further interest, was that the deletion site was in close proximity to the triplet repeat sequence of TTC·GAA. The deletion of a set of TTC repeats was identified both in the patient and the patient's healthy daughter. It is implied that such genetic alterations could cause genomic rearrangement or an alteration to the DNA structures, possibly through a slipped strand mispairing mechanism during DNA replication.

P06.025
BRCA1 and BRCA2 germline mutations in 100 high risk Iranian breast cancer families

F. Keshavarzi[1], *S. Zeinali*[2];
[1]*Department of Biology, Islamic Azad University, Sanandaj branch, Kurdistan, Sanandaj, Islamic Republic of Iran,* [2]*Kawsar Human Genetics Research Center, Tehran, Islamic Republic of Iran.*

Objective: Breast cancer is the most common cancer in Iranian women. Genetic predisposition accounts for 5-10% of all breast cancers and germline mutations in breast cancer susceptibility genes, *BRCA1* and *BRCA2* are responsible for a substantial proportion of high-risk breast and breast/ovarian cancer families. Therefore, the aim of this study was to investigate mutations of *BRCA1/2* in high risk Iranian families.
Methods: We screened 100 families who met our minimal criteria. The entire coding sequences and each intron/exon boundaries of *BRCA1/2* genes were screened by direct sequencing and MLPA.
Results: In the present study, we could detect the novel following mutations:
p.Gly1140Ser, p.Ile26Val, p.Leu1418X, p.Glu23Gln, p.Leu3X, p.Asn1403His, p.Asn1403Asp, p.Lys581X, p.Pro938Arg, p.Thr77Arg, p.Leu6Val, p.Arg7Cys, p.Leu15Ile, p.Ser177Thr, IVS7+83(-TT), IVS8 -70(-CATT), IVS2+9(G>C), IVS1-20(G>A), IVS1-8(A>G), p.Met1Ile, IVS2+24(A>G), IVS5-8 (A>G), IVS2(35-39)TTcctatGAT, IVS13+9 G>C in BRCA1 and p.Glu1391Gly, p. Val1852Ile, IVS6-70(T>G), 1994-1995 (InsA) in *BRCA2*.
The missense substitutions p.Leu3Stop codon, Leu1418Stop codon, p.Lys581Stop, CD26SmallINSGTCCC^ATCTG E212catctgGTAAGTCAGC,p. Ile21Val, p. Gly1738Glu, IVS2-1(G>C) in BRCA1 and p. Leu1522Phe and 1994insA 1995 in BRCA2 are pathogenic (%7).
Based on our preliminary results two haplotypes may have a pathogenic role in breast cancer development:
1. Glu23Gln, Ile26Ieu, Ile15Ieu, Arg7Cys
Gly1140Ser Leu871Pro, GLu1038Gly, Ser1613Gly, 2.
Conclusion: In agreement with findings in other populations, we found that family history is a good predictor of being a mutation carrier. Further studies are required to confirm the hypothesis that genetic polymorphisms are associated with breast cancer.

P06.026
Description of *BRCA1/2* mutations in 2.908 Spanish breast/ovarian cancer families and development of a probability model for mutation prediction

Description of BRCA1/2 *mutations in 2.908 Spanish breast/ovarian cancer families and development of a probability model for mutation prediction*
Introduction: *BRCA1* (MIM# 113705) and *BRCA2* (MIM# 600185I) germ-line mutations cause inherited susceptibility to breast/ovarian cancer (BC/OC).
Objectives: 1) To know the variety and prevalence of *BRCA1* and *BRCA2* mutations in Spanish BC/OC families. 2) To assess the association between mutation status and individual and family characteristics. 3) To estimate the probability of *BRCA1/BRCA2* mutation detection.
Patients and Methods: index cases of 2.908 BC/OC families were analyzed for *BRCA1/BRCA2* germ-line mutations, and results were correlated with individual and familiar history. A multivariate logistic regression model was fitted for either *BRCA1* or *BRCA2*. Model discrimination and calibration was measured with the area under the ROC curve and the Hosmer-Lemeshow statistic.
Results: We identified mutations in 702 families (24.5%), 355 *BRCA1* (119 different) and 347 in *BRCA2* (138 different). Proband characteristics related to mutation were: a) *BRCA1*: OC+BC (OR=7.7 and 9.6 for uni or bilatBC), OC (OR=2.8) and bilatBC (OR=2.2). Family characteristics were: OC (OR=3.5 for 1 member, OR=7.3 for $\geq$ 2 members) and bilatBC (OR=1.54 for $\geq$ 1 members). b) *BRCA2*: bilatBC and OC (OR=8.5) and male BC (OR=3.1). Family characteristics were male BC (OR=6.9 for $\geq$ 1 members), BC (OR=1.9 for $\geq$ 2), OC (OR=1.6 for $\geq$ 1 members). Ages at diagnosis were inversely associated with risk of *BRCA1/BRCA2* mutations. Areas under the ROC curve were 0.77 for *BRCA1* and 0.71 for *BRCA2*.
Conclusions: Knowledge of individual and familiar variables associated to the presence of a mutation will allow a more effective detection strategy.

P06.027
Brca2 heterozygosity promotes Kras(G12D)-driven carcinogenesis in a murine model of familial pancreatic cancer

F. Skoulidis[1], *L. D. Cassidy*[1], *V. Pisupati*[1], *J. G. Jonasson*[2], *H. Bjarnason*[3], *J. E. Eyfjord*[3], *F. A. Karreth*[4], *M. L. Lim*[1], *L. M. Barber*[1], *S. A. Clatworthy*[1], *S. E. Davies*[5], *K. P. Olive*[6], *D. Tuveson*[4], *A. R. Venkitaraman*[1];
[1]*Department of Oncology and the Medical Research Council Cancer Cell Unit, University of Cambridge, Cambridge, United Kingdom,* [2]*Department of Pathology, Faculty of Medicine, Landspitalinn-University Hospital, University of Iceland and the Iceland Cancer Registry, Reykjavik, Iceland,* [3]*Cancer Research Laboratory, Faculty of Medicine, University of Iceland, Reykjavik, Iceland,* [4]*Li Ka Shing Centre, Cambridge Research Institute, Cancer Research UK, Cambridge, United Kingdom,* [5]*Addenbrooke's Hospital, Cambridge, United Kingdom,* [6]*Herbert Irving Comprehensive Cancer Centre and Department of Medicine and Pathology, Columbia University, New York, NY, United States.*

Inherited heterozygous BRCA2 mutations predispose carriers to tissue-specific cancers, but somatic deletion of the wild-type allele is considered essential for carcinogenesis. Using a murine model of familial pancreatic cancer that accurately recapitulates the clinical, histological and molecular features of the human disease, we find that germline heterozygosity for a pathogenic Brca2 mutation suffices to promote pancreatic ductal adenocarcinomas (PDACs) driven by Kras(G12D), irrespective of Trp53 status. Unexpectedly, tumour cells retain a functional Brca2 allele. Correspondingly, three out of four PDACs from patients inheriting the founder 999del5 mutation in BRCA2 did not exhibit loss of heterozygosity (LOH). On the other hand, three tumours from these patients with confirmed LOH were acinar carcinomas, normally a rare pancreatic neoplasm. Acinar carcinomas were also observed solely in mice bi-allelic Brca2 inactivation in the context of mutant Trp53(R270H) expression. Based on these findings we suggest a revised model for tumour suppression by BRCA2 with implications for the therapeutic strategy targeting BRCA2-mutant cancer cells.

P06.028
Predicted deleterious BRCA2 missense variants detected in Czech high-risk hereditary breast cancer families: segregation analysis and clinical data.

E. Machackova[1], *M. Mikova*[1], *T. Hucl*[2], *L. Foretova*[1];
[1]*Masaryk Memorial Cancer Institute, BRNO, Czech Republic,* [2]*Institute for Clinical and Experimental Medicine, PRAHA, Czech Republic.*

In the analysis of genes associated with the cancer predisposition the deleterious mutations can be relatively easily distinguished if it is obvious that there is disruption in the coding sequence. However, rare missense and non-truncating variants found in cancer predisposing genes often create difficulties in clinical interpretation of laboratory mutation screening results.
Here we present available segregation data and clinical information

of four predicted deleterious BRCA2 missense variants located in C-terminal DNA bindings domain (exons 17 and 18) detected in Czech high-risk hereditary breast cancer families: p.His2623Arg, p.Trp2626Cys; p.Glu2663Val; Asp2723Gly; as well as two not yet described novel variants: p.Lys2630Gln and in-frame deletion p.Ala2633_Glu2635del. Other rare missense variants detected in Czech families in this region that were previously predicted or determined by functional assays as likely neutral were: p.Arg2666Thr; p.Ser2704Phe, p.Ala2717Ser; p.Val2728Ile and p.Lys2729Asn. None of all these BRCA2 variants was detected in 100 unrelated elderly (>60 years of age) healthy Czech women without any personal history of cancer and without family history of breast, ovarian, pancreas or colorectal cancers.
Segregation analysis in hereditary breast cancer families provides information to distinguish between deleterious and neutral missense alterations identified in BRCA2 gene, but most mutations are very rare and familial data are often insufficient. There is an enormous need to have a reliable functional assay. A novel functional assay using a syngeneic knock-in cancer cell line model is going to be applied to some of these variants.

P06.029
Search for novel germ-line mutations in familial BRCA1/2-negative breast cancers

A. Sokolenko[1,2], *E. Suspitsin*[1,2], *A. Iyevleva*[1,2], *E. Chekmariova*[1], *N. Mitiushkina*[1], *S. Abysheva*[1], *E. Imyanitov*[1,2];
[1]*N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation,* [2]*St.-Petersburg State Pediatric Medical Academy, St.-Petersburg, Russian Federation.*

Major breast cancer (BC) genes, BRCA1 and BRCA2, contribute to no more than 20-25% familial BC clustering; therefore the majority of BC-predisposing mutations remain to be identified. We have selected 95 BC cases, which showed accumulation of clinical signs of the genetic disease (e.g., occurrence of BC among multiple relatives and/or bilaterality and/or young age), but could not be explained by BRCA1/BRCA2 alterations or recurrent mutations in CHEK2 (c.1100delC, c.444+1G>A, del5395) or NBN (c.657_661delACAAA) genes. The analysis of coding regions was performed using HRM (high resolution melting) followed by DNA sequencing. First, we considered the extended study for the CHEK2 and NBN: these genes are well known for the founder BC-predisposing mutations, but, surprisingly, they have not been subjected to a systematic full-length screen. However, no novel mutations in CHEK2 or NBN have been detected in our series. Next, we investigated the PALB2, BRIP1, BARD1, and RAD51C. These genes were shown to cause familial BC in selected publications, but their global-wide relevance remains to be evaluated. We have identified 2 instances of the PALB2 mutation (p.R414X, p.Q921X) in bilateral BC cases. We then continued the analysis of other genes involved in double-strand break DNA repair; by the time of abstract submission, the CHEK1, PARP1, PARP2, ERCC1, XPE, BLM, BRD7, RNF8, RAD51A, and FANCG have been investigated. One BC case contained insertion/deletion mutation in the FANCG gene (c.520_524delTCTAinsC). We suggest that HRM/sequencing analysis of candidate genes in BRCA1/2-negative familial BC cases is a realistic approach to pinpoint new hereditary cancer mutations.

Evaluation of *RAD51C* as a new breast cancer susceptibility gene in the Belgian/Dutch population

K. De Leeneer[1], *M. Van Bockstael*[1], *N. Swietek*[1], *J. Van den Ende*[2], *K. Storm*[2], *B. Blaumeiser*[2], *K. Leunen*[3], *C. J. van Asperen*[4], *J. T. Wijnen*[4], *E. Legius*[5], *G. Michils*[5], *G. Matthijs*[5], *M. J. Blok*[6], *E. B. Gomez-Garcia*[6], *A. De Paepe*[1], *B. Poppe*[1], ***K. Claes***[1];
[1]*Center of Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Center of Medical Genetics, University Hospital of Antwerp, Antwerp, Belgium,* [3]*Department of Gynaecological Oncology, Catholic University of Leuven, Leuven, Belgium,* [4]*Dep. of clinical genetics, Leiden University Medical Center, Leiden, Netherlands,* [5]*Department of Human Genetics, Catholic University of Leuven, Leuven, Belgium,* [6]*Department of Clinical Genetics, Maastricht University Medical, Maastricht, Netherlands.*

Recently, germline mutations in *RAD51C* were found to be associated with an increased risk for breast and ovarian cancer. Meindl et al. (2010) detected six monoallelic pathogenic mutations in *RAD51C* by screening 1.100 unrelated German women with gynaecologic malignancies (breast and/or ovarian tumors). Strikingly, all six deleterious mutations were exclusively found within 480 *BRCA1/2* negative breast and ovarian cancer families and not in breast cancer only families.
With this study we aim to determine the prevalence of germline *RAD51C* mutations in Belgian/Dutch breast and ovarian cancer families, previously found to be negative for *BRCA1&2* mutations. We performed mutational analysis in 350 index patients. Mutation detection was performed with High resolution melting curve analysis (HRMCA), followed by Sanger sequencing of the aberrant melting curves.
Besides frequent single nucleotide polymorphisms and some novel, rare variants of which the clinical significance is currently under evaluation, we did not identify any deleterious mutation. To increase the number of probands to a similar number as in the initial report, we screened 100 additional families with HRMCA. Sequencing analysis of the fragments with aberrant melting curves is currently ongoing. We are the first group to investigate a cohort of breast and ovarian cancer families of comparable size as Meindl et al., and based on their findings, we had expected to detect at least three deleterious mutations. As other studies on (male) breast cancer families also did not identify deleterious germline *RAD51C* mutations, these may be less frequent than initially reported.

P06.031
Germ-line mutations and sequence variants of breast cancer susceptibility genes BRCA-1 and BRCA-2 in a Sri Lankan cohort of breast cancer patients

K. H. Tennekoon[1], *E. H. Karunanayake*[1], *S. Silva*[1], *W. Silva*[1], *I. Amarasinghe*[2], *P. Angunawela*[3];
[1]*Institute of Biochemistry, Molecular Biology and Biotechnology, University of Colombo, Colombo, Sri Lanka,* [2]*National Cancer Institute, Maharagama, Sri Lanka,* [3]*Department of Pathology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka.*

A cohort of familial (N=66 for BRCA-1; N=55 for BRCA-2) and sporadic (N=64 for BRCA-1 and N=54 for BRCA-2) breast cancer patients and at risk individuals (those with a positive family history of breast cancer but not yet affected by the disease; N=70 for BRCA-1 and N=20 for BRCA-2) were studied to identify possible mutations and sequence variants in the breast cancer susceptibility gene *BRCA-1* and *BRCA-2* . DNA extracted from peripheral venous blood samples was amplified by polymerase chain reaction using target specific primers and the PCR products were analysed using single strand conformation polymorphism and DNA sequencing.
Nineteen sequence variants including six previously unreported variants were identified in the *BRCA1* gene and twenty three sequence variants including ten previously unreported variants were identified in the BRCA2 gene. Novel *BRCA-1* sequence variants included two deleterious frame-shift insertion mutations, c.3086delT/exon11 and c.5404delG/exon21. Novel *BRCA-2* sequence variants included two deleterious frame-shift mutations, 2403 insA / exon 11 and 2667 insT / exon 11, two possibly pathogenic mutations, 1191 A>C /exon 10, 5695 A>C /exon 10 and one unclassified intronic variant IVS15-21 insTT.
Prevalence rate of pathogenic and possibly pathogenic mutations in familial breast cancer was 6.25% for *BRCA-1* and 12.73% for *BRCA-2.* Of these, one pathogenic mutation (c.2403insA in exon 11) was seen in four unrelated breast cancer patients. Thus screening for *BRCA-2* mutations, in particular for 2403 insA / exon 11 is likely to be useful in Sri Lankan clinical practice.

Large genomic aberrations in BRCA1 and BRCA2 genes in Bulgarian breast cancer patients

R. I. Dodova[1,2], *D. Dacheva*[1], *A. Vlahova*[3], *T. Dikov*[3], *S. Hristova*[3], *S. Valev*[4], *C. Timcheva*[4], *V. Mitev*[1,2], *R. Kaneva*[1,2], *A. Mitkova*[1,2];
[1]*Molecular Medicine Center, Medical University -Sofia, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University – Sofia, Sofia, Bulgaria,* [3]*Central Laboratory of Clinical Pathology, UMHAT "Aleksandrovska", Medical University – Sofia, Sofia, Bulgaria,* [4]*Chemotherapy*

Clinic, NSHATO, Sofia, NSHATO - Sofia, Sofia, Bulgaria.
Background: Studies on different population worldwide have shown that the large-fragment aberration in BRCA cancer susceptible genes account for the large amount of hereditary breast and ovarian cancer cases.
Material and methods: In the present study we performed MLPA analysis of the large genomic BRCA1 and BRCA2 alterations in 100 Bulgarian breast cancer patients fulfilling the BCLC criteria. MLPA was carried out by SALSA MLPA KIT P002 -C1 BRCA2 and SALSA MLPA KIT P090 BRCA2 (MRC-Holland). The results analyzed by Coffalyser data analysis software.
Results and discussion: The frequency of the large genomic BRCA1/2 alterations found in the present study was 8%, which was in consistency with previous studies in other populations. Four genomic alterations were found in the *BRCA1* gene (4%): del *BRCA1* ex 11A in patient with both breast and ovarian cancer; del *BRCA1* ex 13 in a women with early onset and family history of breast cancer; dup *BRCA1* ex 14-15 and dup *BRCA1* ex 20 in two patients with family history of breast cancer. The observed *BRCA2* mutations were also four (4%): del *BRCA2* ex 3 in a patient with family history of breast cancer; del *BRCA2* ex 25-27 in a young women with early onset and family history; dup *BRCA2* ex 9 and dup *BRCA2* ex 27, respectively, in two women with early onset and family history of breast cancer.
Conclusion: Combination of MLPA with the conventional methods for mutation screening will assist the discovery of all spectra of mutations in Bulgarian breast cancer patients.

P06.033
Mutation screening of *BRCA2* exons 11 in Bulgarian breast cancer patients

D. R. Dacheva[1], *R. Dodova*[1,2], *A. Vlahova*[3], *T. Dikov*[3], *S. Christova*[3], *S. Valev*[4], *C. Timcheva*[4], *V. Mitev*[1,2], *R. Kaneva*[1,2], *A. Mitkova*[1,2];
[1]Molecular medicine centre, MU- Sofia, Sofia, Bulgaria, [2]Department of Medical Chemistry and Biochemistry, Medical University – Sofia, Sofia, Bulgaria, [3]Central Laboratory of Clinical Pathology, UMHAT "Aleksandrovska", Medical University – Sofia, Sofia, Bulgaria, [4]Chemotherapy Clinic, NSHATO, Sofia, Sofia, Bulgaria.
Background: Studies on different populations worldwide demonstrate that germ line mutations in *BRCA* genes account for the majority of hereditary breast and ovarian cancers.
Materials and methods: We have screened 130 breast cancer patients, fulfilling the BCLC criteria, for germ-line mutations in BRCA2 exon 11. Mutation analysis was performed by direct sequencing using 17 primer pairs.
Results: The founder mutation described in Ashkenazi Jews: 6174delT was observed in one patient with bilateral breast and ovarian cancer. The mutation was also found in the healthy daughter of the patient. Another deleterious mutation 5854delAGTT was detected in two patients with family history of breast cancer. In addition we found one rare missense alteration in codon 1915(C>T) leading to replacement of Thr with Met in three patients - one with early onset and two with strong family history of the disease. *Conclusions:* Protein-truncating mutations of BRCA2 are usually deleterious and increase the risk of breast cancer up to 80% over a lifetime. The mutations discovered in the studied Bulgarian breast cancer patients were previously observed in other European populations. It has been known that 6174delT founder mutation occurs very frequently (1.5%) among Ashkenazi Jews, but also appears in non-Jewish individuals from Europe, Canada etc. The Thr1915Met polymorphism (European population diversity C/T 6.4%) is a common variant in Poland that increases the risk of DCIS with micro-invasion. Further analysis of the other BRCA2 exons is necessary in order to ascertain the full spectra of the BRCA2 mutations in the Bulgarian breast cancer patients.

P06.034
The Risk of Breast Cancer in Women with a CHEK2 Mutation with and without a Family History of Breast Cancer

C. Cybulski, *D. Wokołorczyk, A. Jakubowska, T. Huzarski, T. Byrski, J. Gronwald, T. Dębniak, B. Górski, S. A. Narod, J. Lubiński;*
Pomeranian Medical University, Szczecin, Poland.
PURPOSE: To estimate the risk of breast cancer in a woman who has a CHEK2 mutation depending on her family history of breast cancer. To evaluate whether CHEK2 mutation testing may be useful in clinical practice.
PATIENTS AND METHODS: 7,494 BRCA1-mutation negative breast cancer patients and 7,217 controls were genotyped for four founder mutations in CHEK2 (del5395, IVS2+1G>A, 1100delC, I157T). Odds ratios were constructed for the cases, subdivided by the number of breast cancer cases reported in first-and second-degree relatives.
RESULTS: A truncating mutation (IVS2+1G>A or 1100delC or del5395) was present in 227 (3.0%) cases and in 70 (1.0%) controls (OR = 3.0; 95% CI = 2.4 to 4.2). The OR was higher for women with a first- or second-degree relative with breast cancer (OR = 4.4; 95% CI = 3.1 - 6.2) than for women with no family history (OR = 2.9; 95%CI = 2.2 - 3.8). If both a first- and second-degree relative was affected with breast cancer, the odds ratio was 6.4 (95% CI 2.9 - 14.3). Based on the observed odds ratios, and assuming a baseline risk of 6%, we estimate the lifetime risks for carriers of CHEK2 truncating mutations to be 25% for a woman with one second-degree-relative affected, 30% for a woman with one first-degree relative affected, and 38% for a woman with both first- and one-second degree relative affected.
CONCLUSION: CHEK2 mutation screening detects a clinically meaningful risk of breast cancer.

P06.035
Development of a new method in BRCA1 and BRCA2 genetic analysis based in CSGE

s. rezaee[1], *n. Khazamipour*[1], *h. Shabanloo*[1], *s. Mohamadi Fateh*[1], *M. Noruzinia*[2];
[1]Sarem Cell Research Center and Sarem women hospital, Tehran, Islamic Republic of Iran, Tehran, Islamic Republic of Iran, [2]. Department of Medical Genetic and Hematology, faculty of medical sciences, Tarbiat Modares University, Tehran, Iran., Tehran, Islamic Republic of Iran.
Breast cancer is the most frequent cause of cancer in women. Inherited breast cancer tend to occur earlier in life than sporadic cases and are more likely to involve both breasts. The BRCA1 protein acting as a gatekeeper in maintaining genome integrity. Therefore, any loss of function in BRCA1 protein will result in accumulation of genetic defects leading to cancer. Mutations in BRCA1 and BRCA2 are inherited in an autosomal dominant pattern. Each offspring of an individual with a BRCA1 or BRCA2 cancer-predisposing mutation has a 50% chance of inheriting the mutation. Mutation detection is thus important to detect anu susceptibility in family members. Molecular genetic testing of asymptomatic family members at risk of inheriting either a BRCA1 or BRCA2 cancer-predisposing mutation is possible once the family-specific mutation has been identified.
In this paper we present two families with new mutation in BRCA1 and BRCA2, both of them have family history of breast cancer.
To detect mutations in all exons we developed a new method based on CSGE(conformation sensitive gel electrophoresis) this new method permitted us to examine all exons and important intronic regions of BRCA1&2 will minimum of expense and with high sensitivity. PCR products that show heteroduplex pattern on CSGE gel, were subjected to direct DNA sequencing to identify the causative mutation. This molecular genetic test have shown mutation in BRCA2 gene (IVS 10+12 delT) in the first proband. The other one has a transition mutation (C to T) that results in a stop codon in codon 934.

P06.036
Aberrant promoter hypermethylation of Dickkopf-1 (DKK1) gene in tumor and adjacent normal tissue in breast cancer patients.

M. Acar[1], *T. Cora*[1], *H. Toy*[2], *H. Acar*[1];
[1]Department of Genetic, Konya, Turkey, [2]Department of Pathology, Konya, Turkey.
Breast cancer is the most common malignancy in women worldwide. Dickkopf-1 (DKK1) gene product is a potent inhibitor of Wnt pathway. In this study, DKK1 methylation status and its protein expression were examined in normal and cancer tissues of same patients.
DKK1 promoter methylation was assessed by bisulfite-converted-MSP technique in breast cancer patients. We examined methylation changes in 83 tumors and adjacent normal tissues and also in 6 out of 9 normal breast tissues from unaffected women (no breast cancer history) as controls. Immunohistochemical staining was used to investigate DKK1 protein expression in 9 controls and 70 out of 83 tumors as well as adjacent normal tissues. Immunohistochemical result was categorized as positive or negative for DKK1.

DKK1 gene methylation was detected in normal breast tissue from unaffected women (33%). DKK1 gene was highly methylated in tumors (70%) and adjacent normal tissues (61%). Immunohistochemically, 67% normal breast tissue from unaffected women, 69% tumors and 83% adjacent normal tissues were DKK1 negative. DKK1 promoter methylation and protein expression were not associated with age, tumor size, lymph node status, histological grade, and oestrogen receptor or progesteron receptor or CERB2 positivity. Our results showed that there is a positive correlation between hypermethylation pattern and lower expression level. However, there were no differences DKK1 promotor methylation and protein expression levels between tumor and adjacent tissues. This result indicates that there is no different methylation pattern in either breast tumor or normal breast tissue, indicating that DKK1 is not specific for breast tumor.

P06.037
Differential allelic expression of BRCA1 and BRCA2 in normal cells does not drive specificity of allelic imbalance in tumors of breast cancer patients

M. Vreeswijk, F. Blanken, P. Van der Bent, C. Meijers, E. Van Zwet, C. Cornelisse, R. Tollenaar, V. Smit, ***P. Devilee****;*
Leiden University Medical Center, Leiden, Netherlands.

Differential allelic expression (DAE) is a phenomenon in which the two alleles of a gene are not expressed at equal levels. DAE affects a substantial fraction of the human genome, and has been suggested to be an important cause for human phenotypic variability, including complex traits and diseases. We have explored the hypothesis that DAE at *BRCA1* or *BRCA2* may play a role in the pathogenesis of breast cancer. Both *BRCA1* and *BRCA2* are tumor suppressor genes; breast tumors developing in women who have inherited an inactivating mutation in either of these genes have virtually always lost the wild type allele at the gene locus. In a series of 130 breast cancer cases, we determined allele-specific expression levels of *BRCA1* and *BRCA2* in normal skin fibroblasts cultured from mastectomy tissue. DAE was detected in 23% of patients at *BRCA1*, and 38% of patients at *BRCA2*. We then analyzed the allelic status of both genes in genomic DNA isolated from matching tumor samples. Allelic imbalance was detected in 73% and 52% of tumors at *BRCA1* and *BRCA2*, respectively. DAE at *BRCA1* in normal fibroblasts was not correlated with allelic imbalance at the *BRCA1* gene locus in the tumor, nor did we observe a preferential loss in the tumor of the allele that was expressed at highest level in corresponding normal tissue. A similar finding was made for *BRCA2*. We conclude that DAE at *BRCA1* and *BRCA2* does not operate in conjunction with allelic imbalance to contribute to tumorigenesis in the breast.

P06.038
Investigating FGFR2 and B7-H4 gene polymorphisms and their effects in breast cancer

A. Özgöz*[1], H. Şamlı[2], K. Hekimler[1], B. Orhan[3], F. Mutlu İçduygu[1], F. Aktepe[4], N. İmirzalıoğlu[1];*
[1]Afyon Kocatepe University, School of Medicine, Department of Medical Genetics, Afyonkarahisar, Turkey, [2]Uludağ University, Faculty of Veterinary Medicine, Department of Genetics, Bursa, Turkey, [3]Acıbadem University, School of Medicine, Department of Medical Oncology, İstanbul, Turkey, [4]Afyon Kocatepe University, School of Medicine, Department of Pathology, Afyonkarahisar, Turkey.

FGFR2 is amplified and overexpressed in breast cancer. In recent years, some publications have reported the role of FGFR2 polymorphisms in breast cancer risk. B7-H4 is reported to be highly expressed in almost all breast ductal and lobular carcinomas. B7-H4 overexpression seems to occur early in breast carcinogenesis. In a study performed, an association was detected between B7-H4 polymorphisms and breast cancer risk.
In our study, FGFR2 gene rs1219648, rs2981582 SNPs were studied by sequence analysis and B7-H4 gene rs10754339, rs10801935, rs3738414 SNPs were studied by PCR-RFLP method in 31 cases with breast cancer and in 30 women control.
Although statistically not important, the frequency of FGFR2 rs1219648, rs2981582 heterozygous polymorphisms and B7-H4 rs10801935 polymorphism AA, AG genotypes were found to be higher in breast cancer cases. In contrast to the previously found, B7-H4 rs3738414 polymorphism GG genotype frequency was found to be higher in the control group (p=0,018).
According to the literature scan it seems that our study is the first study results evaluating FGFR2 and B7-H4 gene polymorphisms together in breast cancer, frequency of these polymorphisms and their relations with breast cancer should be revealed with studies including large case numbers.

P06.039
The influence of MDR1 gene C3435T, T1236C, G2677T/A, A2956G polymorphisms on breast cancer development risk

F. Mutlu İçduygu*[1], H. Şamlı[2], T. Evrensel[3], A. Özgöz[1], K. Hekimler[1], M. Canhoroz[3], N. İmirzalıoğlu[1];*
[1]Afyon Kocatepe University School of Medicine Department of Medical Genetics, Afyonkarahisar, Turkey, [2]Uludağ University School of Veterinary Medicine Department of Genetics, Bursa, Turkey, [3]Uludağ University School of Medicine Department of Medical Oncology, Bursa, Turkey.

The P- glycoprotein (P-gp), encoded by the MDR1 (ABCB1) gene, is a member of the family of ATP binding cassette (ABC) transporter proteins. P-gp, which needs ATP energy to be functional, prevents the accumulation of potentially toxic substances and metabolites by extruding them out of the cell. The single nucleotide polymorphisms (SNPs) of the MDR1 gene can cause differences in P-gp expression levels and this is associated with predisposition to some diseases including breast cancer. In the current study MDR1 gene polymorphisms [C3435T (rs1045642), T1236C (rs1128503), G2677T/A (rs2032582), A2956G] were identified by Polymerase Chain Reaction - Restriction Fragment Length Polymorphism Method (PCR - RFLP) in 30 cases with breast cancer and 20 women control. When the patient group and healthy controls were compared, the only significant difference was observed in the C3435T polymorphism. TT genotype frequency was higher in the patient group compared to the healthy controls (p= 0.047) and CT genotype frequency was higher in the control group compared to the patient group (p= 0.08). According to our results TT carriers may have an increased risk for developing breast cancer. However more studies with large case numbers must be carried out in order to determine the role of MDR1 gene SNPs in the risk of breast cancer development.

P06.040
Exome sequencing of 12 familial breast cancer cases without a mutation in *BRCA1* or *BRCA2*

F. S. M. Hilbers*[1], P. M. Nederlof[2], N. Hoogerbrugge[3], J. C. Oosterwijk[4], A. M. W. van den Ouweland[5], J. T. den Dunnen[1], C. J. van Asperen[1], P. Devilee[1];*
[1]Leiden University Medical Centre, Leiden, Netherlands, [2]The Netherlands Cancer Institute NKI/AvL, Amsterdam, Netherlands, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]University Medical Center Groningen, Groningen, Netherlands, [5]Erasmus Medical Center, Rotterdam, Netherlands.

The large majority of families with multiple cases of breast cancer can not be linked to mutations in *BRCA1* or *BRCA2*. In this study, we investigate the possibility that a proportion of the non-*BRCA1/2* families is due to rare high-risk genes.
To reduce the genetic heterogeneity, we selected six non-*BRCA1/2* families in which the breast cancers of most patients shared a particular array CGH profile. By means of next generation sequencing, we performed exome sequencing on germline DNA of two family members affected with breast cancer per family. Only variants that were shared between the family members were considered. Intergenic, intronic or synonymous coding variants, together with homozygous variants were excluded. Variants present in dbSNP or 1000 genomes were excluded if the allele frequency in any population was higher than 1%.
The selected families collectively showed a linkage peak on chromosome 4 with a homogeneity LOD score of 2,49. When focusing on this region, there were no genes in which breast cancer patients of all six families had a variant.
At the moment of abstract submission, we are following up on genes having variants in two or more families and are extending the data analysis to genes outside the chromosome 4 region.

P06.041
Silencing of a ubiquitin specific protease; USP32 in HeLa and MCF7 cancer cell lines

H. B. Akman Tuncer, *A. E. Erson Bensan;*
Middle East Technical University, Ankara, Turkey.

Previous studies identified chromosomal band 17q23 as a frequent site of gene amplification in breast cancer. *USP32* is one of the oncogene candidates in this region. Ubiquitination changes activity, localization, half-life, conformation, and stability of proteins. Hence, ubiquitination and deubiquitination may have important consequences in cells. Previously, USP32 was shown to be an active deubiquitinating enzyme by an *in vivo* deubiquitination assay in our laboratory. We hypothesized that amplification of *USP32* may contribute to breast tumorigenesis by its deubiquitinating activity. Real time RT-PCR was performed to detect *USP32* overexpression in breast cancer cell lines and primary tumors. Our results showed that *USP32* was expressed more than 5-folds in 30% of human breast cancer cell lines and 2-folds in 22% of human primary breast tumors.

RNAi silencing of *USP32* was achieved by pSUPER shRNA and confirmed by real time RT-PCR. Proliferation rate of *USP32* silenced cells was determined by the MTT Assay. Transwell migration assay was used to compare migration abilities of *USP32* silenced cells. Stable silencing of *USP32* in HeLa and MCF7 cells caused a decrease in the proliferation rate up to 35%. Migration abilities of HeLa and MCF7 cells were decreased after *USP32* silencing as tested by transwell migration assay. In short, we detected that *USP32* had roles in cell proliferation and migration which may be important for understanding the complex mechanisms of breast tumorigenesis. We are conducting expression experiments in non-tumorigenic breast cell line MCF10A to further delineate its function in cells and contribution to tumorigenesis.

P06.042
IDH1, IDH2 and TP53 mutations in Bulgarian patients with glial tumours

G. Stancheva[1,2], *T. Goranova*[2], *M. Laleva*[3], *M. Kamenova*[4], *A. Mitkova*[1,2], *N. Velinov*[3], *R. Kaneva*[1,2], *G. Poptodorov*[3], *V. Mitev*[1,2], *N. Gabrovsky*[3];
[1]*Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria,* [2]*Molecular Medicine Center, Medical University, Sofia, Bulgaria,* [3]*Department of Neurosurgery, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria,* [4]*Department of Pathology, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria.*

Glioma is the most common primary brain cancer and it is characterized with high mortality. A recent analysis of gliomas has revealed somatic mutations in the *IDH1* and *IDH2* genes, which encode cytosolic and mitochondrial NADPH-dependent isocitrate dehydrogenase, respectively. Genetic aberrations in *IDH1* or *IDH2* genes have been commonly found together with mutated *TP53* gene and associated with good prognosis for the patients.

Materials and methods:

To validate prognostic significance of genes *IDH1*, *IDH2* and *TP53* in Bulgarian patients, we screened 50 primary intracranial tumours, including astrocytomas and oligodendrogliomas. All samples were examined by direct sequencing of exon 4 of *IDH1* and *IDH2* genes, and exon 5-8 of *TP53* gene.

Results:

IDH1 mutations were detected in 12 (24%) gliomas, all were G>A changes within the isocitrate binding site (R132) at position 395. No mutation was found in *IDH2*. Aberrations in *TP53* were detected in 12 (24%) tumours. Five (42%) of them carried also an *IDH1* mutation. Patients with mutations in both *IDH1* and *TP53* were younger (median age 35) then those with an aberration only in one gene (49.5) or non-mutated cases (55; p=0.016). Median survival of patients harbouring mutations in two genes was 44.3 months compared to those with mutation in one of the genes and non-mutated cases - 11.9 and 7.3 months, respectively (p=0.04).

Conclusions:

IDH1 and *TP53* mutations are common in gliomas with good survival and may be used as specific prognostic biomarkers in Bulgarian patients with brain tumours.

P06.043
The expression of multiple cancer-testis antigens in cancerous cell lines

S. Yousef amoli[1,2], *L. Kokabee*[1], *H. Rahimi*[1], *M. Karimipour*[1];
[1]*Molecular Medicine Department of Pasteur Institute, Tehran, Islamic Republic of Iran,* [2]*Faculty of Science, Science and Research Campus, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Cancer-testis antigens (CTAs) are a gene family which only express in testis tissue, but some of them are randomly expressed in some types of cancers. Since testis is an immune privileged site, if these genes are expressed in tumors, they can be immunogenic. Therefore, these antigens are promising targets for cancer-specific immunotherapy. We studied the expression of NY-ESO-1 1a, NY-ESO-1 1b, SCP-1, SSX-2 and MAGE-3 in different cell lines (A375 , U373MG , 1321N1 , RPMI , MCF , MDAM13 453 and PC3) by Multiplex RT-PCR method.

Total RNA was extracted from the cell lines and cDNA synthesized, after wards Multiplex PCR performed by using primers of each CTA gene and GAPDH as internal control. The expression of these genes was detected with gel electrophoresis and staining with ethidium bromide (the results are presented in Table-1).

This preliminary study is in agreement with previous data on expression of CTAs in tumors and the potential use in immunotherapy of cancers.

Table 1; The results of expression of CTAs in seven diferent cell lines. N.D=Not Determind

Canine mammary tumours are excellent models for human breast cancer

M. Melin[1], *P. Rivera*[1], *M. Arendt*[2], *T. Fall*[1], *T. Biagi*[3], *S. Westberg*[1], *K. Borge*[4], *J. Häggström*[1], *F. Lingaas*[4], *M. Starkey*[5], *H. von Euler*[1], *K. Lindblad-Toh*[2,3];
[1]*Swedish University of Agricultural Sciences, Uppsala, Sweden,* [2]*Science for Life Laboratory, Uppsala University, Uppsala, Sweden,* [3]*Broad Institute, Cambridge, MA, United States,* [4]*Norwegian School of Veterinary Science, Oslo, Norway,* [5]*Animal Health Trust, Newmarket, United Kingdom.*

Breast cancer is a major contributor to overall morbidity and mortality in women and the genetic causes underlying the disease are unclear in the majority of the cases. Canine mammary tumours (CMT) are suitable naturally occurring tumour models for human breast cancer and share many similarities, including epidemiological, clinical, morphological and prognostic features. The knowledge about the inherited risk factors underlying CMT is limited, but clear breed predispositions exist, with 36% of English Springer Spaniels (ESS) in Sweden being affected.

We have collected a large material of ESS samples with in-depth clinical information about each dog. Ten human breast cancer genes (*BRCA1*, *BRCA2*, *CHEK2*, *ERBB2*, *FGFR2*, *LSP1*, *MAP3K1*, *RCAS1*, *TOX3* and *TP53;* 4-9 SNPs per gene) have been evaluated for association with canine mammary tumours ESS female dogs, 212 CMT cases and 143 controls. The two tumour suppressor genes *BRCA1* and *BRCA2* were significantly associated with CMT (p_{Bonf}=0.005, and p_{Bonf}=0.0001 respectively). Both *BRCA1* and *BRCA2* confer a ~4 fold increased risk for CMT. Preliminary genome-wide association results from the ESS cohort suggest that at least ten loci contribute to the disease and several associated regions contain plausible candidate genes. Further work includes targeted resequencing of candidate loci as well as DNA and RNA tumour/normal comparisons.

Our results suggest that CMT is an excellent model for human breast cancer, indicating that both humans and dogs can benefit from further comparative studies. This could provide a unique opportunity to

improve prevention, diagnosis and treatment of both CMT and human breast cancer.

P06.045
Analysis of CD38 and ZAP70 mRNA expression within cytogenetic subgroups of chronic lymphocytic leukemia in Iranians

H. Teimori[1], *M. Akbari*[2];
[1]*Cellular and Molecular Research Center, Shahrekord, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University,, tehran, Islamic Republic of Iran.*

Chromosomal abnormalities, CD38 and ZAP70 expression profile are major independent prognostic markers in B-cell chronic lymphocytic leukemia (B-CLL). The present study was designed to investigate possible correlation between these three markers. CD38 was determined using flowcytometery in 65 patients' blood and ZAP70 expression using Real Time RT-PCR was examined in 20 B-CLL patients with del13q14, 13 patients with del11q22, 15 patients with trisomy 12 and 16 patients with undetected chromosomal abnormalities. CD38 shows weak prognostic value and also weak correlation with ZAP70 expression. Molecular analysis revealed that ZAP70 expression in del13q subgroup was the same as control group whilst it increased 2.7838 fold in del11q subgroup and 2.9547 fold in trisomy 12 subgroups compared to 15 cases of control group. Comparison of the mean and Standard Deviation of the ZAP70 expression profile within the subgroups showed that its value between the individuals of the del11q and trisomy 12 subgroups were highly variable, as against tight clustering for del13q subgroup. Therefore, there is a correlation between del13q aberration which has good prognosis with normal level of ZAP70 expression, whereas due to wide variation, no conformity is seen for del11q and trisomy 12 subgroups as poor prognostic discriminators.
It could be concluded that CD38 could not be regarded as a reliable prognostic factor, and has a poor concordance with ZAP70 expression profile whereas ZAP70 shows a good concordance with cytogenetic abnormalities and simultaneous analyzing of these two markers produce better prognosis.

P06.046
CHEK2 contributes to hereditary susceptibility to breast cancer in non-BRCA families

A. Desrichard[1,2], *Y. Bidet*[2], *N. Uhrhammer*[1], *Y. Bignon*[1,2];
[1]*Centre Jean Perrin, Clermont Ferrand, France,* [2]*Université d'Auvergne, Clermont Ferrand, France.*

Mutations in the *BRCA1* and *BRCA2* genes are responsible for only a part of hereditary breast cancer (HBC). The origins of "non *BRCA*" HBC families may be attributed in part to mutations in genes giving moderate risk, such as *CHEK2*. We investigated the contribution of *CHEK2* mutations to non-*BRCA* HBC by direct sequencing of its entire coding sequence. Fifteen mutations were discovered among 507 non-*BRCA* HBC cases and four among 513 controls. The frequency of *CHEK2* variants was significantly higher among cases (p= 0.0076), and gave an OR for breast cancer of 4.72 for deleterious mutation carriers. We then used both in silico tools and in vitro kinase activity to evaluate recombinant mutant proteins. Tumor characteristics and tumor grade of paraffin-embedded tissue blocks from 8 *CHEK2* mutated patients were evaluated by histology. To further caraterize those tumors, breast cancer immunohistochemical markers such as hormone receptors, HER2 and P53 were assessed. Because the mechanisms of tumorigenesis in association with *CHEK2* variants are still unclear, we performed genetic and epigenetic analysis of those tumors. Three revelant SNPs spanning the *CHEK2* gene locus were used to determine loss of hetherozygosity (LOH). Also, the proximal CpG islands of the *CHEK2* gene were investigated for hypermethylation. Our results suggests a contribution of *CHEK2* mutations to non-*BRCA* HBC, though the usefulness of moderate penetrance genes for genetic counseling remains controversial.

P06.047
The analysis of NPM1, FLT3 and c-KIT gene mutations in childhood acute myeloid leukemia in Russia.

Y. Yatsenko[1], *O. Kalennik*[1], *M. Maschan*[2], *I. Kalinina*[2], *T. Nasedkina*[1];
[1]*Engelhardt Institute of Molecular Biology RAS, Moscow, Russian Federation,* [2]*Federal Research Center for Pediatric Hematology, Oncology, and Immunology, Moscow, Russian Federation.*

Acute myeloid leukemia (AML) patients without chromosomal abnormalities are classified into intermediate risk group; however they have various prognosis and clinical outcome. To estimate new prognostic and diagnostic markers we studied the frequencies of NPM1, FLT3 and c-KIT genes mutations in childhood AML in Russian population. 188 de novo AML paediatric patients with the median age of 8 have been studied. In parallel, samples were analyzed for most common AML chromosomal aberrations using diagnostic biochip, and the aberrations were found in 76 (40.4%) of 188 AML patients. The NPM1 mutations appeared in patients without cytogenetic aberrations only. The frequency was 3.7% (7/188) of total AML patients group and 6.2% (7/112) of patients without cytogenetic aberrations. The FLT3 mutation appeared in 10.5% (21/188) of all AML patients, in 11.6% (13/112) of patients without cytogenetic aberrations and in 10.5% (8/76) of patients with aberrations. The FLT3/ITD and FLT3/TKD were found in 7.9% (15/188) and in 3.2% (6/188) of all AML patients, correspondingly. The c-KIT mutations were found in 2.7% (5/188) of all AML patients. The mutation in c-KIT exon 17 was found in 0.5% (1/188) of all AML patients. Different mutations in c-KIT exon 8 were found in 2.1% (4/188) of AML cases. Since the mutations in NPM1 gene are significantly associated with normal karyotype (P<0.05) it makes them convenient diagnostic markers for MRD monitoring. The biochip for the analysis of mutations mentioned may be useful for clinical practice.
The work was supported by Russian Foundation for Basic Research (project no. 08-04-01480).

P06.048
Comparison between two molecular methods for the monitoring of post-transplant chimerism

A. Lari, *G. Iaquinta, S. Iozzi, B. Minuti, I. Giotti, F. Torricelli;*
SOD Diagnostica genetica, AOU Careggi, Florence, Italy.

Hematopoietic stem cell transplantation (HSCT) is the gold standard treatment in a multitude of malignant and non-malignant disorders, like severe aplastic anemia, acute and chronic leukaemia and lymphomas. In the early post-transplant period after allogeneic HSCT, coexistence of the host and donor lympho- and hematopoietic systems will develop. This period, which is temporary in the majority of successful stem cell transplants, is referred to as mixed chimerism, whereas complete chimerism denotes the situation when all cell lineages are reconstituted by donor-derived cells. Successful engraftment correlates with the engraftment of donor cells and relapse is thought to evolve from occult autologous malignant cells that survive to the pretransplant marrow-ablative conditioning regimen and escape surveillance by allogeneic immune effector cells. Early analysis of donor and recipient chimerism patterns after HSCT gains importance in predicting engraftment and rejection as well as in persistent and recurrent disease. It is also helpful in guiding risk-adapted immunotherapy for prophylaxis and interventional therapy of graft-versus-host disease (GvHD) or imminent relapse.
Several techniques have been reported for this purpose. The intent of the present study is to test a novel approach for the quantification of mixed chimerism using a Indel- marker RT-PCR methode and to compare this technique to the gold standard one, i.e. STR-PCR, to assess the sensibility of RT-PCR in the analysis of chimerism and its ability to predict relapse.

Dysregulation of apoptotic pathways in chordoma involving FAS and FASL: implications on notochord regression in zebrafish model

L. Ferrari[1], *A. Pistocchi*[2], *N. Boari*[3], *M. Venturin*[1], *F. Gagliardi*[3], *P. Mortini*[3], *F. Cotelli*[2], ***P. Riva***[1];
[1]*Dip. di Biologia e Genetica per le Scienze Mediche, University of Milan, Milano, Italy,* [2]*Dip. di Biologia, University of Milan, Milano, Italy,* [3]*Dip. di Neurochirurgia,*

San Raffaele Scientific Institute - Vita-Salute University, Milano, Italy.
Chordoma is a rare malignant bone tumor arising from notochord remnants, characterized by local invasiveness and variable tendency for recurrency. Given the implication of apoptosis in notochord regression, we studied the expression of 8 proapoptotic genes mapping in 1p36 region by RT-PCR in 32 tumours showing loss of heterozigosity (LOH) in 83% of cases. None of the analyzed tumour expression profiles overlaps with that of the control and the absence of 1p36 LOH has been correlated to a better prognosis. As the apoptotic pathway mediated by FAS-FASL was found to be involved in notochord regression, we studied their expression in 34 chordomas and observed that most of them express FAS, but not FASL. To verify a possible implication of FAS/FASL pathway dysfunction during tumorigenesis, we started *in vivo* studies on zebrafish. We investigated *zfas/zfasl* expression in embryos' total RNA during different developmental stages and observed that, while *zfas* has maternal and ubiquitous zygotic expression, *zfasl* has maternal and specific developmental stages expression. Notochordal cells were then sorted by FACS, following the injection of a GFP construct activated by a specific physaliphorous cell promoter, to study z*fas/zfasl* expression. While *zfas* expression was detected at both 24hpf and 48hpf, *zfasl* was not found expressed; further developmental stages will be studied to define the *zfas/zfasl* expression profiles. Further analyses are in progress to address functional studies aimed at opportunely silencing *zfas/zfasl*. Aberrant phenotypes during development will be analyzed verifying whether the reactivation of *zfas/zfasl* pathway might rescue normal phenotype.

P06.050
The effect of silymarin and kaempferol on the expression levels of microRNAs

S. Yilmaz[1]*, Z. O. Dogan Sigva*[1]*, C. Biray Avci*[1]*, M. Yucebas*[1]*, T. Balci*[1]*, G. Saydam*[2]*, C. Gunduz*[1]*;*
[1]*Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey,* [2]*Ege University Medical Faculty Department of Hematology, Izmir, Turkey.*
MicroRNAs (miRNA), single strand, non-coding RNA molecules with the length of 18-25 nucleotides, play a major role in the regulation of gene expression. Mature miRNA molecules are partially complementary to one or more tumor suppressor or oncogenic messenger RNAs (mRNA) and cause mRNA degradation or inhibition of the protein translation.
Silymarin is an active component of Silybum marianum L. and has been shown as a powerful antioxidant, anti-inflammatory and anticancer agent. Kaempferol, a flavonoid, is an active component of Epilobium parviflorum and presents anti- and pro-oxidant activity in various cancers.
In this study, it is aimed to investigate miRNA expression differences in the Chronic Myeloid Leukemia cell line, K562, following the treatment with Silymarin and Kaempferol compounds.
Cytotoxicity analysis was performed with several doses of silymarin (between 4.69 and 300 µM) and kaempherol (between 6 and 30µM) at 24 hours intervals for three days in K562 cell line, using XTT assay. miRNAs were isolated from cells exposed to IC50 doses of silymarin and kaempherol. Relative quantitation of 88 miRNAs was measured by real time online RT-PCR. Alterations in the miRNA expression were compared with kaempherol or silymarin- free K562 cells.
It is found that, IC50 doses of silymarin (29.02 µM) and kaempherol (9.84 µM) inhibited oncogenic miR-21, miR-128 and miR-15b and increased the expression levels of miR-22, miR-29a and miR-29c, which are reported to can function as tumor suppressors. Studies on the effects of selected plant extracts on miRNA expression profiles are may bring new clinical approaches for therapy.

Cisplatin induces apoptosis in MCF-7 and T47D breast cancer cell lines via up regulation of bax gene and down regulation of bcl-2 gene

M. J. Mokhtari[1]*, A. Akbarzadeh*[2]*, M. Hashemi*[1]*, G. Javadi*[1]*, R. Mahdian*[3]*, S. Ghasemi*[2]*, A. R. Kamyab*[1]*, Z. Hosseinian*[1]*, M. R. Mehrabi*[2]*;*
[1]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Pilot Biotechnology department, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [3]*Department of Molecular Medicine, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*
Cancer cell apoptosis can be induced by Cis-diamminedichloroplatinum II (cisplatin), an efficient anticancer agent. Bcl-2 and Bax are members of the Bcl-2 family that play key roles in the regulation of apoptosis. The ratio between Bax and Bcl-2 often determines whether a cell will live or die. In this study, MCF-7 and T47D cells were treated with various concentrations of cisplatin for different times (24, 48 and 72h). Then, cell viability was assessed using MTT assay and IC50 was determined. RNA was extracted and cDNA was synthesized. Quantity of bcl-2 and bax genes expression compare to actb gene were analyzed using very sensitive quantitative Real-time PCR. bcl-2 gene expression was decreased and bax gene was increased in a dose- and time-dependent manner by cisplatin, that was statistically significant ($P<0.05$). The results showed that cisplatin exerted a dose- and time-dependent inhibitory effect on the viability, via up regulation of bax and down regulation of bcl-2 gene, in MCF-7 and T47D cells.

P06.052
Nurse-like cells support CLL lymphocytes survival in vitro via induction of SURVIVIN and BCL2 family genes.

A. A. Filip[1]*, D. Koczkodaj*[1]*, B. Ciseł*[2]*, E. Wąsik-Szczepanek*[3]*;*
[1]*Department of Cancer Genetics, Medical University, Lublin, Poland,* [2]*Department of Oncologic Surgery, Medical University, Lublin, Poland,* [3]*Department of Hematooncology and Bone Marrow Transplantation, Medical University, Lublin, Poland.*
B-cell chronic lymphocytic leukemia (B-CLL), the most common leukemia in Europe and North America, is characterized by progressive accumulation of mature lymphocytes in peripheral blood, bone marrow and secondary lymphatic organs. This accumulation is due both to decreased apoptosis and increased proliferation. Altered mechanisms of programmed cell death and proliferation are not the intrinsic features of leukemic cells, but result from specific microenvironmental effect.
Histological markers of CLL are pseudofollicles (proliferation centers), dispersed in involved tissues. Pseudofollicles are made up from stromal cells, T lymphocytes, follicular dendritic cells, endothelial cells as well as others. These create protective microenvironment for CLL lymphocytes. Nurse-like cells (NLCs), first found in CLL mononuclear cells cultures, are also the part of this microenvironment.
Mechanisms that improve survival and increase proliferation of CLL cells are crucial in the context of effective therapy. The aim of the study was the analysis of proapoptotic genes expression on mRNA and protein level in CLL lymphocytes cultured with nurse-like cells.
PBMCs of 65 CLL patients were cultured for 14 days. Cell viability, apoptosis, proliferation, gene expression profile and selected proteins expression were assessed at day 0 and 14.
We found that NLCs support CLL lymphocytes survival in vitro, and the effect depends on NLC number. Gene expression profiling and RT-PCR showed the increase of proapoptotic genes *BCL2*, *BCL-XL* and *SURVIVIN* expression, what was further confirmed by their protein products analyses. However, no signs of CLL lymphocyte proliferation (any mitotic figures or Ki-67 expression) were observed.

P06.053
Genome-wide detection of copy number alterations in non-small cell lung cancer

M. Solovjova[1]*, K. Kirotar*[1]*, T. Vooder*[1,2]*, R. Roosipuu*[2]*, A. Metspalu*[1,3]*, N. Tõnisson*[1,2]*;*
[1]*Institute of Molecular and Cell Biology, University of Tartu/ Estonian Biocentre, Tartu, Estonia,* [2]*Tartu University Hospital, Tartu, Estonia,* [3]*Estonian Genome Centre, Tartu, Estonia.*
A great number of chromosomal aberrations detected in association with lung cancer allows to suppose that just a small part of lung cancer specific genes have been identified so far and there is still a lot to be examined and discovered in this field.
The aim of the present study was to develop a technique for genetic and morphological detection of somatic copy number variations (CNVs) in heterogeneous tumour tissue.
Whole-genome genotyping with HumanCytoSNP-12 BeadChips (Illumina Inc.) was applied to analyze non-small cell lung cancer (NSCLC) samples from 12 patients, which were then compared with 12 matching blood control samples screened for germline CNVs using Illumina HumanHap300 BeadChips. Four different algorithms (QuantiSNP, PennCNV, SOMATICs, BAFsegmentation) were used for

genotype analysis and the results were compared by applying Java programming language. CNV areas were plotted to the same graphics for visualisation of the results detected by four programs. That allowed choosing different analysing programs for different purposes and comparing in detail cancer tissue and germline copy number.
About 140 CNVs per patient were detected, most of which were amplifications. Some were found in more than one patient: 3q25-q27, 5p12-p14, 12p13, 9p13, 8p22. The results were further compared with gene expression data obtained from the same patients, and 30 genes with altered copy number showed expected changes in expression. A subset of the found CNVs was further confirmed by qPCR analysis.
The experiments demonstrated that these technique approaches for somatic CNVs detection in heterogeneous tumour tissue can be used for further researches.

P06.054
The *PABPC4L* gene, a candidate gene for colon cancer?

***R. C. Niessen**, M. Viel, L. F. Johansson, T. Dijkhuizen, M. J. W. Olderode-Berends;*
University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

In a large proportion of familial colon cancer cases, the underlying genetic cause for cancer predisposition remains unidentified. Recently, a 237 kb deletion on chromosome 4q28 was identified with array CGH in three individuals with microsatellite stable colon cancer from one family. Only one gene is present in this region: *PABPC4L*, a gene of which the function is unknown. To investigate the hypothesis that *PABPC4L* is a candidate gene for colon cancer, we investigated a group of patients with microsatellite stable colon cancer for germline mutations in *PABPC4L*. Ninety-three patients with colon cancer before the age of 50 were included in this study. Their tumours showed no microsatellite instability and normal mismatch repair protein stainings. In DNA isolated from lymphocytes, mutation scanning of the *PABPC4L* gene was performed with high-resolution melting analysis and direct sequencing. No pathogenic *PABPC4L* mutations were detected in the 93 patients. Therefore, our data do not support the hypothesis that *PABPC4L* is a candidate gene for colon cancer. Currently, analysis for large deletions is performed in 39 patients who did not have heterozygous polymorphisms.

P06.055
Analysis of different apoptosis ways by gene expression analysis and siRNAi silencing in colorectal cancer cells.

***A. S. Bavykin**, A. A. Korotaeva, E. A. Goncharova, E. G. Zenit-Zhuravleva, A. V. Syrtsev, A. V. Karpukhin;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Overexpression of apoptosis inhibitors is considered to be one of the main causative factor of apoptosis reduction and drug resistance of colorectal cancers. We set up a profile analysis of a number of genes related to apoptosis inhibition and cell proliferation in the colon cancer line HT-29: *c-IAP-2*, *cIAP-3*, *XIAP*, *Survivin*, *Livin*, *FLIP*, *HspA5*, *Gstp-1*, *Bcl2*, *c-myc*, *caspase 8*, *TRAP-1*, *Bcl2L*, *Kras*. The analysis has revealed at high level the expression of *TRAP-1*, *Survivin*, *XIAP* and *FLIP*. The oncogene *Kras* was found to be expressed even stronger compared with *TRAP-1* or *Survivin*. Most of tumors contain mutant allele *Kras* in the 2-nd exon. However no *Kras* mutation was found, arising a question of gene's hyperactivation in these cells. As far as cancer cell proliferation is dependent on *Kras* expression, we performed silencing by means of anti-*Kras*-siRNA. 38% of cell apoptosis was a result of this inhibition. The double decrease of cell viability (63%) was observed when used a combination of anti-*Kras, Survivin*, *FLIP* siRNAs. It is interesting that additive effect of three siRNA action was observed. This effect may serve for a good treatment strategy to induce apoptosis of colon tumor cells.

P06.056
Allelic imbalance of the *TGFβR1* is not a major contributor to the genetic predisposition to colorectal cancer

*C. Abadie[1], A. Killian[1], J. Tinat[1,2], M. Bougeard[1], D. Medhaoui[1], A. Cailleux[3], S. Baert-Desurmont[1,2], **T. Frebourg**[1,2];*
[1]Inserm U614, Faculty of Medicine, Rouen University, Institute for Biomedical Research and Innovation, Rouen, France, [2]Department of Genetics, University Hospital, Rouen, France, [3]Clinical Investigation Center, CIC 0204, University Hospital, Institute for Biomedical Research and Innovation, Rouen, France.

An allelic expression imbalance of the *TGFβR1* gene was reported to be a strong risk factor for colorectal cancer (CRC) with an odds ratio (OR) at 8.7 (Valle *et al*, Science 2008) but several reports have reported contradictory results. We therefore conducted a prospective case-control study on carefully selected patients and controls. Patients were selected according to criteria suggestive of an increased genetic risk for CRC: (i) CRC before 61 years of age (or high-risk adenoma before 51) with a first degree relative presenting with CRC; *or* (ii) CRC before 51 years of age (or high-risk adenoma before 41); *or* (iii) multiple primitive colorectal tumors in the same case, the first one diagnosed before 61 years of age if cancer or before 51 if high-risk adenoma. The controls, aged from 45 to 60 years, were CRC-free and had no familial history of CRC. Allelic expression of *TGFβR1* was then measured, using SNaPshot and 4 SNPs (*rs334348*, *rs334349*, *rs1590* and *rs7871490*), by normalizing the ratio of the allelic peaks obtained on RT-PCR with the ratio of the peaks obtained on genomic DNA. Allelic expression ratios ranged between 0.82 and 1.41 in 98 informative controls and between 0.77 and 1.45 in 69 informative patients. No significant difference between patients and controls was observed. We concluded that allelic imbalance of the *TGFβR1* is not a major contributor to the genetic predisposition to CRC. Therefore, measurement of *TGFβR1* allelic imbalance has no clinical utility to identify patients with high CRC genetic risk.

P06.057
Verification of the Three Step Model in Assessing the Pathogenicity of Mismatch Repair Gene Variants

***M. Kansikas**, R. Kariola, M. Nyström;*
University of Helsinki, Helsinki, Finland.

To evaluate whether DNA mismatch repair (MMR) gene variations predispose to Lynch syndrome (LS), a three step assessment model has been proposed. Where LS is suspected, STEP1 is dedicated to the identification of the causative MMR gene and the variation. In STEP2, the functional effect of the variation is assessed in an in vitro MMR and in silico assays. Where LS cannot be confirmed or ruled out, more specific biochemical assays are required in STEP3. Here we verified the proposed model and its ability to distinguish pathogenic MMR variations from variants of uncertain significance by utilizing clinical, laboratory and in silico data of 37 MLH1, 26 MSH2 and 11 MSH6 variations. The proposed model was shown to be appropriate and proceed logically in assessing the pathogenicity of MMR variations. In fact, for MMR deficient MLH1 and MSH2 variations STEP3 is not required. STEP3 is important in assessing MMR proficient variations showing discrepant in silico results after STEP2. MSH6 variations require appropriate selection in terms of ruling out MLH1 and MSH2 variations and MLH1 promoter hypermethylation. Overall, taking into consideration the susceptibility gene, the three step model can be utilized in an efficient manner to determine the pathogenicity of MMR gene variations.

SMAD7 rs4939827 risk variant is associated with poor outcome in colorectal cancer patients from R. Macedonia

***A. Kapedanovska Nestorovska**[1], Z. Sterjev[1], Z. Serafimoska[1], N. Matevska[1], T. Josifovski[2], N. Jankulovski[2], M. Panovski[2], N. Petrusevska[3], L. Suturkova[1], A. J. Dimovski[1];*
[1]Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, University "Ss Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic of, [2]Clinic for Abdominal Surgery, Faculty of Medicine, University "Ss Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic of, [3]Institute of Radiotherapy and Oncology, Faculty of Medicine, University "Ss Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic of.

Several independent GWAS of colorectal cancer (CRC) have identified numerous disease loci that were not previously suspected to influence the risk of developing the disease. We performed a population based case-control association study on DNA samples from 350 CRC patients and 180 controls of 5 low-penetrant variants [rs10505477 (8q24.21), rs3802842 (1q23.1), rs4779584 (15q13.3), rs1800566 (16q22.1) and rs4939827 (18q21.1)]. Genotype-phenotype correlation of each variant with various clinico-pathological parameters (gender, age of onset, tumor location and TNM stage) was also analyzed. Only two SNPs, rs10505477 (8q24.21) (p=0,042, OR=1,372;

95%CI=1,010-1,862) and rs4939827 (18q21.1) (p=0.027; OR=1.831; 95% CI=1.066-3.144), confirmed population susceptibility to CRC in our population, whereas the other 3 showed trend towards, but did not reach statistically significant association. Phenotype/genotype correlation showed significant association of the 18q21.1 (rs4939827) T allele with age >60 (*p=1.662e-06;* OR = 2.665; 95% CI = 1.82-4.07) and advanced disease at diagnosis *(p*=0.0216; OR = 1.499; 95% CI = 1.058-2.092). RT/PCR analysis of paired blood/tumor samples showed that half of the patients had allelic imbalance at the 18q21.1 locus, with preferential selection of the risk allele in 2/3 of the patients. Our data add evidence that 8q24.21 and 18q21.1 genetic variants are markers predisposing to CRC in our population. We also demonstrate for the first time that enrichment of the risk T- allele of rs4939827 at 18q21.1 in tumors is associated with advanced disease at diagnosis, which further supports the notion that genes mapping in the vicinity to this locus are important regulators of colorectal cancerogenesis.

P06.059

Constitutional mono-allelic BUB1 deletion in a patient with non-classical mosaic variegated aneuploidy syndrome and early onset colorectal cancer

***R. M. de Voer**, A. Geurts van Kessel, M. Ligtenberg, D. Smeets, N. Hoogerbrugge, R. Kuiper;*

Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Mosaic variegated aneuploidy (MVA) syndrome is a rare recessive disorder marked by growth retardation, microcephaly, childhood cancer and constitutive aneuploidy. Some cases of MVA have been associated with homozygous mutations in the BUB1B gene, a component of the spindle assembly checkpoint (SAC).

We have applied high-resolution SNP array profiling as an approach to identify novel cancer predisposing genes in patients with early onset mismatch repair proficient colorectal cancer. We encountered a constitutional mono-allelic deletion encompassing another important SAC gene, BUB1, in a patient who developed a colon carcinoma at age 37. Clinical examination revealed microcephaly and brachydactyly, two characteristic features of MVA syndrome. No mutations were found in the remaining BUB1 allele. In addition, no germline mutations in the APC gene were found. Since defects in the SAC are known to be associated with aneuploidy, metaphases of the patient's lymphocytes were analyzed and, by doing so, an increased level of constitutive aneuploidy (32%) was observed.

Regulation of the SAC has been shown to be dependent on gene dosage. Bub1 hypomorphic mice revealed reduced checkpoint activity and increased aneuploidy in a dose-dependent manner with increased spontaneous tumorigenesis. Furthermore, in a patient, who presented with early onset gastrointestinal cancer, a homozygous mutation in BUB1B leading to a reduced BUBR1 expression was recently reported. These data imply that, next to recessively inherited syndromes like MVA, haploinsufficiency of BUB1 or other SAC components may result in non-classical forms of MVA with a predisposition to develop gastrointestinal malignancies.

P06.060

Genetic profile of sporadic colorectal cancer liver metastasis vs. primary tumours by SNP-arrays.

***J. Sayagués**[1], C. Fontanillo[1], M. Gonzalez-Gonzalez[1], E. Garcia[1], M. Iglesias[2], C. Esteban[2], M. Abad[2], E. Fonseca[2], O. Bengoechea[2], J. De las Rivas[1], L. Muñoz-Bellvis[2], A. Orfao[1];*

[1]Centro de Investigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca, Salamanca, Spain, [2]Hospital Universitario de Salamanca, Salamanca, Spain.

Most genetic studies in colorectal carcinomas (CRC) have focused on those abnormalities that are acquired by primary tumours, particularly in the transition from adenoma to carcinoma, while few studies have compared the genetic abnormalities of primary vs. paired metastatic samples. In this study we used high-density 500K SNP arrays to map the overall genetic changes present in liver metastases (n=20) from untreated CRC patients studied at diagnosis versus their paired primary tumours (n=20). Overall, metastatic tumours systematically contained those genetic abnormalities observed in the primary tumour sample from the same subject. However, liver metastases from most cases (n=8/20) showed acquisition of genetic aberrations that were not found in their paired primary tumors. These new metastatic aberrations mainly consisted of 1) an increased frequency of genetic lesions of chromosomes that have been associated with metastatic CRC (1p, 7p, 8q, 13q, 17p, 18q, 20q) and, more interestingly, 2) acquisition of new chromosomal abnormalities (e.g. losses of chromosomes 4 and 10q and gains of chromosomes 5p and 6p). These genetic changes acquired by metastatic tumours may be associated with either the metastatic process and/or adaption of metastatic cells to the liver microenvironment. Further studies in larger series of patients are necessary to dissect the specific role of each of the altered genes and chromosomal regions in the metastatic spread of CRC tumours.

P06.061

Effects of curcumin on global gene expression profile in the highly invasive human breast carcinoma cell line MDA-MB 231

***N. Cine**[1], D. Sunnetci[1], P. Limtrakul[2], H. Savli[1];*

[1]Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey, [2]Biochemistry Department, Chiang Mai University, Chiang Mai, Thailand.

Introduction

Curcumin, or diferuloylmethane, is a major chemical component of turmeric (*Curcuma longa* Linn) that has been consumed as a dietary spice for ages. This yellow colored polyphenol has a surprisingly wide range of beneficial properties, including anti-inflammatory, antioxidant, antitumoral, anti-invasive and antimetastatic activity.

Materials and Methods

In this study, microarray gene expression analysis was applied to identify the curcumin-regulated genes in a highly invasive human breast-carcinoma cell line (MDA-MB-231). Cells were cultured (20μM) with curcumin for 24 hours; total RNA was isolated and hybridized to Agilent Whole Human Genome microarray slides. Gene Set Enrichment Analyses on our whole genome expression data revealed the downregulation of the EGF pathway elements followed by curcumin treatment.

Results

Furthermore, gene network analysis identified a significantly relevant network among the differentially expressed genes centered on the EGR-1 and FOS genes. The members of these pathway and network play an essential role in the regulation of cancer cell growth and development, most of them showed decreased expression level after the treatment of curcumin.

Conclusion

We have demonstrated the decreased expression of pathway elements of the EGF signaling cascade and the decreased expression of *EGR-1* gene on mRNA level in MDA-MB 231 human invasive breast carcinoma cell line. According to our knowledge we were the first who applied comprehensive GSEA and network analysis to analyze the gene expression profile of curcumin treatment on breast carcinoma cell line.These observations suggest that the use of curcumin may be an excellent candidate for prevention and treatment of breast cancer.

High throughput validation of novel single nucleotide polymorphism associated with cytogenetically normal acute myeloid leukemia samples

***K. C. Lo**[1], M. Rossi[2], J. Patel[1], S. Sunay[2], H. Khoury[2], M. Watt[1], X. Zhang[1], T. Albert[1], R. Selzer[1];*

[1]Roche NimbleGen, Madison, WI, United States, [2]Emory University, Atlanta, GA, United States.

Acute myeloid leukemia (AML) is characterized by an arrest of maturation of hematopoietic progenitor cells. Patient prognosis varies widely and is currently stratified based on the presence or absence of specific cytogenetic abnormalities. Currently, cytogenetically normal AML is classified as intermediate risk, with a 5-year overall survival (OS) at 38. The overall 5-year survival rate is less than 50% in adults and significantly lower in the elderly (defined as > 65 years).

Here we describe a study with 4 cytogenetically normal AML patients - 2 of old age (defined as >65 years) and 2 young (< 45 years). Whole exome sequencing of these 4 samples was performed using Roche NimbleGen's SeqCap EZ exome capture and analyzed using Illumina's HiSeq platform. Novel discoveries were distinguished from constitutional single nucleotide polymorphisms (SNPs) by comparing each AML sample to match normal DNA from the same patient. Novel discoveries of the four patients, as well as SNPs that are

known to be associated with AML (i.e. FLT3, NPM1, IDH1, IDH2 and DNMT3A) served as input to a 13,500 custom SNP panel using Roche NimbleGen's AccuSNP custom genotyping platform. The custom SNP array serves as downstream validation of the whole exome sequencing discoveries and a tool to extent these findings to profile an additional 96 AML samples. This serves to demonstrate the power of a multi-tiered approach of combining targeting sequencing and flexibility of the AccuSNP platform to provide an accurate and high-throughput tool for identifying novel polymorphisms associated with AML.

P06.063
Analysis of frequency CCND1 gene polymorphism (rs3862792) in Polish patients with differentiated thyroid cancer

J. Hoppe-Gołębiewska[1], *A. Barańska*[1], *M. Kaczmarek-Ryś*[1], *S. T. Hryhorowicz*[2], *L. Jakubowska-Burek*[3], *K. Ziemnicka*[4], *J. Sowiński*[4], *R. Słomski*[1,5];
[1]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*The Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [3]*Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [4]*Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [5]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

The product of CCND1 gene belongs to the highly conserved cyclin family. Cyclins function as regulators of CDK kinases. Cyclin D1 forms a complex with CDK4 or CDK6, whose activity is required for cell cycle G1/S transition. This protein interact with tumor suppressor protein Rb and the expression of CCND1 gene is regulated positively by Rb. Mutations, amplification and overexpression of this gene, which influences on cell cycle progression, are observed frequently in a variety of tumors and may contribute to tumorigenesis.

Thyroid carcinomas are the most often carcinomas of endocrine system. Most often occurs papillary and follicular thyroid cancer: tumors with well prognosis, low benignity and slow progress but often giving recurrences and regional or remote metastasis and as well progression from well differentiated thyroid cancer to malignant anaplastic carcinoma.

We analyzed synonimic substitution c.669C>T (rs3862792) in CCND1 gene. Group of 628 patients (560 females and 68 males) with differentiated thyroid cancer and 378 individuals (185 females and 193 males) from population group were examined. Sequence variants were determined by pyrosequencing.

No significant differences in allele frequencies in patient with differentiated thyroid cancer and population group were observed. In DTC patient group allele T was present with frequency 0,024 and allele C with frequency 0,976. In population frequency for allele T was 0,037 and 0,963 for allele C. Project was supported by Polish Ministry of Science and Higher Education grant N N402 2874 36.

P06.064
Analysis of frequency ERCC2 gene polymorphism (rs3916891) in Polish patients with differentiated thyroid cancer

M. Kaczmarek-Ryś[1], *J. Hoppe-Gołębiewska*[1], *S. T. Hryhorowicz*[2], *K. Ziemnicka*[3], *L. Jakubowska-Burek*[4], *M. Szalata*[1,5], *J. Sowiński*[3], *R. Słomski*[1,5];
[1]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*The Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [3]*Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [4]*Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [5]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

Thyroid carcinomas are the most often carcinomas of endocrine system with still growing up frequency. Papillary and follicular thyroid cancer are the most frequent and belong to tumors with well prognosis, slow progress and low benignity but with tendency to recurrences and regional or remote metastasis.

In this focus, searching for molecular markers of disease course, good or poor prognosis and response on medical treatment is fundamental. It is expected that SNP polymorphisms research in genes demonstrating association with neoplastic diseases will be helpful in understanding of molecular mechanisms of thyroid gland tumors development and allow to better diagnosing.

We analyzed polymorphism c.*171G>C (rs3916891) in ERCC2 gene. Group of 455 patients (400 females and 55 males) with differentiated thyroid cancer and 320 individuals (144 females and 176 males) from population were examined. Sequence variants were determined by pyrosequencing.

We didn't observed significant differences in allele frequencies in patient with thyroid cancer and population group. In DTC patient group allele C was present with frequency 0,012 and allele G with frequency 0,988. In population frequency for allele C was 0,025 and for allele G 0,975

The differences were observed when considerate men and women separately. Allele C in males was observed with smaller frequency (0,011) comparing with females (0,042). In patient group we did not regard frequencies in these groups, because of much higher frequency of occuring differentiated thyroid cancer in woman. Project supported by Polish Ministry of Science and Higher Education grant N N402 2874 36.

P06.065
Analysis of frequency TNFa gene polymorphism (rs361525) in Polish patients with differentiated thyroid cancer

S. T. Hryhorowicz[1], *J. Kapiński*[2], *M. Kaczmarek-Ryś*[2], *J. Hoppe-Gołębiewska*[2], *L. Jakubowska-Burek*[3], *K. Ziemnicka*[4], *J. Sowiński*[4], *R. Słomski*[2,5];
[1]*The Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [2]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [3]*Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [4]*Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [5]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

TNFA gene encodes a multifunctional proinflammatory cytokine that belongs to the tumor necrosis factor superfamily. This cytokine is involved in the regulation of a wide spectrum of biological processes as cell proliferation, differentiation or apoptosis and has been implicated in a variety of diseases including cancer. The role of TNFalpha in cancer is complex with pro-tumourigenic and anti-tumourigenic role proposed. Differentiated thyroid carcinomas are the most often carcinomas of endocrine system with growing up frequency. In most cases occurs papillary and follicular thyroid cancer and more often it is present in women.

We analyzed polymorphism g.4752G>A (rs361525) in TNFA gene. Group of 607 patients 539 females and 68 males) with differentiated thyroid cancer and 482 individuals (282 females and 200 males) from population group were examined. Sequence variants were determined by pyrosequencing.

We didn't observed significant differences in allele frequencies in patient with differentiated thyroid cancer and population group. In DTC patient group allele A was present with frequency 0,055 and allele G with frequency 0,945. In population frequency for allele A was 0,04 and for allele G 0,96.

In this focus, very important seems to be searching for molecular markers of disease course, good or poor prognosis and response on medical treatment as well. It is expected that SNP polymorphisms research in genes demonstrating association with neoplastic diseases will be helpful in understanding of molecular mechanisms of tumors development and allow to better diagnosing. Project supported by Polish Ministry of Science and Higher Education grant N N402 2874 36.

Dna damage in cultured human mesenchymal stem cells at various passages

A. Chausheva, *V. Nikitina, N. Bochkov;*
Research Center for Medical Genetics, Moscow, Russian Federation.

The cell therapy with multipotent mesenchymal stromal stem cells (MSCs) is promising treatment for various diseases. According to methodology the stem cells requires to cultivation before therapeutic use. It is known, spontaneous malignant transformation of MSCs in long-term culture is possible.

The DNA-damage can be plausible cause of chromosomal abnormalities and gene mutations. We studied the levels of DNA damage in MSC from human bone marrow at various passages of cultivation using single cell gel electrophoresis (comet assay).

Twenty eight samples of MSC's cultures from bone marrow of healthy donors have been analyzed. DNA damage was assessed as percent

of DNA in comet tail. The level of DNA damage and the frequency of apoptotic comets in cultures of MSCs studied at 3-4 passages and 10-11 passages.
The levels of DNA damage in MSC didn't change during culturing (3,5±0,9% on 3-4 passages and 4,4±1,2% on 10-11 passages). The frequencies of apoptotic comets in MSC cultures were 2,8±0,9% on the early passages and 3,6±1,8% on the late ones. In one of the cultures of MSCs we have observed a high level of DNA-damage (16,5% DNA in comet tail) and high rate of apoptotic comets (18,3%).

INTRODUCTION: Glioblastoma multiforme (GBM) is the most common and malignant primary brain tumor which is characterized by a number of different genetic alterations.
AIMS: We aimed to analyze the DNA profiles in an unselected group of Bulgarian patients with newly diagnosed GBM.
MATERIAL AND METHODS: Nine fresh-frozen tumor samples from patients with histologically confirmed primary GBM have been studied using a high-throughput DNA microarray analysis.
RESULTS: The most common numerical chromosomal aberrations were monosomy 10, 13, 14, 22, and trisomy 7 and 20. The most frequently detected copy number changes were deletions at 10p12, 10q23, 1p36, and 14q32; and gains at 7q36, 1q44, and 20q11-13. We identified a number of candidate tumor suppressor genes (KCNMA1, FGFR2, GFRA1, BNIP3, BACH, KLF12, VRK1, NF2, and OSM) and oncogenes (GNAI1, HGF, PCLO, SEMA3D, GRM3, RGS7, OPN3, CDK5, DNAJB6, ZNF658B, CDK5RAP1, and PTPN1), which are probably involved in the development of GBM.
CONCLUSIONS: GBMs are genetically heterogeneous group of tumors with unpredicted therapeutic response. The clinical significance of the DNA-microarray findings needs to be further established.

P06.068
Pharmacogenomics of cisplatin-based chemotherapy in ovarian cancer patients of different ethnic origin

A. V. Khrunin[1], *F. G. Ivanova*[2], *A. A. Moisseev*[3], *D. V. Khokhrin*[1], *Y. S. Sleptsova*[4], *V. A. Gorbunova*[3], *S. A. Limborska*[1];
[1]*Institute of Molecular Genetics RAS, Moscow, Russian Federation,* [2]*Yakutsk Republic Cancer Center, Yakutsk, Russian Federation,* [3]*N.N.Blokhin Cancer Research Centre RAMS, Moscow, Russian Federation,* [4]*Russian State Medical University, Moscow, Russian Federation.*

Background: Interethnic differences are becoming increasingly recognized as important factors accounting for interindividual variations in tolerability and efficacy of anticancer drugs. Although the reasons underlying ethnic diversity in drug responsiveness are likely multifactorial, inherited ethnic differences in drug-related genes may be, at least in part, the cause of the diversity.
Methods: 18 polymorphisms in 10 genes, the protein activities of which may be addressed in different aspects of cisplatin metabolism, were tested for correlations with efficacy and toxicity of cisplatin-based regimen (combination with cyclophosphamide) in Russian (n=104) and Yakut (n=87) women with epithelial ovarian cancer.
Results: There were significant ($p<0.05$) differences between Russian and Yakut patients in genotype distribution for GSTP1 Ile105Val, GSTP1 Ala114Val, *GSTA1* −69C>T, ERCC2 Asp312Asn, ERCC2 Lys751Gln, *ERCC1* 19007T>C, *CYP2E1* 96bp and *CYP2E1* −1053C>T. GSTP1 Ile105Val polymorphism was associated with progression-free survival ($p=0.004$) and overall survival ($p=0.02$) in Russian patients. In Yakuts correlation with progression-free survival were observed for *CYP2E1* 7632T>A polymorphism ($p=0.05$). The associations between genotypes and treatment toxicities were also different between ethnic groups. Russian patients with *GSTM1*-null and *GSTM3* intron 6 AGG/AGG genotypes had a lower risk of anemia. In contrast, in Yakut group anemia was less frequent among patients with *GSTA1* −69C/C genotype. Nephrotoxicity in Russians was associated with two polymorphisms in *ERCC1* gene but in Yakuts it was correlated with ERCC2 Lys751Gln polymorphism.
Conclusions: The marked ethnic differences in relevant pharmacogenetics may be a potential explanation for discordant platinum efficacy and toxicity in Asians and Caucasians, and are worthy of future studies.

P06.069
Polymorphisms of the DNA repair genes XRCC1 in acute leukemia

C. Banescu[1], *M. Dobreanu*[2], *C. Duicu*[2], *I. Benedek*[2], *I. Pascanu*[2], *K. Csep*[2];
[1]*Genetic Department, University of Medicine and Pharmacy, Tg. Mures, Romania,* [2]*University of Medicine and Pharmacy, Tg. Mures, Romania.*

In several DNA repair genes, polymorphisms may result in reduced repair capacity, which has been implicated as a risk factor for various types of cancer. The aim of the study was to investigate the association between genetic polymorphisms of XRCC1 and susceptibility to acute leukemia. We performed a case-control study involving 26 patients with acute leukemia (21 with myeloid leukemia and 5 with acute lymphoblastic leukemia) and 20 healthy controls for polymorphisms of codons 194 and 399 of the XRCC1 base excision repair pathway gene. Polymerase chain reaction (PCR) followed by enzymatic digestion of the PCR products was used for the genotyping of the two polymorphisms. The restricted products were analyzed on 2% agarose gel. The risk of development of acute leukemia was found to be significantly increased when variant XRCC1-399 (Arg/Gln) and XRCC1-194 (Arg/Trp) were present ($p<0.05$). These results suggest that the polymorphism of XRCC1 gene may contribute to the higher risk of acute leukemia.

Comparisons of MDR1 and MRP1 expression at RNA and protein levels using quantitative RT-PCR and Flow cytometry in breast cancer tumors

M. Taheri[1], *F. Mahjoubi*[2], *R. Omranipour*[3];
[1]*Zahedan University of Medical Sciences, Zahedan, Islamic Republic of Iran,* [2]*National Institute of Genetic Engineering & Biotechnology, Tehran, Islamic Republic of Iran,* [3]*Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

One of the limitations in the treatment of cancer patients with chemotherapy is the development of multidrug resistance (MDR). This means that tumor cells become insensitive to a wide range of chemotoxic drugs which are structurally and functionally different. A well-known mechanism responsible for drug resistance is over-expression of ABC-transporter genes.The aim of the present study was to investigate the expression level of MDR1and MRP1 in breast cancer tumors and adjacent normal tissues of breast cancer patients at levels of RNA as well as protein levels and examine whether the expression of either or combination of these genes in breast cancer correlates with response to chemotherapy.
Fifty four patients with breast cancer who had undergone breast cancer surgery were enrolled in the study.Expression levels of MDR1 and MRP1in normal and tumoral breast tissues were evaluated by quantitative Real time PCR and flowcytometry.
Results showed that the expression levels of MDR1 and MRP1 in tumoral breast tissue were increased significantly than those of normal samples.
Our findings showed that evaluation of the expression at RNA or protein levels using Real time RT-PCR or flowcytometry are compareable but Real time RT-PCR is faster and cost benefit .

Cell-cell adhesion plays a crucial role in epithelial tissue polarity and structural integrity and E-cadherin is a key player is this process. Reduced cell-cell adhesiveness results in destruction of the histological structure and increase invasion, the morphological hallmark of malignant tumors. Despite the strong correlation between E-cadherin impairment and malignancy, the cause underlying its impairment remains unknown in most epithelial cancers.In the present work, we identified a novel E-cad transcript, characterized its tissue specific expression and its functional role in a cancer context.A new E-cad exon was identified within intron 2 splicing with exon 3 at its canonical splice-site. 5'-RACE and CAGE analysis pinpointed two potential transcription start sites (TSS) and an ORF. This transcript includes all downstream canonical exons of E-cad gene, is expected to be translated and was named CDH1a. CDH1a is specifically expressed in spleen, a non-epithelial tissue and is absent from the stomach epithelia. In stomach cancer cell lines, it becomes overexpressed. Forced overexpression of CDH1a in cell lines expressing the canonical E-cad promotes cell invasion and angiogenesis and modifies their expression pattern as proved by microarray analysis. We identified a novel E-cadherin protein isoform cis-regulating the function of the canonical form. This finding may enclose a previously unrecognized mechanism leading to E-cadherin impairment in cancer.

P06.072

Frequency of EGFR mutations in Bulgarian patients with NSCLC

S. Bichev[1], *D. M. Marinova*[2], *Y. G. Slavova*[2], *R. Kaneva*[3], *A. Savov*[1], *I. Kremensky*[1];

[1]National Genetic Labortaory, Sofia, Bulgaria, [2]Univesity hospital for pulmonary diseases "St. Sofia", Sofia, Bulgaria, [3]Molecular Medicine Center, Sofia, Bulgaria.

Background: Lung cancer is the leading cause for death among many other cancer types. Non-small cell lung carcinoma (NSCLC) comprises approximately 80- 85% of all cases with lung cancer. According to publications in the last 5 years, some epidermal growth factor receptor (EGFR) mutations, correlate with positive response to treatment with tyrosine kinase inhibitors (TKI) such as genfitinib and erlotinib. While EGFR mutation profiles have been reported for certain Asian and Caucasian population there is no such report for Bulgarian population. It is established that 30- 40% of Asian and 10- 15% of Caucasian patients with NSCLC are carriers of EGFR positive mutations.

Aim: Establishing the frequency of EGFR mutations in Bulgarians with NSCLC.

Materials and methods: A group of 341 patients with NSCLC were analyzed so far. DNA was extracted from paraffin embedded tissues. We used high resolution melting (HRM) technology and subsequent sequencing of aberrant profiles to screen 73 patients for mutations in EGFR gene, the rest 268 patients were screened by qPCR based on Scorpions technology.

Results: We have detected TKI activating mutations only in 3% among the group of patients screened by HRM/Sequencing and in 11 % of patients, screened by qPCR. Deletions in 19th exon and two point mutations (L858R; L861T) in 21st exon were observed. Overall 9% of our patients were mutation positive.

Conclusion: Our study is in concordance with previous reports. However appropriate method for analysis has to be used.

P06.073

Complete transcriptomic, epigenomic and proteomic signature upon demethylation treatment of human breast cancer subtypes approached by multi-platform 'omics analyses

R. Radpour[1], *Z. Barekati*[1], *C. Kohler*[1], *I. Lefkovits*[1], *F. Staedtler*[2], *X. Zhong*[1];

[1]Department of Biomedicine / University of Basel, Basel, Switzerland, [2]Biomarker Development, Novartis Institutes of BioMedical Research, Novartis Pharma AG, Basel, Switzerland.

Contribution of aberrant DNA methylation in tumorogenesis through silencing of tumor suppressor genes (TSGs) and microRNAs has been investigated. Since these epigenetic alterations can be reversible, it provides impetus to study both early and late effects of the 5-aza-2'-deoxycytidine (DAC) therapy in breast cancer using omics tools. Here we investigated multi-dimensional models to predict effects of DAC at the level of the genome, epigenome and proteome for subtypes of breast cancer.

The present study initially assessed the effective dosage of DAC for breast cancer therapy based on the cell viability, cytotoxicity, apoptosis and methylation quantification assays for different breast cancer cell lines. Then two breast cancer subtypes including highly aggressive and non-aggressive cell lines were investigated at various time points passages using multi-dimensional omics approaches (gene expression, microRNA expression and proteomics analysis). Complete molecular profile of the studied subtypes was identified. Additionally, the biological interactions and possible early and late systematic stable or transient effects of the methylation inhibition were determined in details.

The present study allows improving the effective optimal DAC dose cycles to establish intervals for epigenetic treatment of patients and also new DAC targets (including genes, miRNAs and proteins) and new involved pathways were identified. Furthermore, the results of the study give new therapeutic clues based on modification of pathological methylation patterns for management of cancer patients.

New biomarkers detected for esophageal squamous cell carcinoma using chemiluminescent cDNA microarray gene expression profiling

E. Dadkhah[1], *H. Naseh*[2], *M. Farshchian*[1], *B. Memar*[2], *M. Sankian*[3], *R. Bagheri*[4], *M. Forghani Fard*[1], *M. Abbaszadegan*[1];

[1]Human Genetics Division, Immunology Research Center, BU-Ali Research Institute, Mashhad University of Medical Sciences (MUMS), Mashhad, Islamic Republic of Iran, [2]Department of Pathology, Omid Hospital, MUMS, Mashhad, Islamic Republic of Iran, [3]Division of Immunobiochemistry, Immunology Research Center, Bu-Ali Research Institute, MUMS, Mashhad, Islamic Republic of Iran, [4]Department of Surgery, Quaem Hospital, MUMS, Mashhad, Islamic Republic of Iran.

Esophageal cancer is the fifth leading cause of cancer related deaths in Iran. Esophageal squamous cell carcinoma (ESCC) is most often diagnosed in the advanced stages with a very low survival rates. No standard early diagnostic guideline has been proposed to date. Gene expression profiling using cDNA microarray can be an effective method in finding new molecular markers in ESCC. Ten samples including five tumors and five corresponding adjacent normal tissues of patients with ESCC were used for microarray analysis using Chemiluminescent Human Cancer GEArrays. Fifteen genes were detected with equal to or more than 1.5-folds significant overexpression compared to the normal tissue RNA. Thirty three genes showed equal to or more than 1.5-folds underexpression significantly (P<0.05). Overexpressed genes included AP2M1, CDC25B, FTL, HLA-C, HLA-G, HSPA8, ITGB4, MCM2, MMP2, PCNA and UBEL2L6 with a significant p-value (P < 0.05). Significantly underexpressed genes were CD24, RAP1A, RASGRF1, XRCC5 and TP53I3 (P < 0.05). AP2M1, FTL, UBE2L6, HLA-C and HSPA8 from overexpressed genes and XRCC5, TP53I3 and RAP1A from underexpressed genes have not been reported to date in gene expression profiling of ESCC. Validity Verification was performed using Real-time PCR for three randomly selected markers. MMP2 and HLA-G overexpression and XRCC5 underexpression were confirmed in 94 tumor and matched normal tissue samples of forty seven Iranian patients with ESCC, showing two tailed significancy of 0.008, 0.003 and 0.000 respectively. These molecular biomarkers may be suitable targets for further studies to find specific diagnostic, prognostic and therapeutic biomarkers especially in the Iranian population.

Dipartimento di Medicina Sperimentale e Diagnostica e Centro Interdipartimentale per la Ricerca sul Cancro, Università di Ferrara,, Ferrara, Italy.

It has shown that some risk factors for increasing of squamous cell carcinoma of esophagus such as obesity and occupational dust exposure could be affected on aberrant DNA methylation. For this reason, we studied for methylation at the p14 and p15 gene promoters by methylation-specific polymerase chain reaction assay (MSP) on DNAs extracted from 44 fresh tumor tissues and 19 non-tumor adjacent normal tissues, obtained from 44 patients affected by squamous cell carcinoma of esophagus (SCCE) in Iran. Statistical analysis was used to assess association of promoter methylation with bio-pathological, clinical and personal information data, including obesity and airborne exposures. The results showed that Methylation at the p14 and p15 gene promoters was detected in 9% and 41% of tumor samples respectively, but none of the non-tumor tissues exhibited the aberrant methylation. Moreover, we found the significantly associated with p14 promoter methylation and obesity (P=0.02) as well as p15 promoter methylation and occupational exposure (P=0.025). This study provides evidence that obesity and occupational exposure increase the risk of developing esophageal cancer through an enhancement of p14 and p15 promoter methylation.

P06.076

The functioning of important for tumor development genes in ovarian cancer tumor and its microenvironment.

V. P. Shubin[1], *A. N. Loginova*[1], *A. U. Kashurnikov*[2], *A. N. Gritsay*[2], *A. V. Karpukhin*[1];

[1]*Research Centre For Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

The estrogen receptor α (*ESRα*), osteopontin (*OSTP*) and *BRCA1*, *BRCA2* gene expression in samples of ovarian cancer, in tumour microenvironment and in distant from tumour regions were investigated. In accordance with *ESRα* and *OSTP* role in cancer development, their expression in tumor relatively normal ovarian tissue was increased in 35-40% of cases. Important, that in tumour microenvironment these genes were activated higher than in tumor in 25-30% of cases, sometimes even if the expression in tumor was near to normal. Possibly this reflects the postulated effect of tumor instigation by microenvironment and should be taken into account in practical diagnostics, especially ESR. The *BRCA1* role in *ESRα* and *OSTP* regulation as it was observed for breast cancer was not found for ovarian cancer in our work. However we revealed a correlation of *BRCA2* gene expression with both *ESRα* and *OSTP* expression in ovarian cancer tumor. In this aspect it is interesting inverse correlation of relations of expression levels in tumor and microenvironment for *BRCA1* and *BRCA2* revealed by us. The data for the first time highlight the functional interrelation of important for tumor development genes in the ovarian tumor and its microenvironment.

P06.077

Methylation of estrogen receptor alpha (ERα) gene promoter is a frequent event in Iranian women with sporadic breast cancer

P. Izadi[1], ***m. noruzinia***[2], *M. Karimipoor*[3], *M. Karbassian*[4], *M. Akbari*[5], *F. Fereidooni*[6], *Z. Mostakhdemin Hosseini*[6], *F. Kamali*[6];

[1]*department of medical genetics, School of Medical Sciences, Tarbiat Modares university, tehran, Islamic Republic of Iran,* [2]*department of medical genetics, tehran, Islamic Republic of Iran,* [3]*Molecular Medicine Department, Biotechnology Research Center, Pasteur institute of Iran, tehran, Islamic Republic of Iran,* [4]*Day Hospital, tehran, Islamic Republic of Iran,* [5]*Department of Medical Genetics, School of Medical Sciences, Tarbiat Modares university, tehran, Islamic Republic of Iran,* [6]*Pathology department, Cancer Institute, Tehran University of Medical Sciences, tehran, Islamic Republic of Iran.*

Breast cancer affects Iranian women at least one decade earlier than western patients with noticeably different clinical manifestation. Breast tumors are classified based on estrogen receptor alpha status to ER negative (30-40%) and ER positive. Considering to the challenging nature of ERα- tumors treatment, and its innate poor prognosis, clarification of the molecular mechanisms that control expression of ERα are essential. Aberrant methylation of gene promoter region is one of the mechanisms for gene silencing in breast tumors which are potentially reversible and so they are good targets for new therapeutic strategies. For analyzing the methylation status of ERα gene, ER3 region were assessed with methylation specific polymerase chain reaction (MSP). ERα methylation was detected in 64 of 91(70%) breast tumors. A strong correlation was found between ERα methylation in ER3 region and ER negativity in tumors as 88.9% of ER negative versus 52.2% of ER positive cases were methylated (P< 0.00001). There were significant correlations between methylation in ER3 region and negative status of progesterone receptor in tumors (P< 0.01). Presence of ERα methylation in a sizable fraction of ER+ cases, maybe due to cellular heterogeneity in breast tumors. ER positivity in breast tumors is a dynamic phenotype and over the natural course of cancer progression, ER can be lost and many ER+ tumors become ER- in the course of the disease. Presence of ERα methylation in ER+ tumors is a manifestation of this heterogeneity and may contribute to endocrine therapy resistance or recurrence.

P06.078

Molecular sub typing of breast tumors in Iranian breast cancer patients and its association with estrogen alpha receptor (ERα) methylation

P. Izadi[1], *M. Noruzinia*[1], *M. Karimipoor*[2], *M. Karbassian*[3], *M. Akbari*[1];

[1]*Department of Medical Genetics, School of Medical Sciences, Tarbiat Modares university, Tehran, Islamic Republic of Iran,* [2]*Molecular Medicine Department, Biotechnology Research Center, Pasteur institute of Iran, Tehran, Iran., Tehran, Islamic Republic of Iran,* [3]*Day Hospital, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Breast cancer is one of the most frequent malignancies among Iranian women and its age of onset seems to be about 10 years earlier in comparison to European countries. This cancer is a heterogeneous disease that includes many morphological and molecular entities. We had shown that ERα promoter methylation is a frequent event in Iranian patients. Therefore we investigated the association of this epigenetic event in different molecular subtypes of breast tumors. Although breast cancer subtypes were originally identified by gene expression analysis using DNA microarrays, large-scale sub typing using gene expression profiling from formalin fixed, paraffin-embedded samples is not currently feasible. According to recent approaches about immunohistochemical (IHC) based classification of breast tumors to molecular subtypes, we used IHC surrogates to identify breast tumor intrinsic subtypes in 91 breast tumors in Iranian patients. ER-/PR-/Her2- tumors were classified as triple negative (basal like) (25%), ER-/PR-/her2+ tumors as her2+ group(24%), ER+/PR+/Her2- as luminal A (34%) and ER+/PR+/Her2+ as luminal B tumors(17%). Methylation status of estrogen receptor promoter was investigated in these subtypes. There was a significant correlation between methylation in ERα and triple negative subtype where 20/23 (86.7%) of them were methylated. Also significant correlation were found in Her2+ subtype tumors with 20/22 (90.9%) methylation in ERα (*P*<0.002). These two non-luminal subtypes have poor prognosis and it has shown that they are associated with significant decrease in survival.

APC germinal mosaicism in a patient with Familial Adenomatous Polyposis carrying the c.4666del mutation

C. Mongin[1], *C. Colas*[1], ***F. Coulet***[1], *M. Eyries*[1], *Y. Lahely*[1], *J. H. Lefevre*[2], *Y. Parc*[2], *F. Soubrier*[1];

[1]*Laboratoire d'Oncogénétique Moléculaire, GH Pitié-Salpêtrière, AP-HP, PARIS, France,* [2]*Chirurgie Digestive, Hôpital Saint-Antoine, AP-HP, PARIS, France.*

We report a case of germinal APC mosaicism in 36 years-old male patient diagnosed for Gardner syndrome with features of adenomatous polyposis and without family history of polyposis. No mutation in APC gene was initially found. The APC gene of his daughter was sequenced because of the occurence of osteomas at five and nine years old, and the germline heterozygous mutation c.4666del was detected. This mutation was detectable in father's lymphocytes DNA but in low proportion (9%), suggesting the presence of somatic mosaicism in the father. The detection of the mutation in other tissues (buccal swab, normal colon tissue) and in the offspring suggests that it may have occurred early during embryogenesis, before the separation of the embryonic layers. As expected, the higher level of mutated allele was detected in adenomas. Several dilutions of mutated DNA in wild

type DNA show that the High Fusion Resolution (HRM) technique allows a 2.5% proportion of the mutated allele to be detected. Sanger sequencing alone is not sensitive enough to detect low mosaicism levels and pre-screening methods like HRM could be used for APC analysis. Mosaicism is an important consequence of the high rate of *de novo* APC mutations and must be considered in the diagnosis of apparently *de novo* cases. Mutation screening of offspring with the disease could be preferred when possible because of the risk of mosaicism. When no mutation is detected it can be envisioned to sequence adenomas DNA as a first step toward identifying APC mosaicism.

Introduction: Germline mutations in adenomatous polyposis coli (APC) are associated with the development of familial adenomatous polyposis (FAP), a hereditary colorectal cancer syndrome with autosomal dominant inheritance pattern. This syndrome is characterized by the presence of hundreds to thousands of adenomatous polyps in the colon and rectum. Attenuated familial adenomatous polyposis (AFAP), is related to mutations in the end 5 ‘, in exon 9 and in the end 3’ of the APC gene. Biallelic mutations in MYH gene have also been identified in patients with multiple colorectal adenomas and in APC-negative patients with FAP.

Materials and Methods: We collected samples from peripheral blood to probands belonging to 55 families of high risk for familial adenomatous polyposis. Genomic DNA was extracted from peripheral blood cells. Amplified PCR products were analyzed by CSGE, dHPLC, restriction enzymes, MLPA, In silico analysis and direct sequencing.

Results: Molecular analysis of APC gene, has allowed the identification of pathogenic germline mutations in 75% of FAP families and 17% of AFAP families. We found 41 different mutations in the APC gene, which have been cataloged in pathogenic mutations, variants of unknown significance and neutral polymorphisms. In MYH gene, the analysis revealed 6 different pathogenic germline mutations in 7 unrelated families, including 6 families with biallelic and 1 with monoallelic variants.

Conclusions: We described 14 pathogenic mutations in APC gene; eight of them are reported for the first time. Additionally, we confirm that germline mutations in MYH gene are responsible for a significant fraction of colorectal polyposis.

P06.081
Mutation screening of *PALB2* gene in breast/ovarian cancer families by Enhanced Mismatch Mutation Analysis (EMMA).

I. Schultz[1], ***D. Muller***[1], *C. Cordier*[2], *J. Abecassis*[1], *J. Fricker*[2];

[1]*Regional Cancer Centre P. Strauss, Oncogenetic laboratory, Strasbourg, France,* [2]*Regional Cancer Centre P. Strauss, Clinical oncogenetic department, Strasbourg, France.*

A family history of breast cancer is one prerequisite criterion for testing for *BRCA1* and *BRCA2* germ-line mutations. However, germ-line mutations in *BRCA1-BRCA2* genes account for only 15-20% of breast cancer families. Recently, the *PALB 2* gene, known as one of the Fanconi anemia genes (FANCN), has been identified as a Partner and Localizer of *BRCA2* and was reported to contribute to breast and pancreatic cancer susceptibility. Monoallelic germ-line mutations in *PALB2* have been reported in 1% to 3% of early-onset and/or familial cancer cases and confer more than a two-fold increased risk to develop breast cancer.

In a series of patients previously analysed for *BRCA1/BRCA2* with no detectable point mutation or large rearrangement, we screened 94 index patients for germ-line mutations in *PALB2* by EMMA (Enhanced Mismatch Mutation Analysis). EMMA is, a new fast and cost-effective method based on heteroduplex analysis by capillary electrophoresis. The 13 coding exons and intron-exon junctions of *PALB2* were amplified as 19 amplicons in 6 multiplex PCR using a single condition. To validate the EMMA method we sequenced directly the exons for all samples. We did not observe any discrepancy between the two methods. We identified one truncating *PALB2* mutation in a family with three breast cancer cases (mean age 53 years) and 1 ovarian cancer case. Four novel missense mutations were also identified.

This study is the first report of *PALB2* mutation screening on French breast-ovarian cancer families. Although *PALB2* mutations seem rare, their contribution to hereditary breast/ovarian cancer susceptibility needs further investigation.

Esophageal squamous cell carcinoma (ESCC) is the 6th most common fatal cancer in men and 9th in women in the world And the 5th leading cause of cancer in Iran. A high frequency of ESCC in northeastern Iran has been reported. BRCA2 may play an important role in ESCC carcinogenesis as indicated study from Iran, India and China suggested that. The incidence of multiple primary cancers is reported between 0.3% and 4.3%. Sequential primary ESCC followed by primary Breast Cancer (BrCa) has not been reported previously. Mutational analysis of BRCA2 in several familial ESCC/BrCa pedigrees with affected ESCC individuals who later contracted BrCa was performed.

Individuals with ESCC were treated successfully by surgery and chemotherapy, however, after several years some of the pedigree members contracted invasive ductal carcinoma BrCa. We screened patients for BRCA2 mutations in germline DNA by whole gene sequencing. Some known BRCA2 mutations and a novel splice variant, c.426-2A>G were detected. Novel mutation tracking ruled out SNP in 50 healthy individuals. The related family members, 60 sporadic and 12 familial ESCC were negative for this new mutation. The novel splice variant mutation was found in two affected ESCC/BrCa sisters, 54 yrs and 48 yrs old, and their sons and daughters, two brothers and two nephews. Sequencing of BRCA2 cDNA, exons 4 to 7, revealed that c.426-2A>G mutation lead to exon 5 skipping in splicing process.

These results intrigued a possible link between ESCC and BrCa through BRCA2 tumorigenesis pathway.

Identification of a homozygous nonsense mutation of FANCM in a case with polycythemia vera carrying uniparental disomy 14q

A. Harutyunyan[1], *T. Klampfl*[1], *B. Gisslinger*[2], *T. Berg*[1], *D. Olcaydu*[1], *H. Gisslinger*[2], *R. Kralovics*[1,2];

[1]*Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria,* [2]*Department of Internal Medicine I, Division of Hematology and Blood Coagulation, Medical University of Vienna, Vienna, Austria.*

Polycythemia vera is a chronic myeloid neoplasm characterized by elevated erythrocyte mass and susceptibility to acute myeloid leukemia (AML). Acquired uniparental disomies (UPD) are frequent lesions in cancers that were shown to amplify heterozygous somatic mutations. UPDs of the long arm of chromosome 14 (14qUPD) are frequent defects in myeloid neoplasms, however, the mutant gene target remains unknown. In an attempt to find the target of 14qUPD we performed exome sequencing on tumor DNA sample from a patient with polycythemia vera and carrying 14qUPD. We analyzed the exome sequencing data for point mutations and focused on the chromosomal region of 14qUPD. A homozygous nonsense mutation, R658X, was found in gene *FANCM*. Germline mutations in *FANCM* cause Fanconi anemia and an increased susceptibility to AML. We confirmed the

homozygous mutation in myeloid cells by Sanger sequencing, while the buccal mucosa control sample was heterozygous for the mutation. Clinical data showed that the patient was initially diagnosed with polycythemia vera and had high hemoglobin levels, while at sample the patient was anemic and later transformed to AML. It is unclear whether the nonsense mutation in *FANCM* caused proliferative advantage in the patient or there is a second, somatic mutation that drives the clonal outgrowth. In any case, acquired homozygosity for the germline mutation changed the clinical course of the disease. The interplay of somatic genetic events and germline deleterious variants provides another dimension in clonal evolution of cancers.

Novel mutation and polymorphism of the APC gene in patients with FAP

***Z. Akbari**, M. Montazer Haghighi, M. Yaghoob Taleghani, A. Irani Shemirani, B. Damavand, S. Fatemi, M. Zali;*
Research Center for Gastroenterology and Liver Diseases, Taleghani Hospital, Shaheed Beheshti Medica, tehran, Islamic Republic of Iran.

Background: Colorectal cancer which has become specially prevalent in developed countries. Familial adenomatous polyposis (FAP) is an autosomal dominant disease characterized by hundreds of adenomatous polyps in the colon and rectum and by a variety of extracolonic features.Mutation of the adenomatous polyposis coli (APC) gene, a tumor suppressor , is though to be an early event in patients with FAP.
Method: This study was conducted on 15 patient with FAP. Genomic DNA was extracted according to standard salting out protocol. Whole coding region of the gene was scanned using bidirectional sequencing analysis.
Results: In the present study the screening of APC gene led to the identification of two novel missense mutations and one novel polymorphism. The mutations were including a A>G transition (AAG→AGG) at nucleotide 6226 in exon 15. This alteration substitute an arginine to the normal lysine at residue 2057 (Lys 2057 Arg). The other mutation, G>C transition (AGC→ ACC), was identified at nucleotide 6772 in exon 15. This alteration replaces serine with threonine at residue 2239 (Ser 2239 Thr) in another proband. Moreover, 1novel polymorphism determined in codon 15, C>G transition (ACT→ AGT) at nucleotide 6820. It causes replacement of threonine with serine at residue 2255 (Thr 2255 Ser).
Conclusions: Our findings showed that probably the mutations have been located in these regions are responsible for some cases of FAP deficiency. Therefore, we could consider these types of mutations in order to predict individuals at risk of FAP in our population.

P06.085
The APC gene mutation analysis in Familial Adenomatous Polyposis, a large cohort study from Iran

***T. Hamzehloei**, A. Hoseini, A. Sarli;*
Mashhad university of medical sciences, Mashhad, Islamic Republic of Iran.

Familial Adenomatous Polyposis (FAP) is a rare dominant disease accounting for approximately 1% of all colorectal cancers. The gene responsible is APC mapped to chromosome 5q21-22 and isolated by positional cloning. APC is a tumour suppressor gene which is inactivated as a gate keeper in either familial or sporadic FAP. In this study the germline mutations in FAP patients determine possible genotype-phenotype correlations in these cases. The germline mutations were detected in 63% of patients using heteroduplex analysis on genomic DNA and cDNA. This is the first report of molecular analysis of FAP in a large cohort study from Iran.

P06.086
Prognostic and predictive significance of the bcl -2/IgH translocation in malignant follicular lymphomas

***M. Neagu**[1], C. M. Ardeleanu[2], G. Butur[2];*
[1]National Institute of Pathology Victor Babes, Bucharest, Romania, [2]national institute of pathology victor babes, bucharest, Romania.

In Europe, follicular lymphomas constitute up to 30% of non-Hodgkin lymphomas.
Prognostic markers, identified by 2 different working groups, immunohistochemical (CD10, bcl 2 positivity) and molecular (the bcl 2/ IgH hybrid gene, the t(14;18)(q32:q21.
The aim of our study was to analized the cytogenetical aberrations in malignant follicular lymphomas, in order to identify the prognostic and predictive value of bcl2-2/IgH translocation in these malignancies.
Material and method: We conducted a study on 79 patients with follicular lymphomas. The study was carried out on tissue samples selected from the “Victor Babes” National Institute of Pathology files. These samples were formalin-fixed paraffin embedded-tissues, routinely processed for histology.
The t(14;18) translocation, realized by the bcl 2/IgH rearrangement, supposedly occurs in almost all follicular lymphomas (FL) can be detected by FISH methods
We employed the PathVysion LSI IGH Spectrum Green/ LSI bcl2 Spectrum Orange (VYSIS) kit.
Results: Asingnificant positive correlation was found between the IHC positivity for bcl 2 and the FISH detection of t (14;18) translocation (p=0,04).
Twenty two cases were selected for FISH analysis, five cases were excluded because of the processing artifacts , ten of the 17 cases without artifacts (58.8 %) presented t(14:18) translocation: two cases of FL grade 1-2, two cases of FL grade 1, six cases of FL grade 3.
In 66.6% of cases with t(14;18) translocation, the immunohistochemical reaction for bcl 2 protein was positive.
Bcl2 t(14;18) translocation plays an important role in the pathogenesis of follicular lymphoma, and is an important tool in the diagnosis and treatment.

P06.087
FLT3 internal tandem duplication and *FLT3-D835* mutation in 80 AML patients categorized into cytogenetic risk groups.

***D. Januszkiewicz**[1,2,3], E. Mały[3], M. Przyborska[3], J. Nowak[1];*
[1]Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland, [2]Department of Pediatric Hematology, Oncology and Transplantology of the Medical University, Poznan, Poland, [3]Department of Medical Diagnostics, Poznan, Poland.

Acute myeloid leukemia (AML) is a clonal disorder characterized by various genetic abnormalities and variable response to treatment. About 50% of patients with AML have no cytogenetic aberrations, presenting normal karyotype, and are categorized in the intermediate risk group. In this group detection of FLT3 mutations move a patient from the intermediate to the adverse risk group. Bone marrow from 80 AML patients was cultured to obtain chromosome slides and then karyotype. Simultaneously DNA was isolated from bone marrow and PCR reaction was conducted to test the FLT3 mutation status (ITD and D835). For statistical analysis Chi squared test was used. From the group of 80 AML patients seven were classified as a favorable risk group and FLT3/ITD was found only in one of these patients (14.28%), and FLT3/D835 in another one (14.28%). Fifteen patients showed a complex karyotype with more than three aberrations or with any aberration known as a poor prognosis. Among the adverse group FLT3/ITD was detected in three patients (20%) and D835 mutation in two other patients (13.33%). Among 58 patients with normal karyotype in GTG banding FLT3/ITD occurred in six cases (10.34%) and D835 mutation in two cases (3.45%). No significant difference was found among these three risk groups regarding presence or absence of FLT3/ITD and FLT3/D835. Molecular characterization of mutations in several genes, such as FLT3, NPM1, MLL, CEBPA, in acute myeloid leukemia, especially in normal karyotype cases, could be another factor after cytogenetic analysis to stratify AML patients into different prognostic categories.

P06.088
FOXE1 locus is a major genetic determinant for radiation-induced papillary thyroid carcinoma

***F. Damiola**[1], A. Fillon[1], M. Moissonnier[2], V. Tenet[2], S. McKay-Chopin[1], F. Le Calvez-Kelm[1], I. Malakhova[3], V. Masyakin[4], E. Cardis[5], A. Kesminiene[2], F. Lesueur[1];*
[1]GCS Group, International Agency for Research on Cancer, Lyon, France, [2]RAD Group, International Agency for Research on Cancer, Lyon, France, [3]Republican Scientific-and Practical Center for Medical Technologies, Informatisation, Administration and Management of Health, Minsk, Belarus, [4]Republican Research Center of Radiation Medicine & Human Ecology, Gomel, Belarus,

[5]Center for Research in Environmental Epidemiology, Barcelona, Spain.
After the Chernobyl nuclear power plant accident in April 1986 an increase in thyroid cancer incidence, essentially papillary thyroid carcinoma (PTC) in children, occurred in the contaminated areas. Previous studies demonstrate that children exposed to ionising radiation show an increased risk of PTC, and carry it with them into adult life. Given the inter-individual variation in response to radiation dose and familial aggregation of thyroid cancer, it is likely that genetic factors affect radiation-related thyroid cancer.
In 1999, the RAD group at IARC set up a population-based case-control study in Belarus and the Russian Federation to evaluate the risk of thyroid cancer after radiation exposure in childhood. The study aimed to investigate how environmental and host factors interplay to modify this risk. In the current analyses, we included 413 subjects from Belarus (83 PTC cases and 330 matched controls); all of them were aged 15 or younger at the time of the accident. We genotyped, in this unique series, 8 SNPs shown to be associated with sporadic PTC: rs965513 (nearby *FOXE1* on 9q22.33), rs944289 (*NKX2* on 14q13.3), rs4704397 (*PD8B*), rs2252696 (*TG*), rs2910164 (Pre-miR-146a), rs2145418 (1q12), rs4658973 (*WDR3*), rs4903957 (*TSHR*).
Consistent with findings from the Genome Wide Association Studies (GWAS), the SNP on 9q22.33 appears to double the risk of radio-induced PTC for carriers (OR=2.39 [1.22-4.68], p=0.026). By contrast, the second GWAS SNP on 14q13.3 and the other candidate SNPs were not replicated in this series.
Further studies are underway to understand the role of *FOXE1* in thyroid carcinogenesis.

P06.089
A novel pathogenomic mechanism in FPD/AML by a constitutional t(16;21) involving 16p13 ATF7IP2 and 21q22 RUNX1 loci

A. Buijs[1], *S. van der Crabben*[1], *B. van der Zwaag*[1], *E. van Binsbergen*[1], *M. Poot*[1], *O. de Weerdt*[2], *M. van Gijn*[1], *K. Nieuwenhuis*[1];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*St . Antonius Hospital, Nieuwegein, Netherlands.*
Familial platelet disorder with propensity to myeloid malignancy (FPD/AML) is an autosomal dominant disorder characterized by platelet abnormalities and a predisposition to acute myeloid leukemia (AML). FPD/AML is caused by constitutional point mutations and copy number changes in 21q22 *RUNX1*. Given the clinical heterogeneity of FPD/AML, the syndrome could be overlooked. In the past this has resulted in stem cell transplantation (SCT) of patients from affected siblings before detection of the inherited *RUNX1* mutation. Therefore, adequate diagnostics are essential to exclude FPD/AML. The identification of novel mutations is required to define clinical features and could contribute to risk stratification given the heterogeneous manifestation of this rare disorder. Here we report novel p.Gly143Arg and p.Gln235X (*RUNX1b* variant) mutations in two pedigrees. In a third pedigree no *RUNX1* anomaly was detected by sequencing or copy number analyses using array CGH. We hypothesized that FISH analysis could reveal a balanced 21q22 *RUNX1* translocation. A rearrangement of the *RUNX1* locus by a constitutional t(16;21)(p13;q22) was identified as a novel pathogenomic mechanism in FPD/AML. The 16p13 breakpoint was confined to the proximity of the *ATF7IP2 (MCAF1)* locus, encoding a transcription factor involved in proliferation in human cancer by epigenetic transcriptional control of Sp1-dependent maintenance of telomerase activity. This is the first report on a constitutional chromosome translocation with an oncogene rearrangement as a pathogenomic mechanism in a hematological malignancy. Our data indicate that FISH analysis of *RUNX1* for structural aberrations has to be included in the FPD/AML diagnostic sequel.

MicroRNA-101 modulates E-cadherin expression and function through EZH2 up-regulation in gastric cancer

J. Carvalho[1], *N. C. van Grieken*[2], *S. Sousa*[1], *M. Tijssen*[2], *T. E. Buffart*[2], *B. Diosdado*[2], *H. Grabsch*[3], *G. Meijer*[2], *R. Seruca*[1], *B. Carvalho*[2], *C. Oliveira*[1,4];
[1]*Institute of Molecular Pathology and Immunology of the University of Porto (IPATIMUP), Porto, Portugal,* [2]*Pathology Department, VU University Medical Center, Amsterdam, The Netherlands, Amsterdam, Netherlands,* [3]*Pathology and Tumour Biology, Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, Leeds, United Kingdom,* [4]*Faculty of Medicine, University of Porto, Portugal, Porto, Portugal.*
Inactivation of E-cadherin (*CDH1*), by genetic and epigenetic mechanisms, is recognised as a pivotal step in gastric cancer initiation and progression. Yet, a considerable proportion of gastric cancers lack classical *CDH1* inactivation mechanisms (*CDH1* mutation, loss of heterozygosity and/or DNA methylation), but nevertheless loss or mislocalisation of E-cadherin expression is still frequently observed. To address this issue, we explored an indirect pathway involving chromosomal abnormalities, a microRNA (miR-101) and a histone methyltransferase (EZH2), which may contribute to E-cadherin impairment in sporadic gastric cancer. We confirmed that, independently of the histological type, E-cadherin is frequently impaired (95%) in our series of sporadic gastric cancer. However, only 30% of the cases harbour classical inactivation mechanisms. We found that miR-101 expression is downregulated in most of these cases and proved, for the first time, that this occurs via (micro) deletions at one of the microRNA-101 loci in chromosome 9p24.1 (miR-101-2 locus). Moreover, 40% of cases showing decreased levels of miR-101 displayed overexpression of EZH2 (a known target gene of miR-101) which, in turn, associates with loss or aberrant E-cadherin expression. Conversely, we demonstrated that depletion of EZH2, by short interference RNA, rescues E-cadherin cell-membrane expression. Overall, we show that loss of miR-101 with parallel EZH2 upregulation may constitute an additional mechanism that can either directly impair E-cadherin expression or may co-exist with classical E-cadherin inactivating mechanisms seen mainly in advanced cancers with intestinal morphology.

P06.091
The IL1-RN +2018T>C polymorphism is associated with increased susceptibility to gastric adenocarcinoma

F. Burada, *C. Angelescu, M. Ioana, F. Mixich, P. Mitrut, S. Popa, E. Buteica, M. Cruce;*
University of Medicine and Pharmacy from Craiova, Craiova, Romania.
Gastric cancer is the fourth most common cancer and the second most common cause of cancer deaths worldwide. Gastric carcinogenesis is a complex, multistep process, which may be influenced by many factors, including genetic variations. The aim of our study is to investigate the IL-1B -31T>C (rs1143627), IL-1B +3954C>T (rs1143634) and IL1-RN +2018T>C (rs419598) polymorphisms and gastric cancer susceptibility in Eastern Europe (Romanian population), a region in which the association between gastric cancer and these polymorphisms has not previously been studied. A total of 103 patients with gastric adenocarcinoma and 244 healthy controls were included. DNA was extracted from the blood specimen. These polymorphisms were genotyped by allelic discrimination TaqMan PCR. Allelic distributions were examined for deviation from their corresponding Hardy-Weinberg equilibrium. The effects of cytokine alleles on the risk of diseases were expressed as odds ratios (OR) with 95% confidence intervals (CI). A significant association was observed for IL-1RN+2018T>C, the subjects carrying CC genotype were at a 2.5 fold elevated risk for gastric cancer (OR 2.52, 95%CI:1.06-6.01). Separate comparisons between tumor site and controls, and between histology type cancer and controls also showed that IL1-RN+2018T>C was associated with an increased risk of gastric non-cardia adenocarcinoma (OR 2.77, 95%CI:1.10-6.99) and intestinal type (OR 3.08, 95%CI:1.17-8.11). No significant difference was observed between all gastric cancer cases and controls or in stratified analysis for both IL-1B polymorphisms. In conclusion, polymorphism IL1-RN+2018T>C may contribute to gastric cancer risk, mainly for non-cardia and intestinal types of gastric adenocarcinoma in Eastern Europe.

Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor of the gastrointestinal tract, characterized by

expression of CD117 and harboring activating mutations in *KIT* and *PDGFRA* protooncogenes. In this study, we analyzed the distribution of 192 primary mutations identified in 192 patients with GIST in the Slovak population from April 2007 till June 2010. The exons 9, 11, 13 and 17 of *KIT* and exons 12, 14 and 18 of *PDGFRA* were examined using direct dideoxysequencing after PCR amplification. From these 192 mutations, the *KIT* mutations were present in 160 cases (83%) and *PDGFRA* in 32 cases (17%). The most common were exon 11 mutations in 137/160 cases with 84/137 deletions, 37/137 point mutations and 16/137 duplications/insertions. The deletions within exon 11 were divided into two groups, small deletions (<20 bp) and large deletions (>20 bp) and the most affected codons were 558 and 570, respectively. Subsequently, twenty mutations were identified in exon 9, the most common p.A502_Y503dup in 18 cases. Within exons 13 and 17, we found two p.K4642E missense mutations and one p.N822K substitution, respectively. The most common mutation in *PDGFRA* was the p.V842D (18/32) in exon 18. The distribution of mutations in patients with GIST in Slovak population is similar to the previous reports. Analysis of these mutations is important for indication of the targeted therapy and is emerged as a paradigm for genotype-driven therapy.

Impact of *SHMT* C1420T polyorphism in head and neck cancer

L. M. R. B. Silva[1], *M. Succi*[2], *L. S. Raposo*[1], *J. V. Maniglia*[1], *É. C. Pavarino*[1], *E. M. Goloni-Bertollo*[1];

[1]*São José do Rio Preto Medical School (FAMERP), São José do Rio Preto - SP, Brazil,* [2]*Universidade Estadual Paulista Júlio de Mesquita Filho, São José do Rio Preto - SP, Brazil.*

INTRODUCTION: Head and neck squamous cell carcinoma (HNSCC) is considered one of the most frequent tumors in developing countries and the main risk factors are tobacco and alcohol. Alterations in folate metabolism may contribute to the process of carcinogenesis by influencing DNA methylation and genomic stability. Polymorphisms in genes encoding enzymes involved in this pathway may alter enzyme activity and consequently interfere in concentrations of homocysteine, S-adenosylmethionine and other metabolism products that are important for DNA synthesis and cellular methylation reactions. The objective was to investigate *SHMT* C1420T polymorphism involved in folate metabolism on head and neck cancer risk and the association between this polymorphism with risk factors. **PATIENTS AND METHODS:** Polymorphism was investigated in 731 individuals (241 patients and 490 controls) by Real Time-PCR. Chi-square and Multiple logistic regression were used for the statistical analysis. **RESULTS:** Multiple logistic regression showed that tobacco, male gender and age over 48 years were predictors for the disease (P<0.05). *SHMT* C1420T polymorphism associated to risk factors were not related to HNSCC (Table 1). **CONCLUSION:** The present study suggests that tobacco, male gender and age over 48 years modulate HNSCC risk. However, further investigation of gene interactions in folate metabolism and studies in different populations are needed to investigate HNSCC risk.

Genistein-induced miR-23b expression via hyperthermia inhibits the growth of breast cancer cells

C. Biray Avci*, Z. O. Dogan Sigva, S. Yilmaz, M. Yucebas, T. Balci, C. Gunduz; Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey.*

MicroRNAs (miRNA), non-coding RNA molecules, play a major role in the regulation of gene expression. Mature miRNAs cause mRNA degradation or inhibition of protein translation via complementary or partly binding to the mRNAs, so they act as oncogenes and tumor suppressor genes.

Genistein, an isoflavonoid, is a prime anti-cancer component of soybean and plays roles in the inhibition of protein tyrosine kinase phosphorylation, tumor progression, apoptosis, induction of cell differentiation and disruption of free radicals. Hyperthermia is the exposure of cells to higher temperatures (41-44°C) than normal psychological degrees.

This study aimed to induce oxidative stress by exposing MCF-7 breast cancer cell line to hyperthermia and determine the IC_{50} dose of genistein and evaluate the combined effect of this isoflavone and hyperthermia in terms of miRNA expression levels.

The IC_{50} dose of genistein was 175μM and hyperthermia caused 40% cytotoxicity in MCF-7 cell line. The combination of hyperthermia and genistein showed highest cytotoxicity during the 72nd hour of the experiment.

miRNA expression profilings of 88 miRNAs and 4 housekeeping miRNAs were quantified using real-time online RT-PCR. miR-23b, a miRNA which is reported to be down-regulated in human cancers, was found to be up-regulated 56.69, 739.29 and 918.10 folds following the treatment of genistein, hyperthermia and genistein-hyperthermia combination respectively, compared to the control group of genistein-free cells not exposed to hyperthermia.

In conclusion, up-regulation of miR-23b may offer an alternative miRNA-based therapeutic strategy, as an additional protocol for the treatment of breast cancer.

P06.095

Investigation of the Inhibitory Effect of Soy-derived Genistein on the Metastasis Potential of A549 Lung Cancer Cell Line

M. R. Noori-Daloii*, M. Safari, O. Saydi Dinekaboodi, A. Ghazariyan; Departmetn of Medical Genetics,School of Medicine,Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran.*

The lung cancer is one of the most dangerous cancer in the world . There are two main types of lung cancer: non-small cell lung cancer and small cell lung cancer.

The metastasis of lung cancer is highly dependent of expression of matrix metalloproteinases, and correlated with phosphorylation of ERK1/2 and PI3K/Akt pathways. Here, we showed that genistein decreased the migration and invasion of human non-small cell lung cancer cells (A549 cell line) in vitro, because the combination of anti-cancer drugs with nutritional factors is a potential strategy for altering to increase the efficacy and decreasing the toxicity of chemotherapy. This study examined the effects of genistein on the level expression of mRNA and protein of MMP-2 in lung cancer A549 cell line by qRT-PCR and Zymography.The cytotoxicity effects and proliferation rates does-dependent of genistein in this cell line were determined by MTT and LDH assays. A549 cells were treated for 24, 48 and 72

hrs, with genistein concentrations of 0, 25, 50, 75 and 100 mmol/ml. These results have shown that the most effect of inhibition in growth and proliferation of A549 cell line is 75 mmol/ml concentration. Also, these results indicate that genistein downregulates MMP-2 mRNA and protein expression in A549 cell line, and result of inhibition of ERK1/2 and PI3K/Akt pathways phosphorylation by ELISA indicated that genistein inhibited phosphorylation rate of both pathways. Therefore that it can decrease recurrence and metastatic rates in lung cancer. This issue should be further examined for the clinical treatment.

Germline epigenetic silencing of the tumor suppressor gene *PTPRJ* in early onset familial colorectal cancer

*R. Venkatachalam[1], M. J. L. Ligtenberg[1], N. Hoogerbrugge[1], H. K. Schackert[2], H. Görgens[2], **M. Hahn**[1], E. J. Kamping[1], L. Vreede[1], E. Hoenselaar[1], E. van der Looij[1], M. Goossens[1], M. Churchman[3], L. Carvajal-Carmona[3], I. P. M. Tomlinson[3], D. R. H. de Bruijn[1], A. Geurts van Kessel[1], R. P. Kuiper[1];*
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Universitätsklinikum Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, [3]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

INTRODUCTION: Recently we showed that 3' deletion of the *EPCAM* gene leads to allele-specific epigenetic silencing of the neighbouring *MSH2* gene in Lynch syndrome patients. The underlying mechanism was found to involve *MSH2* promoter hypermethylation mediated by transcriptional read-through, thus providing an explanation of how colorectal cancer (CRC) susceptibility in these families could be inherited. Here we have investigated whether similar copy number variation (CNV)-based silencing mechanisms may underlie unexplained familial CRC cases.
METHODS: A genome-wide SNP array-based screen for constitutional CNVs was performed on a carefully selected cohort of microsatellite stable CRC patients without polyposis. Epigenetic silencing of one of the candidate genes showing CNV was established using allele-specific transcription and bisulfate sequencing.
RESULTS: We identified a constitutional duplication encompassing the 5' end of the *PTPRJ* gene, which was absent in >2,650 non-affected individuals. The duplication showed a head-to-tail in-tandem configuration. Transcriptional read-through and concomitant allele-specific silencing of the downstream *PTPRJ* locus by promoter hypermethylation was demonstarted in patient-derived tissues, but not in controls. Targeted screening of an independent cohort of unexplained familial CRC patients revealed a second case with again a partial, but not identical, *PTPRJ* duplication and a concomitant promoter hypermethylation. *PTPRJ* is a tumor suppressor gene that was previously identified as a CRC susceptibility gene in mice.
CONCLUSIONS: Our data indicate that *PTPRJ* may predispose to CRC through epigenetic gene silencing in humans, suggesting that CNV-based epimutations may serve as a more general mechanism in CRC predisposition.

P06.097

Research for new combinations of clinical and epigenetic markers significant in glioblastoma survival

*D. Skiriutė, **V. Ašmonienė**, A. Tamašauskas;*
Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Glioblastoma (GBM) is the most common and malignant tumor of the Central Nervous System. GBM occur in 6.6 - 100 000 cases of Lithuania population per year. Also, GBM is the main cause of patient`s morbidity and high mortality rates. Due to infiltrative growth of those tumors the radical surgical removal becomes impossible. The prognosis for patients with diagnosed glioblastoma remains poor because of morphological and biological heterogenity determining inefficient effect of other types of treatment - chemotherapy and radiotherapy. GBM treatment results are still unsatisfactory. Therefore, the investigations of more precise and early diagnostic methods of these tumors become a topical issue.
Investigation on epigenetic alterations in glioblastomas is important for understanding of tumor biology as well as the disease pathogenesis for evaluation of early diagnostic possibilities and prognosis. In this study we investigate methylation of four epigenetic markers (MGMT, NDRG2, MLH, CASP8) involved in cell growth, DNA reparation and apoptosis, in glioblastoma tumor tissue, and select biomarkers significant in disease prognosis. Next, we investigate the relevance of set of clinical (patient age, gender, relapse free survival (RFS) and overall survival (OS)) and tumor characteristics (diameter, location) and epigenetic markers in glioblastoma patients prognosis.
All results we will present in a poster presentation.
This research are funded by a grant (No. LIG-17/2010) from the Research Council of Lithuania.

Analysis of MMR system in human gliomas

***I. Rodríguez-Hernández**[1,2], J. García[2], J. González-Valero[2], Á. Santos-Briz[3], J. Gómez-Moreta[4], M. Sánchez-Martin[1,5], R. González-Sarmiento[1,2];*
[1]Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain, [2]IBMCC, Centro de Investigación del Cáncer (USAL/CSIC), Salamanca, Spain, [3]Department of Dermatology, Hospital Universitario de Salamanca, Salamanca, Spain, [4]Department of Neurosurgery, Hospital Virgen Vega, Salamanca, Salamanca, Spain, [5]5Genetically Engineered Mouse Facility, SEA, University of Salamanca, Salamanca, Spain.

DNA mismatch repair (MMR) system defects result in an accumulation of mutations throughout the genome that can alter normal function of proteins and trigger tumorigenesis. We examined the MMR system in 27 low-grade astrocytomas, 19 anaplasic astrocytomas and 60 glioblastomas. MLH1, MSH2 and MSH6 protein expression was evaluated by immunohistochemical analysis, MMR genes methylation status by MS-MLPA, and microsatellite instability (MSI) of the tumors with 8 marker sequences. High-MSI was evident in 4.7% of gliomas, low-MSI in 38.4%, whereas MSS was found in 57%. More instable markers were BAT 40, MYCL1 and BAT25, instead of the frequently BAT26 instable marker related to colorectal cancer. MLH1, MSH2 and MSH6 protein expression was scored negative in 19.4%, 23.8% and 32.0% of cases. Furthermore, 9.3% of glial tumors showed loss of all of them and 43.3% had no expression of one or more MMR proteins. There was a correlation between MMR protein levels and grade of malignance. Tumors showed MLH1, MSH2 and MSH6 methylation in 80.7%, 49.1% and 49.1% of cases. We have not found fully association between methylation status, protein expression and microsatellite instability, suggesting that there could be other repair system which compensates the loss of MMR expression in MSS tumors and promotes MSI in other cases. The study of MLH1 promoter SNP (rs1800734) showed an association between AA genotype and loss of MLH1 expression. Finally, we also analyzed p53 protein expression. P53 overexpression was demonstrated in 46.5% of gliomas and it correlated with MLH1 gene methylation and MSH2 protein levels.

Polymorphisms of the CYP1A1 and CYP2E1 genes in head and neck squamous cell carcinoma risk.

*A. L. S. Galbiatti, N. M. Cury, A. Russo, M. T. Ruiz, L. S. Raposo, J. V. Maniglia, E. C. Pavarino, **E. M. Goloni-Bertollo**;*
Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil.

Introduction: Polymorphisms in genes that encode P450 cytochrome enzymes may increase carcinogens activation or decrease their inactivation ability and consequently, developing cancer. The aims were identify the MspI-CYP1A1, PstI-CYP2E1 and DraI-CYP2E1 polymorphisms in patients with head and neck cancer (HNSCC) and compare with individuals without cancer; to evaluate the association of these polymorphisms with clinical-histophatological parameters.
Patients and Mehtods: In the case group, were evaluated 313 patients for CYP1A1, 217 for CYP2E1 (PstI) and 211 for CYP2E1 (DraI). In the control group were evaluated 417 individuals for CYP1A1, 334 for CYP2E1 (PstI) and 374 CYP2E1 (DraI). Molecular analysis was performed by PCR-RFLP technique and for statistical analysis were used chi-square and multiple logistic regression tests.
Results: We confirmed that age, smoking and alcohol consumption are risk factors for HNSCC. The Hardy-Weinberg analysis showed that genotypic frequencies are in equilibrium in the patients. For control group, the CYP2E1 (PstI) is in equilibrium and the others genes there were not in equilibrium. The result for CYP1A1 (MspI) showed that age (OR:8.15; CI 95% 5.57-11.92) and smoking (OR:5.37; CI 95% 3.52-8.21) were predictors for the disease; to the CYP2E1 (PstI and DraI), there were an association of age (PstI-OR:9.10; CI 95% 5.86-14.14/

DraI-OR:8.07 ; CI 95% 5.12-12.72), smoking (PstI-OR:4.10; CI 95% 2.44-6.89/ DraI-OR:5.73; CI 95% 3.34-9.82), alcohol (PstI-OR:1.93; CI 95% 1.18-3.16/ DraI-OR:1.69; CI 95% 1.02-2.81), respectively with disease development. CYP2E1 (PstI) was less frequent in patients group (OR:0.48; CI 95% 0.23-0.98). **Conclusion:** CYP2E1 PstI polymorphism may have a protective role in the disease.

P06.100
Association between 11 genetic polymorphisms in folate metabolizing genes and head and neck squamous cell carcinoma risk

A. L. S. Galbiatti, *L. M. R. B. Silva, M. T. Ruiz, L. S. Raposo, J. V. Maniglia, E. C. Pavarino, E. M. Goloni-Bertollo;*
Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto - SP, Brazil.

Introduction, Objectives and Methods: Polymorphisms in genes involved in metabolism folate may affect folate status due to their involvement in DNA methylation and synthesis and, therefore, the risk of head and neck cancer (HNSCC). We conducted a case-control study of 265 HNSCC cases and 466 non-cancer controls to investigate associations of *MTHFR* C677T and A1298C, *MTR* A2756G, *MTRR* A66G, *RFC1* A80G, *MTHFD1* G1958A, *CBS* 844ins68, *TC2* C776G and A67G, *SHMT* C1420T and *BHMT* G742A folate metabolism polymorphisms with HNSCC risk. Gene-environment interactions between polymorphisms and survival time, tobacco and alcohol habits, age and gender were evaluated by multiple logistic regression analysis. **Results:** We found that age ≥ 49 years (p<0.001), male gender (p=0.03), tobacco habit (p<0.001), *MTHFR* 1298AC/CC (P=0.028), *MTR* 2756AG/GG (P=0.010) and *RFC1* 80AG/GG (P=0.015) variant genotypes were associated with an increased risk of HNSCC. There were interactions between lower survival and *CBS* 844ins68 (P=0.005); age ≥ 49 years and *MTR* 2756 AG/GG (p=0.004) and *RFC1* 80AG/GG (p=0.006) genotypes; male gender and *MTHFR* 1298 AC/CC (p=0.030), *MTR* 2756 AG/GG (p=0.006) and *RFC1* 80 AG/GG (p=0.009) genotypes; tobacco non- habit and *MTHFD1* 1958GA/AA genotype (p=0.040); tobacco habit and *MTHFR* 1298 AC/CC (p=0.054) and *MTR* 2756 AG/GG (p=0.010); alcohol non- consume and *RFC1* 80 AG/GG (p=0.008) genotype with HNSCC increased risk. **Conclusions**: Our data provide evidence that folate metabolism genetic polymorphisms associated with variables as advanced age, male gender, tobacco and alcohol increase HNSCC development and *CBS* 844ins68 polymorphism is associated with less survival time.

P06.101
Genetic analysis of hematologic myeloid malignancies with acquired trisomy 21 as the sole cytogenetic change

N. E. Larsson, *H. Lilljebjörn, C. Lassen, B. Johansson, T. Fioretos;*
Lund University, Lund, Sweden.

Although acquired trisomy 21 is one of the most common numerical abnormalities in acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), and myeloproliferative neoplasms (MPN), little is known about its pathogenic impact or accompanying submicroscopic changes. Furthermore, previous studies have mainly focused on cases in which +21 was part of a complex karyotype. We performed single nucleotide polymorphism array and mutation analyses of the *FGFR1*, *FLT3*, *GATA1*, *JAK2*, *KIT*, *NPM1*, *NRAS*, *RUNX1*, and *TET2* genes on 11 myeloid malignancies with trisomy 21 as the sole cytogenetic aberration. Copy number alterations and uniparental disomies were observed in six (55%) cases, with none of the changes being recurrent. Mutations in *RUNX1*, *TET2*, and *NPM1* were detected in 5 (45%) cases. These results show that trisomy 21-positive myeloid malignancies are molecularly heterogeneous.

P06.102
Evolution of genomic instability in diethylnitrosamine-induced hepatocarcinogenesis in mice

K. Aleksic[1], *C. Lackner*[2], *J. B. Geigl*[1], *M. Schwarz*[3], *M. Auer*[1], *P. Ulz*[1], *M. Fischer*[4], *Z. Trajanoski*[4], *M. Otte*[3], *M. R. Speicher*[1];
[1]*Institute of Human Genetics, Medical University of Graz, Graz, Austria,* [2]*Institute of Pathology, Medical University of Graz, Graz, Austria,* [3]*Oridis Biomed, Forschungs- u. Entwicklungs GmbH, Graz, Austria,* [4]*Biocenter, Division for Bioinformatics, Innsbruck Medical University, Innsbruck, Austria.*

Diethylnitrosamine (DEN) is a hepatic procarcinogen which is frequently used as an inducer of hepatocellular carcinoma (HCC) in mice. Although mice after DEN exposure are among the most widely used models for liver tumorigenesis, a detailed, mechanistic characterization of the longitudinal changes in the respective tumor genomes has never been performed. We established the chronological order of genetic alterations during DEN carcinogenesis by examining mice at different points in time. Tumor samples were isolated by laser micro-dissection and subjected to array-comparative genomic hybridization (array-CGH) and sequencing analysis. Chromosomal gains and losses were already observed in tumors by week 32 and increased significantly by week 56. Loss of distal chromosome 4q, including the tumor suppressors *Runx3* and *Nr0b2/Shp*, was a frequent early event and persisted during all tumor stages. Surprisingly, sequencing revealed that β-catenin mutations occurred late and were clearly preceded by chromosomal instability. Thus, contrary to common belief, β-catenin mutations and activation of the Wnt/β-catenin pathway are not involved in tumor initiation in this model of chemical hepatocarcinogenesis. *Conclusion:* Our study suggests that the majority of the current knowledge about genomic changes in HCC is based on advanced tumor lesions and that systematic analyses of the chronologic order including early lesions may reveal new, unexpected findings.

P06.103
Type II MHC loci predispose hepatocellular carcinoma in a genome-wide association study of Hong Kong Chinese

N. L. Tang[1], *Y. Qiu*[1], *C. Liao*[1], *P. Tsai*[2], *W. Yeo*[3], *P. B. Lai*[4];
[1]*Department of Chemical Pathology, The Chinese University of Hong Kong, Shatin, Hong Kong,* [2]*Institute of Genome Sciences, Yang-Ming University, Taipei, Taiwan,* [3]*Department of Oncology, The Chinese University of Hong Kong, Shatin, Hong Kong,* [4]*Department of Surgery, The Chinese University of Hong Kong, Shatin, Hong Kong.*

Hepatocellular carcinoma (HCC) is one of the world's leading causes of cancer-related death, especially in East Asia countries. Environmental factors had been identified for the development of HCC, such as chronic infection with heptatitis B virus (HBV) in Asian populations. Although there is a high degree of familial segregation of HCC cases, the genetic risk factors of HCC development are little understood. We are one of the first to perform a genome-wide association study (GWAS) of Chinese HCC patients in this study. The study cohort consisted of 300 Hong Kong Chinese male patients who were all positive for HBV surface antigen (HBsAg). Using the allele distribution of a Chinese population control sample, we detected four most significant hits on chromosome 6 (P-value ≤ 5.0×10^{-6}). These 4 SNPs, located in the major histocompatibility complex (MHC) region around the HLA-DQB2 and HLA-DPB2 gene loci, were significant even after correction for population structure. This result supported previous findings that HLA loci have a putative role in the clearance of HBV virus and the progression to chronic liver disease among HBV carriers. Haplotype analysis is being performed and suggests that certain type II alleles are associated with HCC.

P06.104
The BRCA1 variants c.692C>T and c.693G>A affect a putative ESE motif and increase exon 11 skipping

R. D. Brandão[1,2], *K. van Roozendaal*[1], *D. Tserpelis*[1], *E. Gómez García*[1,2], *M. J. Blok*[1];
[1]*Maastricht University Hospital, Maastricht, Netherlands,* [2]*GROW- School for Oncology and Developmental Biology, Maastricht, Netherlands.*

BRCA1 variants c.692C>T (p.T231M) and c.693G>A (p.=), of unknown clinical significance, were identified in two different patients from HBOC families. The variants lie in exon 11, within a region previously described as "critical region", which spans between codons 200-300. Others suggested that this region was an important regulatory region and suggested the presence of two ESE motifs, one of these covering positions c.690 to c.695. We assessed the putative effect of these variants on RNA splicing.

For splicing analysis, lymphocytes from the carriers and healthy controls were cultured and a fraction of these was treated with puromycin to prevent nonsense-mRNA mediated decay. The relative contribution of each allele to different transcripts was assessed based on allele specific cDNA analysis. In addition, an exon trapping vector

including the putative ESE motif will be used to show its functionality in presence or absence of the variants.
The alleles with either variant give rise to normal levels of the full-length transcript, but also induce higher expression of in-frame *BRCA1*Δ11 isoform, which was found to be weakly expressed in controls. Results of the ESE-dependent splicing assay will be reported.
We now provide experimental evidence for the presence of a functional ESE motif in exon 11. Both variants in this motif affect splicing by increasing the expression of the *BRCA1*Δ11 transcript, besides expressing the full-length transcript. Currently, the clinical relevance of these variants remains elusive, as both the function and the critical expression level of the *BRCA1*Δ11 transcript are unknown.

P06.105
RAD51C - a novel predisposing gene for breast and ovarian cancer: validation of other RAD51 paralogs and missense mutations

A. Meindl[1], *H. Hellebrand*[1], *D. Endt*[2], *K. Eirich*[2], *A. Becker*[3], *T. Kasparek*[1], *H. Hanenberg*[4], *D. Schindler*[2], *R. Schmutzler*[3];
[1]*Klinikum rechts der Isar der Technischen Universität München, Munich, Germany,* [2]*Department of Human Genetics, University of Würzburg, Würzburg, Germany,* [3]*Center for Familial Breast and Ovarian Cancer and Center for Integrated Oncology, University of Cologne, Cologne, Germany,* [4]*Department of Pediatric Hematology, Heinrich-Heine University of Düsseldorf, Düsseldorf, Germany.*

Even high risk families for breast and ovarian cancer families can only partially be explained by mutations in the known highly penetrant genes *BRCA1* and *BRCA2*. Therefore, extreme genetic heterogeneity serves as a model for inherited predis-position to breast cancer. In agreement with this hypothesis, we have recently identified a novel high penetrant predisposing gene for breast and ovarian cancer. The gene encoding RAD51C, one of five known RAD51 paralogs, has been found mutated in six out of 480 breast- and ovarian cancer (BC/OC) families (1.3%). In addition, we have identified a more common missense mutation (2%), exhibiting an OR of 3.44 in BC/OC families only (c.790G->A; G264S).
In order to test whether other RAD51 paralogs are mutated in BC/OC or BC families, we now screened the genes encoding RAD51B and XRCC3, respectively. Apart from one and two misense mutations, respectively, no mutations were found in the *RAD51B* and *XRCC3* genes. Although the application of several algorithms is indicating pathogeneity of the identified missense aberrations, mutations in the other RAD51 paralogs seem therefore to be rare.
To validate further missense mutations identified in the *RAD51C* gene, we employed different functional assays. E. g. the functional characterization of novel missense mutations by a transfection assay found in the *RAD51C* gene led to the identification of at least five further pathogenic mutations in the *RAD51C* gene and will also be reported.
In summary, our data confirm RAD51C as a novel predisposing gene for BC/OC, but might exclude other genes encoding RAD51 paralogs.

Predominant RET germline mutations in exons 10, 11, and 16 in Iranian patients with hereditary medullary thyroid carcinoma

M. Hedayati[1], *M. Zarif Yeganeh*[1], *S. Sheikhol Eslam*[1], *S. Rezghi Barez*[1], *F. Azizi*[2];
[1]*Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Medullary thyroid carcinoma occurs in both sporadic (75%) and hereditary (25%) forms. The missense gain-of-function mutations of the RET proto-oncogene in MTC development has been well demonstrated.
The aim of this study was to investigate the spectrum of predominant RET germline mutations in exons 10, 11, and 16 among Iranian hereditary MTC patients.
Materials & Methods: In this study 217 participants (151 MTC patients and 66 their first-degree relatives) were included. Genomic DNAs were extracted from the leukocytes according to the standard Salting Out/Proteinase K method. Mutation detection was performed through PCR-RFLP analysis. For Positive patients direct DNA sequencing was carried out.
Results: In 217 participants, 43 missense mutations were identified in exons 10(6%, 13 of 217), 11(13%, 28 of 217) and 16(0.9%, 2 of 217). Moreover, a novel germline mutation was detected at codon 686 in exon 11(S686N). Also four different polymorphisms were found in intron 16 of the RET proto-oncogene in eight patients that most of them carried another mutation in exons 10 or 11.
Conclusion: The obtained data in this study showed the frequency profile of the RET proto-oncogene mutations in a sample of 217 Iranian individuals with MTC (19.8%). The most frequent mutation in our population was C634G; whereas in most population it was C634R. Therefore the transforming activity and functional effect(s) of a new RET mutants such as S686N and intronic polymorphisms remain to be elucidated. Altogether, these results underline the importance of the genetic background of family members of any patient with MTC.

P06.107
Methylation of proximal MLH1 promoter region is a sensitive and specific molecular method to distinguish HNPCC from sporadic CRCs

S. Y. Kang, M. J. Kwon, ***K. M. Kim****;*
Samsung Medical Center, Seoul, Korea, Republic of.

Hereditary Nonpolyposis Colorectal Cancer (HNPCC) is an inherited colorectal cancer syndrome and accounts for 5% of all colorectal cancer (CRC). A significant breakthrough in the diagnosis of HNPCC was made with the discovery of mismatch repair (MMR) genes that cause HNPCC. An alternative method for identifying HNPCC patients is microsatellite instability (MSI). In sporadic CRCs, inactivation of MLH1 gene by promoter methylation causes MSI. Significant differences in the clinical phenotype between HNPCC families from South Korea and from the Netherlands were observed.
To investigate methylation status in both distal and proximal regions of MLH1 gene, we used methylation-specific PCR (MSP) and quantitative real-time PCR (MethyLight) using 14 HNPCC and 37 sporadic MSI-H CRCs. Germline mutations for MMR genes were tested in HNPCC patients, and BRAF V600E mutation and MLH1 protein expressions were analyzed in all CRCs.
Germline mutations of MLH1 (n=7) and MSH2 (n=3) were detected in 10 of 14 HNPCC patients. BRAF mutations were detected in 2 (5.4%) sporadic CRCs.
In CRCs from HNPCC patients, proximal and distal promoter regions of MLH1 gene was methylated 0% and 28.6% of cases, respectively. In sporadic MSI-high CRCs, 62.2% and 67.6% were methylated in the proximal and distal promoter regions of MLH1 gene. After combining both proximal and distal regions of MLH1 promoter, methylation frequencies increased up to 82%.
In MSI-H CRCs, methylation test using proximal MLH1 promoter region is an important molecular method to distinguish HNPCC from sporadic CRCs with high sensitivity and specificity.

Epidemiology of HPV infection and possible polymorphisms associated with cervical cancer in Azores - Portugal.

I. Dutra[1,2], *F. Rocha*[1,2], *B. F. Bettencourt*[1,2], *A. R. Couto*[1,2], *A. Gonçalves*[3], *M. Ribeiro*[3], *V. Carneiro*[4], *J. Bruges-Armas*[1,2];
[1]*Serviço Especializado de Epidemiologia e Biologia Molecular, Angra do Heroísmo, Portugal,* [2]*Genetic and Arthritis Research Group, Institute for Molecular and Cell Biology (IBMC), University of Porto, Porto, Portugal,* [3]*Serviço de Anatomia Patológica, Hospital de Santo Espírito de Angra do Heroísmo E.P.E., Angra do Heroísmo, Portugal,* [4]*Serviço de Anatomia Patológica, Hospital do Divino Espírito Santo E.P.E., São Miguel, Portugal.*

Cervical cancer (CC) is the third most common cancer in women worldwide, and the seventh overall, with an estimated 530 000 new cases and 275 000 deaths in 2008. Human papillomavirus (HPV) is mainly responsible for this disease and HPV16 and HPV18 are the most important oncogenic types.
The genetic factors that contribute to the development of CC have not yet been fully identified but numerous studies suggest that the immune response is preponderant in the success or failure of the HPV infection and subsequent progression to cancer.
In this study we sought to identify and genotype HPV in CC in the Azorean population. We also tried to investigate the possible

association between this disease and polymorphisms chosen from 5 genes involved in the immune response to CC.
A total of 78 paraffin sections, with tissue samples of CC were retrospectively evaluated between 1992 and 2008. After viral and genomic DNA extraction we proceeded to HPV genotyping, and identification of six polymorphisms in the TP35 , MTHFR, IL23R, IL12A and IL12B genes.
The most frequently detected HPV type was HPV16 followed by HPV58 and HPV31. The less frequent types were HPV18, HPV33, HPV45, HPV35, HPV51 and HPV52. Regarding genetic susceptibility factors, the most common variants identified in patients were, the variant GG in TP53, CC in MTHFR, CC in IL-23R Rs10889677 and GT in Rs7517847, GG in IL-12A and variant AA in IL-12B. No statistically significant association was identified between the genetic polymorphisms and progression to CC.

P06.109
SESN3-dependent regulation of 2-Cys Prx by HSF1

M. Zamkova, *P. Kopnin, B. Kopnin;*
Institute of Carcinogenesis, Blokhin Russian Cancer Research Center, Moscow, Russian Federation.

Induction of heat shock response is accompanied by elevated transcription of Heat Shock Proteins, which are controlled by HSF1. Under normal conditions HSF1 appears as a repressed monomer shuttling between cytoplasm and nucleus. Upon stress HSF1 becomes activated which is associated with trimerization, nuclear accumulation, hyperphosphorylation, acquisition of DNA-binding and transactivation capacity. HSF1 protects cells from various stresses and increases cellular viability. It can also promote tumor survival as cancer cells depleted in HSF1 show significantly reduced growth and survival. Interestingly, HSF1 regulates up to 3% of genome beside HSPs and regulation mechanisms differ between tumor and normal cells. HSF1 role in the regulation of genes beside HSPs and their link to tumorigenesis has not been well studied.
We found that promoters of sestrin family genes contained heat shock elements. We assumed that HSF1 may influence peroxiredoxins' activity and subsequently regulate the level of Reactive Oxygen Species via regulation of sestrins.
Our results show that introduction of constitutively-active HSF1 into carcinoma cells increases the level of ROS and decreases the level of SESN3 mRNA. Surprisingly, introduction of active HSF1 into normal fibroblasts causes opposite effects. Active HSF1 slightly decreases tumor cell growth and increases cell growth of normal cells. According to our study HSF1 influences the activity of 2-Cys-Prx and this effect seems to be SESN3-dependent as it was proved by shRNA analysis. We believe that our study will contribute to our better understanding of HSF1 role in the regulation of pathways beside HSP induction and subsequently in tumorigenesis.

P06.110
Global methylation levels in oral potentially malignant disorders

A. Acha-Sagredo[1], *N. G. Bediaga*[2], *M. Martinez de Pancorbo*[2], *M. A. Echebarria*[1], *J. M. Aguirre*[1];
[1]*Oral Medicine and Pathology Unit. Faculty of Medicine and Dentistry. University of the Basque Country EHU, Leioa, Spain,* [2]*BIOMICS Research Group. CIEA-Lucio Lascaray Building. University of the Basque Country EHU, Vitoria, Spain.*

Background: Epigenetic alterations are common events in human cancer. Tumor cells show an aberrant reduction of global methylation levels and aberrant increase of gene-specific methylation. In this regard, global hypomethylation seems to be a significant factor driving oncogenesis. However, so far, little is known about the global methylation levels in common potentially malignant disorders such as oral lichenoid disease (OLD) and oral leucoplakia (OL), which malignant potential is controversial. The aim of our study was to assess the degree of global genomic hypomethylation in oral scrapings of patients with oral potentially malignant disorders compared to normal patients.
Methods: We analyzed 205 cytological samples; 153 OLD patients, 22 OL patients and 30 controls. DNA was extracted from the oral scraping and the global methylation level was asses by analyzing the methylation of repetitive elements (LINE1) by pyrosequencing after bisulphite treatment.
Results: OLD and LO samples displayed a mean global methylation level of 65.64% (SD=2.46) and 65.56% (SD=1.36) respectively. The reduction of the methylation level in both groups was statistically significant (p=0.002 and p=0.005) when compared to the control group. About 37.9% of OLD and 45.5% of LO samples were globally hypomethylated when evaluated against the minimum level of methylation in control samples.
Conclusion: In oral malignant disorders the presence of global hypomethylation may indicate that carcinogenic processes could be taking place and may favour the development additional alterations.
†Grant supports: Carlos III Health Institute-FIS(PI081516) and Government of the Basque Country (IT-435-10). A Acha-Sagredo is supported by a fellowship from UPV/EHU.

P06.111
Association of Inflammatory Pathway Genes Polymorphism in Genetic Predisposition to Prostate Cancer Risk: A Pilot Study from Northern India

R. K. Mandal, *A. Mandhani, R. Kapoor, R. D. Mittal;*
Department of Urology and Renal Transplantation, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: Prostate cancer (PCa) is the most frequently diagnosed cancer and one of the major causes of death in men. An understanding of factors associated with PCa mortality is increasingly important. Accumulating evidence implicates inflammation in PCa. Genetic variations within the sequence of candidate inflammatory genes like *TLRs* 2, 3, 9 and *COX-2* genes may lead to suboptimal inflammatory capacity and therefore increased PCa risk.
Material and Methods: We genotyped 195 PCa and 250 healthy controls for *TLR2* (−196 to −174 Del), *TLR3* (c.1377C/T) [rs3775290], *TLR9* (G2848A) [rs352140], and *COX-2* (-765 G>C) [rs20417], (+8473 T>C) [rs5275] promoter gene polymorphisms using PCR-RFLP.
Results: Variant allele carrier of *TLR2* (ID+DD) and *COX-2* -765 (GC+CC) demonstrated increased risk (p= 0.007; OR=2.00; p=0.016; OR=1.74) for PCa. Similarly (TC+CC) of *COX-2* +8473 also exhibited borderline risk. Variant genotype CC of *COX-2* +8473 was found to be significantly associated with the overall higher risk of PCa (p=0.045; OR=1.82). The diplotype C-C of *COX-2* was observed to be associated with a significant increased PCa risk (p=0.004; OR=4.26). Stratification of cases based on clinical pathological grade only combined genotype (CT+TT) of *TLR3* demonstrated borderline significant (p=0.051; OR=2.14) conferring a marginal increased risk with high Gleason grade of PCa patients.
Conclusion: Our findings confirm that the *TLR2*, *COX-2* polymorphism and diplotype of *COX-2* could be a risk factor for susceptibility of PCa. Further validations in large population-based studies are needed to elucidate the role of these SNPs for PCa risk.

P06.112
Association of -607 C/A polymorphism of Interleukin-18 with breast cancer in Zahedan Southeast Iran

M. Hashemi, *E. Eskandari, A. Fazaeli, F. Arbabi, A. Moazeni-roodi, M. Taheri;*
Zahedan University of Medical Sciences, Zahedan, Islamic Republic of Iran.

OBJECTIVE: Interleukin-18 (IL-18) is a multifunctional cytokine that induces the production of interferon-γ (IFN-γ) and play a key role in antitumor immunity. The aim of the present study was to determine whether the -607 C/A polymorphism of IL-18 is associated with breast cancer susceptibility in a sample of Iranian women.
MATERIAL AND METHODS: This case-control study was performed on 74 women with breast cancer and 93 healthy women. Genomic DNA from patients and control subjects were extracted from peripheral blood using salting out, and IL-18 gene promoter polymorphismat position -607 C/A was determined by tetraprimer-ARMS PCR.
RESULTS: No significant difference was found regarding -607 C/A polymorphism of IL-18 among case and control groups ($\chi 2=1.89$, P=0.389).
CONCLUSION: Our results indicate that -607 C/A polymorphism of IL-18 is not a risk factor for breast cancer in the southeastern Iranian subjects.

The insulin receptor substrate 4 (*IRS4*) gene is mutated in paediatric T-cell acute lymphoblastic leukaemia

K. Karrman, *K. Paulsson, M. Isaksson, B. Johansson;*
Department of Clinical Genetics, Lund, Sweden.

We recently reported that the t(X;7)(q22;q34) in a paediatric T-cell acute lymphoblastic leukaemia (T-ALL) results in overexpression of the insulin receptor substrate 4 (*IRS4*) gene through illegitimate recombination with the T-cell receptor ß locus, and hypothesised that *IRS4* may be activated through other mechanisms in additional cases, akin to what has been shown for *NOTCH1*. The *IRS4* gene consists of only one exon, which was sequenced in 21 paediatric T-cell ALL cases. Apart from three known polymorphisms in four cases, two (10%) were shown to harbour a mutation - a 594 bp deletion and a missense mutation, respectively. The former was an interstitial in-frame deletion depriving the protein of the pleckstrin homology domain, a well-conserved region important for the function of the IRS family, whereas the latter was shown to be acquired and to replace a proline with a threonine. We conclude that *IRS4* is mutated in a proportion of T-ALL. However, the pathogenetic impact and clinical ramification of such mutations remain to be elucidated.

P06.114
The JAK2 V617F mutation incidence in patients with myeloproliferative neoplasms.

D. Januszkiewicz[1,2,3], E. Mały[3], M. Przyborska[3], ***J. Nowak***[1];
[1]Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland, [2]Department of Pediatric Hematology, Oncology and Transplantology of the Medical University, Poznan, Poland, [3]Department of Medical Diagnostics, Poznan, Poland.

A point mutation V617F in the *JAK2* gene occurs in nearly all patients with polycythaemia vera (PF) and in other myeloproliferative neoplasms like essentail thrombocythemia (ET) and myelofibrosis (MF). The *JAK2* V617F mutation was study in 491 patients with diagnosis or suspect of myeloproliferative neoplasms. In nearly 80% of patients mutation was detected. Althought discover of *JAK2* V617F mutation has provided important insight into the molecular etiology of PV, ET and MF there is still frequent set of patients without this mutation. Further study of genetic events in pathogenesis in myeloproliferative neoplasms are necessary to evaluate prognosis especially for patients without *JAK2* V617F mutation.

Frequency of V617F JAK2 mutation in patients with myeloproliferative neoplasms.

Diagnosis	No of patients	No of patients with homozygotic *JAK2* V617F mutation	No of patients with heterozygotic *JAK2* V617F mutation	No of patients with without *JAK2* V617F mutation
Essential thrombocythaemia	216	0 (0%)	133 (62%)	83 (38%)
Polycythaemia vera	132	20 (15%)	86 (65%)	26 (20%)
Nonclassified myeloproliferative disorders	82	4 (5%)	47 (57%)	31 (38%)

Chromosomal study among CML patients

F. Farzanfar[1], *C. Azimi[1], Z. Safari[2];*
[1]Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Young Researchers Club, Varamin-Pishva Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.

Many different chromosome aberrations have been shown in cancers. For the first time, Dr. Janet Rowley, American geneticist, discovered a translocation of 22q to another chromosome, generally 9q, in the bone marrow cells of more than 90% of patients with chronic myelogenous leukemia (CML), which called the Philadelphia chromosome. On the other hand, many malignancies exhibit multiple chromosome abnormalities.

The aim of this study was to investigate chromosome aberrations among the CML patients. During the last four years a total of 94 patients were referred to our Department from different hospitals with the primary diagnosis of CML. These patients consisted of 46 men(48.9%) and 48 women (51.1%). Specific technique for the bone marrow culture and also the G-banding technique for karyotyping were applied for all the samples.

Out of 94 cases, 44 patients (46.8%), consisted of 20 males (21.3%) and 24 females (25.5%), showed normal karyotypes.

50 patients (53.2%) showed abnormal karyotypes. 33 patients (35.1%) revealed Philadelphia positive, consisted of 17 males (18.1%) and 16 females (17%).

We observed different numerical aberrations among 8 (8.5%) patients (5 males and 3 females). We also found structural aberrations among 7 (7.4%) patients (5 males and 2 females). The results were obtained as follows:

t(2;5) (one male), inv(16) (one male), del5p (one male), t(1;3;13;18) (one male), t(2;3;14;17) (one male), t(8;21) (one female). t(1;12) (one female).

Genotyping KRAS and BRAF mutations in paraffin-embedded cancer research samples

R. Petraroli[1], C. Lauricella[2], S. Veronese[2], E. Moragón[3], L. Martínez-Avilés[3], B. Bellosillo[3], T. Sepp[1], ***J. Walker***[1];
[1]Life Technologies, Foster City, CA, United States, [2]Molecular Pathology Unit, Niguarda -Ca' Granda Hospital, Milan, Italy, [3]Pathology Department of the Hospital del Mar, Barcellona, Spain.

The epidermal growth factor receptor (EGFR) pathway is a complex signalling cascade that is associated with the development and progression of many cancer conditions. It has been shown that approximately 35-45% of metastatic colorectal cancer tumors may have a KRAS or BRAF mutation, which makes them less likely to respond to anti-EGFR therapies. The identification of these mutations is therefore of great importance in clinical and pharmaceutical research. The Applied Biosystems® KRAS Mutation Analysis Reagents and BRAF Mutation Analysis Reagents were developed to facilitate research aimed at elucidating the role of these regulatory proteins in oncology. The reagents offer a simple protocol for the detection of 12 mutations in the KRAS gene and 3 mutations in the BRAF gene. In this collaborative research study, we made use of the Applied Biosystems® KRAS and BRAF Mutation Analysis Reagents and the Applied Biosystems 3500 Dx, 3100 and 310 Genetic Analyzers to genotype known variants on 35 cancer research samples. The KRAS and BRAF Mutation Analysis Reagents results were easy to interpret and equivalent between the Applied Biosystems® 3100 and 310 Genetic Analyzers. The 3500 Dx instrument technology may also ease the analysis and create standardization for genetics laboratories, which will help alleviate the different quality of results that stem from varying technologies and chemistries.The Applied Biosystems® KRAS and BRAF Mutation Analysis Reagents are For Research Use Only. Not for use in diagnostic procedures

Accurate and Sensitive Detection of KRAS Mutations in Heterogeneous Cancer Specimens

R. Petraroli[1], *Y. Bao[1], D. Merrill[1], D. Le Corre[2,3], S. Sproul[1], B. Ching[1], L. Sapinoso[4], I. Casuga[1], S. Desai[1], D. Deng[1], P. Brzoska[1], H. Blons[3,2,5], P. Puig[3,2,5], C. Chen[1];*
[1]Life Technologies, Foster City, CA, United States, [2]Université Paris Descartes, Paris, France, [3]3UMR-S775, INSERM, Paris, France, [4]Acrometrix, by Life Technologies, Benicia, CA, United States, [5]Hospital Européen Georges Pompidou, Paris, France.

The discovery of pivotal genetic alterations and the understanding of their role in cancer is leading to remarkable successes in therapeutics

and patient care. Molecular diagnosis methods such as DNA sequencing and conventional genotyping of tumor biopsies have advanced research in this field, but are limited in sensitivity due to stromal contamination and by genetic heterogeneity in cancer. We have developed competitive allele specific TaqMan® PCR (castPCR) assays assays for detecting cancer-associated sequence variations. CastPCR not only maintains the wide dynamic range, high sensitivity and reproducibility of TaqMan® assays but also greatly improves the specificity. The technology enables detection, of as little as 1 mutant allele molecule in 10,000,000 wild type molecules. We report here sensitive and accurate detection of cancer-associated KRAS mutations within formalin-fixed paraffin-embedded (FFPE) heterogeneous cancer specimens. Eight FFPE model cell lines were initially used to validate the assays. Mutant FFPE cell line DNAs were titrated in the FFPE wild type cell line DNAs from 100% to 0.1%. Mutations were easily identified at the level of 0.1% with high reproducibility. 24 anonymous tumor tissues and 12 non-tumor tissues from FFPE specimens were also examined. No positive samples were found in non-tumor tissues. The results obtained by castPCR for the 24 tumor tissues were concordant to those previously reported by three different methods (Taqman® PCR, Taqman® PCR + PNA and Sequencing). Our results demonstrate that castPCR as a new rare mutation detection technology, has greater sensitivity, specificity and can thereby facilitate accurate molecular diagnosis of heterogeneous cancer specimens.

P06.118
Detection of K-RAS point mutations in colon tumors by PCR-RFLP method

G. Cardos[1], *F. Cionca*[1], *A. Grigore*[1], *M. C. Stoicea*[1], *C. M. Ardeleanu*[1,2];
[1]*„Victor Babes" National Institute of Pathology, Bucharest, Romania,* [2]*„Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.*

The prognosis of patients with metastatic colorectal carcinomas (CRC) was improved by the new anti-Epidermal Growth Factor Receptor (EGFR) therapy. KRAS mutation status is a crucial parameter for selecting patients for anti-EGFR therapy, only patients without mutant tumors benefit from the new therapy. Gain-of-function K-RAS point mutations, present in 25-45% CRC, maintain the active form of the K-RAS protein, leading to EGFR-independent activation of intracellular Ras/Raf/mitogen-activated protein kinase (MAPK) signaling pathways, making the anti-EGFR tumor therapy ineffective.

The aim of our study was to detect K-RAS mutation status in codons 12 and 13 (about 99 % of all mutations in the K-RAS gene) in CRC patients in order to contribute to the selection of patients for applying the new therapy with Avastin (an anti-EGFR agent) in Romania.

DNA was isolated from fixed and paraffin embedded primary and/or metastatic tumors from 169 CRC patients. K-RAS mutation status was analyzed by the PCR-Restriction Fragment Length Polymorphism (RFLP) method optimized in our laboratory.

Up to now, gain-of-function mutation was detected in 62 patients (36,69%), of which 58 in codon 12 and 4 in codon 13.

The international validation of our PCR-RFLP method by successfully participating to the "Ring trial Molecular-Pathological KRAS Mutationtest of Colorectal Carcinoma" (organized by the German Society of Pathology and the German Federal Association of Pathologists) and to the EQA testing has offered the opportunity to assess the K-RAS mutation status in our laboratory by the low cost and the European analysis standard.

P06.119
K-ras exon1mutations in colorectal cancer patients and its association with clinicopathological information

s. sobhani[1], *M. Ghaffarpour*[2], *Z. Mostakhdemin Hosseini*[3], *F. Kamali*[3], *Z. Nour Mohammadi*[1], *M. Houshmand*[4];
[1]*Islamic Azad University Science &Research Branch, Karaj, Islamic Republic of Iran,* [2]*Iranian Research Organization for Science and Technology, Tehran, Islamic Republic of Iran,* [3]*Imam Khomeyni Hospital, Cancer Institute, Tehran, Islamic Republic of Iran,* [4]*Special Medical Center, Tehran, Islamic Republic of Iran.*

Colorectal cancer (CRC) is the most gastrointestinal cancer in United States and Europe. It is the third most common cancer in Iranian men, and fourth in Iranian women. According to recent researches, somatic mutations in codons 12, 13 (exon1) of K-ras gene are discovered in 20% - 50% human CRCs. The aim of this study was to estimate the contribution of K-ras gene mutations in codons 12, 13 in the incidence, and its association with clinicopathologic information like age, sex, familial history, site of primary and histology in Iranian Colorectal cancer patients. We have analyzed 59 tissue specimens of colorectal cancer patients using PCR/sequencing method for codons 12, 13 of K-ras gene. 20.3% of patients (10 in codon 12 and 2 in codon 13) have shown a point mutation. About 60% of mutations occur in rectum and 41.7% in colon. More than 80% of mutations were in adenocarcinomas and less mutations in mucinous. Most mutations were found at the age of 60 and more. Only two of patients had a familial history for cancer. Mutations in codons 12, 13 are not common in Iranian patients. The mutation pattern for Iranian patients differs from other nationalities. Perhaps we can find point mutations in other exons, and we suggest whole genome sequencing for our patients.

P06.120
Spectrum of kras mutations in colorectal cancer: adenoma vs. adenocarcinoma

M. Montazer Haghighi[1], *A. Irani Shemirani*[2], *M. Taleghani*[3], *S. Milanizadeh*[3], *Z. Akbari*[3], *S. Fatemi*[3], *B. Damavand*[2], *M. Zali*[2];

Introduction: The evolution of colorectal cancer from polyps was approved. It was recognized that most colorectal cancers arise in a process progressing from adenomas to carcinomas. Kras, a small intracellular GTPase, is a central intermediary of the epidermal growth factor receptor (EGFR) pathways. Kras mutations can be detected in approximately 30-60% of patients with colorectal cancer. The most hot spot of the gene is located in exons 2 and 3. The aim of the current investigation was to examine profile of Kras mutations in adenomas and carcinoma in these exons.

Methods: In this study exon 2 and 3 Kras gene in 48 tumors and 47 polyps biopsy were analyzed. DNA of the specimens were scanned using PCR sequencing.

Results: Six mutations in tumors including 5 mutations in codon 12 (3 Gly12Asp ,1 Gly12Ala and 1Gly12Gly) and 1 mutation in codon 13, Gly13 Asp, were detected. Moreover, 3 mutations determined in polyps including 2 in codon12, Gly12Asp, and one in codon 13 ,Gly13 Cys.

Conclusion: Our findings showed that probably the profile of mutations in adenocarcinoma is not entirely compatible with the pattern of mutations in adenomas. However, just one of the mutations,Gly12Asp, was similar in the both group. Therefore, it seems that scanning the mutation in young individuals with polyps will be helpful for early diagnosis clinically and genetically and it would be useful for other follow up.

P06.121
Frequency and type of KRAS mutation in Turkish colorectal carcinoma population

S. Ainechi, *S. Erdamar Cetin;*
Istanbul University,Cerrahpasa Faculty of Medicine, Istanbul, Turkey.

Molecular-targeted agents by blocking epidermal growth factor receptor improve survival in patients with metastatic colorectal carcinoma (mCRC). But anti-EGFR therapy is only applicable to a subset of patients. It has become clear that mutations in intracellular signaling pathway negatively predict success of anti-EGFR therapies. In the intracellular signaling cascade, gain of function mutation in KRAS gene is the most documented one.

We aimed to analyze the frequency and type of KRAS mutation and its correlation with other clinicopathological parameters which was not well documented so far in Turkish mCRC patients.

A hundred and twenty three cases of mCRC were screened for KRAS mutational status of codon 12 and 13 of the KRAS by using Real-time based assay. The correlations with KRAS mutation status and clinicopathological parameters were analyzed statistically.

Male/female was 75/48 and mean age was 60.64. KRAS mutation was found in 53 (43.1%) cases. The most common mutation type was

12 ASP (33.3%) and second was 12VAL (26.3%). 13ASP mutation was approved in 17.5% of cases. The frequency of KRAS mutation in mucinous carcinomas was higher than in adenocarcinomas. Most common mutation type was 13ASP in mucinous carcinomas. There was not significant correlation between KRAS mutation and tumor grade, Lymph node metastases and perineural invasion.
The frequency and type of KRAS mutation in Turkey showed similarity with the other studies. Mucinous tumors have poor prognosis since they have tendency towards higher KRAS mutation. More detailed studies questioning the association between KRAS mutation and histological subtypes are necessary.

P06.122
Promoter hypermethylation of DNA repair genes in Bulgarian patients with laryngeal carcinoma

R. Tzveova[1], G. Stancheva[1,2], S. Jordanov[3], A. Mitkova[1,2], I. Chalakov[3], R. Kaneva[1,2], V. Mitev[1,2], ***T. E. Goranova****[1];*
[1]Molecular Medicine Center, Medical University – Sofia, Sofia, Bulgaria, [2]Department of Medical Chemistry and Biochemistry, Medical University –Sofia, Sofia, Bulgaria, [3]Department of ENT, Clinic of ENT, UMHAT "Tsaritsa Yoanna – ISUL", Sofia, Bulgaria.

Background: Promoter hypermethylation is a central mechanism for epigenetic inactivation by which key genes are silenced in cancer cells. Genes that are frequently methylated in laryngeal tumours are involved in cell cycle control, DNA damage repair, apoptosis and tumour cell invasion. The aim of the current study was to examine promoter hypermethylation in two highly methylated in laryngeal carcinoma genes - *MGMT* and *MLH1*. They are both involved in DNA repair and are also associated with chemotherapeutic sensitivity.
Methods: DNA was extracted from fresh frozen tumour tissues of 50 patients with laryngeal cancer. After sodium bisulfite conversion, promoter regions of *MGMT* and *MLH1* were each amplified by PCR using two sets of primers - specific for methylated and unmethylated DNA.
Results: MGMT promoter was found to be methylated in 10 (20%) patients, while hypermethylation in *MLH1* was detected in 34 (68%) tumours. Epigenetic changes in *MGMT* were more frequent in older patients (p=0.02). No methylation of *MGMT* was observed in patients with early stage (T1-T2) carcinoma of the larynx. Hypermethylation of *MLH1* was significantly increased in the group of active smokers with excess alcohol consumption (p=0.04).
Conclusion: Epigenetic inactivation of DNA repair genes *MGMT* and *MLH1* plays a significant role in laryngeal carcinogenesis of Bulgarian patients.

P06.123
Global hypomethylation and expression level of the DNA methyltransferses in patients with laryngeal cancres - preliminary results.

A. Stembalska*[1], P. Leszczynski[1], J. Gil[1], G. Pitala[2], D. Ramsey[3], M. Fraczek[4];*
[1]Wroclaw Medical University, Wroclaw, Poland, [2]2Department of Clinical Otolaryngology, 4th Military Hospital, Wroclaw, Poland, [3]Department of Mathematics and Statistics, University of Limerick, Limerick, Ireland, [4]Department of Otolaryngology, Wroclaw, Poland.

Laryngeal cancer is one of the most frequent head and neck cancers (HNSCC, Head and Neck Squamous Cell Carcinoma). About 95% of laryngeal cancers are squamous cell carcinomas (LSCC). The aetiology of LSCC is very complex, with both environmental (alcohol and tobacco use), genetic and epigenetic factors involved. One of the common epigenetic events, which has been recognized as a cause of carcinogenesis in a variety of tumors, is global DNA hypomethylation, namely reduced level of methylation compared with healthy tissue. Hypomethylation affects many repetitive sequences as well as a number of single-copy genes (e.g. growth regulatory genes, tissue specific genes) and may lead to chromosomal instability, loss of imprinting, retrotransposons and oncogene activation. DNA hypomethylation may occur at least partly as a consequence of cell cycle deregulation disturbing the coordination between DNA replication and activity of DNA methyltransferases.
The aim of study was 1) to assess the overall level of 5-methyldeoxycytosine in dinucleotide CpG sites in the genome of primary LSCC compared to normal laryngeal tissue; and 2) to examine of the expression level of the methyltransferases (Dntm1, Dntm3A, Dntm3B).
The study was carried out on a homogenous group of 70 patients with laryngeal squamous cell carcinoma.
Analysis of hypomethylation was performed using Ultra Performance Liquid Chromatography (UPLC) method. To analyze expression of panel genes, Real−Time PCR was used. We compare the results of the global level of DNA methylation and the activity of DNA methyltransferases with clinical and histopatological data as well tobacco and alcohol consumption.

P06.124
Investigation of mutations in ABL and BCR gene in *BCR/ABL* transcript of patients with ALL and CML

V. B. Kocabıyık*[1], H. Acar[2], Ü. Çalışkan[3];*
[1]Department of Medical Genetic, Selçuk University,Selçuklu Medical Faculty, Konya, Turkey, [2]Department of Medical Genetic, Selçuk University, Selcuklu Medical Faculty, Konya, Turkey, [3]Selçuk University, Department of Hematology, Selcuk University, Meram Medical Faculty, Konya, Turkey.

Chronic Myelogenous Leukemia (CML) is characterized as a presence of the *BCR/ABL* gene fusion or Ph chromosome. The breakpoints can be changed on BCR and ABL genes and resulting in different molecular weights of the fusion gene products. Different size deletions and mutations are seen in ABL and BCR genes along with the presence of the *BCR/ABL* fusion gene. These mutations are associated with patient's prognosis and related to therapy. In the present study, F317L, F311I, M351T, T315I and F359V mutations was analized in ALL and CML patients with *BCR/ABL* fusion gene and control cell line K562 having *BCR/ABL* fusion gene and Raji (Burkitt lymphoma) cell lines without *BCR/ABL* fusion gene on *BCR/ABL* transcript (cDNA), by using PCR-RFLP technique.
Fourteen out of 67 patients showed these five type mutations either alone or along with others. These mutations include F317L in 7 patients, F311I in 3 patients, M351T in 2 patients, T315I in one patient and F359V mutations in 3 patients and also M351T and F317L in one patient, T315I and F317L in the other patient. As a conclusion, in order to determination of certain mutations in the *BCR/ABL* fusion gene is important for treatment and follow up treatment response.
Key Words: Leukemia; *BCR/ABL* , PCR-RFLP

Micro RNA expression profiling in childhood acute leukemia by microarray platform

M. Duyu[1], ***O. Cogulu****[1], B. Durmaz[2], C. Gunduz[3], A. Turedi Yildirim[4], S. Aksoylar[1], D. Yilmaz Karapinar[1], F. Ozkinay[1], C. Vergin[4], K. Kavakli[1], G. Irken[5], N. Cetingul[1];*
[1]Ege University, Faculty of Medicine, Department of Pediatrics, Izmir, Turkey, [2]Ege University, Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey, [3]Ege University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey, [4]Behcet Uz Children's Hospital, Izmir, Turkey, [5]Dokuzeylul University, Faculty of Medicine, Department of Pediatrics, Izmir, Turkey.

The aim of this study is to evaluate the associations between miRNAs and childhood acute leukemias to find out their clinical and therapeutic implications. Sixty children with newly diagnosed acute childhood leukemia and 15 age-matched controls were included in the study. Follow-up period was between 9 and 18 months. During this period, two patients relapsed and 7 patients died. MicroRNA expression profiling consisting of 1136 miRNAs from peripheral blood (PB) and bone marrow (BM) samples of patients and control cases were analysed. Aberrant microRNA expressions associated with the diagnosis, differential diagnosis, outcome and prognosis of acute leukemia were prospectively evaluated. The effect of significant miRNAs on overall and event free survival for ALL and AML separately were also presented. The results were confirmed by real time RT-PCR. PB miRNA profile does not reflect BM miRNA profile. Significant dysregulation according to the BM results compared to the control group was found in ALL, AML, high risk ALL and AML, T-cell and B-cell ALL, and exitus groups . miR-548i, miR-640, miR-606, miR-3140, miR-3115, miR-369-3p, miR-574-3p, miR-613 and miR-140-3p are described for the first time in leukemia. miR-145 for ALL and miR 140-3p for AML were associated with overall survival. Novel miRNAs which are associated with childhood acute leukemia were identified. In

conclusion, miRNA expression profiles may be a powerful tool for the diagnosis and differential diagnosis of acute leukemia and may have a prognostic significance.
*The research was supported by Scientific and Technical Research Council of Turkey.

HTFA (High - Throughput FISH Analysis): A new sensitive approach to screen hematological malignancies

N. Uzulmez, *N. Cine, D. Sunnetci, E. Gumuslu, B. Enguzel, S. Eren, Z. Ilkay, D. Yavuz, R. Akkoyunlu, H. Savli;*
Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.

INTRODUCTION: Multiple probes developed by using bacterial artificial chromosome (BAC) for the diagnosis of hematologic malignancies are new diagnostic tools facilitating the detection and mapping of genomic alterations in target genes. This method helps screening of several deletion-duplication regions unlike conventional techniques and it provides a hematologic approach. High-Throughput FISH Analysis platforms contain 31 regions of somatic chromosomes related to hematologic malignancies.
MATERIALS and METHOD: 20 cases diagnosed as leukemia from Kocaeli University Faculty of Medicine Hematology Policlinic were analysed in this study. DNA samples which labelled according to the protocol were hybridized with High-Throughput FISH Analysis platforms and they were screened and analysed with the help of BlueFuse Multi v2.1 software.
RESULTS: According to the data given, deletion was detected in one patient with the size of 55,414,419.5 bp between the bands 5(q21.2)-q33.3). 3 deletions were detected in another patient at the following bands: between the bands 7(p22.3-q31.3) with the size of 118,801,746.5 bp, between the bands 7(q31.3-q35) with the size of 17,543,770.0 bp, between the bands 7(q35-q36.3) with the size of 11,622,058.0 bp. 1 duplication was detected in one patient with the size of 558,808.5 bp on the band 3q11.2.
CONCLUSION: The results of three cases were used in the differential diagnosis of AML-MDS by the Department of Clinical Hematology. Diagnosis and treatment of two patients were given according to the results we provided. Preliminary findings showing that BAC based HTFA are effectively applicable in the diagnosis of hematological malignancies.

Li-Fraumeni syndrome (LFS), resulting from mutations of the *TP53* tumor suppressor gene, is a devastating inherited form of cancers, characterized by an early onset and a broad spectrum of tumors. We have identified, thanks to a national recruitment of more than 1000 families suggestive of LFS, *TP53* alteration in 156 affected families. To estimate the contribution of deleterious CNVs (*Copy Number Variations*) to LFS in families without detectable *TP53* alteration, we have developed a custom-designed CGH microarray. This microarray contains 24000 probes at a very high density covering 400 kb around the *TP53* locus and different genes belonging to the p53 pathway, and 150000 probes covering the rest of the genome. The analysis with this microarray of 30 families strongly suggestive of LFS, without detectable *TP53* mutation, allowed us (i) to characterize for the first time an intragenic deleterious duplication of *TP53*, (ii) to show the absence of quantitative alterations affecting the 5' and 3' regulatory regions of *TP53,* and (iii) to detect 9 singleton CNVs not recorded in the Database of Genomic Variants. Targeted analysis of these CNVs, using QMPSF, in 500 controls revealed that one CNV covering a miRNA was in fact polymorphic and that the 8 others were exclusive of LFS. Remarkably, 3 of these CNVs alter genes involved in the p53 pathway.

Genes for nicotinic acetylcholine receptors (nAChRs) are members of region on chromosome 15q24-25.1 known as a lung cancer susceptibly locus 2 (LNCR2). We have introduced the SNaPshot analysis of four SNPs in the vicinity of the CHRNA5 and CHRNA3 genes to look for association between haplotypes in this region and the diagnosis of (or even the predispositition to) lung cancer in Czech population. First, we followed these four SNPs in genomic DNA samples of three groups of patients (with NSCLC, with non-neoplastic pulmonary diseases, and anonymized individuals from routine laboratory, respectively). The highest difference in genotypic frequencies was seen between the groups of NSCLC patients and control subjets with non-neoplastic pulmonary diseases (P = 6.3 x 10-5 for rs1051730 and P = 7.9 x 10-5 for rs8034191). Further, we applied this analysis to a set of 47 pairs of DNA samples from NSCLC tumor and normal lung tissue of the same patient. We observed quantitative allelic imbalance in tumor DNA in 4/19 (21%) of heterozygotes, where reduced signals of SNPs alleles could be seen compared to signals of ancestral alleles, and vice versa. This allelic imbalance was not found in any non-tumor (normal) lung DNA sample. Finally, we evaluated this allelic imbalance by quantitative Real-Time PCR of other loci in LNCR2 region by measurement of cycle threshold (CT) value of tumor DNA compared with CT value of DNA from normal lung tissue against to CT value for TFCR, a housekeeping gene.

A *BACH2-BCL2L1* fusion gene resulting from a t(6;20)(q15;q11.2) chromosomal translocation in the lymphoma cell line BLUE-1

S. Türkmen[1], *M. Riehn[1], E. Klopocki[1], M. Molkentin[2], T. Burmeister[2];*
[1]*Charité Virchow-Klinikum Institute of Medical Genetics, Berlin, Germany,* [2]*Medizinische Klinik für Hämatologie, Onkologie, Charité CBF, Berlin, Germany.*

Abnormalities of the long arm of chromosome 6 are a common feature in various B-cell malignancies. In most cases the genes involved have not yet been clearly identified. We have molecularly characterized the recently established Burkitt lymphoma cell line BLUE-1 that carries a t(6;20)(q15;q11.2) rearrangement in addition to the typical t(8;14) with *MYC-IgH* fusion. To identify the gene loci involved on both chromosomes we applied a sequential BAC clone mapping strategy. Using RT-PCR we were finally able to detect a fusion mRNA transcript showing a fusion of the first (non-coding) exon of *BACH2* (basic leucine zipper transcription factor 2) on 6q15 to the second exon of *BCL2L1* (*BCL-X*) on 20q11. Various fusion transcripts were detected for different *BCL2L1 (BCL-XL)* isoforms. The fusion ultimately results in strong expression of the Bcl2l1 *(*Bcl-xL*)* anti-apoptosis protein, as demonstrated by immunoblotting. This is the first report that shows involvement of both *BCL2L1* and the transcription factor *BACH2* in a chromosomal rearrangement. It points to *BACH2* as a possibly important target in lymphomas with 6q aberrations, although other genes on 6q are probably also involved in these cases. Moreover, it suggests that other members of the *BCL2* anti-apoptosis gene family other than *BCL2* itself might also be involved in lymphoma.

P06.130
Role of EBNA-1 in carcinogenesis of line 59 transgenic mice

Y. A. Al-Sheikh;
King Saud University, Riyadh, Saudi Arabia.

Generating EBNA-1 transgenic mice (line 59, which succumbed monoclonal B cell lymphoma) was designed to explore the effects of expressing EBNA-1 independent of the remaining viral components. Transgene was generated by placing the IgH intronic enhancer (Eμ) and the Polyoma virus early promoters (Py) upstream to EBNA-1

coding sequence of EBV strain B95-8. To characterize the transgene structural status, restriction enzyme and Southern blot analysis were performed. Several aspects of the integration and expression of an EBNA-1 transgene were also explored. The 3' genomic sequence flanking the transgene were isolated by IPCR and aligned to mouse chromosome 4 band D2.3. This was achieved by Fluorescent in situ hybridization (FISH) analysis. Genomic sequences surrounding the transgene segment region was analysed by the *in silico* Ensemble and NCBI online genomic database softwares. No cellular gene was found directly at the site of integration, however, genes in the proximity of this site include Laptm5, syndcan 3, yamagushi sarcoma virus gene (Yes1) oncogene and interleukin 6 (IL-6). These genes could have oncogenic potential. The yamagushi sarcoma virus gene (Yes1) oncogene and interleukin 6 (IL-6). These genes could have potential involvement in the lymphoma process. In addition the potential cooperation of EBNA-1 with cellular oncogenes leading to lymphoma was explored by differential gene expression analysis. Genes such as small GTPase *ran*, *p53*, *Rap1GDS1* and RAG-2 were found to be differentially gene expressed.

Integration of mutation scores in the diagnosis of Lynch syndrome reduces the need for microsatellite instability testing

W. M. J. van Rijen[1], *R. Riedl*[1], *C. Tops*[2], *M. Weijenberg*[3], *E. Blom*[1], *S. Sallevelt*[1], *S. Sanduleanu*[1], *F. Bot*[1], *E. B. Gómez García*[1];
[1]*Maastricht University Medical Centre, Maastricht, Netherlands,* [2]*Leiden University Medical Centre, Leiden, Netherlands,* [3]*Maastricht University, Maastricht, Netherlands.*

Tumor-based diagnostic techniques are currently the first diagnostic step for Lynch syndrome (LS). However, these techniques are expensive, time-consuming and have low specificity.

Our aim was to evaluate the current diagnosis of LS and to investigate the role of clinically-based mutation probability methods (MMR-pro, Wijnen) to optimize it. We included 229 consecutive patients, counseled between 2000 and 2008, who fulfilled the revised Bethesda criteria and underwent further diagnosis of LS. From them, 67 (29%) had an MSI tumor, 39 of them (17%) was due to LS. The average MMR-pro score of LS patients was 0,73 (95% CI 0,63-0,82), significantly higher than the average score of non-LS patients (p <0,001). A score of more than 0,9 was present in 12% of all cases, 55% of them were LS. An MMR-pro score <0.2 was obtained in 93 (41%) of patients, including three with LS. All three patients fulfilled the Amsterdam II (AMS II) criteria compared to only one in the non-LS group.

Based on these results a diagnostic flowchart was designed, as follows: MSI is not performed if MMR-Pro scores <0.20 (except for cases that are AMS II positive) or >0.90. In the high score group detection of the four MMR proteins and/or direct DNA-sequencing of the MMR-genes can be performed. This approach was validated in 67 additional patients: 49% could be excluded from tumor analysis without missing any LS.

Therefore, integrating mutation probability scores in diagnosis of LS, can reduce the number of tumors tested by half with the same sensitivity.

Inherited pathogenic mutations in the mismatch repair (MMR) genes *MLH1*, *MSH2*, and *MSH6* predispose to Lynch syndrome. Major challenges in Lynch syndrome diagnostics are the DNA variants with an unclear pathogenic nature (unclassified variants, UVs) such as single amino acid substitutions and small in-frame deletions. In particular, MSH6 UVs account for a substantial proportion of these UVs. This study has been performed to evaluate the pathogenicity of five of such inherited MSH6 UVs found in patients suspected of Lynch syndrome.

The mutated MSH6 proteins, all containing single amino acid substitutions, were tested for expression, stability and sub cellular localization in an MSH2/MSH6-proficient cell line (HEK293T). Moreover, interaction of the MSH6 mutants with MSH2 was analyzed by yeast two-hybrid experiments.

Protein expression of the MSH6 mutants p.Ser144Ile, p.Ala326Val, p.Gln522Arg, p.Ala1021Asp, and p.Thr1219Ile was comparable with the expression of wild type MSH6 co-expressed with MSH2. Analysis of *MSH6* expression levels by real time PCR corroborated these findings. These experiments showed a high similarity between the protein and the gene expression patterns. Furthermore, no effects were observed on protein-protein interactions and all five MSH6 UVs showed a normal nuclear localization. Our different functional assays yielded no evidence that the five *MSH6* UVs tested are the cause of Lynch syndrome in these patients.

P06.133
Somatic mutations in *MLH1* and *MSH2* are a frequent cause of mismatch-repair deficiency in Lynch syndrome - like tumors.

A. R. Mensenkamp[1], *W. A. G. van Zelst-Stams*[1], *M. Goossens*[2], *M. Kwint*[2], *N. Hoogerbrugge*[1], *M. J. Ligtenberg*[1,2];
[1]*Department of Human Genetics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands,* [2]*Department of Pathology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Introduction - Lynch syndrome (previously called hereditary nonpolyposis colorectal cancer (HNPCC)) is caused by germline mutations in the mismatch repair (MMR) genes *MLH1*, *MSH2*, *MSH6,* and *PMS2* and *EPCAM,* and accounts for ~3% of all colorectal cancers. Tumors associated with Lynch syndrome are characterized by microsatellite instability (MSI) and loss of expression of one or more MMR proteins. In a considerable number of patients with tumors that fulfill these criteria a germline mutation cannot be identified. To elucidate the cause of the MMR-deficiency in these tumors, we analyzed whether somatic mutations in the suspected MMR gene could explain the phenotype.

Methods - In total 13 unexplained MLH1-deficient tumors and 9 unexplained MSH2-deficient tumors were screened for somatic mutations in *MLH1* and *MSH2*, respectively.

Results - In 10 out of 22 (45%) tumors one mutation could be identified that was not present in the surrounding normal tissue. In 4 MSH2- and 3 MLH1-deficient tumors (32% in total), a second mutation or LOH was identified.

Conclusion - In 10 tumors, especially those that are MLH1-deficient, we could only identify one mutation, suggesting the presence of an as yet unidentified second mutation in either the tumor or the germline. In the 32% of cases with two tumor-specific mutations in *MLH1* or *MSH2* the presence of an additional germline MMR gene mutation is unlikely, thereby reducing their familial risk for Lynch syndrome-related tumors considerably.

Providing accurate and unbiased estimates of cancer risks is a major challenge in the clinical management of Lynch syndrome. This study aimed to determine the age- and gene-specific cumulative risks of developing various tumors using the largest series to date of families with *MLH1*, *MSH2* and *MSH6* gene mutations.
Enrolled from forty French family cancer clinics, 537 families with mutated genes (248 *MLH1*, 256 *MSH2*, 33 *MSH6*) were analyzed. Risks were estimated using the Genotype Restricted Likelihood method accounting for ascertainment bias (*Bonaïti et al. Eur J Hum Genet 2011; 19:173-9).*
Significant differences were found between the three mutated genes ($p < 0.01$). The cumulative risks of colorectal cancer by age 70 were 41% (95% CI: 25-70) for *MLH1* mutation carriers, 48% (30-77) for *MSH2* and 12% (8-22) for *MSH6*. For endometrial cancer, corresponding risks were 54% (20-80), 21% (8-77) and 16% (8-32) and for ovarian cancer they were 20% (1-65), 24% (3-52) and 1% (0-3). The cumulative risks by age 40 did not exceed 2% for endometrial cancer and 1% for ovarian cancer, irrespective of the gene. The lifetime risks for other tumor types did not exceed 3%.
Compared with *MLH1* or *MSH2* mutations, *MSH6* mutations were associated with markedly lower cancer risks of both colorectal and gynecologic cancers. Lifetime ovarian and endometrial cancer risks associated with *MLH1* or *MSH2* mutations were high but increased only after age 40. Our findings should lead to adaptation of preventive strategies according to the mutated gene.

P06.135
Grawitz tumour, paraganglioma, ovarian and colorectal cancer in an *MSH6* mutation carrier

R. P. Stulp[1], *Y. J. Vos*[1], *A. Karrenbeld*[2], *J. C. Oosterwijk*[1], *R. H. Sijmons*[1];
[1]*department of Genetics, University Medical Center Groningen, Groningen, Netherlands,* [2]*department of Pathology, University Medical Center Groningen, Groningen, Netherlands.*
Lynch syndrome (HNPCC) is an autosomal dominant tumour syndrome caused by germline mutations in DNA mismatch repair (MMR) genes. Tumours are predominantly colorectal and endometrial, but other types have been reported, typically associated with MSH2 mutations (1). Such diversity is very uncommon in patients with MSH6 mutations. We present a 58 year-old woman with a truncating mutation in the *MSH6* gene (c.651dupT), who has been diagnosed with two recto-sigmoid adenomas (at age 26 and 30 years), ovarian carcinoma (51 yrs), a Grawitz tumour (52 yrs) and colorectal cancer (58 yrs). The colorectal and ovarian tumours were microsatellite unstable, the Grawitz tumour was not. All three tumours showed loss of the MSH6 protein demonstrated by immunohistochemical expression. Recently, our patient developed a paraganglioma; MMR staining and microsatellites will be tested after surgery.
Grawitz tumours and paragangliomas have so far not been associated with Lynch syndrome; analysis of the paraganglioma is pending. Our case demonstrates that germline MSH6 mutations can be associated with a previously unreported diversity of tumours. In general, immunohistochemistry for MMR proteins appears to be more sensitive in identifying underlying Lynch syndrome in tumours other than colorectal cancer (2).

Seven years of MUTYH genetic screening in unrelated Czech APC-mutation-negative polyposis patients

M. Florianová, J. Štekrová, L. Schwarzová, K. Hirschfeldová, Z. Kleibl, V. Kebrdlová, ***M. Kohoutová****;*
the First Faculty of Medicine and General Teaching Hospital, Prague, Czech Republic.
The MUTYH associated polyposis (MAP) is an autosomal recessive syndrome associated with 5-100 colorectal adenomas and caused by mutation in the MUTYH gene. Patients with MAP present with clinical features similar to familial adenomatous polyposis (FAP) or attenuated polyposis (AFAP) but in the absence of a strong multigenerational family history of polyposis. The MUTYH gene (NM_001048171.1) is localized on chromosome 1p.
We examined the whole MUTYH gene in 120 APC-mutation-negative probands and thereto we screened for mutations in the exon 7 and 13 of MUTYH gene in 121 APC-mutation-negative probands. Mutation screening was performed using denaturing high performance liquid chromatography (dHPLC) or high resolution melting (HRM) analysis. Samples showing unique profiles were sequenced in both directions.
We have detected 6 patients with biallelic mutation in MUTYH and 6 patients with monoallelic MUTYH mutation. The “hot spots” mutations: c.494A>G (p.Y165C) and c.1145G>A (p.G382D) were found, as well as two already reported mutations c.891+3A>C (p.Gly250TrpfsX7) and c.1105delC (p.Ala371ProfsX23).
MUTYH and MSH6 proteins act in cooperation during the DNA repair process. Based on this interaction, it was hypothesized that the combination of heterozygote germline mutations in both genes could result in an increased CRC risk. Hence we have tested the presence of MSH6 mutation in 6 carriers of monoallelic MUTYH mutation. We would like to confirm the association between MUTYH and MSH6 mutations. Unfortunately there is no evidence for this association.
Supported by the Scientific Project No. MSM0021620808 of the Ministry of Education, Youth and Sports of the Czech Republic.

P06.137
Molecular analysis of the *TP53* and *NBN* genes in pediatric patients with medulloblastoma

M. Borucka-Mankiewicz*, D. Piekutowska-Abramczuk, E. Ciara, W. Grajkowska, P. Kowalski, D. Jurkiewicz, S. Łuczak, A. Tańska, J. Trubicka, M. Pelc, M. Krajewska-Walasek, K. Chrzanowska;*
Children’s Memorial Health Institute, Warsaw, Poland.
Medulloblastoma (MB) is an invasive embryonic tumor of the cerebellum and the most common malignant brain tumor in children. The main cause of MB are chromosomal aberrations. Recently, we identfied germ_line mutations in *NBN* gene as a predisposition factor for MB development. The aim of this study was to investigate the involvement of germ line mutations in both *TP53* and *NBN* genes in a group of 75 MB pediatric patients. Molecular analysis was performed by PCR-SSCP and sequencing of the whole *NBN* gene and *TP53* gene exons 5 to 8. In 6 patients the *TP53* mutations were identified, including five missense substitutions: c.481G>A in exon 5 (p.Ala161Thr), c.638A>G in exon 6 (p.Arg213Arg), c.746G>C in exon 7 (p.Arg249Ser), c.760A>G in exon 7(p.Ala254Val) , c.814G>A in exon 8 (p.Val272Met) and one insertion in exon 8 (c.801_802insC) All *TP53* gene mutations identified in this study have not been described before. No pathogenic mutation but polymorphic variants in *NBN* gene were found in our MB group: c.102G> (p.Leu34Leu), c.553G>C (p.Glu185Gln), c.1197C>T (p.Asp339Asp), c.1397+45delA, c.2016A>G (p.Pro672Pro), c.1915-7A>G, c.2120-30A>T. Our study may suggest a role of TP53 mutation in the pathogenesis of medulloblastoma.
The study was supported by CMHI project S112/2009

P06.138
Clinical features of medulloblastoma in heterozygous carriers of the *NBN* gene germline mutations

K. H. Chrzanowska*, M. Perek-Polnik, B. Dembowska-Bagińska, E. Ciara, D. Piekutowska-Abramczuk, W. Grajkowska, M. Krajewska-Walasek, D. Perek;*
The Children’s Memorial Health Institute, Warsaw, Poland.
Medulloblastoma (MB) is the most common malignant brain tumor in childhood. Epidemiological data indicate that the *NBN* gene can be considered as a susceptibility factor for cancer development. We documented significantly higher frequency of two *NBN* germ-line mutations in a cohort of Polish pediatric patients with MB (6.36%) than in general Polish population (0.5%). Aim of our study was to compare clinical features, toxicity profile and treatment outcome of MB in carriers and non-carriers of two *NBN* germline mutations, c.511A>G and c.657_661del5. Patients and methods: 98 MB patients (including 7 carriers of *NBN* mutation) were analyzed for age at diagnosis, duration of symptoms, disease stage, extent of resection, treatment complications, chemotherapy compliance and survival. Results: Median age at diagnosis was 5.17 in heterozygotes and 8.83 years in

others. There was no difference in symptoms duration. Dissemination and tumor residual were present in 43% of heterozygotes and in 29 % and 30 % of others respectively. Chemotherapy doses were reduced to 77 % and 86% respectively. Grade 3 and 4 toxicities were more frequent in heterozygotes. Event free and overall survival were better in patients without *NBN* mutation.
Conclusions: Younger age and advanced disease at diagnosis, and unwanted considerable chemotherapy dose reductions in heterozygous *NBN* mutation carriers suggest that molecular variants in this gene may have an impact on clinical course and outcome of childhood MB. To confirm our observations further investigations of larger group of patients are necessary.
This study was partially supported by CMHI, Warsaw, Poland (grant S112/09).

Medulloblastoma is the commonest malignant brain tumor in childhood accounting for approximately 20% of all primary brain tumors between 0 and 14 years of age. Familial medulloblastoma is rare and usually demonstrates an autosomal dominant pattern of inheritance with variable penetrance. *PTCH1* and *SUFU* are both regulators of the sonic hedgehog signalling pathway and germline inactivating mutations in both genes are associated with multisystem phenotypes including medulloblastoma. Recently, *SUFU* mutations were reported in two unrelated families with multiple cases of medulloblastoma (desmoplastic/MBEN subtype) without additional phenotypic features. We recruited three familial medulloblastoma pedigrees within the FACT study. Family 1 contains two second cousins with classical medulloblastoma, family 2 contains four affected individuals in three generations including one case of anaplastic medulloblastoma and family 3 contains two affected second cousins, one with desmoplastic medulloblastoma. We performed full-gene mutational analysis of both *PTCH1* and *SUFU* in affected individuals from each family. We identified no mutations in *PTCH1* or *SUFU* in the three familial medulloblastoma pedigrees. These data indicate that familial medulloblastoma is a genetically heterogeneous disorder with at least one further susceptibility gene to be discovered.

Network-guided analysis of genes with altered somatic copy number and gene expression reveals pathways commonly perturbed in metastatic melanoma

A. Valsesia[1], *D. Rimoldi*[1], *D. Martinet*[2], *M. Ibberson*[3], *I. Xenarios*[3], *S. E. Antonarakis*[4], *J. S. Beckmann*[2], *C. V. Jongeneel*[1], *C. Iseli*[1], *B. J. Stevenson*[1];
[1]*Ludwig Institute for Cancer Research, Lausanne, Switzerland,* [2]*Service of Medical Genetics, CHUV, Lausanne, Switzerland,* [3]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [4]*Department of Genetic Medicine and Development, Geneva, Switzerland.*
Cancer genomes frequently contain somatic copy number alterations (SCNA) that can significantly perturb the expression level of affected genes and thus disrupt pathways controlling normal growth. In melanoma, many studies have focussed on the copy number and gene expression levels of the BRAF, PTEN and MITF genes, but little has been done to identify new genes using these parameters at the genome-wide scale. Using karyotyping, SNP and CGH arrays, and RNA-seq, we have identified SCNA affecting gene expression ('SCNA-genes') in seven human metastatic melanoma cell lines. We showed that the combination of these techniques is useful to identify candidate genes potentially involved in tumorigenesis. Since few of these alterations were recurrent across our samples, we used a protein network-guided approach to determine whether any pathways were enriched in SCNA-genes in one or more samples. From this unbiased genome-wide analysis, we identified 28 significantly enriched pathway modules. Comparison with two large, independent melanoma SCNA datasets showed less than 10% overlap at the individual gene level, but network-guided analysis revealed 66% shared pathways, including all but three of the pathways identified in our data. Frequently altered pathways included WNT, cadherin signalling, angiogenesis and melanogenesis. Additionally, our results emphasize the potential of the EPHA3 and FRS2 gene products, involved in angiogenesis and migration, as possible therapeutic targets in melanoma. Our study demonstrates the utility of network-guided approaches, for both large and small datasets, to identify pathways recurrently perturbed in cancer.

A new MEN1 mutation: report of a Belgian family

U. Ullmann[1], *V. Brigitte*[2], *W. Wim*[3], *B. Maryse*[1];
[1]*Center for Medical Genetics, Brussels, Belgium,* [2]*Department of Internal Medicine, Brussels, Belgium,* [3]*Department of Medical Genetics, University Hospital of Antwerp, Antwerp, Belgium.*
Multiple endocrine neoplasia type 1 (MEN1) is an autosomal dominant cancer syndrome that is caused by a germ-line mutation in the MEN1 gene encoding a tumor-suppressor protein, menin, on 11q13. MEN1 causes a combination of endocrine tumors such as parathyroid adenomas, pituitary adenomas, glucagonomas, gastrinomas, insulinomas, adrenocortical adenomas and non-endocrine tumors. Primary hyperparathyroidism is the most frequent expression of MEN1 with a 100% penetrance at 50y. The prevalence of entero-pancreatic islet tumors and pituitary tumors in MEN1 patients vary from 30 to 75% and from 20-65% respectively.
We here present a large MEN1 family where the carriers (n=8) developed mild hyperparathyroidism (3/8), multiple well differentiated functionally active neuro-endocrine tumors of the pancreas (2/8) and adrenal adenoma (1/8). The age range of the first symptoms was from 29y to 54y. No affected family member developed a pituitary tumor. The causal mutation is a new double substitution in the coding region of exon 2 in the MEN1 gene at position 428 where a thymidine was exchanged for an adenosine and at position 429 where a cytosine was exchanged for a thymidine (CTC>CAT), and consequently a leucine for histidine c.(428T>A; 429C>T)(p.Leu143His).
This new mutation in the MEN1 gene is clinically relevant leading to a milder spectrum of MEN1 compared to literature data. Genetic testing allowed identification of asymptomatic carriers, their early follow-up and will improve clinical outcome. Longer follow-up of carriers will allow further characterisation of this phenotype and contribute to the genotype-phenotype discussion.

Lateral prostate lobes - zinc accumulating and citrate secreting prostate parts, are the major sites of initiation of prostate cancer malignancy. Compared to healthy prostate cells, cancer cells are characteristic by decreased ability to uptake and accumulate zinc ions, which have serious impact for the cells. Zinc is in prostate implicated in important processes - energy metabolism, proliferation, differentiation and apoptosis. Therefore, it is higly expectable that zinc plays an important role in prostate cancer pathogenesis. Intracellular zinc is buffered mostly by metallothioneins (MTs), low-molecular weight cysteine-rich proteins. MTs play a key role in metabolism, transport and storage of heavy metals and protect cells against oxidative stress. In our study we focused on zinc treatment effect on PC-3 prostate cancer cell line and PNT1A, healthy prostate cells. We've been concerned on monitoring of redox status influenced by zinc ions, especially on gene expression of metallothionein 1A and 2A and then on protein and peptide level of metallothionein and reduced/oxidized glutathione. We also focused on cell quality and proliferation after zinc ions treatment. Conventionally,

most of the standard methods for cell viability or proliferation determination like MTT, XTT are based on a time-consuming end-point analysis not capable register very small and fast changes in cellular morphology. This study for the first time describes application of new, label free and noninvasive method based on impedance determination for real-time analysis of cell proliferation, adhesion and spreading as well as utilization of electrochemical methods in redox state determination concering on tumour/non-tumour prostate cell lines.

Methylation signature of metastasis and non-metastasis lymph nodes in breast cancer patients

Z. Brekati, *R. Radpour;*
Laboratory for Prenatal Medicine and Gynecologic Oncology., Basel, Switzerland.

Present study investigated the contribution of aberrant methylation profile of cancer related genes, *APC, BIN, BMP6, BRCA1, CST6, ESR-b, GSTP1, P14, P16, P21, PTEN,* and *TIMP3,* in paired metastasis and non-metastasis axillary lymph nodes in comparison to the primary tumor tissue and the adjacent normal tissue from the same breast cancer patients.

The quantitative methylation analysis of the candidate genes showed higher methylation proportion for the primary tumor tissue versus matched normal tissue and the differences were significant for *APC, BIN, BMP6, BRCA1, CST6, ESR-b, P16, PTEN* and *TIMP3* promoter regions (P<0.05). Among the significant methylated genes, *APC, BMP6* and *BRCA1* represented high methylation proportion in paired metastasis and non-metastasis lymph nodes compared to the normal tissue (P<0.05) whereas the *P16* promoter was methylated only in the metastasis lymph node (P<0.05). We identified even greater hypermethylation proportion of *BMP6* in the metastasis lymph node than the primary tumor tissue (P<0.05). Conversely, the promoter region of *BIN1, GSTP1* and *P14* significantly showed less methylation proportion in both the lymph node metastasis and non- metastasis compared to the matched normal tissue (P<0.05).

Taken together present study showed methylation heterogeneity between primary tumors and metastatic lesion. Contribution of aberrant methylation alterations of *APC, BMP6, BRCA1* and *P16* genes in metastasis lymph node suggests more investigation for the pathways and networks related to these genes which might improve knowledge of mechanism underlying metastasis and might improve prognosis and therapeutic strategies for the breast cancer patients.

P06.144
Methylation as a prognosis factor in patients with malignant pleural effusion

L. De Chiara[1], M. Botana Rial[2], V. Leiro Fernández[2], C. Represas Represas[2], A. Fernández-Villar[2], ***D. Valverde Pérez***[1]*;*
[1]Universidad de Vigo, Vigo, Spain, [2]Complejo Hospitalario Universitario de Vigo. Servicio de Neumología, Vigo, Spain.

Introduction: DNA methylation in the promoter region of tumor-suppressor genes constitutes an important mechanism in cancer development. The aim of this study was to determine if methylation analysis of *p16/INK4a*, *BRCA1*, *RARβ* and *MGMT* is a prognostic factor in patients with malignant pleural effusion (MPE).

Methods: Forty-nine patients with MPE were included. Methylation status was achieved using methylation-specific-PCR. Patients were followed-up for at least 1 year. Kaplan-Meier and Cox regression analyses were done to study survival.

Results: According to diagnosis, patients were classified as 37 lung cancers (75.5%), 5 breast cancers (10.2%) and 7 other epithelial neoplasias (14.3%). *p16*, *BRCA1*, *RARβ* and *MGMT* were found methylated in 20.4%, 57.1%, 36.7% and 30.6% patients, respectively; methylation of at least one gene was observed in 87.8% of the patients.

According to Kaplan-Meier analyses *p16* (p=0.225), *BRCA1* (p=0.796), *RARβ* (p=0.824) and *MGMT* methylation (p=0.541) were not related to survival; the absence of at least one methylated gene (p=0.048) and metastasis (p=0.048) showed association with reduced survival.

Furthermore, Cox multivariate analysis also showed that absence of at least one methylated gene (p=0.063) and metastasis (p=0.049) were the covariates that better correlated with patients' prognosis. In the subgroup of lung cancer patients, absence of at least one methylated gene (p=0.046) was more related to survival than metastasis (p=0.089).

Conclusion: The presence of methylation in at least one gene is related with a better prognosis in patients with MPE; this correlation is increased in patients with lung cancer.

P06.145
Methylation analysis of MicroRNA-Associated CpG Islands and LINE-1 repeats in Hereditary and Sporadic Carcinomas by MS-MLPA method.

W. H. Pavicic, *S. Kaur, P. Peltomäki;*
Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland.

MicroRNAs are small noncoding RNAs that contribute to tumorigenesis by acting as oncogenes or tumor suppressor genes. Many miRNA genes have associated CpG islands, suggesting epigenetic regulation of their expression. Compared to sporadic cancers, the role of miRNAs in hereditary or familial cancer is poorly understood. A custom Methylation-Specific Multiplex Ligation-dependent Probe Amplification (MS-MLPA) assay, developed for 11 miRNA loci, was used to study 96 CRC, 58 GC, and 41 EC, occurring as part of inherited DNA MMR deficiency (Lynch syndrome), familial CRC without MMR gene mutations, or sporadically. Compared with the respective normal tissues, the predominant alteration in tumor tissues was increased methylation for the miRNAs 1-1, 124a-1,124a-2,124a-3, 148a, 152, and 18b; decreased methylation for 200a and 208a; and no major change for 373 and let-7a-3. Interestingly, by linear correlation analysis, we found that miRNAs methylation was significantly correlated with transcriptional repression, indicating the observed methylation changes are likely to be functionally important. Moreover, hypermethylation at miRNA loci correlated with hypermethylation at classical TSG promoters in the same tumors. Furthermore, evaluation of global levels of DNA methylation using LINE-1 as a surrogate marker, were assessed by developing a second MS-MLPA assay. Preliminary observations indicate that FCCX tumors, besides including high and low methylator subgroups based on TSG and miRNA loci (studied by MS-MLPA), also showed evidence of global hypomethylation based on LINE-1. Our results highlight the importance of epigenetic events in hereditary and sporadic cancers and suggest that MS-MLPA is an excellent choice for quantitative analysis of methylation.

P06.146
Microsatellite instability detection by high-resolution melting analysis

R. Janavicius, *D. Matiukaitė, L. Griškevičius;*
Hematology, oncology and transfusion medicine center, Vilnius, Lithuania.

BACKGROUND: Microsatellite instability (MSI) is an important marker for screening for hereditary nonpolyposis colorectal cancer (Lynch syndrome) as well as a prognostic and predictive marker for sporadic colorectal cancer (CRC). The mononucleotide microsatellite marker panel is a well-established and superior alternative to the traditional Bethesda MSI analysis panel, and does not require testing for corresponding normal DNA. The most common MSI detection techniques-fluorescent capillary electrophoresis and denaturing HPLC (DHPLC)-both have advantages and drawbacks. A new high-resolution melting (HRM) analysis method enables rapid identification of heteroduplexes in amplicons by their lower thermal stability, a technique that overcomes the main shortcomings of capillary electrophoresis and DHPLC.

METHODS: We investigated the straightforward application of HRM for the detection of MSI in 70 archival CRC samples. HRM analysis for 2 MSI markers (BAT25 and BAT26) was evaluated, and 2 different HRM-enabled instruments were compared-the LightCycler® 480 (Roche Diagnostics) and the LightScanner(TM) (Idaho Technology). We also determined the analytical sensitivity and specificity of the HRM assay on both instruments using 11 known MSI-positive and 54 microsatellite-stable CRC samples.

RESULTS: All MSI-positive samples were detected on both instruments (100% analytical sensitivity). The LightScanner performed better for analytical specificity, giving a combined specificity value of 99.1% compared with 92.3% on the LightCycler 480.

CONCLUSIONS: We expanded the application of the HRM analysis method as an effective MSI detection technique for clinical samples, which can be used to include additional markers.

P06.147
Somatic and constitutional *MLH1* methylation analysis for Lynch syndrome screening and diagnosis.

MLH1 somatic methylation in tumors has been considered as the main molecular feature of the sporadic microsatellite unstable cancers. Constitutional *MLH1* methylation, as causes of Lynch syndrome (LS), is a rare condition that might be underestimated because of an inadequate analysis strategy.

A total of 61 index subjects from Spanish families suspected of having LS and with immunohistochemical loss of expression of MLH1, were recruited from the Genetic Counseling in Cancer units from the Comunidad Valenciana. Somatic *MLH1* methylation and germline mutations were assessed by MS-MLPA and sequencing plus MLPA, respectively.

MLH1 somatic methylation was negative in 38 cases and *MLH1* germline mutations were present in 12 of them (31.6%). The remaining 26 cases were triple negative for *MLH1* expression, methylation and mutation. *MLH1* somatic methylation was detected in 23 cases (37.7%). Sixteen of these patients were analyzed for constitutional *MLH1* methylation and we found one case with *MLH1* methylation in peripheral blood, colorectal mucosa of normal appearance and oral mucosa epithelial. This subject was diagnosed of colorectal cancer at age of 30, with no familial history of cancer and initially considered as a sporadic cancer with microsatellite instability.

Our results show that 6.25% (1/16) of the tumors with loss of expression of MLH1 and somatic methylation, had actually, a constitutional silencing of *MLH1* gene by methylation. The LS genetic/epigenetic diagnosis strategy should incorporate the constitutional methylation analysis in all cases where *MLH1* tumor methylation is detected.

P06.148
Detection of splicing defects in the molecular diagnosis of the Lynch syndrome: evaluation of the effect of unclassified variants in MMR genes using minigene assays

***P. Gaildrat**[1], A. Killian[1], I. Tournier[1], M. Vezain[1], M. Buisine[2], S. Olschwang[3], S. Baert-Desurmont[4], J. Tinat[5], T. Frébourg[4], A. Martins[1], M. Tosi[1];*

[1]Inserm U614, Faculty of Medicine, Institute for Biomedical Research and Innovation, Rouen, France, [2]Molecular Genetics, University Hospital, Lille, France, [3]Inserm U891 Institut Paoli-Calmettes, Marseille, France, [4]Inserm U614, Faculty of Medicine, Institute for Biomedical Research and Innovation and Department of Genetics, University Hospital, Rouen, France, Rouen, France, [5]Inserm U614, Faculty of Medicine, Institute for Biomedical Research and Innovation and Department of Genetics, University Hospital, Rouen, France.

A fraction of the variants of unknown significance (VUS) found in genetic screenings may be deleterious by affecting RNA splicing. We have added to our molecular diagnostic procedure a functional minigene assay that assesses the impact on splicing of VUS identified in the MLH1 and MSH2 genes, involved in the Lynch syndrome. The assay relies on the use of patient genomic DNA, which is always available in the molecular diagnostic laboratory. We have so far tested a total of 167 VUS (105 in MLH1 and 62 in MSH2), corresponding to 50 intronic and 117 exonic variants, identified in the French national network of oncogenetic laboratories. We found that 49 VUS (29%) have an effect on splicing. Among them, 32 VUS (19%) lead to a major splicing defect by affecting intronic or exonic sequences close to a splice site or by creating a new splice site. In addition, 17 VUS are responsible for incomplete effects on splicing. Using an ESE (enhancer splicing regulatory element)-dependent splicing assay, we showed that 4 VUS potentially affect splicing regulatory elements. Moreover, using this assay, we identified ESE-containing sequences in eight different exonic regions of the MLH1 gene and four exonic regions of the MSH2 gene. Functional splicing minigene assays represent powerful tools to assess the impact of variants on splicing and can be used as a complementary approach to RT-PCR analyses of patient blood RNA, together with clinical and family data and tumor analyses.

P06.149
MSH6 mutation carriers and selection criteria

***M. Morak**[1,2], A. Laner[3], C. Engel[4], V. Steinke[5], H. K. Schackert[6], B. Royer-Pokora[7], K. Schulmann[8], M. Kloor[9], E. Holinski-Feder[1,2];*

[1]University Hospital of the Ludwig-Maximilians-University, Munich, Germany, [2]MGZ - Center of Medical Genetics, Munich, Germany, [3]MGZ - Center of Medical Genetics, Munich, Germany, Munich, Germany, [4]Institute of Medical Informatics, Statistics and Epidemiology, University Leipzig, Leipzig, Germany, [5]Institute of Human Genetics, University Bonn, Bonn, Germany, [6]Department of Surgical Research, University of Dresden, Dresden, Germany, [7]Institute of Human Genetics, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany, [8]Medical Department, Ruhr-University Bochum, Knappschaftskrankenhaus, Bochum, Germany, [9]Institute of Pathology, University of Heidelberg, Heidelberg, Germany.

The phenotype of MSH6-related Lynch Syndrome (LS) patients differs from MLH1/MSH2 patients and a Norwegian study showed that selection criteria are not sensitive enough for 3,3% of MSH6 mutation carriers. We investigated the clinical characteristics of 177 MSH6 mutation carriers from 95 families of the database of the German HNPCC-Consortium. 101 patients had a diagnosis of colorectal or LS-associated cancer between 19 and 75 years of age. 14 families fulfilled the Amsterdam-criteria, however, 15 met none of the revised Bethesda criteria, but two families would have met the original B7 criterion, which is no longer applied. Of the 16% of missed MSH6-related families, all tumours analysed indicated LS by immunohistochemical (IHC) loss of MSH6/MSH2 protein staining in all 13 tumours, and/or high microsatellite instability (MSI-H) in all 9 tumours analysed.

Considering tumours of all MSH6 mutation carriers, 64 were MSI-H, 4 MSI-L (all IHC loss of MSH6) and 5 MSS: one breast cancer, one initial MSS tumour showed MSI-H after dilution and re-testing, and in three cases another tumour in the family was MSI-H. Immunohistochemistry showed lack of MSH6 in 75 tumours -also including 4 of the 5 MSS tumours, whereas 3 tumours retained MSH6 staining but were MSI-H. We conclude, that clinical selection of potential MSH6 mutation carriers (sensitivity 84%) would be enhanced by re-inclusion of the “adenoma before age of 40 years” (original B7) and “family history with adenomas” (original B2) criterion. Furthermore, combined analysis of microsatellite instability and IHC is highly sensitive to identify MSH6 mutation carriers.

P06.150
Effects of Common Methylene Tetrahydrofolate Reductase (MTHFR) Polymorfhisms on the Risk of Bladder Cancer in Turkey.

***M. Izmirli**[1], N. Inandiklioglu[2], O. Demirhan[2], D. Abat[2], Y. Bayazit[2], Z. Tansug[2], D. Alptekin[2];*

[1]Bezmialem Vakif University, Istanbul, Turkey, [2]Cukurova University, Adana, Turkey.

Bladder cancer is the fourth most common cancer in men and was estimated to be the eighth leading cause of cancer-related deaths in men in 2009. The different potential pathways for bladder cancer tumorigenesis have been shown in various studies. Many biomarkers have been used for the diagnosis, surveillance, and management of bladder cancer. Here, we used methylene tetrahydrofolate reductase (MTHFR) biomarkers. MTHFR enzyme plays a keyrole in the folate metabolism which is present in many bio-chemical pathways such as homocysteine methylation and nucleotide bio-synthesis. The purpose

of this study is to examine relationship between MTHFR gene (677 C→T and 1298 A→C polymorphisms) and bladder cancer in Turkey. For this purpose, regions where polymorphisms are located were amplified with Polymerase Chain Reaction (PCR) method. Polymorphisms were determined by using Restriction Fragment Length Polymorphism (RFLP) method with the suitable restriction enzymes which were *HinfI* and *Fnu4HI*. We found statistically significant relationship between 677 C→T polymorphism (OR=2.36; CI 95%, 1.16-4.78; p=0.015<0.05) and bladder cancer. However, we found that there was no association between 1298 A→C polymorphism (OR=0.65; CI 95%, 0.36-1.17; p= 0.151>0.05) and bladder cancer. This is the first report that found statistically significant correlation between MTHFR gene (677 C→T) polymorphism and bladder cancer in Turkey.

P06.151
MUTYH gene mutations in Polish polyposis patients

M. Podralska[1], *E. Byzia*[1], *T. Banasiewicz*[2], *D. Lipinski*[1], *R. Słomski*[1], *A. Plawski*[1];

[1]*Institute of Human Genetics, Poznan, Poland,* [2]*Karol Marcinkowski University of Medical Sciences, Poznan, Poland.*

Colorectal adenomatous polyposis, autosomal recessive MIM #608456 also called MUTYH-associated polyposis (MAP), is an autosomal recessive disorder predisposing to occurrence of colorectal cancer. MAP was described in 2002 by Al-Tassan. The number of polyps observed in MAP patients not exceeds 1000. The colonic phenotype of disease is corresponded to attenuated form of FAP. Penetrance of CRC in MAP patients is approximately 100% by age 65 years. The colorectal cancer risk in MAP patients is 93 time higher then in general population. The MAP is caused by mutations of MUTYH gene in homozygotic or compound heterozygotic state. The MUTYH gene encoding protein with glicosylase activity, involved in repair of oxidative DNA damages. The MUTYH activity avoids the chances of pairs G:C to A:T accruing as results of oxidative DNA damages. In MUTYH gene the increased frequency Y165C and G382D was observed. Those two mutations in homozygotic or biallelic state are observed in most cases of MAP with diagnosed mutation. In our study we checked prevalence of Y165C and G382D in 338 polyposis probants with out APC gene mutation. In group with one of above mentioned mutations detected, the entire coding sequence of MUTYH gene was studied by mutations screening and direct PCR product sequencing method. In our studies we detect the MUTYH mutations in 19 probants. In one probant we observed homozygote of Y165C, five probants were compound heterozygote and remaining 13 were heterozygotes.

P06.152
Survival of MUTYH-associated polyposis Patients with colorectal cancer and matched control colorectal cancer patients.

M. Nielsen[1], *L. van Steenbergen*[2], *F. J. Hes*[1];

[1]*Centre of Human and Clinical Genetics, Leiden, Netherlands,* [2]*Eindhoven Cancer Registry, Comprehensive Cancer Centre South, Eindhoven, Netherlands.*

Background: *MUTYH*-associated polyposis is a recessively inherited disorder characterized by a lifetime risk of colorectal cancer that is up to 100%. Because specific histological and molecular genetic features of *MUTYH*-associated polyposis colorectal cancers might influence tumor behavior and patient survival, we compared survival between patients with *MUTYH*-associated polyposis colorectal cancer and matched control patients with colorectal cancer from the general population.

Methods: In this retrospective multicenter cohort study from Europe, 147 patients with *MUTYH*-associated polyposis colorectal cancer were compared with 272 population-based control patients with colorectal cancer who were matched for country, age at diagnosis, year of diagnosis, stage, and subsite of colorectal cancer. Kaplan-Meier survival and Cox regression analyses were used to compare survival between patients with *MUTYH*-associated polyposis colorectal cancer and control patients with colorectal cancer. All statistical test were two-sided.

Results: Five-year survival for patients with *MUTYH*-associated polyposis colorectal cancer was 78% (95% confidence interval [CI] = 70% to 84%) and for control patients was 63% (95% CI = 56% to 69%) (log rank test *P*<.001). After adjustment for differences in age, stage, sex, subsite, country, and year of diagnosis, survival remained better for *MUTYH*-associated polyposis colorectal cancer patients than for control patients (hazard ratio of death = 0.48, 95% CI = 0.32 to 0.72).

Conclusions: In a European study cohort, we found statistically significantly better survival for patients with *MUTYH*-associated polyposis colorectal cancer than for matched control patients with colorectal cancer.

NPM1 gene mutations in children with myelodysplastic syndromes

B. Jekic[1], *V. Dobricic*[2], *I. Novakovic*[1], *L. Lukovic*[1], *B. Popovic*[3], *J. Milasin*[3], *T. Damnjanovic*[1], *N. Maksimovic*[1], *V. Bunjevacki*[1];

[1]*Institute of Human Genetics, School of Medicine, University of Belgrade, Belgrade, Serbia,* [2]*Clinical Centre of Serbia, Institute of Neurology, Belgrade, Serbia,* [3]*Institute of Biology and Human Genetics, School of Dentistry, University of Belgrade, Belgrade, Serbia.*

Myelodysplastic syndromes (MDS) are a heterogeneous group of haematopoietic stem cell clonal disorders. MDS are rare in children and there are few studies analyzing molecular mechanisms underlying these diseases. The *NPM1* gene encodes for nucleophosmin (NPM), a protein which is, among its different functions, essential for the regulation of haematopoiesis. MDS are characterized by susceptibility to acute myeloid leukaemia (AML) and findings obtained from AML patients may serve as a clue for analyses in MDS. Mutations in exon 12 of the *NPM1* gene that cause the cytoplasmic dislocation of protein represent the most frequent genetic alterations in adult patients with karyotypically normal acute myeloid leukaemia. We used archival bone marrow samples from 17 children with MDS in order to analyze mutations of *NPM1* gene. PCR-SSCP and direct sequencing methods revealed mutation in one among 17 analyzed MDS patients. The detected mutation was the transition C to T in the codon 293 that changes serine to proline. To our knowledge, this is the first analysis of *NPM1* mutations in childhood MDS and the very first missense mutation of *NPM1* gene reported so far.

Transcription factors are frequent targets of chromosomal aberrations in myeloproliferative neoplasms

T. Klampfl[1], *A. Harutyunyan*[1], *T. Berg*[1], *B. Gisslinger*[2], *M. Schalling*[1], *K. Bagienski*[1], *D. Olcaydu*[1], *F. Passamonti*[3], *E. Rumi*[4], *D. Pietra*[4], *R. Jäger*[1], *L. Pieri*[5], *P. Guglielmelli*[5], *I. Iacobucci*[6], *G. Martinelli*[6], *M. Cazzola*[4], *A. M. Vannucchi*[5], *H. Gisslinger*[2], *R. Kralovics*[1,2];

[1]*Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria,* [2]*Department of Internal Medicine I, Division of Hematology and Blood Coagulation, Medical University of Vienna, Vienna, Austria,* [3]*Division of Hematology, Azienda Ospedaliera Universitaria Fondazione Macchi, Varese, Italy,* [4]*Department of Hematology, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy,* [5]*Section of Hematology, University of Florence, Florence, Italy,* [6]*Department of Hematology and Oncological Sciences "L. and A. Seragnoli", University of Bologna, Bologna, Italy.*

Myeloproliferative neoplasms (MPN) are clonal hematopoietic disorders with an increased production of terminally differentiated cells. The disease course of MPN is generally chronic, however a proportion of the patients show disease progression to secondary myelofibrosis, accelerated phase and/or secondary acute myeloid leukemia, associated with a poor prognosis. We investigated chromosomal aberrations in 408 MPN patients using high-resolution SNP microarrays to identify disease-associated somatic lesions. Of the 408 patients 37.5% had a wild type karyotype and 62.5% harbored between one and fifteen chromosomal aberrations. We identified 25 chromosomal regions that were recurrently affected (in at least three patients). In 6 of these 25 regions, the aberrations mapped single target genes including *FOXP1* (chromosome 3p), *TET2* (4q), *IKZF1* (7p), *CUX1* (7q), *ETV6* (12p) and *RUNX1* (21q). The aberrations of chromosome 4q, 7p, 7q, 12p and 21q, which overlapped with *TET2*, *IKZF1*, *CUX1*, *ETV6* and *RUNX1* respectively, were associated with disease progression, whereas aberrations of 3p (overlapping *FOXP1*) were equally distributed between disease progression stages and chronic-phase MPN. Five of these six genes (all, except *TET2*) are known transcription factors. Our data confirm the association of *TET2*, *RUNX1* and *IKZF1* with MPN, as reported before. For the first time we show that ETV6 is a target gene of chromosome 12p aberrations and

with *FOXP1* and *CUX1* we introduce two new genes involved in the disease. As the majority of the here identified genes were transcription factors, our data indicate an important, so far unrecognized, role of transcription factors in MPN pathogenesis.

P06.155
An association of three tagged SNPs of JAK2 46/1 haplotype with myeloproliferative neoplasms and non-splanchnic venous thrombosis

K. Zerjavic[1], *B. Zagradisnik*[1], *L. Lokar*[2], *M. Glaser Krasevac*[3], *N. Kokalj Vokac*[1,4];

[1]*Laboratory of medical genetics, University Medical Center Maribor, Maribor, Slovenia,* [2]*Department of Transfusiology, University Medical Center Maribor, Maribor, Slovenia,* [3]*Department of Hematology and Hematological Oncology, University Medical Center Maribor, Maribor, Slovenia,* [4]*Medical Faculty Maribor, University of Maribor, Maribor, Slovenia.*

Myeloproliferative neoplasms (MPNs) are hematological malignancies frequently associated with somatically acquired JAK2V617F mutation, also found in a portion of patients with splanchnic venous thrombosis (SVT). Additional, a putative association of particular JAK2 46/1 haplotype with the development of JAK2V617F-positive MPNs and SVT has been described.

288 patients with MPNs, 443 patients with non-SVT, and 458 controls were genotyped for the JAK2V617F mutation and three tagged SNPs of JAK2 46/1 haplotype.

We found that the CC+CG genotype and the C allele of rs12342421 were significantly more frequent in JAK2V617F-positive MPNs in comparison with the controls (p=5.87x10-6 and p=8.05x10-7, respectively), as well as in JAK2V617F-positive MPNs in comparison with MPNs (p=0.026 and p=0.007, respectively) and JAK2V617F-negative MPNs (p=3.83x10-4 and p=7.47x10-6, respectively). The higher prevalence of the GG+CG genotype and the G allele of rs10974944 in JAK2V617F-positive MPNs (p=9.76x10-5 and p=5.95x10-5, respectively), as well as in MPNs (p=5.87x10-4 and p<0.001, respectively) was found. In non-SVT, no significant differences in alleles or genotypes distribution of rs10974944 were observed. Furthermore, the CC+CT and the C allele of rs12343867 were significantly enriched in non-SVT in comparison with the controls (p=0.020 and p=0.013, respectively), MPNs (p=0.021 and p=1.84x10-4, respectively), and JAK2V617F-negative MPNs (p<0.001 and p=6.74x10-6, respectively).

In the present study, further evidence of the significant association of rs12342421 and rs10974944 with MPNs is provided. More importantly, the higher prevalence of rs12343867 in non-SVT indicates the related genetic background of SVT and non-SVT and reflects a feasible role of the JAK2 signaling pathway in pathogenesis of non-SVT.

Neuroblastic tumor: Genetic profile Comparison Fresh versus cultured tumor cells

S. TRABELSI[1], *D. H'MIDA*[1], *M. BEN BRAHIM*[2], *S. SASSI*[1], *T. YACOUBI*[3], *A. ZAKHAMA*[4], *A. SAAD*[1];

[1]*Unit of Cytogenetic, Biology of Reproduction and Molecular Genetic, Sousse, Tunisia,* [2]*Department of Pediatric Surgery, Monastir, Tunisia,* [3]*Unit of Cytopathology, Sousse, Tunisia,* [4]*Unit of Cytopathology, Monastir, Tunisia.*

Neuroblastic tumors (NB) are the most common extra-cranial solid neoplasm in childhood. The three histological stages of NB differ by cellular maturity and aggressiveness. In addition, NB are characterized with genetic profile high heterogeneity.

The wide variability of maturity stage and chromosomal rearrangement in tumor cell interferes closely with Tumor evolution. Certainly during cell proliferation genetic profile of tumor cells changes. It is influenced by genetic abnormality background or tumors surrounding environment. This change is reflected in tumor behavior witch fluctuates from regression to more aggressiveness.

The aim of this study is to compare genetic modifications between primitive and cultured neuroblastic tumor. Using MLPA, we followed the evolution of chromosomal rearrangement before and after in vitro proliferation of neuroblastic metastatic lymphadenopathy cells.

Our results show that in vitro proliferation leads to the loss of initial genetic abnormalities noticed in fresh metastatic tumor cells. Whereas the primitive tumor seems to be of a very bad prognosis because of its localization, size, and patients' age.

This comparative study demonstrates that analysis of genetic markers of cultured metastatic lymphadenopathy cells does not reflect the status of these same markers in fresh metastatic tissue. Such results indicate that analysis of genetic markers even performed on fresh metastatic lymphadenopathy cells does not reflect the genetic status of primitive NB. Therefore, tumor prognosis and therapeutic strategy that flows from could not rely on metastatic cells analysis.

In fact, either a differentiation or a dedifferentiation of primitive tumor cells once migrated in metastatic lymphadenopathy could occur.

The development of the cutaneous neurofibromas

E. Jouhilahti[1], *S. Peltonen*[2], *T. Callens*[3], *E. Jokinen*[1], *A. M. Heape*[4], *L. Messiaen*[3], *J. Peltonen*[1];

[1]*Department of Cell Biology and Anatomy, Institute of Biomedicine, University of Turku, Turku, Finland,* [2]*Department of Dermatology, University of Turku and Turku University Hospital, Turku, Finland,* [3]*Department of Genetics, Medical Genomics Laboratory, University of Alabama at Birmingham, Birmingham, AL, United States,* [4]*Department of Anatomy and Cell Biology, Institute of Biomedicine, University of Oulu, Oulu, Finland.*

Cutaneous neurofibromas are the hallmarks of neurofibromatosis type 1 (NF1), which is the most common cancer predisposition syndrome caused by a mutation in *NF1* gene. Cutaneous neurofibromas occur in virtually all adults with NF1 appearing at puberty and increasing in number and size with age and pregnancy. They are composed of multiple cell types, and are traditionally believed to arise from small nerve tributaries of the skin. Genetically, neurofibromas are lesions characterized by a bi-allelic inactivation of the *NF1* gene in a subpopulation of Schwann cells, but the tumorigenesis can only occur in an $NF1^{+/-}$ background. The $NF1^{-/-}$ genotype obviously provides these cells with a growth advantage, but it is not known what proportion of the Schwann cells within a cutaneous neurofibroma carries an $NF1^{-/-}$ genotype and how much of the tumor growth can be explained by the increase in the number of other cells with an $NF1^{+/-}$ genotype. In the present study, our aim was to further elucidate the pathogenesis of cutaneous neurofibromas. The histological analyses of apparently normal skin from NF1 patients revealed minute neurofibromas, presumably in the early stages of development, in the immediate vicinity of the hair follicular apparatus. Furthermore, we showed that human cutaneous neurofibromas contain multipotent *NF1+/-* precursor cells capable of differentiating *in vitro* into cell types found in neurofibromas, including Schwann cells, fibroblasts and epithelial cells. Together these results suggest that the multipotent cells present in the hair follicles may contribute to the development of cutaneous neurofibromas.

P06.158
Development of a probe-based qPCR assay to detect constitutional and tumour *NF1* deletions

E. Terribas[1], *C. Garcia-Linares*[1], *C. Lázaro*[2], *E. Serra*[1];

[1]*Institut de Medicina Predictiva i Personalitzada del Càncer (IMPPC), Badalona, Barcelona, Spain,* [2]*Programa de Diagnòstic Molecular de Càncer Hereditari, Laboratori de Recerca Translacional, Institut Català d'Oncologia (ICO)-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain.*

Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic disorder caused by mutations in the *NF1* gene. Approximately 5-10% of NF1 patients bear constitutional microdeletions encompassing *NF1* and its neighboring genes. In addition, our group has recently shown that approximately 10% of dermal neurofibromas (dNFs) from NF1 patients carry somatic second hit *NF1* deletions ranging in size from ~80kb to ~8 Mb. To date, a wide range of techniques has been developed to identify copy number losses, such as Southern blot, microsatellite analysis, FISH, array-CGH and MLPA. Although quantitative PCR (qPCR) has not been frequently used for detecting DNA copy number changes, it represents an alternative methodology due to its high sensitivity and precision, relatively low screening cost and fast assay development time. We have thoroughly designed a qPCR-based copy number assay using several hydrolysis probes from the Universal Probe Library (UPL) set, specifically distributed along a ~3Mb region including the *NF1* gene. A set of DNA samples with constitutional or somatic *NF1* deletions (previously analyzed) and control samples with a diploid status of *NF1* have been used to determine the specificity and sensitivity of the assay. Our results indicate that qPCR assay

has a high sensitivity, even in contexts of mosaicism or somatic *NF1* deletion. The utilization of this technique may represent a useful quick first screening step or a validation technique for the detection of *NF1* constitutional microdeletions and also a routine method to identify *NF1* somatic mutations in dNFs.

Metagenes associated with survival in NSCLC

E. Urgard[1], *T. Vooder*[1], *U. Võsa*[1], *K. Välk*[1], *M. Liu*[2], *C. Luo*[1], *F. Hoti*[3], *R. Roosipuu*[4], *T. Annilo*[1], *J. Laine*[5], *C. M. Frenz*[6], *L. Zhang*[2], *A. Metspalu*[1,7];
[1]*Department of Biotechnology, Tartu, Estonia,* [2]*Department of Computer Science, Virginia Tech, Blacksburg, VA, United States,* [3]*Department of Information and Computer Science, Aalto UNiversity School of Science and Technology, Espoo, Finland,* [4]*Department of Pathology, Tartu University Hospital, Tartu, Estonia,* [5]*Department of Pathology, University of Turku, Turku, Finland,* [6]*Department of Computer Engineering Technology, New York City College of Tech., New York, NY, United States,* [7]*Estonian Genome Center, Tartu, Estonia.*

NSCLC comprises about 80% of all lung cancer cases worldwide. Surgery is most effective treatment for patients with early-stage disease. However, 30 - 55% of these patients develop recurrence within 5 years. Therefore, markers that can be used to accurately classify early-stage NSCLC patients into different prognostic groups may be helpful in selecting patients who should receive specific therapies.

Previously published dataset [1] was used to evaluate gene expression profiles of NSCLC different subtypes. Moderated two-sample t-test from R package LIMMA was used to find differentially expressed genes between all tumor samples and adjacent controls, SCC samples and AC/BC samples. The gene expression microarray results were validated using qRT-PCR . Bayesian regression analysis and Kaplan-Meier survival analysis were performed to determine metagenes associated with survival.

We identified 599 genes which were down-regulated and 402 genes which were up-regulated in NSCLC compared to the normal lung tissue and 112 genes which were up-regulated and 101 genes which were down-regulated in AC/BC compared to the SCC. Further, for stage Ib patients the metagenes potentially associated with survival were identified.

Genes that expressed differently between normal lung tissue and cancer showed enrichment in gene ontology terms which were associated with mitosis and proliferation. Bayesian regression and Kaplan-Meier analysis showed that gene-expression patterns and metagene profiles can be applied to predict the probability of different survival outcomes in NSCLC patients.

MicroRNA expression profiling in Estonian patients with non-small cell lung cancer

U. Võsa[1], *T. Vooder*[2], *R. Kolde*[3], *K. Välk*[1], *R. Roosipuu*[4], *J. Vilo*[3], *A. Metspalu*[1,5], *T. Annilo*[1];
[1]*Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Clinic of Cardiovascular and Thoracic Surgery of Tartu University Hospital, Tartu, Estonia,* [3]*Department of Computer Science, University of Tartu, Tartu, Estonia,* [4]*Department of Pathology, Hospital of Tartu University, Tartu, Estonia,* [5]*Estonian Genome Center, Tartu, Estonia.*

Lung cancer is one of the most common types of cancer, showing poor survival and high relapse rate. MicroRNAs (miRNAs), small noncoding RNA molecules, are important gene regulators on transcriptional level and involved in variety of cancers, including non-small cell lung cancer. In the current study, we analyzed the expression levels of 858 miRNAs in 38 Estonian non-small cell lung cancer samples (stages I and II) and 27 adjacent non-tumorous tissue samples using Illumina miRNA array. We identified 47 up-regulated and 30 down-regulated miRNAs in cancer samples compared with the normal lung tissue ($P<0.01$). Aberrantly were expressed several well-known tumorigenesis-related miRNAs (up-regulated miR-9, miR-182 and miR-205, down-regulated miR-101, miR-130a and miR-206), as well as some miRNAs with currently unknown function (up-regulated mir-708 and miR-941, down-regulated miR-1273). We also identified one miRNA, which expression showed association with patient survival (miR-374a). The combinatorial effect of most aberrantly expressed miRNAs is predicted to affect pathways involved in cell migration, differentiation and growth, e.g. focal adhesion, cytoskeleton regulation and several signaling pathways.

Molecular-genetic analysis of EGFR gene in NSLC patients: Searching for the Gold Standard approach?

M. Konecny[1], *K. Zavodna*[1], *I. Gloznekova*[1], *J. Jozefakova*[1], *M. Culagova*[2], *K. Arpasova*[3], *L. Sanislo*[1], *J. Kausitz*[1], *Z. Bartosova*[1];
[1]*St. Elizabeth Cancer Institute, Bratislava, Slovakia,* [2]*Teaching Hospital, Trnava, Slovakia,* [3]*Policlinic Hospital, Nove Zamky, Slovakia.*

Non-small cell lung cancer (NSLC) is the leading cause of death related to cancer worldwide. The epidermal growth factor receptor (EGFR) is frequently overexpressed in the NSLC. Somatic mutations of the EGFR are associated with the response of advanced NSLC to EGFR-specific tyrosine kinase inhibitors. The most significant of the reported EGFR mutations were several types of deletions in exon 19 and missense mutation p.Leu858Arg in exon 21, which account for about 90% of all mutations.

In the presented study, we have analyzed EGFR mutations in NSLC tumours from 141 patients. Samples were tested by direct sequencing of exons 19 (deletions) and 20 (insertions) and by SNaPshot analysis of exons 18 (p.Gly719Ala/Ser/Cys), 20 (p.Ser768Ile, p.Thr790Met) and 21 (p.Leu858Arg, p.Leu861Gln). Altogether 9 mutated samples were identified, 6 of them carried mutation p.Leu858Arg in exon 21 and 3 harboured c.2235_2249del15 in exon 19. Mutation detection rate has been estimated at 6.4%.

To achieve an optimal quality of material and higher percentage of tumor cells, we used and compared different approaches. We have isolated tumor DNA from bronchial swabs, FFPE biopsies and also peripheral blood. However, after comparation, acquisition of adequate material for DNA analysis still remains a problem. More detailed results of EGFR mutation and variant analyses and DNA isolation approaches will be presented.

Effects of genetic variants of CCR5 chemokin receptors on oral squamose cell carcinoma

Z. B. Çinçin[1], *B. Ağaçhan Çakmakoğlu*[1], *M. Ünür*[2], *B. Gökçen Röhlig*[3];
[1]*Istanbul University Institute of Experimental Medicine Department of Molecular Medicine, Istanbul, Turkey,* [2]*Istanbul University Department of Oral Surgery and Medicine, Faculty of Dentistry, Istanbul, Turkey,* [3]*Istanbul University Faculty of Dentistry Department of Maxillofacial Prosthodontics, Istanbul, Turkey.*

Purpose: To evaluate the effect of genetic variants of CCR5 chemokin receptors in the pathogenesis of OSCC

Material & Methods: 127 patients, 104 healthy individuals requiring dental treatment followed-up in the Department of Oral Diseases were included in the study. The control group had no history of cancer. CCR5 59029 and CCR5-delta 32 genes polymorphism were assessed with PCR method in the peripheral blood samples of both groups. The standard SPSS 11.0 for windows was used in all statistical tests. To determinate of the genotype and allele frequency between the groups, chi-square and Fisher's test were used.

Results: CCR5 59029 genotype and allele prevalence were higher in study group. AA genotype and A allele were higher in control group, where GG genotype and G allele frequency were higher in study group. CCR5 59029 GG genotype was found higher in the later stages of cancer (P:0,025). The tumor diameter is greater than 4 cm increased 2.18 times in patients with GG genotype (P:0,059) and 2.34 times in patients with G allele (GG + AG genotypes) (P:0,083). Keratinization presence was 3.52 times more in patients with CCR5 59029 G allele (P:0,010). Patients with AA genotypes demonstrated 3.57 times more defence against keratinization (P:0,010). There was no statistically difference in the prevalence of CCR-5 delta 32 genotype between the groups. CCR5-delta 32 II genotype was higher in patients with history of cancer in the families (P:0,029). CCR5-delta 32 D allele was higher in the later stages of cancer (P:0,010).

P06.163
Genotyping GSTT1 and GSTM1 polymorphisms in patients with oral squamous cell carcinoma

B. Popovic[1], *M. Boskovic*[1], *D. Jelovac*[2], *J. Milasin*[1];
[1]*Institute of Human genetics, School of Dentistry, Belgrade, Serbia,* [2]*Clinic for Maxillofacial surgery, School of Dentistry, Belgrade, Serbia.*

The glutathione S-transferase (GST) genes, GSTM1 and GSTT1, play an important role in detoxification of a broad range of carcinogens contributing to development of oral squamous cell carcinomas (OSSCs). One common genetic polymorphisms of the GSTM1 and GSTT1 genes, resulting from a homozygous deletion (null genotype) leads to the lack of enzyme activity. The absence of GSTs enzymes involved in the metabolism of xenobiotics could lead to increased risk for OSSCs.

In a case-control study a possible association between GSTM1 and GSTT1 null polymorphisms and susceptibility to OSCCs was assessed by simultaneous analysis of both genes in a single reaction using real-time PCR. Genotype discrimination was determined by melting curve analysis, using DNA extracted from 84 tumor and 175 control samples. After comparison of the melting peaks of the GSTM1 (215bp), GSTT1 (480bp) and control B-globin (110bp) genes, the following results were obtained: 45% of tumor samples had the GSTM1 null genotype vs only 33% of controls samples (p=0.04; Fisher's exact test). The frequency of GSTT1 null genotypes did not show statistical difference between OSCCs and controls (p>0.05).

GSTM1 null genotype represents a risk factor for developing OSCC in Serbian population.

P06.164
Genomic profiling of ovarian cancer for chromosome 8 by array CGH analysis

I. Dimova[1], *B. Orsetti*[2], *R. Dimitrov*[3], *N. Doganov*[3], *C. Theillet*[2], *D. Toncheva*[1];
[1]*Medical University Sofia, Sofia, Bulgaria,* [2]*University of Montpellier, Montpellier, France,* [3]*University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.*

We analyzed genomic imbalances affecting chromosome 8 by array-CGH in 28 primary ovarian cancers and 9 ovarian cancer cell lines, using a home made BAC-array covering this chromosome at a mean density of 1 BAC clone/0.8 Mb. We identified regions of highly frequent gains or losses, since they affected more than 40% of ovarian cancers and determined sites showing alterations of elevated amplitude (amplifications or homozygous deletions). Doing this we also identified at least two adjacent changed clones. Finally, we characterized the smallest regions of overlap for gains. This allowed us to determine anomalies strongly associated to the disease such as: deletions at 8p23 and 8p21 or amplifications at 8q24.21 and 8q13.2 The resolution of array-CGH gives an almost direct link to the human genome sequence and, hence, to a list of candidate genes. Certain regions that we identified harbor genes that have known roles in ovarian carcinogenesis or are excellent candidates for such a role, in particular the oncogene c-myc at 8q24.12-q24.13, and the tumor suppressor gene DLC1 (8p22-p21).

Of particular note was gain of 8q13.2 occurring at a high frequency in OC, especially in serous and late stage tumors. This region has not been reported so far and it contains the zinc finger transcription factor PRD14 and the transcription coactivator for steroid receptors and nuclear receptors TIF2, which could be potential oncogenes.

P06.165
Contribution mutations of CHEK2 gene in ovarian cancer development in populations of the Volga-Ural region of Russia

D. Prokofyeva[1], *M. Bermisheva*[1], *S. Gantsev*[2], *V. Frolova*[2], *V. Kononova*[1], *O. Popov*[1], *T. Dörk-Bousset*[3], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Center of Russian Academy of Sciences, RAS, Ufa, Russian Federation,* [2]*Clinical Oncological Center of the Republic Bashkortostan, Ufa, Russian Federation,* [3]*Department of Gynaecology and Obstetrics, Hannover Medical School, Hannover, Germany.*

The growth of cancer pathologies are observed in Russia. 12,000 - 15,000 cases of ovarian cancer (OC) are diagnosed every year. Special attention focused on genes that are involved in DNA repair, including *CHEK2*. Germ-line mutations in the cell-cycle checkpoint kinase *CHEK2* have been associated with breast cancer. It is of interest whether *CHEK2* is also relevant to ovarian cancer pathogenesis.

In this study, we analyzed *CHEK2* mutations *CHEK2**1100delC, IVS2+1G>A, I157T, *CHEK2*(dele 9,10) in cases (n=220) and controls (n=363) from the Volga-Ural region of Russia. Protein-truncating mutation *CHEK2**1100delC was not identified neither in cases nor controls. Splicing mutation IVS2+1G>A was absent in cases but was detected with minor frequency in control samples (0,6%). Missense substitution I157T was observed in cases and controls (4,6% and 5,5%) (OR=0,82; 95% CI:0,35-1,9; p>0,05). *CHEK2*dele9,10(5kb) mutation was seen in 0,9% of woman with ovarian cancer of slavic origin without a family history OC. At one of women observed a bilateral lesion of ovarian. In addition, we investigated frequency *CHEK2**1100delC, IVS2+1G>A, I157T, *CHEK2*(dele 9,10) mutations of *CHEK2* in three populations of the Volga-Ural region of Russia (Russians (n=192), Bashkirs (n=192) and Tatars (n=153)). Missense substitution I157T was observed in 8,34% in Russians, in 1,1% in Bashkir population and in 2% in Tatars. Significant differences among populations were found between Russians and Bashkirs (p=0,01). CHEK2*1100delC mutation was observed in Tatar population (0,66%). Mutations IVS2+1G>A and *CHEK2*(dele 9,10) were absent in three populations of the Volga-Ural region of Russia.

P06.166
Germline mutations in the PALB2 gene are population specific and occur with low frequencies in familial breast cancer

E. Gross[1], *H. Hellebrand*[1], *C. Sutter*[2], *B. Wappenschmidt*[3], *H. Deißler*[4], *C. R. Bartram*[2], *R. Schmutzler*[3], *D. Niederacher*[5], *N. Arnold*[6], *A. Meindl*[1];
[1]*Clinic of Gynaecology and Obstetrics, Division of Tumor Genetics, Technische Universität München, Munich, Germany,* [2]*Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany,* [3]*Department of Obstetrics and Gynaecology, Division of Molecular Gynaeco-Oncology, University of Cologne, Köln, Germany,* [4]*Department of Obstetrics and Gynaecology, University of Ulm, Ulm, Germany,* [5]*Department of Obstetrics and Gynaecology, Heinrich Heine Universität, Düsseldorf, Düsseldorf, Germany,* [6]*UKSH Campus Kiel, Department of Obstetrics and Gynaecology, University of Kiel, Kiel, Germany.*

Screening of more than 7000 German breast and ovarian cancer families by PCR based techniques revealed that in high risk groups, mutation frequencies in the two known *BRCA* genes reach between 20-50%. In contrast, mutations in other predisposing genes like *CHEK2* and *ATM* were detected with very low prevalence. As still a significant proportion of our families are lacking mutations in these known genes, we decided to screen them for mutations in another recently detected predisposing gene for breast cancer, called *PALB2/FANCN.*

Using direct sequencing, dHPLC- and/or HRM-based technologies, we performed a comprehensive mutation analysis of the entire *PALB2* gene in 818 familial cases of breast cancer from Germany. All affected index patients had been screened for small nucleotide alterations in *BRCA1* and *BRCA2* and tested negative for pathogenic mutations. We found seven truncating *PALB2* mutations (six of them novel) and two novel, potentially pathogenic missense mutations. Only one mutation, previously reported in another population, was identified in the German population. Remarkably, also some cases of ovarian cancer were reported for these PALB2 families, and breast tumor samples were either hormone receptor positive or negative.

Therefore, our observations indicate firstly, low prevalence of deleterious *PALB2* mutations, supporting the existence of individually rare disease-causing mutations, and secondly, a specific mutation profile within the German population, requiring screening of each population separately. However, as PALB2-deficient tumors were shown to be sensitive to Poly(ADP-ribose) Polymerase (PARP) inhibitors, our study has implications for newly developed, favorable treatment options in familial breast cancer.

PALB2 ("Partner and Localizer of BRCA2") is a breast cancer susceptibility gene of moderate penetrance, accounting for about 1% of BRCA1/2 negative familial and early onset breast cancers. PALB2 encodes a protein that functions in genome maintenance. This protein interacts with BRCA2 and BRCA1, and it is required in the double-strand break repair. Different recent analyses suggested that the frequency of PALB2 mutations could be increased in breast cancer families with cases of pancreatic cancer.

We aimed to evaluate the contribution of PALB2 mutations in 138 BRCA1/2 negative families with pancreatic cancer cases, collected from 11 centers throughout Spain. For this, direct sequencing and MLPA analysis of PALB2 gene has been performed.

We identified two novel truncating mutations, the nonsense c.1653T>A (p.Tyr551Stop) located at exon 4 and the frameshift c.3362del (p.Gly1121ValfsX3) in exon 13 together with one missense variant in the second base of exon 3 (c.110G>A, p.Arg37His), likely affecting the splicing process. None of these families had ovarian cancer. Moreover, 11 common polymorphisms and 9 rare or unique variants of uncertain clinical significance, 7 not previously reported, have been detected.

Conclusion: In our series of breast ovarian cancer families with pancreatic cancer cases the frequency of PALB2 truncating mutations was 1.45% (2/138). Further analysis of the putative splicing variant of exon 3 as well as of the variants of uncertain clinical significance could increase this frequency.

P06.168

Detection of *BRAF* mutation status in papillary thyroid carcinoma using SNaPshot analysis

***K. Zavodna**, Z. Bartosova, J. Podoba, S. Galbavy, M. Vallova, M. Konecny, J. Kausitz;*

St. Elisabeth Cancer Institute, Bratislava, Slovakia.

Papillary thyroid cancer (PTC) is a common endocrine malignancy that frequently harbors the oncogenic V600E *BRAF* mutation. As a novel prognostic molecular marker, this mutation has received considerable attention in recent years for its potential utility in the risk stratification and management of PTC. Many studies have reported that the BRAF mutation is a marker of poor prognosis. The presence of the *BRAF* mutations in papillary thyroid cancer patients correlates with older age, extrathyroidal tumor invasion, distant metastases, higher tumor stage, and even higher rates of recurrent disease. Use of this unique molecular marker, in conjuction with conventional clinicopathological risk factors, to assist the prognostication of PTC is likely to improve the efficiency of contemporary management of thyroid cancer.

The aim of our study was to establish methods for rapid, sensitive and cost efficient detection of *BRAF* mutation status in tumour tissues. As we have a lot of experience with SNaPshot analysis for detection of somatic mutations, we have concentrated on this method. The sensitivity of SNaPshot analysis (2-2.5%) is comparable to commercial DxS BRAF mutation test kit (1%). We used the optimized SNaPshot analysis to detect somatic mutations in *BRAF* gene in the set of 124 patient samples, and detected mutations in 54 tumours (43,5%). SNaPshot analysis proved to be highly sensitive and cheap method, which also works with material of relatively low quality.

P06.169

Paraganglioma and pheochromocytoma upon maternal transmission of SDHD mutations.

*J. P. Bayley[1], R. A. Oldenburg[2], J. Nuk[3], C. A. van der Meer[2], E. Korpershoek[2], B. McGillivray[3], A. H. T. J. Vriends[1], E. P. M. Corssmit[1], W. N. M. Dinjens[2], R. R. de Krijger[2], J. C. Jansen[1], P. Devilee[1], **F. J. Hes**[1];*

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]BC Cancer Agency, Vancouver, BC, Canada.

It is now 21 years since van der Mey and colleagues first described clear cases of hereditary, parent-of-origin related tumorigenesis. They showed that development of the rare tumor, paraganglioma, occurs exclusively upon transmission via the paternal line. The causative gene, SDHD, encodes a subunit of mitochondrial succinate dehydrogenase. The genomic mechanism behind this phenomenon was studied by Hensen and colleagues, who presented a model involving an imprinted modifier gene located on Ch11p15.5.

Here we describe three cases of apparent maternal transmission of an SDHD mutation, leading to a paraganglioma or pheochromocytoma. We established the mode of inheritance of the mutations by analyzing all available family members. We then carried out both genetic and functional analyses of the available tumors to confirm bone fide SDHD-related tumorigenesis.

We found convincing genetic and functional evidence for the maternally-related occurrence of a case of pheochromocytoma, and suggestive evidence in a pre-operative case with vagal and carotid body paragangliomas. Haplotype analysis of tumor DNA from the first patient demonstrated somatic recombination, resulting in the loss of the paternal region of chromosome 11 including the remaining functional copy of SDHD, and the maternal chromosome including the centromere and the p arm. The third case appears to be sporadic, with no functional or genetic evidence to support a causal link between the mutation and the tumor. These data conform to the Hensen model and show that the transmission of SDHD mutations via the maternal line can, in rare cases, lead to tumorigenesis.

P06.170

Comparison of MRP1 mRNA Expression between Complete Remission and Relapse Cases among Iranian Pediatric Acute Leukemia Patients

***S. Nazari**[1], M. Sadeghi Koupaei[2];*

[1]Shahid Beheshti Medical University ,Mofid Pediatric Hospital,Hematology Oncology Section,, Tehran, Islamic Republic of Iran, [2]Shahid Beheshti Medical University ,Pharmacy School, Tehran, Islamic Republic of Iran.

Background and Aim: Leukemia is the most common cancer in childhood. Treatment for acute leukemia usually begins by chemotherapy and sometime continues with radiation therapy and bone marrow transplantation. Patients with acute leukemia disorder really suffer from frequent relapse after chemotherapy. Recent studies show that one of the effective causes of failure in chemotrapeutic treatment of malignant disorder such as acute leukemia is multiple drug resistance (MDR).In addition, one of the well - known gene responsible for MDR is MRP1 Gene. The aim of this study was to The aim of this study was to determines the expression level of MRP1 Gene in Pediatric Acute Leukemia patients who were in complete remission compared to relapse patients and to explore the potential for Prediction of relapse cases.

Material and Methods: In this study, using RT-PCR technique, the research team investigated MRP1 Gene expression in peripheral blood lymphocyte cells (PBMC) of forty Acute Leukemia complete remission patients and twenty relapse individuals.

Results: The results showed that the MRP1 Gene expression was significantly higher at relapse than Acute Leukemia patients who complete remission after chemotherapy.

Conclusion: In this research the association between expression level of MRP1 and response to chemotherapy was investigated present study and it was indicated that there is a MRP1 Gene over expression in Pediatric Acute Leukemia patient at relapse stage.

Approximately 20% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) patients relapse, mostly within 2.5 years after diagnosis. Detailed characterization of diagnosis and relapse samples has shown that both disease presentations are clonally related in most cases, but may also show distinct genomic features. In contrast, consecutive leukemic presentations of patients with a suspected predisposition to leukemia are expected to be fully discordant at the genomic level. Recently, we characterized diagnosis and presumed relapse samples of 22 patients with very late disease recurrence (>2.5 years), and identified eight patients with fully discordant leukemic presentations (Szczepanski et al., J.Clin.Oncol., in press). One patient showed a germline deletion comprising the recombination activating genes *RAG1* and *RAG2*, and regulatory sequences of *LMO2*, genes frequently affected somatically in T-ALL, suggesting genomic predisposition to leukemia.

In the current study, we sequenced the exomes of remission and both leukemic samples of two patients with late discordant T-ALL recurrences. In one of the patients, the two leukemic samples harbored 106 unique independent rare variants. Four genes were recurrently affected, suggesting an important role in leukemogenesis. In addition, 215 rare variants were shared between the two leukemic samples and remission sample, of which 5 nonsense, 1 canonical splice site, 4 potential frameshift and 54 non-synonymous missense variants at highly conserved positions. Filtering of these variants for known T-ALL associated genes resulted in several interesting novel candidate predisposing genes. We conclude that a considerable proportion of late T-ALL recurrences may in fact represent second leukemias, caused by predisposing germline abnormalities.

Objective Aim of the study was to analysis the expression level of multidrug resistance related proteins, Pgp, MRP1 and MRP2 in human colorectal carcinoma.

Methods expression level of three protein was detected by immunohistochemistry method using monoclonal antibody against each MRP1, MRP2 and MDR1 protein in 50 paraffin embedded tumor and adjacent normal tissue of CRC patients. Patients (30 male and 20 female) were in stage II and III of cancer and had no received prior chemotherapy and radiotherapy.

Results 32/50, 36/24 and 24/50 of patients expressed Pgp, MRP1 and MRP2 in their tumor region respectively, while 30/50, 38/50 and 7/50 of patients expressed three protein in their normal regions. Interestingly, MRP2 was over expressed in tumor tissues of patients. MRP1 and MDR1 were expressed in most tumor and normal tissue with high intensity and extension. Also most of males expressed MRP1 protein compared to females patients (P=0.052). In the contrary MRP2 expression was observed in patients with low extension and intensity.

Conclusion Unlike MDR1 and MRP1, over expression of MRP2 was frequently observed in cancerous region compare to normal. Therefore MRP2 is intrinsically not expressed in normal tissue of CRC patients. But malignancy of tumor was leaded to over expression of it. The mechanism in which MRP2 is over expressed in malignant colorectal tumor remains to be clarified. To the best of our knowledge this is first study to evaluate three protein, MDR1, MRP1 and MRP2 in Iranian CRC patients

P06.173

Association between UGT1A1 Polymorphism and Adverse Events in Gynecological Patients Treated with Low-dose Irinotecan

A. Hirasawa[1], *T. Akahane*[1], *T. Tsuruta*[1], *H. Nomura*[1], *N. Susumu*[1], *Y. Tanigawara*[2], *D. Aoki*[1];

[1]*Gyne/Obst, Sch. of Med, Keio Univ., Tokyo, Japan,* [2]*Dept. Clin. PK/PD, Sch. of Med, Keio Univ., Tokyo, Japan.*

Irinotecan is indicated for the treatment of ovarian and cervical cancers in the field of gynecologic oncology. The association between UGT1A1 polymorphism and adverse events associated with irinotecan therapy has conventionally been reported in relation to the dose of irinotecan, but no consensus has been reached on this issue. It is currently thought that an association between gene polymorphism and adverse events is seen even at such low doses of irinotecan.

The dose of irinotecan used as for gynecologic cancers is lower than that used for the treatment of other types of cancer. In addition, an association with gene polymorphisms other than *28 also draws attention in east Asia. Thus, we investigated the association between these UGT1A1 gene polymorphisms and onset of adverse events in gynecological patients treated with irinotecan.

The study involved 49 patients treated with irinotecan at our hospital for gynecological cancers. UGT1A1*28, *6, *27 and *60 were analyzed. The association between each gene polymorphism and adverse events was retrospectively examined. Adverse events associated with anti-cancer drug therapy were evaluated in accordance with the CTCAE v4.0.

The incidences of grade 3 or higher neutropenia and grade 3 or higher diarrhea were significantly increased in heterozygotes for UGT1A1*28 and *6 and homozygotes for UGT1A1*6. Furthermore, the incidence of grade 3 or higher diarrhea was significantly increased in patients having any of UGT1A1 polymorphism.

These findings revealed that an association between UGT1A1 polymorphism and onset of adverse events also exists in patients treated with irinotecan at low doses.

P06.174

Molecular genetic analysis of pheochromocytoma and paraganglioma

Z. Musil[1], *T. Zelinka*[2], *A. Vícha*[3], *A. Křepelová*[4], *A. Puchmajerová*[5], *M. Simandlová*[5], *H. Turková*[2], *Z. Fryšák*[6], *J. Václavík*[6], *J. Widimský*[2], *M. Kohoutová*[4];

[1]*Institute of Biology and Medical Genetics of the First Faculty of Medicine, Prague, Czech Republic,* [2]*3rd Medical Department - Clinical Department of Endocrinology and Metabolism of the 1stFaculty of Medicine, Charles University, Prague, Czech Republic,* [3]*Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University, Prague, Czech Republic,* [4]*Institute of Biology and Medical Genetics of the 1st Faculty of Medicine and General Teaching Hospital, Charles University, Prague, Czech Republic,* [5]*Department of Biology and Medical Genetics of the Second Faculty of Medicine, Prague, Czech Republic,* [6]*3rd Medical Department - Clinical Department of Nephrology, Rheumatology and Endocrinology of the Faculty of Medicine, Olomouc, Czech Republic.*

Pheochromocytoma is sympathetic tumour of chromaffin cells in the adrenal medulla that may produce and secrete catecholamines. This endocrine disorder occurs in approximately 75 % as a sporadic disease, or as a hereditary disorder either as a component of cancer syndromes: multiple endocrine neoplasia type 2 (germ-line mutations in the RET proto-oncogene located on 10q11.2), von Hippel-Lindau syndrome (germ-line mutations in the VHL tumour suppressor gene located on 3p26-p25) and, much lesser in neurofibromatosis type 1 (germ-line mutations in the NF1 gene) also known as von Recklinghausen disease or nonsyndromic familial disease. Germline mutations in genes SDHB (1p36.1-p35) and SDHD (11q23) that encode subunits of succinate dehydrogenase, which participate in aerobic electron transport and the Crebs tricarboxylic acid cycle, have been identified to cause susceptibility to familial pheochromocytoma.

Head and neck paraganglioma is tumour of chromaffin cells, which

arise from parasympathetic ganglia, most commonly at the bifurcation of the carotid artery (carotid body tumour). The causes of the hereditary paragangliomas are germline mutations in the SDHB, SDHC (1q23) and SDHD genes, which encode three of the four subunits of enzyme succinate dehydrogenase (SDH). Genomic imprinting might be a possible cause as mentioned in some recent studies.
Among 205 sporadic pheochromocytoma patients 7 germline mutations were found in the VHL gene. Further, 11 mutations in SDHB gene were detected. In addition, in 4 examined patients with paraganglioma we detected mutation of the start codon in SDHD gene.

P06.175
Mutagenic and Antimutagenic Activities of *Phoneix dactylifera pollen grain* Using Ames Test

G. Barzin[1], *M. Entezari*[2], *M. Hashemi*[2], *S. Hajiali*[2], *M. Ghafoori*[2];
[1]*Islamic Azad University,Islamshahr Branch, Tehran, Islamic Republic of Iran,* [2]*Islamic Azad University,Tehran Medical Branch, Tehran, Islamic Republic of Iran.*

Phoneix dactylifera pollen grain is a medicinal plant that has been used traditionally to enhance energy *Phoneix dactylifera pollen grain* was screened for the potential of mutagenic and antimutagenic activity using Ames Test. For Ames Test the particularity of the strain *of salmonella typhimurium* chosen TA100 resides in the fact that undergone a specific mutation in the Histidine operon,and for this same reason it requires histidine from a foreign supply to ensure its growth.The afore mentioned strain gives rise to reverted colonies when expose to carcinogen substance (Sodium Azide)**.** Ames Test involved the pre-incubation assay against *Salmonella typhimurium* TA 100 bacterial strain in the presence and absence of metabolic activator S9 system. Grain was evaluated using two-fold value of number of revertant's colony in negative control plate as cut-off point to determine the mutagenicity effects.
The reverted mutations and the hindrance percent of *pollen grain* was 46% in Antimutagenicity test and this value in anticancer test was 49% respectively.
This is the first study that have revealed antimutagenicity and anticancer effect of *Phoneix dactylifera pollen grain*.

P06.176
Association of Polymorphisms in the Interleukin-22 and Interleukin-22 receptor alpha-1 Genes with Colorectal Cancer

F. Rostami, *S. Mohebbi, E. Arbabi Aval, P. Azimzadeh, B. Damavand, A. Sharifian, F. Derakhshan, M. Zali;*
Research Center for Gastroenterology and Liver Disease, Tehran, Islamic Republic of Iran.

Background: IL-22 is recognized a key player in the chronic inflammatory disorders. IL-22 signals through a class II cytokine receptor composed of an IL-22-binding chain, IL-22Rα1and the IL-10Rβ subunit, which is shared with the IL-10R. Chronic inflammation is a risk factor for colorectal cancer and polymorphisms in the inflammatory genes could modulate the levels of inflammation. We have investigated 4 single nucleotide polymorphisms (SNPs) in genes of the IL-22 (rs1179251 & rs1179246) and IL-22Rα (rs4648936 & rs10794665) in Iranian population.
Methods: Genomic DNA is isolated from peripheral blood leukocytes by salting out method. Two hundred eight patients with colorectal cancer and 253 healthy control subjects were genotyped using polymerase chain reaction-restriction fragment length polymorphism. PCR-RFLP was confirmed using the sequencing.
Result: The rs1179246 G/T (3' UTR) polymorphism of the IL-22 gene was significantly associated with CRC (p=0.01). Nevertheless, the others studied polymorphisms in IL-22 and IL-22 R α did not show any significant associated with CRC risk.
Conclusion: Our data suggest that IL-22 polymorphism in 3'-UTR region (rs1179246) may contribute to CRC susceptibility.

P06.177
Polymorphisms in alcohol metabolizing enzymes in relation to develop oral and larynx cancer in patients from de Basque Country (Spain)

X. Marichalar-Mendia[1], *N. Rey-Barja*[1], *M. Rodriguez-Tojo*[1], *M. Hernando-Rodriguez*[1], *M. Martinez de Pancorbo*[2], *J. Aguirre-Urizar*[1], *A. Acha-Sagredo*[1];
[1]*Oral Medicine. Oral & Maxillofacial Pathology. Genetic Unit. Faculty of Medicine and Dentistry. University of the Basque Country UPV/EHU, Leioa, Bizkaia, Spain,* [2]*BIOMICS Research Group. CIEA-Lucio Lascaray Building. University of the Basque Country EHU., Vitoria, Alava, Spain.*

Background: Alcohol consumption is a risk factor in oral carcinogenesis. Alcohol metabolism primarily imply three groups of enzymes: alcohol dehydrogenase (ADH), cytochrome P-450 oxidase (CYP) and acetaldehyde dehydrogenase (ALDH). Several studies have suggested that certain polymorphisms of those enzymes could be carcinogenic susceptibility factors associated with alcohol consumption. Due to the high incidence of oral and larynx cancer in our region, the aim of this study was to analyze the ADH1B (rs1229984), ADH1C (rs698 and rs1693482), CYP2E1 (rs2031920 and rs3813867) and ALDH2 (rs440 and rs886205) polymorphisms in our region.
Methods: We analyzed 326 samples: 46 patients with an oral carcinoma, 38 patients with a larynx carcinoma, and 242 controls. DNA was extracted from oral cytological samples using a phenol-chloroform-isoamilalcohol method. The genotypes were determined by PCR using Taqman assays.
Results: When comparing the distribution of alleles, we only found differences between the controls and HNSCC cases for ADH1B (p=0.014) and ADH1C rs1693482 (p=0.034). Significant differences in relation to the risk of developing cancer were found only in 2 polymorphisms: ADH1B rs1229984 (His: OR 0.152, 95% CI 0.04-0.584) and CYP2E1 rs3813867 (T: OR: 0.157, 95% CI 0,024-1,029)
Conclusion: The results suggest that ADH1B rs1229984 and CYP2E1 rs3813867 polymorphisms could be associated with a higher risk of oral and larynx cancer in our region.
Grant support: BIO07/CA/025 EITB-Maratoia2006, 2008111018 Health Department, and IT-192-07 Research Groups (Government of the Basque Country). X. Marichalar and A. Acha-Sagredo are supported by fellowships from The University of the Basque Country (UPV/EHU).

Studying colorectal polyposis to identify genes that predispose for colorectal cancer

D. Ruano[1], *R. van Eijk*[1], *M. Nieuwenhuis*[1,2], *H. Vasen*[1,2], *C. Tops*[1], *J. Oosting*[1], *H. Morrreau*[1], *F. Hes*[1], *T. van Wezel*[1];
[1]*LUMC, Leiden, Netherlands,* [2]*Netherlands Foundation for the Detection of Hereditary Tumours, Leiden, Netherlands.*

Colorectal polyps or adenomas are the precursor lesion for colorectal cancer (CRC). The GAMBA (Genomic Analysis of Multiple Bowel Adenoma) study aims to identify CRC-predisposing genes in patients with multiple polyps (polyposis) where the involvement of high-risk mutations in the APC and MUTYH CRC-predisposing genes were excluded. Polyposis patients, particularly those diagnosed at a young age, are very likely to have a, yet unidentified, genetic predisposition to CRC.
In this study we aim to identify CRC-predisposing genes by a combined approach of homozygosity mapping and next-generation sequencing. Homozygosity mapping can identify genomic regions that harbor potential recessively inherited CRC-predisposing genes. Exome sequencing is performed on at least 50 polyposis cases with early onset, high polyp count and regions of homozygosity. The findings are validated using the second largest European cohort of familial polyposis patients (over 500 adenoma cases).

P06.179
Influence of MLH1 -93G>A promoter polymorphism in hereditary vs. sporadic colon cancer.

M. Durán[1], *N. Martínez*[2], *L. Pérez-Cabornero*[1], *M. Infante*[1], *E. Velasco*[1], *A. Acedo*[1], *E. Lastra*[3], *N. Martínez*[1], *L. Hernández*[1], *C. Miner*[1];
[1]*IBGM, Valladolid, Spain,* [2]*Hospital Clínico Universitario, Valladolid, Spain,* [3]*Hospital General Yagüe, Burgos, Spain.*

The -93 SNP of MLH1 gene is associated with colorectal cancer. It has been reported to be associated with an increased risk of microsatellite unstable.
We genotyped 48 case patients and 93 control subjects from Genetic Counselling Surgery and the Hemotherapy Center of Castilla and León (Spain). DNA from peripheral blood cells was extracted and DNA extraction of tumour tissue and normal tissue from paraffin-embedded material was done by microdissection.
Tumor microsatellite instability (MSI), immunohistochemical staining

(IHC) and -93 G>A genotype were determined.
We genotyped the polymorphism -93G>A by heteroduplex analysis in capillary array (HA_CAE), three different patrons were founded: -93GG, -93G>A and -93G>A plus -269 C>G. We not founded the genotype AA in cases and controls.
The relationship between the -93 G>A polymorphism, age, sex, MSI and IHQ in familial CRC group was not statistically significant; although the odds ratio for the GA genotype in individuals with unstable tumors and a positive IHC was higher than we expect, thus GG genotype and negative IHC.
In conclusión: we found similar frequency of -93G>A in our population than in literature, the exception is that genotype AA is not present. In addition, and in contrast to the previous study we found no relationship with CRC MLH1 mutation carriers.
It not shows a correlation between GA genotype and IHC negative CRC in patients with family history.
This results shown that the -93G>A polymorphism exert a negative effect in the MLH1 gene expression and thus we found negative IHC and MSI.

P06.180
The expression profiles of genes important for prostate cancer development.

I. O. Kovnatsky[1], *V. A. Chernyaev*[2], *V. B. Matveev*[2], *A. V. Karpukhin*[1];
[1]*Research Centre For Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Comparative investigation of gene expression profiles in samples of prostate cancer and distant from tumour regions was conducted. The gene expression (AR, CYP17, EGFR, HER2, m-TOR, PDGFR, PI3K, PTEN, VEGF121, VEGF165) was determined comparative to expression of GAPDH gene by RT-PCR (Step One Plus, ABI). More frequently androgen receptor (AR) gene expression was increased relatively to expression in healthy tissue: in 90% of cases more than twice and in 40% - more than 5 times. The CYP17 was activated only in 15% of cases. At least one of the angiogenic cascade genes was activated in 50% of cases but never all three genes investigated (VEGF121, VEGF165, PDGFR) simultaneously. All but one of PTEN decreasing cases (40%) were accompanied by PI3K and mTOR expression increasing. The mTOR expression was increased in 73% of cases. All activated HER2 cases (27%) coincided with increased mTOR. Likewise, EGFR was co-activated with PI3K and mTOR. It is interesting that increased PTEN expression coincided with increased mTOR but not with PI3K (increased in 50% of cases). Possibly, the mTOR may be activated in these cases by another way than through PI3K/AKT.
In summary, we shown simultaneouse activation a number of genes important for prostate cancer development. For this reason targeted monotherapy may not be effective and combined therapy aimed at several genes are required. The approach developed may be a base of diagnostics for individualized therapy.

P06.181
Association analysis in Bulgarian prostate cancer patients adds support to a newly identified susceptibility locus on chromosome 8q24

D. L. Kachakova[1,2], *E. Popov*[3], *A. Mitkova*[1,2], *A. Vlahova*[4], *T. Dikov*[4], *S. Christova*[4], *C. Slavov*[3], *V. Mitev*[1,2], *R. Kaneva*[1,2];
[1]*Molecular Medicine Centre, MU- Sofia, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University –Sofia, Sofia, Bulgaria,* [3]*Department of Urology, Medical University –Sofia, Clinic of Urology, Alexandrovska University Hospital, Sofia, Bulgaria,* [4]*Department of Pathology, MU-Sofia, Central Pathology Laboratory, Alexandrovska University Hospital, Sofia, Bulgaria.*

Background: The molecular pathology of Prostate Cancer (PC) is complex with more than 30 identified susceptibility loci. Linkage, admixture mapping and GWAS have found at least three distinct regions within 8q24, associated with PC risk. Recent studies have differentiated new PC susceptibility loci on 8q24, one of them overlapping a breast cancer associated region (Al Olama AA et al, 2009; Yeagers M et al, 2009). In the current study we attempted to replicate these findings in a case-control study of Bulgarian PC patients.
Material and methods*:* Using TaqMan® method, 183 PC samples and 183 controls were genotyped. Allele, genotype and haplotype analyses were performed for the polymorphic variants rs1016343, rs4871008, rs7841060, rs620861 on locus 8q24.
Results*:* The variant rs620861 did not show association with increased PC risk. Nominally significant results were obtained for the genotypes C/T (OR=1.51, p=0.045) of rs1016343, C/T (OR=1.5, p=0.048) of rs4871008, T/G (OR=1.52, p=0.042) of rs7841060 and the risk alleles were T, C and G respectively, although not reaching significance. The association was stronger when PC cases with high Gleason score or metastasis were compared with controls. Haplotype analysis showed that the rs1016343, rs4871008 and rs7841060 are in a LD block. The haplotype T-C-G (rs1016343- rs4871008- rs7841060) was more common for patients with Gleason score above 7 (p=0.034).
Conclusions*:* The current study adds support to the new PC locus on 8q24. To evaluate the cumulative effect of risk loci on 8q24 and elucidate the mechanism of action related to aggressiveness of PC, additional studies are warranted.

P06.182
Angiotensin -I- converting enzyme (ACE) Polymorphism as genetic risk factor in benign prostatic hyperplasia and prostate cancer

M. Sam Zadeh[1], *M. Hasanzad*[2], *S. H. Jamaldini*[3], *S. S. Sedighi*[4], *N. Khodayari*[5], *L. Rejali*[2], *S. A. M. Ziaei*[1];
[1]*Urology Department, Shaheed Labbafinejad Hospital, Shaheed Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Islamic Azad University; Tehran Medical Branch, Tehran, Islamic Republic of Iran,* [3]*Genetics Research Center, University of Social Welfare and Rehabilitaion Sciences, Tehran, Islamic Republic of Iran,* [4]*St. Matthew's University; School of medicine, Orlando, FL, United States,* [5]*University of Florida,Medicine department, Gainesville, FL, United States.*

Introduction: Prostate tumors generally have a poor prognosis but the connections between tumor development and clinical outcomes are still not well understood. These connections may be determined by genetic variation. The renin-angiotensin system has been shown to play a role in prostate cancer pathology. A change in the human ACE gene occurs by an insertion (I) or a deletion (D) of a 287-bp Alu-repetitive sequence in intron 16, leading to a change in the plasma ACE level. We investigated the association of ACE gene polymorphisms and prostate cancer risk.
Materials and methods: DNA was extracted from 66 samples from individuals with a prostate cancer diagnosis and 80 samples from individuals with a benign prostatic hyperplasia diagnosis. The ACE I/D genotypes were determined by PCR- RFLP analysis.
Results& Conclusion: The comparative analysis of the two groups revealed no significant differences for any of the ACE genotypes. No association between variant genotypes and risk of developing prostate cancer was observed with the ACE variant genotype , but it looks that further samples is needed to produce more significant results.

P06.183
Gene expression of Periostin and SHB in prostate cancer

J. Mares[1], *M. Schmidt*[1], *M. Cerny*[2], *T. Lunak*[1], *M. Mares*[1], *J. Soukup*[1], *L. Jarolim*[1];
[1]*2nd Medical Faculty, Prague 5, Czech Republic,* [2]*JCU, Ceske Budejovice, Czech Republic.*

SHB (adapter protein) is involved in receptor tyrosine kinase signaling and apoptosis regulation. Periostin is a 93 kDa N-glycoprotein, involved in cell adhesion and extracellular matrix structure. Hepsin is a transmembrane serine protease. A detailed analysis of expression of all three genes together has not been conducted in prostate cancer so far.
We evaluated periostin, hepsin and SHB expression in prostate cancer samples by semiquantitative RT-PCR in two cohorts, including a control cohort (n=21, benign hyperplasia of prostate) and tumor cohort (n=55). We analyzed 2 samples classified as T1, 33 samples as T2, 17 as T3 and 3 samples with T4 TNM classification. Relative gene expression of the SHB was significantly higher in control samples (μ = 0.451±0.290) than in tumor samples (μ = 0.351±0.184; p<0.041). Relative gene expression of the periostin gene was higher at control samples (μ = 0.421±0.290) than at tumor samples (μ = 0.351±0.184). Relative gene expression of the hepsin gene was higher at tumor samples (μ = 0.075±0.061) than at control samples (μ = 0.016±0.013).

No correlation of the gene expression with the TNM classification, Gleason score, PSA level and age except the T(1+2) versus T(3+4) expression by hepsin was observed.
It is concluded that the SHB overexpression may be related to decreased tumor growth in prostate cancer and conversely hepsin up-regulation may be related to increased tumor aggressiveness. These data are significant for therapeutic intervention in both early and metastatic prostate cancer.
Research was supported by MSM 0021620808 and GAUK 200090.

P06.184
Aberrant promoter methylation of GSTP1, APC, CycD2 and RASSF1A as potential biomarkers of prostate cancer diagnosis and prognosis

N. Matevska[1], *A. Eftimov*[2], *D. Petrovski*[3], *V. Georgiev*[3], *A. J. Dimovski*[2];
[1]*Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, University "Ss Cyril and Methodius, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, University "Ss Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Clinic of Urology, Faculty of Medicine, University "Ss Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic of.*

Substantial evidence supports the view that epigenetic changes have a role in prostate cancer (PC) development and prognosis. Analyses of the patterns of promoter hypermethylation in different genes have identified specific alterations that may serve as useful diagnostic and prognostic biomarkers. In order to identify and characterize methylation markers in PC patients from Macedonia, we used QMSP to evaluate a panel of 4 genes among 55 samples of benign (BPH) and malignant (PC) prostate lesions. The frequencies of methylation of all 4 genes were significantly higher in PCs (GSTP1 57.14%, APC 82.86%, CycD2 54.29% and RASSF1A 80%) compared to BPH (GSTP 1 5%, APC 10%, CycD2 5% and RASSF1A 10%; P<0.001), which was not age related. The methylation index (MI), defined as ratio of methylated genes to the total number of analyzed genes for each case, was significantly different in malignant compared to nonmalignant tissue (P<0.0001). The combined analysis of selected genes allowed for distinction of PC from BPH with sensitivity of 88.6% and specificity of 90.0% (AUC=0.898). Furthermore, the methylation frequency of GSTP1 and the overall MI were higher in PCs with high Gleason scores (≥7) than in those with low GS (≤6) (p=0.012 and p=0.015) respectively, suggesting association with clinicopathological features of poor prognosis. No statistically significant correlations between MI and age or preoperative PSA levels were found. Our data suggest that promoter hypermethylation is a frequent event, occurs early, and accumulates during prostatic carcinogenesis. High MI might serve as a potential biological marker for aggressive PC.

P06.185
The Prevalence mutation of PTEN gene(7,8 exones) in colorectal carsinoma(CRC)in Iranian patient`s

M. Firoozi[1], *Z. Haj Ebrahimi*[2], *M. Ghaffar Poor*[3], *K. Bidoki*[1], *M. Hooshmand*[3];
[1]*Payam-e-noor University, Tehran, Islamic Republic of Iran,* [2]*Tarbiat Moddarres University, Tehran, Islamic Republic of Iran,* [3]*National Institue Genetics engineering & Biotechnology, Tehran, Islamic Republic of Iran.*

Colorectal cancer(CRC) is the third most common cancer, with a multiple process with tumours presenting various genetic and epigenetic alterations inactivating tumour suppressor genes and/or activating oncogene. PTEN/MMAC1/TEP1 is a tumour suppressor gene encoding a dual- specificity protein phospatase with homology to the cytoskeleton protein, chiken tenssin and bovin auxilin. PTEN acts by inhibiting the activation of Akt/Protein kinase B and is therefore involved in a major pathway controlling cell proliferation PTEN protein has been found to be important for its activity as a tumour suppressor. Alterations have been found to be common in sporadic colorectal tumours. Recently, mutation at an $(A)_6$ repeat of PTEN exons 7 and 8 in colorectal cancer(CRC) patients with microsatellite instability have been detected. Our subjective was to identify PTEN mutation in colorectal tumours and tissue samples from Iranian patients. The entire coding region and flanking sites of the 7,8 exones of PTEN gene was amplified and conformation sensitive gel electrophoresis(CSGE) and sequencing was done to identify alterations. We analysed genomic DNA from 30 tumour tissue samples. We found no PTEN alterations among the colorectal cancer samples we had examind and thereby conclude that there is a lack of PTEN involvement in the carcinogenesis of colorectal cancer in these patients. So we recommend to investigate that level of expression of PTEN gene, such as transcriptom and protein or hyper metilation of PTEN.

P06.186
Mutation screening of RAD51C in Breast and Ovarian Cancer families from Castilla-León (Spain).

M. Infante[1], *M. Durán*[1], *B. Díez-Gómez*[1], *Á. Curiel*[1], *A. Acedo*[1], *L. Pérez-Cabornero*[1], *E. Lastra*[2], *G. Marcos*[3], *C. Miner*[1], *E. A. Velasco*[1];
[1]*Genética del Cáncer, Instituto de Biología y Genética Molecular (UVa-CSIC), Valladolid, Spain,* [2]*Servicio de Oncología, Complejo Hospitalario de Burgos, Burgos, Spain,* [3]*Servicio de Oncología, Hospital Río Hortega, Valladolid, Spain.*

BRCA1 and BRCA2 are the two major genes involved in hereditary breast and ovarian cancer (HBOC). However, mutations in these genes explained only 20% of the familial cases, so the current interest is search for alterations in other susceptibility genes and to identify variants by genome-wide association studies that confer small increases in risk. Meindl and co-workers provided evidence that monoallelic RAD51C mutations were responsible for only 1.3% of BOC German families, but the penetrance could be similar to BRCA's. Screening in Canadian and Chicago population has been carried out without positive results. Therefore, we selected high-risk BOC families BRCA-negative to assess the incidence of RAD51C mutations in our region.
We received 89 families that fulfilled familial history of BOC, 32 of which were carriers of a pathological mutation in BRCA1/BRCA2 genes. Afterwards, we selected 27 families with three or more combined breast and ovarian cases to perform RAD51C genetic testing. The whole coding sequence and intron-exon boundaries were scanned by direct sequencing. Three previously reported variants (c.26C>T, c.904+34T>C and c.859A>G) and a novel variant in three different families (c.838-37G>T) were identified, although Splice-site prediction programmes indicated this novel variant as benign.
The proportion of BOC families available in our population is only 8.5%, a third of which are BRCA1/BRCA2 mutation carriers. Preliminary data suggested a very low prevalence of RAD51C mutations, so its screening would not be recommended in the HBOC-prevention strategy, although analysis of more families would be required to confirm this point.

P06.187
RAD51C mutations in familial breast and ovarian cancer

C. Loveday, *C. Turnbull, D. Hughes, E. Ruark, M. Warren-Perry, A. Renwick, S. Seal, N. Rahman;*
Institute of Cancer Research, Sutton, United Kingdom.

Germline mutations in a number of genes encoding components of the homologous recombinational repair (HRR) pathway confer increased susceptibility to female malignancies. Recently mutations were identified in *RAD51C*, a key player in HRR, in families with both breast and ovarian cancer. It is suggested that *RAD51C* is a high penetrance cancer susceptibility gene comparable to *BRCA1* and *BRCA2*, although formal evaluation of the risks associated with *RAD51C* mutations has yet to be undertaken. Follow-up studies by other groups have failed to identify *RAD51C* mutations in additional series.
We screened *RAD51C* by direct sequencing in 618 families with both breast and ovarian cancer and 622 controls. We identified four deleterious mutations in cases and none in 622 controls (P=0.06). The mutations were not equally distributed within the series; three mutations were detected in the 166 families with two or more cases of ovarian cancer (P=0.009). Testing for the family mutation in samples from 9 relatives revealed that one of two females affected with breast or ovarian cancer had the mutation, whereas six of seven unaffected female relatives did not carry the family mutation. We are currently undertaking segregation analysis to refine the risks of breast and ovarian cancer associated with mutations in *RAD51C* and this data will be presented. These data confirm the original report of *RAD51C* mutations in breast-ovarian cancer families but suggest that the contribution of *RAD51C* mutations to familial breast-ovarian cancer is very small.

P06.188
RB1 Gene Mutations in Iranian Patients with Retinoblastoma: Report of four novel mutations

M. Akbari[1,2], *A. Ahani*[1,3], *H. Khorram Khorshid*[3,4], *B. Behnam*[5];
[1]*Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [2]*Tehran Medical Genetics Laboratory, Tehran, Islamic Republic of Iran,* [3]*Avicenna Research Institute (ACECR), Tehran, Islamic Republic of Iran,* [4]*University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [5]*Tehran (Iran) University of Medical Sciences (TUMS), Tehran, Islamic Republic of Iran.*

Mutations in RB1 gene lead to Retinoblastoma which is the most common intraocular tumor in the children under the age of six. In present survey, the mutations of eighteen unrelated Iranian retinoblastoma patients were characterized for the first time.

Mutation analysis of RB1 gene was performed in patients by sequencing of all coding regions and MLPA analysis. Clinical signs and symptoms of the retinoblastoma patients appeared to be similar to previously described patients with retinoblastoma.

Eight known mutations and four novel mutations in the patients (c.832_833insT, c.1943delC, c.1206C>T and c.2029delG) were determined. Structural analysis of the c.1206C>T variant showed that exon 12 contains an SC-35 consensus sequence and this variation disrupt the splicing enhancer element and causes skipping of exon12. Molecular genetic testing of retinoblastoma patients has great impact on genetic counseling of the families involved, and management of the disease in the patients and at risk relatives.

P06.189
The microRNA profile of ccRCC-derived cell lines

K. Kok*, G. Duns, I. Van Duivenbode, N. Halsema, A. Van Den Berg, E. Van Den Berg - De Ruiter, R. M. W. Hofstra;*
UMCG, Groningen, Netherlands.

Clear cell renal cell carcinoma (ccRCC) is the most prevalent subtype of kidney cancer. ccRCC is thought to originate from the proximal epithelial tubular cells (PTEC) of the kidney. It is now well established that noncoding RNAs, most notably the class of microRNAs, can play a important role in cancer development and progression. We assessed the miRNA expression profile of a panel of 10 clear cell renal cell carcinoma derived cell lines and compared this with the miRNA expression profile of two PTECs. Eight microRNAs were significantly more abundant (p=0.05) in the ccRCC cell lines as compared to the PTEC cells. Fifteen microRNAs were significantly less abundant in the ccRCC cell lines. The latter set includes all members of the miR-200 family and miR-205 that are known to be involved in the epithelial- to mesenchymal transition process by directly repressing transcription factors ZEB1 and ZEB2. These transcription factors on their turn strongly repress the expression of epithelial marker E-cadherin, what indeed is observed in nine out of ten of our ccRCC-derived cell lines. As microRNAs bring about a posttranscriptional downregulation of their target genes, we compared the miRNA profiles with the gene expression profiles of this set of ccRCC derived cell lines. The set of significantly upregulated genes appeared to be 4-fold enriched for genes that were validated targets of the miRNAs significantly downregulated in our panel of ccRCC cell lines. The expression levels of several genes showed an anticorrelation with the respective miR levels.

P06.190
The gene expression profiles by RT-PCR in renal cancer tumor.

N. V. Apanovich[1], *M. V. Peters*[2], *V. B. Matveev*[2], *A. V. Karpukhin*[1];
[1]*Research Centre For Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

The expression of genes, mainly targets for renal cancer therapy (VEGFR1, VEGFR2, VEGF121, PDGFRα, PDGFRβ, PI3K, PTEN, AXL, mTOR, EGFR) was investigated by RT-PCR. The most commonly elevated expression in renal cancer relatively to expression in healthy renal tissue (distant from tumour regions) was observed in the genes of VEGFR1, VEGFR2 and VEGF. Increased expression of at least two of these genes was observed in most of cases, half of the cases have been activated all three of these gene. A frequent lowering PDGFRα expression was found. The level of expression is most pronounced (one to two orders of magnitude) differed in tumors relative to normal tissue in the genes of VEGFR1 and PDGFRα. Moreover, the lowest level of gene expression PDGFRα (500 times below normal) corresponded to the smallest change in gene expression VEGFR1 in tumor compared with healthy tissue. Conversely, the unchanged level of gene expression PDGFRα correspond to an increase of approximately 80 times the level of VEGFR1 gene expression in the tumor. In half of the cases expression of the EGFR was increased. The PTEN expression was observed as increased 4-fold in tumor and so reduced by 3 times compared to control tissue.

The findings provide information about the gene functional features in renal cancer and can be used in future for the development of optimal schemes of effective individualized treatment of patients with renal cell carcinoma.

Investigation of Chromosomal Abnormalities on Sporadic Renal Cell Cancer Cells

T. Cora[1], *H. Acar*[1], *M. Kılınc*[2], *A. Kalaycı*[1], *M. Balasar*[3];
[1]*Department of Medical Genetics, Selcuk University, Selcuklu Medical Faculty, Konya, Turkey,* [2]*Department of Urology, Selcuk University, Meram Medical Faculty, Konya, Turkey,* [3]*Department of Medical Genetics, Selcuk University, Meram Medical Faculty, Konya, Turkey.*

Renal cell carcinoma (RCC) represents 2- 4% of all human neoplasm. Clear cell renal cell carcinoma (CRCC) is the most common type of renal cell carcinoma, and papillary subtype (PRCC). CRCC are often characterized cytogenetically by structural chromosome aberration of different chromosome an especially short arm of chromosome 3, and PRCC are characterized by trisomy 7 or 17 and loss of the Y chromosome. FISH is a robust and highly accurate method for detecting losses, gains and translocations of genetic material . Numeric change of chromosomes 3, 7, 9, 17, and deletion of 9p12 region were analysed in 55 patients with renal cell carcinomas and normal tissue by using fluorescent in situ hybridization (FISH) technique. We report the incidence of chromosomes 3, 7, 9, 17 aneuploidies, and chromosome 9p12 region status and also correlate with clinical parameters.

P06.192
The analysis of somatic mutations of the VHL gene in clear cell renal carcinoma patients from Bashkortostan Republic of Russia

L. R. Mingazova[1], *I. R. Gilyazova*[1], *R. I. Khusainova*[1], *V. N. Pavlov*[2], *A. A. Zagidullin*[2], *A. A. Khaliullin*[2], *A. A. Izmaylov*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Science Centre, RAS, Ufa, Russian Federation,* [2]*State educational institution of higher education Bashkir State Medical University, Ufa, Russian Federation.*

Kidney cancer is a heterogeneous group of malignant tumors, the vast majority of which are renal cell carcinomas of various morphological types. One of clear cell renal carcinoma (CC-RCC) features is the inactivation of tumour suppressor gene *VHL* (von Hippel-Lindau).

The aim of investigation was to analyze somatic mutations in *VHL* gene in 72 CC-RCC patients from Bashkortostan Republic. SSCP analysis followed by direct DNA sequencing was used to investigate somatic *VHL* alterations.

Mutations of *VHL* have been identified in 10 of 72 samples (13.9%) with CC-RCC. All the identified mutations were somatic and found only in tumor tissues that allowed us to exclude a hereditary von Hippel-Lindau syndrome and consider all cases as sporadic forms.

Eight types of mutations were detected in 10 CC-RCC patients: 2 insertions and 8 point mutations in the heterozygous state. Insertions resulted in frameshifts. In the 2nd exon of the *VHL* gene we revealed: p.His115Tyr (in 1.4% of patients), p.Asp143Glu (1.4%) and p.Pro154Leu (2.8%), which change the structure of the binding of *HIF-1α* in β-domain. In the 3d exon of the *VHL* gene we revealed mutations: p.Val170Phe at 1.4% of patients, p.Arg176Trp (1.4%), p.179_Leu178dup (1.4%), p.Glu186_Asp187ins (2.8%), p.Glu186Lys (1.4%), which involve a violation of section interaction elongin C α-domain. We also revealed somatic mutations p.Trp117Arg (1.4%), p.Leu128Val (1.4%) and p.His110Pro (1.4%) that haven't been described previously. Mutations of *VHL* gene result in stabilization of hypoxia-inducible factors, and may contribute to cancer progressions, that allow to consider *VHL* gene as a prognostic marker of RCC.

P06.193

A study of polymorphic xenobiotic-metabolizing enzyme genes in sporadic renal cell carcinoma patients from Bashkortostan Republic (BR) of Russia

I. Gilyazova[1], *L. Mingazova*[1], *R. Khusainova*[1], *A. Izmailov*[2], *V. Khamzin*[2], *V. Pavlov*[2], *E. Khusnutdinova*[1];

[1]*Institute of Biochemistry and Genetics,Ufa Science Centre, RAS, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Renal cell carcinoma (RCC) accounts for 80-85% of malignant renal tumors in adults. The pathogenesis of RCC may be related to higher levels of exposure to certain risk factors. Epidemiological studies showed that environmental factors may be involved in sporadic RCC development.

This case-control study was designed to test for an association between genetic polymorphism of xenobiotic metabolism enzymes and risk of sporadic RCC. Genomic DNA was obtained from 130 patients with RCC (Russians, Tatars, Bashkirs) and 117 controls matched for age, gender, ethnic origin and area of residence. We used PCR-RFLP to investigate polymorphism for the most common alleles at GSTM1 and CYP1A1.The null genotype frequency distribution of GSTM1 gene (0/0 GSTM1) in RCC patients didn't differ statistically significanty from that of the control group (P>0.05). There were interethnic distinctions between control groups of Turkic and Slavic origins. The frequency of 0/0 GSTM1 genotype in Turkic group was 0,291, whereas in Slavic -0,444 (χ2=5,133, P=0,023). The analysis of Ile462Val polymorphism between patients and controls didn't reveal statistically significant differences (P>0.05). There was a higher risk of RCC for Turkic group of patients with *Ile/*Ile of CYP1A1 combined with null GSTM1 genotype (χ2=3,933, P=0,047, OR=2,276, 95%CI=1,002-5,169). The combination of non-null GSTM1 and *Ile/*Val CYP1A1 genotypes in Turkic group of patients also was a risk marker for RCC development (OR=10,705, 95%CI= 0,562-203,907). These findings suggest that variation in the metabolic pathways involved in the functionalization and detoxification of specific xenobiotics is an important susceptibility factor for RCC in Bashkortostan Republic.

P06.194

Karyotypic characterisation of childhood renal tumors

E. STEJSKALOVÁ[1], *M. Jarošová*[2], *J. Mališ*[1], *H. Urbánková*[2], *R. Kodet*[3];

[1]*Department of Pediatric Hematology and Oncology, University Hospital Motol, Prague, Czech Republic,* [2]*Department of Hemato-oncology, Palacky University Hospital, Olomouc, Czech Republic,* [3]*Department of Pathology and Molecular Medicine, University Hospital Motol, Prague, Czech Republic.*

The most common renal neoplasm in children is Wilms´ tumor (WT). Successful treatment of relapsing or nonresponding WT remains a challenge. Cytogenetic abnormalities of presumed prognostic significance include karyotype complexity and allelic losses from the short arm of chromosome 1 and from the long arms of chromosomes 11, 16 and 22 and 1q gain. Genetic alterations seem to be of importance for morphology and tumor growth in distinct subtypes of renal cell carcinomas (RCC), thus distinct abnormalities may assist histologic subtyping. Reports of chromosomal analysis of RCC in children are scarce.

We present a series of 27 WT, mostly without pre-operation chemotherapy, 2 congenital mesoblastic nephromas (CMN) and 3 rare childhood renal tumors - RCC. We have detected numerical as well as structural changes in WT, which mostly involved chromosome 1, either presenting with a deletion of 1p or the formation of an isochromosome 1q. One WT presented with an i(7)(q10) as the sole cytogenetic change, an aberration characteristic for adult WT. One RCC patient displayed the t(X;1) as the sole cytogenetic abnormality, another one showed numerical aberrations similar to those seen in adults. To gain further insight into genetic events responsible for the pathogenesis, arrayCGH was performed. This technique yielded results not seen by cytogenetics or in cytogenetically unsuccessful cases. Thus we have found non-random losses of 16q12.1-16q24.3 and 17p. In our report, we have correlated these findings with histological and clinical features, patient outcome and the results of previously published studies. **Supported by grant VZ MZ 6715.**

P06.195

The effect of Caffeic acid Phenethyl ester and Resveratrol on the down-regulation of the in vitro growth of human breast cancer cells

T. Balci, *C. Biray Avci, Z. O. Dogan Sigva, S. Yilmaz, M. Yucebas, C. Gunduz; Medical School, Izmir, Turkey.*

Several compounds are used in traditional and alternative medicine. Caffeic acid Phenethyl ester (CAPE) is a component of beehive propolis and because of its anti-inflammatory, antiviral and anticancer properties, it has been used for treatment of several diseases including the breast cancer. Resveratrol, a compound found primarily in red grapes, has been reported to inhibit cell growth and induce apoptosis in various solid and hematological cancer cell lines.

The purpose of our study is to determine the expression profiles of 48 cell cycle control genes following the treatment of induced MCF-7 cell lines with the IC50 doses of resveratrol, CAPE and resveratrol-CAPE combination.

The IC50 values of resveratrol and CAPE for MCF-7 cells were found as 150µM and 75µM respectively, by XTT assay. Total RNA was isolated from the cells exposed to IC50 doses of resveratrol, CAPE and resveratrol-CAPE combination, the expressions of 45 genes each from apoptotic pathway and cell cycle controls were studied by real time online RT-PCR. Results were compared with resveratrol or CAPE -free cells.

The expression profiles of CCND2, RB1, ATM, CDC34, CDK5RAP1 genes showed a significant increase, compared to the control cells. Up-regulation of these genes following the treatment with resveratrol and CAPE, provide evidence that these compounds may serve as potentially effective chemoprevention agents.

P06.196

A new germline mutation at codon 918 of the RET protooncogene in a patient with concurrent lymph node metastases of medullary and papillary thyroid carcinoma

F. A. Amosenko[1], *O. Shchagina*[1], *V. Khvostovoy*[2], *A. Polyakov*[1];

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Regional Oncological Hospital, Kursk, Russian Federation.*

We report a new germline RET mutation (c.2752 A>G; p.M918V) found in a 62-year-old man with synchronous medullary thyroid carcinoma and papillary thyroid carcinoma in cervical lymph node metastases. In 2006 patient underwent total thyroidectomy based on the cytological diagnosis of PTC. Postoperative histopathologic examination of the thyroid showed multifocal bilateral PTC (T3N0M0). In 2010 the patient presented with recurrent disease and underwent surgical treatment including resection of neck lymph nodes. Histological and immunohistochemical studies revealed the presence of concurrent MTC and PTC metastases in all resected nodes, with significant predominance of MTC. Postoperative CT was 20 pg/ml (N=2-6 pg/ml). Pheochromocytoma, hyperparathyroidism and MEN 2B associated abnormalities were excluded. Familial history, clinical and biochemical examination of first-degree relatives were negative for MEN 2A and familial medullary thyroid carcinoma. Genetic screening showed that one of them was a carrier of new ATG>GTG transition at position c.2752 of the RET protooncogene (serum CT - 5.9 pg/ml). A 96-year-old mother of the patient has not this mutation. The father was not available because he died of a stomach malignancy while 66. The mutation was not revealed in 50 unrelated normal individuals.

Conclusion: we detected a new germline mutation within the catalytic core of the RET thyrosinkinase domain converting methionine 918 into valine in proband and his healthy sun (37-year-old). Apparently this mutation is associated with late manifestation of MTC in the proband. But transfection studies with RET (M918V) mutant are needed to understand whether the discovered transition has oncogenic potential.

P06.197

Abnormal splicing pattern caused by a novel samesense mutation in an Iranian retinoblastoma patient

A. Ahani[1], *H. Khorram Khorshid*[2,3], *B. Behnam*[4], *M. Akbari*[1,5];

[1]*Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [2]*Avicenna Research Institute (ACECR), Tehran, Islamic Republic of Iran,* [3]*University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [4]*Tehran (Iran) University of Medical Sciences (TUMS), Tehran, Islamic Republic*

of Iran, [5]Tehran Medical Genetics Laboratory, Tehran, Islamic Republic of Iran.

Mutations in RB1 gene lead to Retinoblastoma which is the most common intraocular tumor in the children under age of six. Retinoblastoma is a malignant proliferation of immature retinal cells. To date a wide spectrum of the mutations have been reported in RB1 gene; in other hand, mutation analysis has great impact in the management of the disease in the affected families. Many of the reported mutations in the human genes, affect splicing; some mutations target the main splicing sequences and some altered splicing regulatory elements.

In the present survey, mutation analysis was done in an Iranian patient with sporadic unilateral retinoblastoma using direct sequencing and MLPA. As a result, a same sense nucleotide change (g.70320C>T) was found near the 5' end of exon 12. This alteration, disrupt the consensus sequence of an exonic splicing enhancer and changes the binding site of SC-35 protein. Structural analysis of cDNA in this patient showed disruption of normal splicing pattern and skipping of exon 12 from the RB1 transcript. Based on our findings it is reasonable to mentioned the above nucleotide change as a pathogenic mutation. Also for the first time we report evidence for presence an exonic splicing enhancer in exon 12 of the RB1 gene.

P06.198

Parent-of-origin effect in SDHD hereditary tumours explained by requirement for additional molecular steps.

E. S. Tobias[1], *P. M. Yeap*[2], *E. Mavraki*[3], *A. Fletcher*[1], *M. E. Freel*[4], *N. Bradshaw*[5], *V. A. Murday*[5], *C. Perry*[4], *R. S. Lindsay*[4];

[1]Institute of Medical Genetics, Yorkhill Hospital, University of Glasgow, Glasgow, United Kingdom, [2]Department of Diabetes, Glasgow Royal Infirmary, Glasgow, United Kingdom, [3]Human Genetics Unit, Ninewells Hospital, Dundee, United Kingdom, [4]Department of Endocrinology, Western Infirmary, Glasgow, United Kingdom, [5]Ferguson Smith Centre for Clinical Genetics, Yorkhill Hospital, Glasgow, United Kingdom.

In SDHD mutation families, paragangliomas and phaeochromocytomas usually occur only after paternal transmission of the mutation. This unexplained parent-of-origin effect is not due to imprinting of SDHD itself as SDHD is biallelically expressed in several tissues. In paternally inherited SDHD there is loss of the entire maternal chromosome 11 in tumour DNA, implying that tumourigenesis requires loss of maternal SDHD and a further, imprinted, tumour suppressor gene (TSG).

We report the second case of an SDHD-related tumour (a phaeochromocytoma in a 33 year old woman possessing the common pathogenic mutation, p.Pro81Leu) occurring after maternal transmission. It is the first reported investigation of tumour DNA in this situation. Tumour DNA revealed loss of heterozygosity (LOH) at paternal 11q23 causing loss of the wild-type SDHD allele and LOH affecting maternal 11p15, including H19. These two LOH regions were separated by a region exhibiting clearly retained heterozygosity, containing SDHAF2 (a recently reported paraganglioma TSG), which therefore appears uninvolved here.

This case provides molecular evidence that the tumourigenic requirement for maternal 11p15 loss (in addition to inactivation of both SDHD alleles) drives the observed parent-of-origin effect. Paternal inheritance of SDHD mutations is more commonly associated with tumour formation as the necessary loss of both the wild type SDHD allele and maternal 11p15 can occur by a single event (loss of maternal chromosome 11). These findings have important implications regarding the clinical management of carriers of maternally inherited SDHD mutations - who we confirm can develop phaeochromocytomas - and the understanding of the parent-of-origin effect.

Selenoprotein gene variants and selenium (Se) plasma concentration are major risk factors for breast and prostate cancers

J. Lubinski, *E. Jaworska, S. Gupta, M. Muszyńska, G. Sukiennicki, K. Durda, T. Huzarski, O. Oszurek, A. Tołoczko, J. Gronwald, C. Cybulski, A. Gołąb, A. Sikorski, D. Wokołorczyk, J. Kładny, G. Wilk, A. Jakubowska;*

Pomeranian Medical University, Szczecin, Poland.

Aim

Evaluation of associations between selected selenoprotein genomic variants, total Se plasma concentration and breast and prostate cancer risk.

Material and methods

Patients

105 pairs of consecutive patients (unselected except for exclusion of BRCA1 carriers) and unaffected females matched for year of birth, adnexectomy, cancer family history and smoking were included for breast cancer studies. 81 pairs of unselected patients and unaffected men matched similarly were included for prostate cancer studies.

Genes

The most polymorphic four SNPs were identified among selenoprotein genes (GPX1, GPX4, TXNRD2, Sep15) by sequencing of representative cases.

Se plasma level was analyzed using spectroscopy (Analyst600).

Statistics

Depending on Se level quartiles including at least 25 persons each were identified for all possible genotypes.

Results

The strongest associations have been detected for genotypes listed in table below.

Cancer site	Genotype	Quartiles compared	Se concentration range (µg/l)	Cases/controls in compared groups	Fisher's Exact Test		
					p	OR	CI
Breast	TXNRD2 (rs 1139793) GG	II/III vs I/IV	59.6-79.2 vs 40.2-59.0 and 79.3-106.4	21/35 vs 38/17	0.0012*	0.27	0.12-0.59
	GPX1 (rs 1050450) CC	I/II vs III/IV	40.2-69.8 vs 69.9-107.9	32/18 vs 22/29	0.0465	2.34	1.052-5.22
Prostate	GPX4 (rs713041) nCC	I/II vs III/IV	22.0-71.4 vs 71.6-136.8	33/17 vs 20/31	0.0096*	3.01	1.34-6.77

* significant after Bonferoni correction

Conclusion

Option of diet aimed to keep serum Se level associated with the lowest cancer risk may be considered by persons with increased risk of breast/prostate cancers provided their genotype is determined.

P06.200

Molecular and clinical findings in Czech juvenile polyposis families

V. Peter;

Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine, Prague, Czech Republic.

Juvenile polyposis (JP) is an autosomal dominant syndrome characterized by the occurrence of juvenile polyps and predisposition to cancer of the gastrointestinal tract (GIT). Characteristic feature of juvenile polyps are irregular cystic glands filled with mucus not observed in other colorectal cancer syndromes. Germline mutations in the *SMAD4* and *BMPR1A* genes are found in 40% of the JP individuals. Hereditary hemorrhagic telangiectasia (HHT) and higher frequency of gastric polyposis are associated mostly with *SMAD4* mutations. We report here on clinical findings and molecular analysis of 12 individuals from 4 Czech families. Two probands were initially analysed for the suspicion of familial adenomatous polyposis (FAP) and hereditary nonpolyposis colorectal cancer (HNPCC) syndromes. We analysed entire coding regions including the splice-site boundaries of the *SMAD4* and *BMPR1A* genes in genomic DNA of the probands by sequencing analysis and multiplex ligation probe-dependent amplification (MLPA) assay. By direct sequencing of the genes we have identified three pathogenic mutations (p.Gln442X, p.Pro198GlnfsX4, p.Arg445X) in *SMAD4* gene only. Seven germline mutation carriers from three families had various manifestation of the disease. No mutation was found in a sporadic patient with cutaneous telangiectasias and GIT juvenile polyps. In summary, due to variable penetrance and expressivity of the disease it is extremely important to know family history and information related to the number, localization, size and histology of the polyps predominantly to establish a correct diagnosis and further follow-up.

P06.201
Low mutation rate in the mutation cluster region of the *APC* gene in patients with sporadic colorectal cancer in Southwest Iran

M. Hasanpour[1], *H. Galehdari*[1], *A. Masjedizadeh*[2], *A. Froughmand*[1];
[1]*Shahid Chamran University, Ahvaz, Islamic Republic of Iran,* [2]*Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran.*

Introduction: Colorectal cancer (CRC) is the third most common cancer in men and the second in women worldwide. The majority of CRC cases are sporadic that occur in persons without a family history of CRC and are caused by somatic mutations. Adenomatous Polyposis Coli (*APC*) is a tumor suppressor gene of Wnt pathway and is mutated in 34-80% of sporadic CRC cases. About 60% of all mutations in *APC* occur in the mutation cluster region (MCR) between codons 1286 and 1513 in exon 15. Our objective was to identify mutations in *APC* gene of sporadic CRC patients.
Methods: Tumor and normal tissue samples were obtained from 29 Iranian sporadic CRC patients. We designed four primer pairs due to amplifying four overlapping fragments (codons 654-885, 853-1242, 1213-1482 and 1404-1613) of exon 15. Direct sequencing was used for analyzing of four amplified fragments.
Results: We found four frameshift mutations c.2804dupA, c.4317delT, c.4464_4471del and c.4468_4469dupCA, three missense mutations T1079S, P1176L and E1317Q and two nonsense mutations Q1367X and R1450X in eight patients. One of patients showed two mutations.
Conclusion: Mutations were detected in 8 (27.6%) of 29 CRC patients. This mutation frequency is lower in comparison to the previous studies from other countries. The c.4468_4469dupCA and T1079S are novel mutations. The identified six frameshift and nonsense mutations are pathogenic and lead to truncated APC protein. The pathogenicity of the T1079S and P1176L missense mutations is unknown but the E1317Q mutation is considered being a predisposing variant for the CRC progression.

Case-control *association* study of COX-2 gene polymorphism (-765G>C) with Sporadic colorectal cancer (CRC)

F. Khorshidi, *M. Montazer Haghighi, S. Mohebbi, M. Yaghoob Taleghani, M. Zali;*
The Research Center for Gastroenterology and Liver Diseases, Tehran, Islamic Republic of Iran.

Background : Colorectal cancer (CRC) is a common disease in both men and women. CRC is ranked the third most common form of cancer worldwide in terms of incidence .Cyclooxygenase (COX) is a key enzyme in the formation of prostaglandins, and an inducible isoform of COX, COX-2, has been implicated in colorectal carcinogenesis.
Aim: The aim of our study was to investigate associations of COX-2 polymorphism (-765G>C) with risk of colorectal cancer (CRC) in an Iranian population.
Methods: The study subjects were 115 cases of colorectal cancer and 62 controls with no polyps who underwent total colonoscopy. Genotypes were determined using the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method with genomic DNA extracted from the buffy coat.
Result: Our finding revealed that a significant difference between cases and controls (P=0.001).Therefore -765G>C polymorphism was associated with colorectal cancer development .Moreover, GG genotype was detected just in cases.
Conclusion: These findings suggest a modulating role for the COX-2 polymorphism (-765G→C) in the development of colorectal cancer in an Iranian population.

STAT3 a Molecular Target in High-Grade Gliomas.

L. Roque[1], *C. Martins*[1], *M. Moedas*[1], *S. Fragoso*[1], *V. Moura-Nunes*[1], *C. Faria*[2], *J. Lobo Antunes*[2], *M. Santos*[2], *J. Pimentel*[3];
[1]*CIPM-Portuguese Cancer Institute, Lisbon, Portugal,* [2]*Neurosurgery Department - Hospital de Santa Maria, Lisbon, Portugal,* [3]*Neuropathology Department - Hospital de Santa Maria, Lisbon, Portugal.*

Background: High-grade gliomas are the most common primary brain neoplasms and are generally lethal. Disruption of EGFR was defined as critical for gliomagenesis and anti-EGFR therapies were believed to be an attractive therapeutic approach to the classical regimens, however, they revealed no improvements.
Aim: The goal of this work was to analyse the expression of genes that make-up the EGFR activated signalling pathways and identify molecules that would be a better therapeutic target.
Methods: We characterize 100 high-grade gliomas by Chromosomal Comparative Genomic Hybridization (cCGH) and determined the incidence of EGFRvIII mutations and amplification, respectively, by RT-PCR and FISH. In 20 tumours, gene expression analysis was evaluated with GeneChip HuGene1.0ST arrays (Affymetrix) and data processed with Partek and Ingenuity Pathway Analysis (IPA) software. Array validation was performed by immunohistochemistry with pY705 STAT3 (Abcam) in 50 of the tumours. **Results:** Concomitant gain of chromosome 7 and loss of 10q, a hallmark of glioblastomas, was found in 83% of the cases. EGFR amplification was observed in 58.3% of the tumours and EGFRvIII mutation detected in 30% of the amplified cases. Gene expression analysis revealed that the most over-expressed genes (FC>10) were genes related with cell cycle control, angiogenesis and cellular invasion and those with the lowest levels (FC<10) were related with neuronal functions (e.g. GABRG2). Functional network analysis of EGFR pathway by IPA defined as hub-molecules: STAT3 and C-MYC. Immunohistochemistry revealed pY705-STAT3-positive tumor cells in all cases.
Conclusion: Our data strongly supports STAT3 as a molecular target in high-grade glioma therapy.

Peutz-Jeghersa syndrome (PJS; MIM 175200) an autosomal dominant disorder associated with increased risk of malignances. The occurrence of PJS is estimated from 1/29,000 to 1/120,000 newborn. In most patient the hamartomatous polyps are observed during second or third decade of life. Polyps can be located throughout digestive tract. Risk of colorectal cancer is lower then in FAP or HNPCC, but PJS can be reason of many gastrointestinal discomforts like bowel obstruction, intussusception or bleeding. In Peutz-Jeghers syndrome high risk to development malignancies such as the pancreas, the breast, female and male reproductive organs is observed. Second manifestations are mucocutaneous hypermelanocytic lesions. The pigmentations are usually brown, dark or blue spots developing on lips, hands and feet, in the mucosa of the nose, conjunctiva or rectum appear in about 90% cases. Mutations in STK11 gene are detected in 70 % patients with familial form of PJS and in 30 to 70% sporadic cases of disease. STK11 gene is located on chromosome 19p13.3. Protein coding by STK11 gene is serine/threonine kinase. Loss of STK11 function causes many defects, since STK11 participates in very important cell signaling pathways. Here we present the study considering 30 Polish families with PJS. The STK11 point mutations were detected 9 families and large STK11 gene rearrangements were detected in 6 families.
The study was financed by the Ministry of Education and Science, Poland, grant number N N402 481537

P06.205
Levels of acetylated H3 histone in papillary and undifferentiated thyroid carcinoma

N. Passon[1], *C. Puppin*[1], *A. Franzoni*[2], *C. Di Loreto*[3], *F. Frasca*[4], *V. Vella*[4], *R. Vigneri*[4], ***G. Damante***[1,2];

Histone acetylation is a major mechanism to regulate gene transcription. This post-translational modification is modified in cancer cells. In various tumor types levels of acetylation at several histone residues are associated to clinical aggressiveness. By using immunohistochemistry we show that acetylated levels of lysines at

positions 9, 14 and 18 (K9-K14 and K18) of H3 histone are higher in papillary thyroid carcinomas (PTC) than in corresponding normal tissues. Differently, in thyroid undifferentiated carcinomas (UC), only higher levels of K9-K14 acetylation is observed. By using rat thyroid cell lines stably transfected with doxycyclin-inducible oncogenes, we show that the oncoproteins RET-PTC, RAS and BRAF increases levels of acetylated K9-K14 and K18. All these oncogenes activate MAP kinase (MAPK) pathway. The involvement of this signal pathway in the modulation of the H3 acetylation was confirmed by studying the effects of its inhibition. Human thyroid cell line WRO, treated with the MAPK inhibitor PD98059, reduces acetylated levels of these lysine residues. In the non-tumorigenic rat thyroid cell line FRTL-5, TSH increases levels of acetylated K18. However, this hormone decreases levels of acetylated K9-K14. In conclusion, our data indicate that the MAPK signalling pathway and TSH control levels of several acetylated lysines in the context of the H3 histone.

P06.206
Contribution of constitutional *TP53* mutations to Wilms tumour

***H. L. Hanson**, S. Hanks, A. Murray, R. Linger, J. Douglas, .. FACT Collaboration, N. Rahman;*
Institute of Cancer Research, Sutton, United Kingdom.

Wilms tumour is the commonest renal tumour occurring in childhood and has been reported to occur at increased frequency in Li-Fraumeni syndrome (LFS), a cancer predisposition syndrome predominantly associated with sarcoma, breast, brain and adrenocortical cancers. Constitutional *TP53* mutations are identified in up to three-quarters of families with clinically defined classic LFS. Mutations are typically missense changes at hotspot codons within the DNA-binding domain. We sought to investigate the contribution of constitutional *TP53* mutations to Wilms tumour outside the context of LFS. We undertook mutation analysis of *TP53* in 489 individuals affected with Wilms tumour recruited from Paediatric Oncology centres in the UK. *WT1* and 11p15 defects had been excluded in all cases.

Overall no clearly pathogenic mutations were identified. Two non-synonymous missense variants were identified; V197A and T256A, neither is reported on the IARC *TP53* database and both are predicted to retain at least partial function of transactivation capacity in a yeast assay. Although both are located in the DNA-binding domain they are not at recognised hotspots and we have also observed non-hotspot variants in this domain in a control series (6/1334, p=1.0). Furthermore V197A was present in an unaffected parent and we have observed T256A in a clinical LFS family in which the variant does not segregate with cancer. These data suggest that constitutional *TP53* mutations do not make an appreciable contribution to Wilms tumour susceptibility, outside the context of a family history of LFS.

P06.207
Investigation of expression level and nucleotide variation of the BAX gene in Iranian patients with transitional cell carcinoma of the bladder cancer

***B. Golestani-Imani**;*
National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.

This is a case-control study within investigation of the BAX gene's expression and its nucleotide change in 36 men with transitional cell carcinoma (TCC) and control group (24 healthy men).

Material and method: BAX gene expression in tumoral, adjacent tissues of bladder and peripheral blood lymphocytes of 32 patients and bladder tissue of control group (24 men) is measured by real time PCR. Nucleotide change in promoter region and 6-coding exons is determined by sequencing in 36 patients and control group.

Results: BAX gene expression level in tumoral tissue of 62.5% of patients was higher than adjacent tissue, in 12,5% it was lower and in 25% was equal. In blood cells of 20,83% of patients the level was higher than adjacent tissue's one. SNP polymorphism was observed at 3 locus of this gene.

Conclusion: Bax gene sequence both in peripheral blood lymphocytes and in tumoral cells of patients was homogenous so it is possible to detect nucleotide change only by peripheral blood lymphocytes and to receive information about this gene expression since the significant relation between heterozygosity in promoter region and expression decrease has been clarified in this study.

P06.208
Detection of circulating tumour cells in the peripheral blood lymphocytes of healthy individuals

***S. N. Kokkinou**, A. Lindou;*
Cytogenetic Unit, Sismanoglion General Hospital, Halandri, Greece.

INTRODUCTION: The detection of circulating tumour cells(CTC)in the peripheral blood (PB)of cancer patients(pts)has a potential prognostic value.But the early detection of CTC in healthy persons offers more.

AIM OF THE STUDY: Our study analyse the presence and frequency of CTC in the PB of phenotypically healthy individuals(HI).

PATIENTS: During the 2005,450 pts were transferred to Cytogenetic unit for various reasons.Among them there were27pts with breast adenomas,15 with HPV,50with H*p* infection,and 60 with anemia/ leukopenia.

All had a cancerous family history.

With routine blood control,mammography,PAPtest,gastric endoscopy,bone marrow aspiration/biopsy,they had no obvious malignant disease.

METHODS: PB lymphocytes were cultured using standard techniques. ThirtyGTG banded metaphases were analyzed(ISCN2005).Used FISH probes were LSI TOP2A/HER-2/CEP17,EGFR/7,IGH/MALT1, AP12/MALT1,CSF1R,EGR1,D7S486(VYSIS),Hterc/C-MYC/SE 7TC, p53/ATM(KREATECH)

Two hundred interface nuclei were counted for any single probe in all pts once in a year.

RESULTS: From the beginning were CTC ranged 4-10%.Till the end of 2010,we confirmed 5malt gastric lymphomas,4 cervical cancers,9 MDS,and 3 breast cancers.

CONCLUSION: In the absence of manifest clinical disease CTC can persist over a 3-yr period in the PB of HI.

Early detection and quantification may identify people at risk of a malignant disease.It needs careful evaluation and analysis of findings so as to speed up the clinicians on early detection of a forthcoming malignant disease.

P06.209
A multifactorial approach to assess the pathogenicity of unclassified sequence variants in hereditary colorectal cancer susceptibility genes

***R. Tricarico**[1], C. Mareni[1,2], F. Crucianelli[1,3], L. Staderini[1], S. Benoni[1,3], G. Giammusso[1], C. Di Gregorio[4], S. Civitelli[3], M. Genuardi[1];*
[1]Section of Medical Genetics, Dept. Clinical Pathophysiology, University of Florence, Florence, Italy, [2]Istituto Toscano Tumori, Firenze, Italy, [3]Dept. Surgery, University of Siena, Siena, Italy, [4]Section of Pathology, Hospital of Modena, Modena, Italy.

Mutations in the mismatch-repair genes MLH1, MSH2, MSH6 and MUTYH are responsible for Lynch syndrome (LS) and MUTYH-associated polyposis (MAP), respectively. About 30% of MisMatch Repair (MMR) and 20% of MUTYH known gene variants are Variants of Uncertain Significance (VUS). Discriminating true pathogenic from benign variants is becoming a major issue in the understanding of the genetic bases of inherited CRC and in the clinical setting.

We undertook a study aimed at defining the significance of 31 VUS (19 missense, 2 silent, 8 intronic, and 2 5'-UTR variants) identified in a series of 188 unrelated probands, referred for either MMR gene sequencing (n = 76) or a suspicion of MAP (n = 112). 6 VUS have been identified in several cases: p.L260R (n = 2) and c.1039-8T>C (n = 2) in MLH1, p.K579K (n = 2), p.L556L (n = 3), c.2005+24T>A (n = 3) and c.1511-9A>T (n = 7) in MSH2.

We evaluated multiple parameters to establish pathogenic significance, including: phenotype of the patients/families in whom the VUS were identified, co-segregation with phenotype, family history, co-occurrence of established pathogenic mutations, evaluation of molecular markers of MMR and MUTYH deficiency in tumour samples, immunohistochemistry analysis for MMR protein expression, frequency in control alleles, in silico prediction of potential effects of the VUS on mRNA and on the encoded protein function. The VUS were classified, when possible obtaining values of posterior probability as recommended by the IARC Working Group on Unclassified Genetic Variants recommendations (Plon et al., Hum Mutat. 2008 29:1282-91).

P06.210
Identification of clonal variations present in tumor through clustering

S. Karmakar, *A. K. Ghosh, A. Basu;*
Indian Statistical Institute,Kolkata, Kolkata, West Bengal, India.

Identification of driver mutations in cancer cells is a challenging endeavor. We hypothesize that these driver mutations arise early in the original cancer cells providing it a selective advantage to form distinct clones. Next generation sequencing data provides an opportunity to construct the allele frequency spectrum for all somatic mutations in a particular tumor. Partitioning the allele frequency spectrum in distinct clusters hence can provide an idea of the number of clones present in the tumor cell mass. We here work with the output of tumor sequence data as generated on the 454 platform (Roche Sequencing) and apply clustering algorithm. Initial clusters were obtained using linkage method.To decide upon no. of cluster we compare AIC and BIC and also Gap Statistic.Davis-Bouldin index,Dunn index and some external quality criterion like rand measure, Jaccard matrix were calculated to compare clustering algorithms. Obtaining initial cluster,we propose a methodology to find out the number of clones as well as clonal proportions using EM algorithm. Same algorithm was repeated for normal blood data and tumor data in order to draw something conclusive. Also in each type of data somatic cell vs germline cell new-position mutation vs insertion deletion has been compared.Comparison between number of initial clusters ,clones and their proportions gave rise to some biologically significant inferences.

Exome sequencing of seven melanomas provides new insights in cancer causation and progression, and identifies additional driver gene candidates

S. I. Nikolaev[1], *C. Iseli*[2,3], *A. Valsesia*[2,3,4], *D. Rimoldi*[2], *C. Gehrig*[1], *K. Harshman*[5], *D. Robyr*[1], *M. Guipponi*[1], *I. Xenarios*[3], *T. Halazonetis*[1], *V. C. Jongeneel*[2,3], *B. J. Stevenson*[2,3], *S. E. Antonarakis*[1];
[1]*University of Geneva, Geneva, Switzerland,* [2]*Ludwig Institute for Cancer Research, Lausanne, Switzerland,* [3]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [4]*University of Lausanne, Lausanne, Switzerland,* [5]*Center for Integrative Genomics, Lausanne, Switzerland.*

Melanoma is the most dangerous form of skin cancer since it frequently metastasizes. Although a few prevalent mutations have been identified with the sequencing of a single melanoma cell line, the full spectrum of somatic driver mutations remains unknown. We have performed exome sequencing to detect somatic mutations in protein-coding regions of seven melanoma cell lines (five unrelated and two derived from the same patient sampled 12 years apart) and their corresponding germline DNA. The number of coding non-synonymous somatic mutations in the cell lines ranged from 158 to 709. The most abundant class of somatic mutations in all melanomas is C>T, a hallmark of exposure to UV light. In the two melanomas derived from the same patient two thirds of the somatic mutations were shared and showed signature of UV light; remaining mutations might have originated during the transition to the invasive phase. Six melanomas had mutations in the BRAF gene around amino acid 600 and one had a mutation (Q61R) in the NRAS gene. In two melanomas we identified novel mutations in genes that are key regulators of the MAPK pathway. These mutations were also observed in two individuals in a larger sample collection. Remarkably, all cases have germline damaging rare variants in genes involved in the HR and NER pathways. The contribution of these variants to predisposition to melanoma is under investigation. Such results will shed light on the natural history of tumour development.

J06.01
Role of metabolic pathways Genes in tumorigenesis and tumor progression

F. Hashemi gorji[1], *M. Karimipoor*[1], *R. Mirfakhraie*[2], *G. Hararanipoor*[1], *S. F. Baniahmad*[1];
[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.*

Maintaining normal body status is controlled by at least three important metabolic cycles that closely regulate synthesis of amino acids and nucleotides. Normal cells use different sources of energy including glycogen, fatty acids and amino acids, but the key energy source is glucose for cell growth. Instead, tumour cells show unusual metabolic pathways with significant re-programming. Cancer cells need a lot of metabolic energy for their rapid proliferation, so a non-oxidative energy source is used such as glucose. This re-programmed activity underlies events in the physiology of tumour cells and sometimes generates harmful products such as reactive oxygen species or oxygen free radicals, and sometimes results in unequal storage of nucleotides for DNA synthesis that increases the mutation rate. Cancer cells have high rates of glycolysis and NADH-oxidation that generate a lot of ROS. Re-programming of genes involved in metabolic pathways is a sign of physiological changes in cancer cells. Expression of some genes is altered dramatically in different stages of tumour growth that directly control metabolic pathways. These changes are characteristic of tumour cells. They help tumour cells to become more aggressive. The genes involved in oncogenesis include *GLUT1*, *G6PD*, *TKTL1* and *PGI*/*AMF* in the glycolytic pathway, *ACLY*, *FAS* and *ACC1* in lipogenesis and *RRM1*, *RRM2*, and *TYMS* for synthesizing nucleotides. Over expression of these genes in many cancer cells was observed. Taken together, down-regulation of these genes can inhibit tumorigenesis and tumour progression.

J06.02
Genetic basis of Rhabdomyosarcoma

M. Barath, *P. Taskar, A. Kanugovi;*
Padmashree Dr.D.Y.Patil University Department of Biotechnology and Bioinformatics, Navi Mumbai, India.

Rhabdomyosarcoma is a cancer of cells which normally develop into skeletal muscles, most common in children under the age of 10. A specific chromosomal abnormality, t(2;13)(q35;q14), was reported in many cases of advanced rhabdomyosarcoma patients by RT-PCR, FISH and spectral karyotyping. The other frequent abnormalities observed were rearrangements of chromosome 1p and trisomy of chromosome 8 using conventional cytogenetic techniques such as G banding. The translocation between chromosome 2 and chromosome 13 causes the movements of the gene called PAX3 (or PAX7 if it's chromosome 1) right next to a gene called FKHR. Paired box (Pax) genes are a family of tissue specific transcription factors containing a paired domain and usually a partial or complete homeodomain. The PAX genes play an important role in causing cells to grow while an embryo's muscle tissue is being formed, but these genes usually shut down once they're no longer needed. The normal function of the FKHR gene is to activate other genes. Moving them together likely activates the PAX genes, which may lead to the formation of tumor. Complete trisomy 8 is a leading cause of miscarriage in women while infants with trisomy 8 mosaicism are likely to survive but with retarded psychomotor development and moderate to severe mental retardation. About 3% of all tumors are found to be rhabdomyosarcomas, with them being rare in teenagers and adults but constituting more than 50% of embryonic tumors making them detectable by chromosomal analysis during pre-natal diagnosis.

J06.03
Breast cancer is the most common cancer in young Iranian women

M. Akouchekian;
Tehran University of Medical Science, Tehran, Islamic Republic of Iran.

Breast cancer is one of the multifactorial diseases in which both genetic and environmental factors are involved in the aetiology. Various factors have been identified as playing an important role in stimulating this cancer. During the last decades the increasing incidence of breast cancer has made it the most prevalent cancer among young Iranian women. The mean age of onset of breast cancer in Iranian women is about 10 years lower than that of their counterparts in developed countries.
A new study of the prevalence of breast cancer in immigrants from Asian countries to Sweden suggested that there are some biological factors that caused early onset of breast cancer in immigrants, including Iranian women, compared to native women of Sweden. Epidemiological aspects of Iranian breast cancer are uncertain and unfortunately no study has specifically addressed breast cancer risk factors in young Iranian women up to now. The purpose of this study was to investigate the influence of polymorphic variants defined by single nucleotide polymorphisms (SNPs) in the displacement loop (D-loop) region of

mitochondrial DNA (mtDNA) on the risk of developing breast cancer in young Iranian women. We used PCR and RFLP analysis in this study. Based on our results we detected a significantly greater incidence of the mtDNA polymorphisms T239C and A263G in early onset of breast cancer patients and we think this may be associated with an increased risk of breast cancer in young Iranian women.
